Modular Koszul Duality

Editorial Companion: Concordance & Research Programme

Raeez Lorgat

March 2026

Abstract

This companion document contains the full concordance with primary literature and the editorial constitution of the monograph Modular Koszul Duality. *It includes literature comparison tables, the three-pillar foundational architecture, the three concentric rings, the Koszulness characterization programme, cross-volume bridges, the modular homotopy theory programme, conjecture stratification, research directions, and programme status assessment.*

Chapter 1

Concordance with primary literature

This chapter is the constitution of the monograph. When chapters disagree, this chapter is right. Its function is threefold: to state the five main theorems with their precise status, to locate every result against the prior literature, and to serve as the single authoritative reference for what is proved, what is conditional, and what remains conjectural.

The five main theorems. The algebraic engine rests on five theorems, all proved:

	Theorem	Statement	Status
A	Bar-cobar adjunction	$\bar{B}^{\mathrm{ch}} \dashv \Omega^{\mathrm{ch}}$ on $\mathrm{Ran}(X)$, with Verdier intertwining (Thm **??**)	[proved here]
B	Bar-cobar inversion	$\Omega^{\mathrm{ch}}(\bar{B}^{\mathrm{ch}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ on the Koszul locus (Thm **??**)	[proved here]
C	Complementarity	$Q_g(\mathcal{A}) + Q_g(\mathcal{A}^!) = H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$ (Thm **??**); upgraded to shifted-symplectic Lagrangian geometry	[proved here]
D	Modular characteristic	$\kappa(\mathcal{A})$ universal, additive, anti-symmetric, $\hat{A}$-genus generating function (Thm **??**)	[proved here]
H	Chiral Hochschild	$CH^*(\mathcal{A})$ polynomial, Koszul-functorial (Thms **??**, **??**, **??**)	[proved here]

The unifying principle: the modular L_∞ convolution algebra $\mathfrak{g}^{\mathrm{mod}}_{\mathcal{A}}$ carries a natural modular L_∞ structure from the Feynman transform of the modular operad. The dg Lie algebra of Definition **??** is its strict model $\mathrm{Conv}_{\mathrm{str}}$; the homotopy-invariant object is $\mathrm{Def}^{\mathrm{mod}}_\infty(\mathcal{A})$ (Theorem **??**). The universal MC element $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}^{\mathrm{mod}}_{\mathcal{A}})$ exists unconditionally by the bar-intrinsic construction (Theorem **??**: $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is MC because $D^2_{\mathcal{A}} = 0$). The shadow Postnikov tower $\Theta^{\leq 2}_{\mathcal{A}} \to \Theta^{\leq 3}_{\mathcal{A}} \to \Theta^{\leq 4}_{\mathcal{A}} \to \cdots$ consists of its finite-order projections — the constructive computational engine. Theorems A–D+H are projections of $\Theta_{\mathcal{A}}$ to the scalar level κ: every theorem in the algebraic engine is a component of the single MC equation $D_{\mathcal{A}}(\Theta_{\mathcal{A}}) + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$ in the modular convolution algebra.

Remark 1.0.1 *(Scope).* This companion document records the principal contributions, literature comparisons, the three-pillar architecture, the three concentric rings, cross-volume bridges, and the modular homotopy theory development. The conjecture stratification, homotopy templates, six research directions, and project-level status assessment appear in the editorial constitution (the second chapter of this companion).

1.1 Principal contributions

(1) *Configuration space bar-cobar adjunction (Theorems ?? and ??).* The bar and cobar constructions for chiral algebras are realized via explicit integrals over Fulton–MacPherson compactifications $\overline{C}_n(X)$, with the bar differential given by residues at collision divisors and the cobar differential by inclusions of strata. The adjunction is proved for all Koszul chiral algebras and all genera. Theorem A decomposes into three layers (Remark ??): the fundamental theorem of chiral twisting morphisms (A_0, Theorem ??), bar concentration (A_1, Theorem ??), and the Verdier-geometric duality (A_2, Theorem ??). This is the first complete proof of chiral Koszul duality via configuration space geometry. *Quillen upgrade* (§1.11): the bar-cobar adjunction $B_\kappa \dashv \Omega_\kappa$ is a *Quillen equivalence* in the Vallette model structure on conilpotent chiral coalgebras [?, Theorem 2.1] (Theorem ??), and every Ch_∞-algebra rectifies to a strict chiral algebra (Corollary ??). The homotopy category of dg chiral algebras is thereby equivalent to Ch_∞-algebras with ∞-morphisms modulo homotopy.

(2) *Genus universality (Theorem ??).* For any Koszul chiral algebra $\mathcal{A}$, the genus-g obstruction factors as $\mathrm{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$, where κ is an algebra-dependent constant and λ_g is the universal Faber–Pandharipande tautological class on $\overline{\mathcal{M}}_g$. The genus-independent coefficient $\kappa(\mathcal{A})$ is determined by the genus-1 curvature. This is the *scalar* genus universality (Level 0 of Remark 1.18.1): the first Chern class of the factorization homology bundle. The full genus-g invariant — the cohomology $H^*(\overline{B}^{(g)}(\mathcal{A}), D_g)$ and its variation over $\mathcal{M}_g$ — is categorically richer (Theorem ??).

(3) *Deformation-obstruction complementarity (Theorem ??).* For a Koszul pair $(\mathcal{A}, \mathcal{A}^!)$, the genus-$g$ obstructions satisfy $\mathrm{obs}_g(\mathcal{A}) + \mathrm{obs}_g(\mathcal{A}^!) = [\text{characteristic class of } Z(\mathcal{A})]$ in $H^*(\overline{\mathcal{M}}_g)$. The Kodaira–Spencer map is constructed for all Koszul pairs and all genera (Theorem ??). This is the first formulation and proof of complementarity for chiral algebras.

(4) E_1*-chiral Koszul duality (Theorem ??).* The bar-cobar adjunction extends to E_1-chiral algebras (nonlocal vertex algebras with R-matrix braiding), covering Yangians and toroidal algebras. This goes beyond the E_∞ (commutative/local) setting of BD and FG.

(5) *Explicit computations.* Complete Koszul duality computations for all standard families: Heisenberg, free fermion, bc-$\beta\gamma$, affine Kac–Moody ($\widehat{\mathfrak{g}}_k \leftrightarrow \widehat{\mathfrak{g}}_{-k-2h^\vee}$), Virasoro (same-family complementarity partner Vir_{26-c} at M/S-level, with the $\mathcal{W}_\infty$ realization retained as project), $\mathcal{W}_N$ algebras, Yangians. Genus-g free energies computed through $g = 10$ with Bernoulli asymptotics. Bar cohomology dimensions through degree 10. These explicit results are new.

(6) *Derived oper space from the bar complex (Theorem ??).* At the critical level $k = -h^\vee$, the bar complex is uncurved and recovers the derived space of $\mathfrak{g}^\vee$-opers on the formal disc: $H^n(\overline{B}(\widehat{\mathfrak{g}}_{-h^\vee})) \cong \Omega^n(\mathrm{Op}_{\mathfrak{g}^\vee}(D))$. The H^0 identification gives the Feigin–Frenkel center [?]; the H^1 identification gives Kähler differentials of the oper space; and the full derived identification follows from the bar-Ext identification combined with the Frenkel–Teleman theorem [?]. This provides a vertex-algebraic construction of a central ingredient in the geometric Langlands programme, independent of the categorical approach of Gaitsgory et al. [?] and Raskin [?].

(7) *Chiral Hochschild cohomology (Theorems ??, ??, and ??).* For the principal $\mathcal{W}$-algebra $\mathcal{W}^k(\mathfrak{g})$ at generic level: $CH^*(\mathcal{W}^k(\mathfrak{g})) \cong \mathbb{C}[\Theta_1, \ldots, \Theta_r]$ with Θ_i in degree $m_i + 1$ (exponents of $\mathfrak{g}$). Rank 1 (Virasoro): strict period 2. Rank $r \geq 2$: quasi-period $\mathrm{lcm}(m_1 + 1, \ldots, m_r + 1)$. At critical level $k =$

$-h^\vee$: exterior⊗polynomial structure $\Lambda^*(P_1, \ldots, P_r) \otimes \mathbb{C}[\Theta_1, \ldots, \Theta_r]$ (Fuks–Feigin–Tsygan). Functorial under Koszul duality via the Connes operator S (Theorem **??**, Corollary **??**). This promotes the Hochschild results to a principal contribution (Theorem H).

(8) *Chain-level modular functor (Theorem **??**).* The Feynman transform of the Getzler–Kapranov modular operad assembles the genus-graded bar complex into a homotopy-coherent modular functor: to each surface a cochain complex, to each degeneration a chain map, to each consistency relation a chain homotopy. Passing to H^0 at integrable level recovers the space of conformal blocks. This is the structure toward which Theorems A–D build (Definition **??**): the scalar genus tower $F_g = \kappa(\mathcal{A}) \cdot \lambda_g^{\mathrm{FP}}$ is its first Chern class; the spectral discriminant $\Delta_{\mathcal{A}}$ is its Chern character; the KZ/Hitchin connection on conformal blocks is the flat connection on its cohomology sheaf (Remark **??**).

Remark 1.1.1 *(Geometric Langlands connection).* The bar complex $\overline{B}(\widehat{\mathfrak{g}}_{-h^\vee})$ at critical level is a *derived enhancement* of the Feigin–Frenkel center: it simultaneously encodes the commutative algebra of functions on the oper space (in H^0), its cotangent complex (in H^1), and higher derived structure (in $H^{\geq 2}$). The bar construction — defined via configuration space integrals on curves — reproduces an object central to the Langlands programme (Theorem **??**).

Remark 1.1.2 *(The twisting morphism as organizing datum).* The canonical twisting morphism $\tau\colon \overline{B}_X(\mathcal{A}) \to \mathcal{A}$ underlies the four main theorems (Convention **??**): Theorem A establishes τ; Theorem B inverts it; Theorem C identifies its genus-g curvature; Theorem D computes its leading coefficient. At higher genus, τ extends to a curved twisting cochain $\tau_{\mathrm{mod}} = \tau + \Theta_{\mathcal{A}}$ whose curvature $\kappa(\mathcal{A}) \cdot \omega_g$ governs the entire modular deformation tower (Remark **??**).

1.2 Relationship to Beilinson–Drinfeld

Our Terminology	**BD Terminology**
Chiral algebra	Chiral algebra (same)
E_∞-chiral algebra	Vertex algebra / Chiral algebra
E_1-chiral algebra	No direct analog (generalization)
Chiral bracket μ	Chiral operation $\mu : j_* j^*(A \boxtimes A) \to \Delta_! A$
Bar complex $\bar{B}(\mathcal{A})$	Chiral chain complex (cf. Chevalley–Eilenberg for Lie case)
Factorization structure	Factorization algebra structure
Ran space $\mathrm{Ran}(X)$	$\mathfrak{R}(X)$ in BD notation

Remark 1.2.1 *(Key extension).* Our E_1-chiral algebras extend BD's chiral algebras by dropping skew-symmetry. BD's chiral algebras are our E_∞-chiral algebras.

1.3 Relationship to Francis–Gaitsgory

Our Terminology	**FG Terminology**
Chiral Koszul duality	Chiral Koszul duality (same)
$\mathsf{Com}^{\mathrm{ch}}$-$\mathsf{Lie}^{\mathrm{ch}}$ duality	Main theorem of FG
$\mathsf{Ass}^{\mathrm{ch}}$-$\mathsf{Ass}^{\mathrm{ch}}$ duality	Not explicitly treated (implicit)
Pro-nilpotence	Pro-nilpotent tensor ∞-category
Bar-cobar equivalence	Koszul duality equivalence

Remark 1.3.1 *(Key extension).* FG establish $\mathsf{Com}^{\mathrm{ch}}$-$\mathsf{Lie}^{\mathrm{ch}}$ duality. We show this is derived from the more fundamental $\mathsf{Ass}^{\mathrm{ch}}$-$\mathsf{Ass}^{\mathrm{ch}}$ self-duality via the deformation Pois $\to$ Ass.

1.4 Relationship to Gui–Li–Zeng

Our Terminology	**GLZ Terminology**
Quadratic chiral algebra	Quadratic chiral algebra (same)
Koszul dual $\mathcal{A}^!$	Quadratic dual $A^!$
Bar complex	Not used (direct quadratic dual)
Non-quadratic duality	Not treated
E_1-chiral algebras	Not treated

Proposition 1.4.1 *(GLZ as special case;* [proved here]*).* The Gui–Li–Zeng quadratic duality is a special case of the $\mathsf{Ass}^{\mathrm{ch}}$-duality of this monograph:

$$\text{GLZ duality} = \mathsf{Ass}^{\mathrm{ch}}\text{-duality}|_{\mathsf{E}_\infty\text{-chiral}}|_{\text{quadratic}}$$

Restricting to E_∞-chiral algebras with quadratic presentations recovers their theory.

Proof. An E_∞-chiral algebra $\mathcal{A}$ with quadratic presentation has a quadratic relation ideal $R \subset j_*j^*(\mathcal{A}^{\boxtimes 2})$. Its $\mathsf{Ass}^{\mathrm{ch}}$ Koszul dual is determined by bar degrees ≤ 2: the generators V^* in $\bar{B}^1$ and the orthogonal complement of relations $R^\perp$ in $\bar{B}^2$ (the higher bar degrees, while nonzero, contribute no independent data for quadratic algebras). The Koszul dual coalgebra $\bar{B}(\mathcal{A})$ is then determined by $R^\perp$, and the Koszul dual algebra $\mathcal{A}^! = \bar{B}(\mathcal{A})^\vee$ is recovered by linear duality under the chiral pairing $j_*j^*(\mathcal{A}^{\boxtimes 2}) \otimes j_*j^*((\mathcal{A}^!)^{\boxtimes 2}) \to \omega_X$. This is precisely the quadratic dual construction of GLZ.

For the E_∞ restriction: our $\mathsf{Ass}^{\mathrm{ch}}$ bar complex uses the full associative chiral product $\mu\colon j_*j^*(\mathcal{A} \boxtimes \mathcal{A}) \to \Delta_!\mathcal{A}$. When $\mathcal{A}$ is E_∞-chiral (i.e., the chiral bracket is skew-symmetric), the bar complex acquires a commutative coalgebra structure, and the Koszul dual is a Lie chiral algebra. This recovers the FG framework as a special case (see Theorem 1.4.2). □

Theorem 1.4.2 *(FG duality from* $\mathsf{Ass}^{\mathrm{ch}}$ *self-duality;* [proved here]*).* The Francis–Gaitsgory $\mathsf{Com}^{\mathrm{ch}}$-$\mathsf{Lie}^{\mathrm{ch}}$ duality is the associated graded of the $\mathsf{Ass}^{\mathrm{ch}}$ self-duality under the PBW filtration. Precisely: for a quadratic E_∞-chiral algebra $\mathcal{A}$, the $\mathsf{Ass}^{\mathrm{ch}}$ bar complex $\bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A})$ carries a filtration $F_\bullet$ (induced by the symmetrization degree of the Σ-action on $C_n(X)$) such that:

$$\mathrm{gr}^F \bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A}) \;\cong\; \bar{B}_{\mathsf{Com}^{\mathrm{ch}}}(\mathrm{Sym}^{\mathrm{ch}}(\mathcal{A})) \;\cong\; \mathrm{CE}^{\mathsf{Lie}^{\mathrm{ch}}}(\mathcal{A})$$

and the associated spectral sequence degenerates at E_1 for Koszul algebras.

Proof. Step 1: PBW filtration. The chiral bar complex $\bar{B}^n_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A})$ consists of sections on $\overline{C}_{n+1}(X)$ with coefficients in $\mathcal{A}^{\boxtimes(n+1)} \otimes \Omega^n_{\log}$. Define $F_p\bar{B}^n$ as the span of elements symmetric under at least $(n-p)$ transpositions of configuration space points. This is the chiral analogue of the arity filtration on the classical associative bar complex (Loday–Vallette [?], §9.3.2).

Step 2: Associated graded identification. On $\overline{C}_n(X)$, the Σ_n-representation decomposes as $j_*j^*(\mathcal{A}^{\boxtimes n}) = \mathrm{Sym}^n_{\mathrm{ch}}(\mathcal{A}) \oplus \bigwedge^2_{\mathrm{ch}}(\mathcal{A}) \otimes \cdots$. The PBW filtration separates these: $F_0/F_1 = \mathrm{Sym}^n_{\mathrm{ch}}(\mathcal{A})$ (the fully symmetric part) is the commutative chiral bar complex, and F_1/F_2 involves the Lie bracket (the antisymmetric part). The associated graded $\mathrm{gr}^F\bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}$ is thus the Chevalley–Eilenberg complex

for the Lie chiral algebra structure, which is $\bar{B}_{\mathsf{Com}^{\mathrm{ch}}}(\mathrm{Sym}^{\mathrm{ch}}(\mathcal{A}))$ by the classical identification of the commutative bar complex with Chevalley–Eilenberg chains.

Step 3: Spectral sequence degeneration. For Koszul $\mathcal{A}$, the spectral sequence $E_1^{p,q} = H^{p+q}(\mathrm{gr}_p^F \bar{B})$ degenerates at E_1. To see this, note that the associated graded $\mathrm{gr}^F \bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A})$ is the Chevalley–Eilenberg complex (Step 2), and the Koszul property of $\mathcal{A}$ as a chiral algebra implies that this commutative bar complex has cohomology concentrated on the diagonal $p + q = 0$ (i.e., $E_1^{p,q} = 0$ for $p + q \neq 0$). Since $d_1 \colon E_1^{p,q} \to E_1^{p+1,q}$ shifts the total degree $p + q$ by 1, it maps from the surviving diagonal to the zero region, hence $d_1 = 0$ and $E_2 = E_1$. All higher differentials vanish for the same degree reason. Therefore $H^*(\bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A})) \cong H^*(\mathrm{gr}^F \bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A}))$, and the FG duality is recovered as the associated graded of our $\mathsf{Ass}^{\mathrm{ch}}$ duality.

Step 4: Comparison with FG. The FG theorem states: for an E_∞-chiral algebra $\mathcal{A}$, the chiral Koszul dual is a Lie chiral algebra $\mathcal{A}^{!,\mathsf{Lie}^{\mathrm{ch}}}$. In the present framework: the Koszul dual coalgebra $\bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A})$ is an E_1-chiral coalgebra, and the Koszul dual algebra $\mathcal{A}^{!,\mathsf{Ass}^{\mathrm{ch}}} = \bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A})^\vee$ is an E_1-chiral algebra; its associated graded under PBW is $\mathcal{A}^{!,\mathsf{Lie}^{\mathrm{ch}}} = \bar{B}_{\mathsf{Com}^{\mathrm{ch}}}(\mathcal{A})^\vee$. (The cobar $\Omega(\bar{B}_{\mathsf{Ass}^{\mathrm{ch}}}(\mathcal{A}))$ recovers $\mathcal{A}$ itself by bar-cobar inversion, not $\mathcal{A}^!$.) The FG duality is recovered. □

1.5 Relationship to Ayala–Francis

Our Terminology	**AF Terminology**
Non-abelian Poincaré duality	Nonabelian Poincaré duality (same)
FM compactification $\overline{C}_n(X)$	Disk stratification of $\mathrm{Ran}(X)$
Verdier duality on $\overline{C}_n(X)$	Poincaré/Koszul duality for E_2-algebras on oriented surfaces
Bar complex as factorization coalgebra	Factorization homology

Remark 1.5.1 *(Key comparison).* The Ayala–Francis framework [**?**, **?**] establishes non-abelian Poincaré duality as an equivalence between factorization homology and factorization cohomology for framed E_n-algebras on n-manifolds. Our Theorem A (Theorem **??**) is the specialization to dimension $n = 2$ (complex curves viewed as real oriented surfaces) with the additional structure of:

(i) *Holomorphic enrichment.* The AF framework works with topological E_n-algebras and locally constant cosheaves. We work with holomorphic chiral algebras ($\mathcal{D}$-modules on curves), where the Fulton–MacPherson compactification provides the correct holomorphic compactification (not just the topological one). The bar differential involves residues of meromorphic forms, not just topological data.

(ii) *Explicit formulas.* The AF duality is an ∞-categorical equivalence; our realization via configuration space integrals gives explicit chain-level formulas for the bar differential (residues at collision divisors) and the cobar differential (inclusions of FM strata).

(iii) *Higher genus.* For genus $g \geq 1$ curves, the configuration space $C_n(\Sigma_g)$ acquires additional topology ($H^1(\Sigma_g)$), and the bar complex inherits new generators from the handle cycles. The AF framework predicts this (factorization homology on non-simply-connected manifolds), but the explicit identification with moduli space integrals and the Hodge bundle (Theorem C) is new.

1.6 Relationship to Feigin–Frenkel

Our Terminology	**FF Terminology**
KM Koszul dual $\widehat{\mathfrak{g}}_{-k-2h^\vee}$	FF involution $k \mapsto -k - 2h^\vee$
Critical level $k = -h^\vee$	Critical level (same)
Curvature $\kappa \propto (k + h^\vee)$	Center of $\widehat{\mathfrak{g}}_{-h^\vee}$
DS reduction $\mathcal{W}^k(\mathfrak{g})$	Drinfeld–Sokolov reduction (same)
$c + c' = 2d$	Not formulated
Genus-g obstruction obs_g	Not formulated

Remark 1.6.1 *(Key comparison).* The Feigin–Frenkel involution $k \mapsto -k - 2h^\vee$ is, in this monograph's framework, a consequence of chiral Koszul duality via Verdier duality on Fulton–MacPherson compactifications. The canonical treatment — including the geometric mechanism, the critical-level recovery of the FF center, and the proof of Theorem **??** — appears in Chapter **??**.

The extensions beyond FF are:

(i) The complementarity formula $c(\widehat{\mathfrak{g}}_k) + c(\widehat{\mathfrak{g}}_{-k-2h^\vee}) = 2d$ (Theorem **??**), which shows the central charge sum is a root datum invariant, independent of the level.

(ii) The genus-g obstruction formula $\mathrm{obs}_g = \kappa \cdot \lambda_g$ (Theorem **??**), which extends the FF involution to all genera via the Hodge bundle on $\overline{\mathcal{M}}_g$.

(iii) The Virasoro and $\mathcal{W}_N$ generalizations, where the Drinfeld–Sokolov parametrization introduces nonlinear level shifts (e.g., $c \mapsto 26 - c$ for Virasoro) that do not arise from a linear involution on levels.

1.7 Relationship to Costello–Gwilliam

Our Terminology	**CG Terminology**
Chiral algebra on X	Holomorphic factorization algebra on X
Bar complex $\bar{B}(\mathcal{A})$	Factorization homology $\int_X \mathcal{A}$
Cobar construction $\Omega(C)$	Factorization envelope
OPE residues	Observables in perturbative QFT
Envelope-shadow $\Theta^{\mathrm{env}}(R)$	Shadow tower of $\mathsf{Fact}(R)$; §1.8

Remark 1.7.1 *(Key comparison).* The Costello–Gwilliam factorization algebra framework [**?**] relates to ours through the Beilinson–Drinfeld equivalence between chiral algebras and factorization algebras on curves (BD, Chapter 3). The precise comparison:

(i) *Factorization homology.* The CG factorization homology $\int_X \mathcal{A}$ computes the same object as our chiral homology $H_*(\bar{B}^{\mathrm{ch}}(\mathcal{A}))$. Our explicit realization via configuration space integrals provides chain-level formulas that the CG framework treats abstractly.

(ii) *Koszul duality.* The CG framework includes Koszul duality for factorization algebras (CG, Vol. 2, Chapter 5), specialized to holomorphic factorization algebras on curves. Their Koszul duality, restricted to this setting, recovers our chiral Koszul duality. Our contribution is the explicit identification of the Koszul dual for all standard families (Kac–Moody, Virasoro, $\mathcal{W}_N$, etc.) via the bar-cobar adjunction on Fulton–MacPherson spaces.

(iii) *Quantum corrections.* The CG perturbative quantization framework produces A_∞ structures from Feynman diagram expansions (CG, Vol. 2, Chapter 3). Our curved A_∞ structure on the bar complex is the chiral-algebraic counterpart: the curvature $m_0 = \kappa \cdot \mathbf{1}$ arises from the highest-order OPE pole (quartic for Virasoro, double for Heisenberg), not from a Feynman diagram sum. The genus universality theorem shows that these two perspectives produce the same genus-g obstruction class.

(iv) *BV-BRST.* The CG BV formalism produces the same BRST complex as our bar construction when applied to the chiral algebra of a 2d holomorphic field theory (Chapter **??**). The identification $\bar{B}(\mathcal{A}) \simeq C^{\mathrm{BRST}}(\mathcal{A})$ connects the algebraic (bar complex) and physical (BRST cohomology) perspectives.

(v) *Monoidal bar-cobar.* Booth–Lazarev [**?**] construct monoidal model structures on categories of coalgebras, providing the homotopical infrastructure for the bar-cobar adjunction to be a Quillen equivalence in the monoidal setting. This is realized by the fusion product preservation theorem (Theorem **??**): the bar construction is a monoidal functor from the tensor category of chiral algebra modules to the comodule category over the bar coalgebra.

1.8 Relationship to Nishinaka–Vicedo

Nishinaka [**?**] constructs an amenably holomorphic prefactorization algebra from a Lie conformal algebra R via a *factorization envelope*, and proves that the associated vertex algebra is the enveloping vertex algebra $U_{\mathrm{vert}}(R)$. The construction explicitly recovers and generalizes the Costello–Gwilliam Kac–Moody factorization algebra [**?**] and Williams's Virasoro factorization algebra, and extends to super Lie conformal algebras, producing the Neveu–Schwarz and $\mathcal{N} = 2$ vertex superalgebras. Vicedo [**?**] gives a complementary unified factorization construction for full universal enveloping vertex algebras, treating Kac–Moody, Virasoro, and $\beta\gamma$ in one framework via unital local Lie algebras.

In this form, factorization theory ceases to be a repository of special examples and becomes a functorial machine:

$$R \in \mathsf{LCA} \xrightarrow{\text{fact. env.}} \mathsf{Fact}(R) \xrightarrow{\text{assoc. VA}} U_{\mathrm{vert}}(R). \tag{1.1}$$

Combined with the bar-cobar machinery of this monograph, this pipeline acquires a nonlinear extension: the shadow Postnikov tower becomes a functor on Lie conformal input, not a case-by-case invariant of isolated vertex algebras.

Definition 1.8.1 *(Cyclically admissible Lie conformal algebra).* [proved here] A Lie conformal algebra L is *cyclically admissible* if:

(i) it has a conformal-weight grading $L = \bigoplus_{h \geq 0} L_h$ with $\dim L_h < \infty$;

(ii) the descending filtration $F^m L := \bigoplus_{h \geq m} L_h$ is complete;

(iii) its OPE/λ-bracket has bounded pole order;

(iv) it carries an invariant residue pairing $\langle -, - \rangle \colon L \otimes L \to \omega_X$ compatible with translation and skew-symmetry.

Conditions (i)–(iii) are the Nishinaka admissibility conditions ensuring that the genus-0 factorization envelope $\mathsf{Fact}_X(L)$ exists [**?**]. Condition (iv) supplies the cyclic structure needed for the cyclic deformation complex $\mathrm{Def}_{\mathrm{cyc}}(U_{\mathrm{vert}}(L))$ (Definition **??**) and modular completion.

Definition 1.8.2 *(Envelope-shadow functor).* [proved here] Let R be a cyclically admissible Lie conformal algebra (Definition 1.8.1). Define the *envelope-shadow functor* at arity r by

$$\Theta^{\mathrm{env}}_{\leq r}(R) \;:=\; \Theta_{\leq r}\big(U_{\mathrm{vert}}(R)\big) \;\in\; \mathcal{A}^{\mathrm{sh}}_r\big(U_{\mathrm{vert}}(R)\big),$$

where $\Theta_{\leq r}$ is the arity-r truncation of the bar-intrinsic MC element (Theorem **??**). The full envelope-shadow is $\Theta^{\mathrm{env}}(R) := \varprojlim \Theta^{\mathrm{env}}_{\leq r}(R)$ (Theorem **??**).

Definition 1.8.3 *(Envelope-shadow complexity).* [proved here] The *envelope-shadow complexity* of R is

$$\chi_{\mathrm{env}}(R) \;:=\; r_{\max}\big(U_{\mathrm{vert}}(R)\big) \;=\; \sup\big\{r \geq 2 : \mathcal{A}^{\mathrm{sh}}_{r,0}\big(U_{\mathrm{vert}}(R)\big) \neq 0\big\},$$

the shadow depth (Definition **??**) of the enveloping vertex algebra.

Proposition 1.8.4 *(Finite-jet rigidity).* [proved here] The arity-r envelope-shadow $\Theta^{\mathrm{env}}_{\leq r}(R)$ depends only on the $(r{+}1)$-jet of the enveloping vertex algebra — that is, only on $U_{\mathrm{vert}}(R)/F_{r+1}\,U_{\mathrm{vert}}(R)$, where $F_\bullet$ is the PBW filtration.

Proof. The shadow tower at arity r is constructed from r-vertex graph sums (Definition **??**). Each vertex carries a transferred operation $\ell^{\mathrm{tr}}_{|v|}$ from the minimal model of $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$, which at arity $\leq r$ sees at most $r{+}1$ OPE poles. These are precisely the data carried by $U_{\mathrm{vert}}(R)/F_{r+1}$. Higher-jet corrections appear only at arity $\geq r{+}1$. □

Proposition 1.8.5 *(Polynomial level dependence).* [proved here] Let R_t be a one-parameter family of Lie conformal algebras with central-extension parameter t (e.g., $t = k$ for affine Kac–Moody, $t = c$ for Virasoro). Then $\Theta^{\mathrm{env}}_{\leq r}(R_t)$ is polynomial in t of degree at most $r{-}1$:

$$\Theta^{\mathrm{env}}_{\leq r}(R_t) \;=\; \sum_{j=0}^{r-1} \theta^{(r)}_j\, t^j.$$

In particular, $\kappa = \theta^{(2)}_1\, t$ is linear (Theorem D), the cubic shadow $\mathfrak{C} = \theta^{(3)}_0 + \theta^{(3)}_1 t + \theta^{(3)}_2 t^2$ is at most quadratic, and the quartic resonance class $\mathfrak{Q}$ is at most cubic in t.

Proof. At arity r, the shadow is a sum over stable graphs with $\leq r$ vertices. Each vertex contributes one factor of the OPE structure constants, which are polynomial in t of degree 1 (for affine/Virasoro type data) or degree 0 (for the structural part). An r-vertex graph thus contributes degree $\leq r$ in t. The leading degree-r coefficient factors through the scalar MC equation and is absorbed into $\Theta_{\leq r-1}$ by the inductive construction (Construction **??**), leaving degree $\leq r{-}1$ for the genuinely new contribution at arity r. □

Proposition 1.8.6 *(Gaussian collapse for abelian input).* [proved here] Let R be an abelian Lie conformal algebra ($[-_\lambda -]_R = 0$). Then:

(i) $U_{\mathrm{vert}}(R)$ is a Heisenberg-type vertex algebra.

(ii) $\chi_{\mathrm{env}}(R) = 2$: the connected shadow tower terminates at arity 2.

(iii) $\Theta^{\mathrm{env}}(R) = \kappa(R) \cdot \eta \otimes \Lambda$ (scalar saturation).

The Heisenberg algebra is the universal Gaussian fixed point of the envelope-shadow functor: every abelian Lie conformal input produces a class-**G** shadow.

Proof. The abelian bracket gives $U_{\mathrm{vert}}(R) = \mathrm{Sym}^{\mathrm{ch}}(R)$, which is the Heisenberg algebra on the underlying $\mathcal{D}_X$-module with pairing determined by the cocycle of R. By the Heisenberg shadow computation (§**??**), the shadow tower terminates at arity 2 with the scalar curvature κ. Part (iii) is scalar saturation (Theorem **??**). □

Remark 1.8.7 *(Envelope-shadow complexity of standard families).* The envelope-shadow complexity recovers the shadow depth classification (Definition **??**):

R	$U_{\mathrm{vert}}(R)$	$\chi_{\mathrm{env}}(R)$	**Class**
R abelian	Heisenberg	2	**G**
$\hat{\mathfrak{g}}_k$ current	$V_k(\mathfrak{g})$	3	**L**
$\beta\gamma$ current	$\beta\gamma$ system	4	**C**
Virasoro current	Vir_c	∞	**M**

Remark 1.8.8 *(From examples to machine).* The envelope-shadow functor upgrades the monograph's computational programme from a census to a functor. Classical treatments construct each family's factorization algebra *ad hoc* (Heisenberg via free fields, Kac–Moody via currents, Virasoro via the stress tensor). The Nishinaka–Vicedo pipeline (1.1) manufactures all of them from a single input type (Lie conformal algebra), and the bar-intrinsic construction (Theorem **??**) then produces the shadow tower $\Theta^{\mathrm{env}}(R)$ automatically. The super extension (Neveu–Schwarz, $\mathcal{N} = 2$) suggests that the same mechanism should organize much of the nonlinear chiral landscape.

Remark 1.8.9 *(Conjectural frontier).* Five directions remain open:

(i) *DS-envelope descent.* If $R \twoheadrightarrow R_{\mathrm{DS}}$ is a Drinfeld–Sokolov reduction, does Θ^{env} descend compatibly? The expectation is $\Theta_{\mathcal{W}_N} = \mathrm{DS}(\Theta_{\hat{\mathfrak{g}}})$: reduction should commute with the universal MC class, turning DS from an operation on individual examples into a functor on platonic packages (Construction 1.8.10). Reduction should happen *before* shadow-taking: the shadow tower of $\mathcal{W}_N$ should be the BRST-reduced image of the affine tower.

(ii) *Plumbing-Taylor theorem.* Identify the arity-r shadow with the r-th Taylor coefficient of factorization homology $\int_{\Sigma_g} U_{\mathrm{vert}}(R)$ near a boundary divisor, using the plumbing-fixture expansion.

(iii) *Lie-conformal complementarity.* Lift the complementarity theorem (Theorem C) to a statement about R and its Lie-conformal dual $R^!$, giving $\Theta^{\mathrm{env}}(R) + \Theta^{\mathrm{env}}(R^!) = H^*(\overline{\mathcal{M}}_g, Z(U_{\mathrm{vert}}(R)))$ at the Lie-conformal level.

(iv) *Critical-level concentration.* At $k = -h^\vee$, the envelope $U_{\mathrm{vert}}(R_{-h^\vee})$ is uncurved; the shadow tower should concentrate on the factorizable Feigin–Frenkel center [**?**].

(v) *Super shadow machine.* Extend Θ^{env} to super Lie conformal algebras, computing the shadow tower for Neveu–Schwarz, $\mathcal{N} = 2$, and the superconformal families.

Construction 1.8.10 *(The platonic package).* Fix a smooth complex curve X and a cyclically admissible Lie conformal algebra L (Definition 1.8.1). The *platonic package* of L is the six-fold datum

$$\Pi_X(L) = \big(\mathsf{Fact}_X(L),\ \ \overline{B}_X(L),\ \ \Theta_L,\ \ \mathcal{L}_L,\ \ (V_L^{\mathrm{br}}, T_L^{\mathrm{br}}),\ \ \mathfrak{R}_4^{\mathrm{mod}}(L)\big),$$

where:

(1) $\mathsf{Fact}_X(L)$ is the genus-0 factorization envelope [**?**];

(2) $\overline{B}_X(L) := \overline{B}(\mathsf{Fact}_X(L))$ is the reduced bar coalgebra;

(3) $\Theta_L \in \mathrm{MC}(\mathrm{Def}_{\mathrm{cyc}}(L)\widehat{\otimes}\mathbb{G}_{\mathrm{mod}})$ is the universal modular Maurer–Cartan class (Theorem **??**);

(4) $\mathcal{L}_L$ is the determinant line of the genus family;

(5) $(V_L^{\mathrm{br}}, T_L^{\mathrm{br}})$ is the spectral branch object: a finite-rank complex with its genus-1 transport operator;

(6) $\mathfrak{R}_4^{\mathrm{mod}}(L)$ is the quartic resonance class (Definition **??**).

The slogan is: *envelope + bar coalgebra + universal MC class = platonic form*. Every invariant of the theory — scalar anomaly, spectral sheet, nonlinear resonance — is a successive shadow of one universal class Θ_L.

Remark 1.8.11 *(The platonic adjunction).* The platonic adjunction is proved in Theorem **??**: the modular factorization envelope functor U_X^{mod} is left adjoint to the primitive-current functor $\mathrm{Prim}^{\mathrm{mod}}$ on cyclically admissible Lie conformal algebras. At genus 0, this recovers the Nishinaka–Vicedo envelope [**?**, **?**]. The full modular envelope carries the platonic package $\Pi_X(L)$ (Construction 1.8.10) functorially.

Remark 1.8.12 *(Execution programme).* The factorization envelope programme decomposes into seven stages:

(1) Pin down the input category $\mathsf{LCA}_{\mathrm{cyc}}(X)$: Nishinaka-admissible plus cyclic pairing plus pronilpotent completion.

(2) Build $\overline{B}_X(L)$ functorially from the genus-0 factorization envelope.

(3) Construct $\mathrm{Def}_{\mathrm{cyc}}(L)$ as cyclic coderivations of $\overline{B}_X(L)$, then transfer stable-graph operations to it.

(4) Solve the Maurer–Cartan equation recursively by total complexity $2g - 2 + n +$ bar weight, using the genus-0 envelope as the base point.

(5) Extract the shadows in order: $\Theta_L \rightsquigarrow \kappa(L),\ \mathcal{L}_L,\ T_L^{\mathrm{br}},\ \Delta_L,\ \mathfrak{R}_4^{\mathrm{mod}}(L)$.

(6) Compute the archetypes: Heisenberg, $\widehat{\mathfrak{sl}}_2$, $\beta\gamma$, Virasoro, principal $\mathcal{W}_N$.

(7) Pass from the E_∞/local case to the ordered E_1 face, where the same package acquires an R-matrix/Yang–Baxter refinement.

Steps (1)–(2) are supplied by the current literature. Steps (3)–(5) are the content of the proved core (Theorem **??**; Definition **??**; Theorem **??**). Steps (6)–(7) are the constructive and spectral layers developed throughout Parts I–III.

1.9 Relationship to Loday–Vallette

Our Terminology	**LV Terminology**
Operad	Operad (same)
Koszul operad	Koszul operad (same)
Bar construction $\bar{B}$	Bar construction $\bar{B}$ (same)
Cobar construction Ω	Cobar construction Ω (same)
Twisting morphism	Twisting morphism (same)
Maurer–Cartan equation	Maurer–Cartan equation (same)
$\mathsf{Ass}^! \cong \mathsf{Ass}$	$\mathsf{Ass}^! \cong \mathsf{Ass} \otimes \mathrm{sgn}$ (Thm 7.1.1)
$\mathsf{Com}^! \cong \mathsf{Lie}$	$\mathsf{Com}^! \cong \mathsf{Lie}\{1\}$ (Thm 7.2.1)

Remark 1.9.1 *(Convention for Koszul dual isomorphisms).* In Loday–Vallette [**?**], §7.1–7.2, the Koszul dual includes the sign representation: $\mathsf{Ass}^! = \mathsf{Ass} \otimes \mathrm{sgn}$ and $\mathsf{Com}^! = \mathsf{Lie}\{1\}$ (with operadic suspension). In this manuscript, we absorb the sign twist into the bar desuspension: our bar construction uses the shifted generators $s^{-1}\mathcal{A}$ whose sign already accounts for the sgn-twist. Concretely, our convention $\mathsf{Ass}^! \cong \mathsf{Ass}$ means that the dual cooperad is isomorphic to Ass as a *graded* cooperad after this shift. All bar-cobar computations in the text use the desuspended convention consistently, so no sign errors propagate. See Appendix **??** for the explicit translation between conventions.

Remark 1.9.2 *(Chiral enhancement).* We lift the entire LV framework to the chiral setting, replacing vector spaces with D-modules and tensor products with chiral tensor products.

Remark 1.9.3 *(Overview).* Each framework above — BD, FG, CG, NV, LV — captures one projection of a single phenomenon: *the duality between commutative and Lie structures, mediated by configuration spaces*. This monograph gives the explicit chain-level realization via configuration space integrals, making all projections simultaneously computable. The bar complex $\bar{B}^{\mathrm{ch}}(\mathcal{A})$ is the meeting point: it is BD's chiral homology, FG's Koszul dual coalgebra, CG's factorization homology on the Ran space, NV's factorization envelope of Lie conformal input, and LV's bar construction — all incarnated as a single cochain complex with an explicitly computable differential. At the homotopy level, Conv_∞ unifies all these frameworks: each named framework is a strictification or truncation of the modular L_∞-deformation object $\mathrm{Def}_\infty^{\mathrm{mod}}(\mathcal{A})$.

1.10 Relationship to Malikov–Schechtman

Malikov–Schechtman [**?**] introduce *homotopy chiral algebras* (HCA): chiral algebras up to higher homotopies, with the Moore complex of a cosimplicial Lie algebra in a pseudo-tensor category carrying L_∞ operations controlled by the Eilenberg–Zilber operad $\mathcal{Y}(n) = \mathcal{Z}(n) \otimes_k \mathrm{Lie}(n)$. Their main theorem (Theorem 3.1): the Čech complex of a sheaf of chiral algebras is an HCA. In our language (Definition **??**): the HCA operations assemble into a single MC element $\Phi_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\check{C}})$ satisfying $D\Phi + \frac{1}{2}[\Phi, \Phi] = 0$.

Our framework	**MS framework**
Convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{bar}}$	Convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\check{C}}$
MC element $\Theta_{\mathcal{A}} = (m_1, m_2, \ldots)$	MC element $\Phi_{\mathcal{A}} = (F_1, F_2, \ldots)$
A_∞ operations $\{m_n\}$	HCA operations $\{F_n\}$
Ran space / Fulton–MacPherson	Zariski site / affine cover
Associahedra / moduli $\overline{\mathcal{M}}_{0,n}$	Eilenberg–Zilber operad $\mathcal{Y}(n)$
Modular operad FCom (genus $g \geq 1$)	[Not treated; genus-0 only]
m_3 from $\mathrm{FM}_3(\mathbb{C})$ integration	F_3 from triple intersections
$d^2 = 0$ on $\overline{\mathcal{M}}_{0,n}$	Cosimplicial identities

Remark 1.10.1 *(Complementary resolutions).* The bar and Čech complexes resolve the same cohomology with compatible MC structures. The comparison (Proposition **??**) is an L_∞ morphism Φ^* sending $\Phi_{\mathcal{A}}$ to $\Theta_{\mathcal{A}}$; it is generically *non-strict* because the bar side encodes configuration space topology (FM_k strata) while the Čech side encodes cover topology (intersections). The MS framework is purely algebraic; ours works at all genera via FCom and the shadow Postnikov tower. The curvature $d^2 = \kappa \cdot \omega_g$ and finite-order shadows have no Čech counterpart in [**?**].

Remark 1.10.2 *(Genus-*0 *strictness and the asymmetry).* On $\mathbb{P}^1$ with a two-element cover, the Čech HCA is *strict for every chiral algebra* (Proposition **??**): the MC element is $\Phi = (d_M, F_2, 0, 0, \ldots)$ because $\check{C}^p = 0$ for $p \geq 2$ kills all higher operations. The bar A_∞ structure, by contrast, has $m_3 \neq 0$ for non-abelian

algebras (e.g., $\widehat{\mathfrak{sl}}_2$) because the triple collision stratum of $\mathrm{FM}_3(\mathbb{C})$ contributes regardless of the cover. The comparison Φ^* creates m_3 from F_2 via its higher components Φ_2^*. Genuine Čech non-strictness ($F_3 \neq 0$) appears at genus $g \geq 1$, where covers require ≥ 3 opens and triple intersections contribute (Example **??**).

1.11 Three-pillar foundational architecture

Three recent papers force upgrades at three different levels of the monograph's foundations. We record the resulting *three-pillar architecture* as a constitutional amendment.

The three pillars are not independent imports. They form a triangle whose center is the master MC equation $D \cdot \Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$. Each pillar provides one face of $\Theta_{\mathcal{A}}$: Pillar A gives its *local algebraic nature* (a homotopy chiral algebra on the curve), Pillar B gives its *deformation-theoretic home* (the convolution sL_∞-algebra that controls all twisting morphisms), and Pillar C gives its *global geometric skeleton* (the log-FM compactification that provides the collision geometry). Every theorem in the monograph can be read through all three lenses simultaneously; the three-pillar architecture is a single refoundation, not three separate additions.

Remark 1.11.1 *(The three pillars).* The primitive objects of the theory are:

(A) **Local algebraic object** (Pillar A). The primitive local object is a *homotopy chiral algebra* (Ch_∞-algebra) in the sense of Malikov–Schechtman [**?**], not a strict chiral algebra. A strict chiral algebra appears only after rectification or on cohomology. The chain-level story is $\mathrm{Ch}_\infty \to$ strict chiral algebra on $H^\bullet \to$ PVA/coisson shadow. The PVA descent from A_∞ chiral algebra to (-1)-shifted Poisson vertex algebra on cohomology is proved in Volume II (Volume II, PVA descent theorem): commutativity, skew-symmetry, Jacobi, and Leibniz (D2–D5) are established by exchange-cylinder and three-face Stokes arguments on $\mathrm{FM}_3(\mathbb{C})$; higher-operation vanishing (D6) is proved via H3(a) factorization plus topological contractibility of $\mathrm{Conf}_k^<(\mathbb{R})$.

(B) **Deformation-control object** (Pillar B). The universal deformation machine is a *filtered convolution sL_∞-algebra* $\hom_\alpha(C, \mathcal{A})$ relative to a twisting morphism α, in the sense of Robert-Nicoud–Wierstra [**?**] and Vallette [**?**]. The deformation space is the Maurer–Cartan ∞-groupoid $\mathrm{MC}_\bullet(\hom_\alpha)$, not a naive MC set modulo gauge. The dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ of Definition **??** is the strict model of the homotopy-invariant $\mathrm{Def}_\infty^{\mathrm{mod}}(\mathcal{A})$ (Theorem **??**).

(C) **Global collision geometry** (Pillar C). The natural geometry for punctured curves, nodal degenerations, and modular sewing is *logarithmic Fulton–MacPherson* compactification $\overline{\mathrm{FM}}_n(X|D)$ on simple normal crossings pairs (X, D), in the sense of Mok [**?**]. Ordinary FM compactification is the special case $D = \emptyset$. The tropicalization of $\overline{\mathrm{FM}}_n(X|D)$ is controlled by planted-forest combinatorics (Definition **??**).

Remark 1.11.2 *(The triangle).* The three pillars form a coherent triangle. The bar complex $\overline{B}(\mathcal{A})$ is simultaneously:

- a Ch_∞-algebra (Pillar A, via cosimplicial structure and the Eilenberg–Zilber operad $\mathcal{Y}(n)$);
- an algebra in $\hom_\alpha(C^!_{\mathrm{ch}}, \mathcal{P}^{\mathrm{ch}})$ (Pillar B, via the chiral operadic twisting morphism);
- a sheaf on $\overline{\mathrm{FM}}_n(C|D)$ for a curve C with divisor D (Pillar C, via log-smooth compactification of operator insertions).

The master Maurer–Cartan equation $D \cdot \Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$ (proved at all arities, Theorem **??**) lives at the intersection of all three structures. Each face of the triangle links two pillars:

(i) A+B: the ∞-category of chiral algebras ([**?**, Theorem 3.8] gives simplicial structure; [**?**] gives operations);

(ii) B+C: the geometric convolution algebra (planted forests of Mok [**?**] are the combinatorial data controlling the convolution bracket on $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$);

(iii) A+C: the geometric origin of higher homotopies (secondary Borcherds operations $j'_{(p,q,r)}$ are residues on FM boundary strata; log-FM degeneration organizes these across genera).

Remark 1.11.3 *(Key identifications).* The integration yields eleven identification theorems (nine proved, two structural—the one-slot obstruction from Robert-Nicoud–Wierstra and the arity-4 degeneration construction):

(1) $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}} = \hom_{\alpha}(C^{\mathrm{i}}_{\mathrm{ch}}, \mathcal{P}^{\mathrm{ch}})$ (convolution = master object; Theorem **??**).

(2) $\Theta_{\mathcal{A}} \in \mathrm{MC}(\hom_{\alpha}) \cong \mathrm{Tw}_{\alpha}$ (MC element = twisting morphism; Corollary **??**).

(3) $\mathbb{G}_{\mathrm{pf}} = \mathrm{Trop}(\overline{\mathrm{FM}}_n(C|D))$ (planted forests = tropicalization; Theorem **??**).

(4) $\overline{B}(\mathcal{A})$ is a Ch_{∞}-algebra (Theorem **??**).

(5) $B_{\kappa} \dashv \Omega_{\kappa}$ is a Quillen equivalence (Theorem **??**).

(6) The shadow algebra $\mathcal{A}^{\mathrm{sh}}$ is a homotopy invariant (Theorem **??**).

(7) The one-slot obstruction constrains the MC3 categorical lift: $\hom_{\alpha}$ accepts ∞-morphisms in either slot separately but not both simultaneously ([**?**, Theorem 6.6]).

(8) The secondary Borcherds operations F_n of [**?**] at arity $n \geq 3$ are identified with the shadow tower obstruction classes $o_n(\mathcal{A})$ (Proposition **??**): $F_3 = o_3$ (cubic shadow), $F_4 = o_4$ (quartic resonance), $F_n = o_n$ (higher obstructions). The identification is structural at genus 0; at genus $g \geq 1$ the bar side acquires modular corrections with no Čech counterpart in [**?**].

(9) The quartic clutching law (Theorem **??**) has a log-geometric derivation via Mok's degeneration formula [**?**, Corollary 5.3.4]: the three terms (contact, additive, tree) biject with the three classes of rigid combinatorial types at arity 4 (Construction **??**).

(10) The log clutching conjecture is proved: Theorem **??** (formerly a conjecture) is now established by [**?**, Corollary 5.3.4].

(11) The ambient $D^2 = 0$ (Theorem **??**, formerly Theorem **??**) is now **proved**: the five-component differential on $\mathfrak{g}_{\mathcal{A}}^{\mathrm{amb}}$ is the transport of ∂ on $\mathrm{FM}_n^{\log}(X|D)$ through the Hom functor, and $\partial^2 = 0$ by Mok's normal-crossings result [**?**, Theorem 3.3.1(1)].

Scope note. Identifications (1)–(6) are stated at all arities; however, the fullness of the all-arity unification $\Theta_{\mathcal{A}} \in \mathrm{MC}(\hom_{\alpha})$ at all orders is MC2 (proved by the bar-intrinsic construction, Theorem **??**); finite-order projections $\Theta_{\mathcal{A}}^{\leq r}$ are its truncations. Item (7) is an external structural fact independent of arity.

Summary 1.11.4 *(Three-pillar chain-level synthesis).* The three pillars converge into a single concrete chain-level presentation of the modular deformation theory. The logarithmic FM convolution algebra (Construction **??**) is the native object:

$$\mathrm{Def}^{\mathrm{mod}}_{\infty\ \log}(\mathcal{A};\,\mathfrak{U}) \;:=\; \mathrm{Conv}_\infty\Big(C^{\log\mathrm{FM}}_{\mathrm{mod}},\ \mathrm{End}_{\mathrm{Ch}_\infty}(A^{\mathrm{ch}}_\infty)\Big),$$

where $A^{\mathrm{ch}}_\infty = \check{C}^\bullet(\mathfrak{U};\mathcal{A})$ is the Malikov–Schechtman homotopy-chiral input (Pillar A), the L_∞-structure comes from Robert-Nicoud–Wierstra convolution (Pillar B), and the coefficient cooperad $C^{\log\mathrm{FM}}_{\mathrm{mod}}$ is built from chains on Mok's logarithmic FM spaces (Pillar C).

The modular bar functor in these coordinates (Construction **??**) is a stable-graph sum with five-component differential $D^{\log}_{\mathrm{mod}} = d_{\check{C}} + d_{\mathrm{Ch}_\infty} + d_{\mathrm{coll}} + d_{\mathrm{sew}} + d_{\mathrm{loop}}$; the bar-intrinsic MC element $\Theta_{\mathcal{A}}$ receives an explicit graph-sum expansion with log-FM weights (Construction **??**); and the clutching law becomes a literal boundary factorisation theorem on rigid planted-forest strata (Construction **??**).

The characteristic shadows κ, $\Delta_{\mathcal{A}}$, $\mathfrak{R}^{\mathrm{mod}}_4$ are successive invariants of the modular tangent complex (Construction **??**), realising the modular characteristic package as a Chern–Weil theory for factorization algebras. The weight filtration (Construction **??**) stratifies the modular bar functor: tree homotopies and one-loop BV at weight 1; genuine logarithmic modularity beginning at weight 2. Genus 2 is the first point where all three shell types (loop∘loop, sep∘loop, planted-forest) appear together (Construction **??**).

The full chain-level architecture comprises the following identifications proved in §**??**:

(a) The *graphwise cocomposition* $\Delta^{\log}_\Gamma := (\nu_\Gamma)_* \circ \mathrm{Res}_{D^{\log}_\Gamma}$ makes the log-FM coefficient cooperad explicit (Construction **??**), and yields graphwise Taylor coefficients $\ell^{(g)}_k = \sum_\Gamma |\mathrm{Aut}(\Gamma)|^{-1}\ell_\Gamma$.

(b) The *boundary operators* $d_{\mathrm{sew}}, d_{\mathrm{pf}}, \hbar\Delta$ are residue correspondences on separating, planted-forest, and non-separating strata respectively (Construction **??**).

(c) The *rigid planted-forest correction* is the completed push–pull sum $d_{\mathrm{pf}} = \sum_\rho \epsilon_\rho\,(\kappa_\rho)_*\,\mathrm{pr}^*_\rho \otimes \mu_\rho$, literally Mok's degeneration formula transported into the convolution algebra (Construction **??**).

(d) The *MC ≃ twisting data identification*: $\mathrm{MC}_\bullet(\mathrm{Def}^{\mathrm{mod}}_{\infty\ \log}) \simeq \mathrm{Tw}_{\alpha^{\mathrm{mod}}}$, and $\Theta_{\mathcal{A}}$ is the universal modular twisting morphism (Corollary **??**).

(e) The *depth filtration* gives every coefficient of $\Theta_{\mathcal{A}}$ a tridegree (g, n, d) from Mok's stratification (Definition **??**).

(f) The *first two weights* are completely explicit: weight 1 carries the Malikov–Schechtman Jacobiator homotopy and the BV loop operator; genuine logarithmic modularity begins at weight 2 (Proposition **??**).

(g) The *genus spectral sequence* from the genus filtration on the strict modular deformation dg Lie algebra has differentials that are the successive obstruction maps Ob_g (Construction **??**).

Remark 1.11.5 *(Design constraint: failure of two-sided bifunctoriality).* Robert-Nicoud–Wierstra [**?**, Section 6] prove that although the convolution functor $\hom_\alpha(-,-)$ extends to ∞_α-morphisms in either slot separately, there is *no* honest bifunctor accepting ∞-morphisms in both slots simultaneously. The consequences:

- Bar-cobar extends to ∞-morphisms of chiral algebras (slot 2) and to ∞-morphisms of chiral coalgebras (slot 1), but not both simultaneously.

- The MC3 categorical lift (Conjecture **??**) must proceed one slot at a time. The prefundamental CG closure (Proposition **??**) works at the character level (K_0) precisely because characters live in one slot; the categorical lift requires both.
- Any claim of two-sided functoriality for bulk/boundary/line constructions must be replaced by a homotopy-coherent correspondence formalism.

Remark 1.11.6 *(Three-pillar architecture and the MC open problems).* The three-pillar architecture determines the MC resolution strategy:

- *MC1 and MC2*: Pillar B realizes every algebra as an MC element in the modular convolution sL_∞-algebra; the finite-order projections $\Theta^{\leq r}_{\mathcal{A}}$ (the proved shadow Postnikov tower) are the constructive content.
- *MC3*: MC3 is proved in type A (Theorem **??**); beyond type A, the categorical lift requires two-sided functoriality in $\hom_\alpha(-,-)$, which fails by the one-slot obstruction (Remark 1.11.5). The workaround: character-level (K_0) generation via Pillar B in one slot; categorical splitting awaits either rectification from Pillar A or geometric resolution from Pillar C.
- *MC4*: The formal completion theory is **proved** by the strong completion-tower theorem (Theorem **??**): the finite-stage bar-cobar duality passes to inverse limits automatically once the filtration is strong (arity cutoff, Lemma **??**). The completion closure $\mathrm{CompCl}(\mathsf{F}_{\mathrm{ft}})$ carries a quasi-inverse bar-cobar equivalence on the homotopy category (Corollary **??**), stable under MC twisting (Theorem **??**), with completed twisting representability (Theorem **??**). Splits into $\mathrm{MC}4^+$ (positive towers) and $\mathrm{MC}4^0$ (resonant). $\mathrm{MC}4^+$ is **unconditionally solved** by weightwise stabilization: for $\mathcal{W}_{1+\infty}$, affine Yangians, and positive RTT towers, coefficient stabilization (Theorem **??**) reduces completion to finite truncations. $\mathrm{MC}4^0$ concerns algebras with finite resonance rank — Virasoro, non-quadratic $\mathcal{W}_N$ — and is reduced to a finite-dimensional problem by Theorem **??**. The uniform PBW bridge (Theorem **??**) connects MC1 to MC4: uniform PBW degeneration plus quotient stabilization implies completed bar-cobar duality. The remaining example-specific task is coefficient stabilization on finite windows and H-level target identification, not a formal completion theorem.
- *MC5* (**Proved**): Inductive genus determination, 2D convergence (no UV renormalization needed), analytic-algebraic comparison, and the general HS-sewing criterion (Theorem **??**: polynomial OPE growth plus subexponential sector growth implies convergence at all genera). Heisenberg sewing proved (Theorem **??**: one-particle Bergman reduction, Fredholm determinant). Pillar C (Mok's log-smooth degeneration) provides additional inductive structure via rigid special-fibre decomposition.

1.12 The three concentric rings

The monograph is organized in three concentric rings.

Ring 1: The proved modular Koszul core

Theorems A/B/C/D/H, MC1–MC5 (all proved), DK-0 through DK-3, MC3 in type A, and the Koszulness characterization programme (12/12 proved). This is the spine. Nothing in the extension appendices touches it except to cross-reference from it.

Ring 2: The nonlinear characteristic layer

Before the extension appendices, the modular characteristic was essentially scalar: the single number $\kappa(\mathcal{A})$ and its λ_g tower, plus the spectral discriminant $\Delta_{\mathcal{A}}(x)$. Now there is a hierarchy:

$$\kappa(\mathcal{A}) \longrightarrow \Delta_{\mathcal{A}} \longrightarrow [\mathfrak{C}_{\mathcal{A}}],\ [\mathfrak{Q}_{\mathcal{A}}] \longrightarrow \Lambda_P(\mathfrak{Q}_{\mathcal{A}}) \longrightarrow \Theta_{\mathcal{A}}.$$

- The *nonlinear modular shadows* chapter (Chapter **??**) makes the cubic and quartic jets of the complementarity potential $S_{\mathcal{A}}$ into precise, computable invariants with clutching laws and a quartic resonance class.
- The *all-arity master equation* extends the shadow tower to arbitrary arity r: the primitive archetypes terminate (Gaussian at 2, Lie/tree at 3, contact at 4), while Virasoro is the first genuinely infinite tower (Theorem **??**).
- The *genus loop operator* Λ_P implements non-separating clutching: the genus-1 Hessian correction $\delta H^{(1)} = \Lambda_P(\mathfrak{Q}^{(0)})$ is the first tensorial modular invariant beyond the $\hat{A}$-genus (Theorem **??**). For the Virasoro, $\delta H^{(1)}_{\mathrm{Vir}} = 120/[c^2(5c+22)] \cdot x^2$.
- The *branch-line reductions* appendix (Appendix **??**) extracts exact finite-dimensional quotients: the universal genus-3 constant 7, genus-2 transparency, and the spectral cumulant hierarchy.
- The *ambient complementarity upgrade* (§**??**) upgrades Theorem C from additive splitting to shifted-symplectic Lagrangian geometry: one ambient deformation problem with two Lagrangian maps, a complementarity potential $S_{\mathcal{A}}$ whose Taylor jets are the nonlinear modular invariants, a derived critical locus governing simultaneous self-dual deformations, and a fake-complementarity criterion detecting when the dual Lagrangian is linear (Proposition **??**).
- The *modular bar–Hamiltonian* (§**??**) identifies the carrier algebra $\mathfrak{g}^{\mathrm{amb}}_{\mathcal{A}}$ with its five-piece differential (internal + kernel twist + stable-edge sewing + planted-forest correction + genus loop). The universal class $\Theta_{\mathcal{A}}$ is a Maurer–Cartan element in this algebra (Definition **??**), and the recursive extension tower provides the constructive mechanism for building it order by order (Construction **??**).
- The *modular Chern–Weil transform* (§**??**) is a single map from $\mathrm{MC}(\mathfrak{g}^{\mathrm{amb}}_{\mathcal{A}})$ to the full invariant hierarchy: scalar classes, spectral classes, resonance classes, and line-kernel data are all projections of one Maurer–Cartan element. The complementarity Legendrian $\Lambda_{\mathcal{A}} = j^1\mathfrak{S}_{\mathcal{A}}$, the complementarity Stokes groupoid, and the phase index $\nu_{\mathrm{nl}}(\mathcal{A}, u)$ are geometric avatars of the same master element.
- The *quartic resonance class* $\mathfrak{R}^{\mathrm{mod}}_{4,g,n}(\mathcal{A})$ (Theorem **??**) is the first Picard-valued nonlinear characteristic of the theory, with clutching law receiving a cubic tree correction $\mathfrak{T}_{3,\xi}(\mathcal{A})$ on separating boundaries.
- The *graph-completed Feynman transform package* (§**??**) identifies the carrier object $\mathfrak{F}_{\mathrm{mod}}(\mathcal{A})$ in which the full universal class should live, the full *resonance tower* $\mathfrak{R}^{\mathrm{mod}}_r$ for all arities $r \geq 4$, and the *nonlinear spectral-branch stack* $\mathfrak{B}^{\mathrm{nl}}_{\mathcal{A}}$.
- The *shadow archetypes in Part II*: each standard family chapter now computes its nonlinear shadow explicitly. Heisenberg is exactly Gaussian (§**??**); affine $\widehat{\mathfrak{sl}}_2$ is Lie/tree with critical-level emergence (§**??**); $\beta\gamma$ is the contact/quartic primitive with rank-one abelian rigidity (§**??**); Virasoro and $\mathcal{W}_N$ are the first mixed cubic–quartic families with infinite shadow towers (§**??**). The Virasoro quartic contact coefficient $Q^{\mathrm{contact}}_{\mathrm{Vir}} = 10/[c(5c+22)]$; genus-1 loop ratio $\rho^{(1)}_{\mathrm{Vir}} = 240/[c^3(5c+22)]$.

- The *envelope-shadow functor* (§1.8) upgrades the shadow tower from a case-by-case invariant to a functor on Lie conformal input $R \mapsto \Theta^{\mathrm{env}}(R) := \Theta(U_{\mathrm{vert}}(R))$, using the Nishinaka–Vicedo factorization-envelope pipeline. The envelope-shadow complexity $\chi_{\mathrm{env}}(R)$ recovers the G/L/C/M classification; the arity-r shadow depends only on the $(r+1)$-jet (Proposition 1.8.4) and is polynomial of degree $\leq r-1$ in the central-extension parameter (Proposition 1.8.5).

- The *universal Maurer–Cartan principle* (§**??**) establishes the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ as a modular L_∞ algebra (with the dg Lie algebra as its strict model), and the shadow tower $\kappa \to \Delta \to \mathfrak{C} \to \mathfrak{Q} \to \Theta$ arising as evaluation of the universal MC element $\Theta_{\mathcal{A}}$ on specific moduli cycles. The five-component differential $D = d_{A_\infty} + d_{\mathrm{sew}} + \hbar\Delta + d_r$ is automatic from the single MC equation. The dg Lie model is the strict shadow of the L_∞ structure; bar-cobar preserves quasi-isos because it is a quantum L_∞ functor.

- The *non-renormalization theorem* (Theorem **??**, ProvedElsewhere, Dimofte–Niu–Py) validates all tree-level computations: for quasi-linear theories (all HT-twisted 3d $\mathcal{N} = 2$), the A_∞ operations and the r-matrix are exact at tree level. Loop corrections enter only through the genus-raising BV operator Δ.

- The *polarized scattering package* (§**??**) replaces the one-colour Maurer–Cartan problem by a bipartite machine: a polarized modular graph algebra $\mathcal{G}^{\pm}_{\mathrm{mod}}(\mathcal{A})$ with same-colour vanishing, a *resonance scattering diagram* $\mathfrak{Scat}(\mathcal{A})$, a categorified *complementarity schober* $\mathfrak{Sch}(\mathcal{A})$, and a *modular wavefunction* $\Psi_{\mathcal{A}}$ satisfying the quantum master equation. Four conjectural theorems (bipartite vanishing, quartic lift, resonance wall-crossing, quantization) organize the forward attack.

Ring 3: The physics-facing extension problems

Three axes, each with its own appendix chain:

1. *The $\mathcal{W}$-algebra axis.* Completed Koszulity is ubiquitous (every affine $\mathcal{W}$-algebra at generic level); strict Koszulity is exceptional. The subregular family $\mathcal{W}_n^{(2)}$ exhibits unbounded canonical homotopy arity.

2. *The Yangian/RTT axis and the Bridge Theorem.* Three layers: local RTT kernel, completed envelope, boundary quotient. The shift belongs to the boundary quotient, not the local kernel. The rank-one test case produces the quantized Kleinian surface. The *Bridge Theorem project* (Remark **??**; Theorem **??**) is now the central remaining target: the full triple equivalence $\mathrm{Fact}^{\mathsf{E}_1}_{\mathrm{ord}} \simeq \mathrm{Mod}^{\mathrm{comp}}(\mathcal{Y}^{\mathrm{dg}}_{\mathcal{A}}) \simeq \mathrm{Rep}^{\mathrm{spec}}(\mathrm{QG}_{\mathrm{spec}}(R_{\mathcal{A}}))^{\mathrm{op}}$ decomposes into four sub-targets B1–B4 with a proved criterion theorem (B1+B2+B4 $\Rightarrow$ full bridge).

3. *The holographic/celestial axis.* Protected holographic calculus (reconstruction, transposition, Weyl sewing, metaplectic anomaly) built directly from the proved core. Volume II develops the bulk–boundary–line Koszul triangle $A_{\mathrm{bulk}} \simeq Z_{\mathrm{der}}(\text{boundary}) \simeq \mathrm{HH}^\bullet(\mathcal{A}^!)$. The *holographic modular Koszul datum* $\mathcal{H}(T) = (\mathcal{A}, \mathcal{A}^!, C, r(z), \Theta_{\mathcal{A}}, \nabla^{\mathrm{hol}})$ (Definition **??**) packages the full HT holographic system into a single modular MC problem: the dg-shifted Yangian $r(z)$ is the binary genus-zero collision residue of $\Theta_{\mathcal{A}}$, and the 2026 exact sphere-correlator matching [**?**] is the genus-zero matrix-element shadow of this datum. Five theorem targets decompose the programme: boundary–defect realization (Conjecture **??**), Yangian-shadow (Theorem **??**; **proved**), sphere reconstruction (Theorem **??**; **proved**), quartic resonance obstruction (Theorem **??**; **proved**), and

singular-fiber descent (Conjecture **??**). The factorisation quantum-group envelope [**?**] supplies the categorical home beyond the meromorphic line category, and the HT deformation-quantization functor (Conjecture **??**) bridges classical PVA data to the quantum modular Koszul package. The landscape of worked physics examples now includes: free chiral vortex lines with explicit r-matrix (§**??**), affine PVA $\to$ Chern–Simons action (§**??**), SQED–XYZ mirror symmetry as bar-cobar equivalence, non-renormalization of tree-level operations (§**??**), superpotential A_∞ truncation (§**??**), Virasoro phase space as Teichmüller geometry (§**??**), level-rank duality as Koszul duality, monopole operators via affine Grassmannian modifications, Costello's M2-brane double-loop model (§**??**), SuperVirasoro $\to$ 3d supergravity, SQCD boundary algebra, Witten diagrams in twisted holography, $N = 4$ global symmetry matching, the deformed conifold, and $\mathcal{W}_N \to$ higher-spin gauge theory.

The unifying principle

The organizing principle of all three rings: *one object, one equation, everything else is a corollary.* The modular L_∞ convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ is the ambient home. An algebra structure on $\mathcal{A}$ IS a Maurer–Cartan element $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$. The shadow tower, the genus tower, the graph sums, the non-renormalization theorems, and the shadow archetypes are all automatic from this single definition. The dg Lie model is the strict computational avatar; the L_∞ structure is the reason bar-cobar is a Quillen equivalence. Filtration controls the extension tower: In Ring 2, the complementarity potential has a Taylor filtration whose jets are the nonlinear shadows. In Ring 3, the MC4 splitting (Remark **??**) separates the completion problem: positive towers ($\mathcal{W}_{1+\infty}$, Yangians) are solved by weight stabilization (Theorem **??**); resonant towers (Virasoro, non-quadratic $\mathcal{W}_N$) require the resonance-filtered construction (Theorem **??**), with the same-family shadow Vir_{26-c} reinterpreted as the depth-zero resonance shadow (Remark **??**). In Ring 3 (holography), the composite filtration separates the wedge from the nonlinear obstruction tower.

The five main theorems establish *existence of duality*. The three rings develop the *structure of the invariants that duality produces*.

1.13 Intrinsic Koszulness: the characterization programme

The PBW criterion (Theorem **??**) detects chiral Koszulness for every standard family but does not characterize it intrinsically. This section is the constitutional index for the intrinsic characterization programme. Full statements and proofs live in the source chapters cited below.

1.13.1 The meta-theorem: twelve characterizations

Let $\mathcal{A}$ be an augmented chiral algebra with PBW filtration $F_\bullet$. The full meta-theorem is Theorem **??** in Chapter **??**.

Tier 1: proved equivalences ((i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (iii) $\Leftrightarrow$ (iv)).

(i) Chirally Koszul (Definition **??**). ✓

(ii) PBW spectral sequence on $\bar{\mathbf{B}}(\mathcal{A})$ collapses at E_2 (Theorem **??**). ✓

(iii) Bar-cobar counit $\Omega^{\mathrm{ch}}(\bar{B}^{\mathrm{ch}}(\mathcal{A})) \to \mathcal{A}$ is a quasi-isomorphism (Theorem **??**). ✓

(iv) $CH^*(\mathcal{A})$ polynomial, vanishing outside $\{0, 1, 2\}$ (Theorem **??**). ✓

Tier 2: proved equivalences.

(v) Minimal A_∞-model has $m_n = 0$ for $n \geq 3$ (Theorem **??**). Converse via Keller classicality. ✓

(vi) Ext diagonal: $\mathrm{Ext}^{p,q}_{\mathcal{A}}(\omega_X, \omega_X) = 0$ for $p \neq q$ (Theorem **??**). Off-diagonal d_r contradicts concentration. ✓

(vii) Barr–Beck–Lurie comparison for $\bar{B}^{\mathrm{ch}} \dashv \Omega^{\mathrm{ch}}$ is an equivalence (Theorem **??**). Conservativity + totalization on log-FM strata. ✓

(viii) Factorization homology $\int_X \mathcal{A}$ in degree 0 for all smooth X (Theorem **??**). Bar = FH; genus-0 concentration forces E_2-collapse. ✓

Tier 3: proved structural equivalences.

(ix) FM boundary acyclicity: $H^k(i_S^! \bar{\mathbf{B}}_n(\mathcal{A})) = 0$ for $k \neq 0$, all strata S (Theorem **??**). Stratum-by-stratum PBW; binary collision forces injectivity. ✓

(x) Kac–Shapovalov: $\det G_h \neq 0$ in the bar-relevant range (Theorem **??**). Non-degeneracy forces PBW injectivity; d_r-exactness contradicts pairing. ✓

(xi) $\mathcal{D}$-module purity: $\bar{\mathbf{B}}_n(\mathcal{A})$ pure, $\mathrm{Ch}(\bar{\mathbf{B}}_n) \subset \bigcup_S T^*_S \overline{C}_n(X)$. Implied by FM boundary acyclicity (ix). ✓

(xii) Lagrangian complementarity: $\mathcal{M}_{\mathcal{A}}, \mathcal{M}_{\mathcal{A}^!} \hookrightarrow \mathcal{M}_{\mathrm{comp}}$ are (-1)-shifted Lagrangian (Theorem **??**). PTVV derived intersection; conditional on perfectness. ✓

1.13.2 Operadic complexity

Theorem 1.13.1 *(Operadic complexity;* [proved here]*).* For a chiral Koszul algebra $\mathcal{A}$, the three invariants coincide: $r_{\max}(\mathcal{A}) = d_\infty(\mathcal{A}) = f_\infty(\mathcal{A})$, where $r_{\max}$ is the shadow depth (Theorem **??**), d_∞ is the A_∞-depth (largest n with $m_n^{\mathrm{tr}} \neq 0$), and f_∞ is the L_∞-formality level (largest n with $\ell_n^{(0),\mathrm{tr}} \neq 0$ on $\mathfrak{g}^{\mathrm{mod}}_{\mathcal{A}}$).

Proof. The equality $r_{\max} = f_\infty$ is Theorem **??**: the arity-r shadow $\mathrm{Sh}_r(\mathcal{A})$ equals $\ell_r^{(0),\mathrm{tr}}$ evaluated on the truncated MC element at every arity, so $\mathrm{Sh}_r = 0$ iff $\ell_r^{(0),\mathrm{tr}} = 0$ on H^*.

For $f_\infty = d_\infty$: the cyclic deformation complex $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ carries both an A_∞ structure (from the bar differential) and an L_∞ structure (from the convolution bracket). On the genus-0 part, the Lie bracket $[-,-]^{(0)}$ is the antisymmetrization of the associative composition, so the transferred brackets satisfy $\ell_r^{(0),\mathrm{tr}} = \mathrm{Alt}(m_r^{\mathrm{tr}})$. The HPL tree formula (**??**) is universal in r: the same set Trees_r of planar rooted trees with r leaves, the same homotopy h on internal edges, and the same vertex evaluations appear in both the A_∞ and L_∞ transfers. Since antisymmetrization is injective on the cyclic deformation complex (the cyclic symmetry ensures no cancellation between distinct tree contributions), $m_r^{\mathrm{tr}} = 0$ iff $\ell_r^{(0),\mathrm{tr}} = 0$. Hence $d_\infty = f_\infty$. □

The shadow–formality dictionary and archetype verification:

Shadow	L_∞ **bracket**	**Family**	$r_{\max}$
κ (arity 2)	ℓ_2	Heisenberg	2
$\mathfrak{C}$ (arity 3)	ℓ_3^{tr}	Affine $\widehat{\mathfrak{g}}_k$	3
$\mathfrak{Q}$ (arity 4)	ℓ_4^{tr}	$\beta\gamma$	4
full tower	all ℓ_k^{tr}	Vir_c	∞

1.13.3 Shadow depth classification

Shadow depth is orthogonal to Koszulness: all standard families are chirally Koszul, yet their shadow depths differ. See Theorem **??**.

Class	**Name**	**Criterion**	**Examples**
G	Gaussian	$r_{\max} = 2$; formal	$\mathcal{H}_k$, free fermion, rank-1 lattice
L	Lie	$r_{\max} = 3$; $\mathfrak{C} \neq 0$, $o_4 = 0$ (Jacobi)	$V_k(\mathfrak{g})$
C	Contact	$r_{\max} = 4$; $\mathfrak{Q} \neq 0$, $o_5 = 0$ (abelian rigidity)	$\beta\gamma$, symplectic fermion ?
M	Mixed	$r_{\max} = \infty$; non-formal	Vir_c, $\mathcal{W}_N$, $Y(\mathfrak{g})$ (E_1-shadow depth from RTT tower)

The inclusions $\mathbf{G} \subset \mathbf{L} \subset \mathbf{C} \subset \mathbf{M}$ are proper. Shadow depth classifies the complexity of $\Theta_{\mathcal{A}}$, not whether the bar complex is acyclic (Remark **??**).

1.13.4 Geometric, physics, and categorical characterizations

Geometric.

- *Ran-space formality*: E_2-collapse $\Leftrightarrow$ genuswise bar-cobar formality $\Leftrightarrow$ $\tilde{m}_n^{(g)} = 0$ for $n \geq 3$ (Proposition **??**); coherent extension to all $\mathrm{Ran}^{\leq n}$ is open.
- *Tropical Koszulness*: acyclicity of $\bar{\mathbf{B}}^{\mathrm{trop}}(\mathcal{A})$ for the planted-forest differential (Definition **??**, Theorem **??**).
- *Curve independence*: chiral Koszulness depends on formal-disk data, not on X; higher-genus propagation governed by MK1–MK3 (Theorem **??**) and the exceptional set $\Sigma(\mathfrak{g})$ (Theorem **??**).

Physics.

- *One-loop exactness*: PBW E_2-collapse IS one-loop exactness (Remark **??**).
- *Kac–Shapovalov*: $\det G_h \neq 0$ in bar-relevant range $\Leftrightarrow$ Koszul (Theorem **??**); proved for $V_k(\mathfrak{g})$ (Proposition **??**), open for $L_k(\mathfrak{g})$ at admissible levels.
- *C_2-cofiniteness*: orthogonal to Koszulness; Koszul duality maps C_2-cofinite to non-C_2-cofinite.
- *Critical level*: $V_{-h^\vee}(\mathfrak{g})$ is uncurved ($\kappa = 0$), self-dual, center $= \mathfrak{z}(\widehat{\mathfrak{g}})$ (Theorem **??**).

Categorical.

- *t-exactness*: $\bar{B}^{\mathrm{ch}}: \mathrm{FactMod}(\mathcal{A}) \to \mathrm{FactCoMod}(\mathcal{A}^!)$ exact for PBW/Ω t-structures (Proposition **??**).
- *Barr–Beck–Lurie*: effective descent for bar-cobar (Remark **??**).
- *Semi-orthogonal decomposition*: weight-indexed SOD on $\mathrm{FactMod}(\mathcal{A})$ is split iff Koszul.
- *BGG*: bar resolution of $V_k(\mathfrak{g})$-modules is linear; Koszul involution maps BGG to Cousin on Gr_G (Corollary **??**).

- *Convolution formality*: $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ formal iff one-channel; stronger than Koszulness.
- *MC smoothness*: $\mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$ smooth at $\Theta_{\mathcal{A}}$ iff Koszul.

1.13.5 Bifunctor obstruction

The RNW no-bifunctor obstruction [?] (§1.11, identification theorem 7) is structural: $\hom_\alpha(\mathcal{C}, \mathcal{A})$ extends to ∞-morphisms in either slot separately but not both. Koszulness does not kill it; Koszulness makes it irrelevant by factoring all constructions one slot at a time (Theorem **??**). This is why the MC3 strategy (Theorem **??**) succeeds.

1.13.6 Computational diagnostics

The bar generating function $\overline{P}_{\mathcal{A}}(x,t)$ is algebraic of degree 2 in t for all standard families with $\dim \mathfrak{g} \leq 8$, sharing the discriminant $\Delta_{\mathcal{A}}(x) = (1-3x)(1+x)$ across $\widehat{\mathfrak{sl}}_2$, $\beta\gamma$, and Virasoro (Theorem **??**).

Decision tree. (1) Pole order ($1 \Rightarrow$ G; $2 \Rightarrow$ L+). (2) Freely generated $\Rightarrow$ Koszul (Proposition **??**). (3) PBW + classical Koszulness of $\mathrm{gr}_F\,\mathcal{A}$ (Theorem **??**). (4) Bar Betti diagonal concentration (Corollary **??**). (5) Generating function fit $\to$ discriminant.

Priority computations.

- $\mathcal{W}_4$ bar Betti numbers (Class M + discriminant universality).
- Bigraded Virasoro to $(n,h) = (4,16)$ (quartic resonance at GF level).
- Symplectic fermion shadow (Class C or M assignment).

Status: all twelve equivalences proved; the Lagrangian criterion (xi) requires perfectness of the ambient tangent complex as an input hypothesis (Theorem **??**). The proved circuit (i)⇔(ii)⇔(iii)⇔(iv) extends to all remaining conditions: A_∞ formality (v) via Keller's classicality theorem, Ext diagonal vanishing via bigrading constraints on PBW differentials, Barr–Beck–Lurie via conservativity + Quillen-equivalence monadic descent ([**?**, Prop. 4.7.3.16]), factorization homology concentration via the bar = FH identification, FM boundary acyclicity via stratum-by-stratum PBW concentration, the Kac–Shapovalov determinant via Shapovalov non-degeneracy forcing PBW injectivity, tropical Koszulness via formality of the real blowup weight spectral sequence, and the Lagrangian criterion (xii) via PTVV derived-intersection theory (conditional on perfectness/non-degeneracy of the ambient tangent complex).

1.14 Non-principal $\mathcal{W}$-algebra duality: the transport frontier

After the principal Feigin–Frenkel case (Theorem **??**), the non-principal duality problem splits into two axes (Principle **??**): *transport along the reduction network* and *identification of the dual orbit/level*.

1.14.0.0.1 Proved core.

- *Principal*: Feigin–Frenkel duality, all simple $\mathfrak{g}$.
- *Subregular/minimal in* $\mathfrak{sl}_3$: Bershadsky–Polyakov duality (Proposition **??**).
- *Hook-type corridor in type A*: full hook-type duality at generic level (Theorem **??**), with inverse reductions connecting all hook-type nodes [**?**, **?**, **?**, **?**, **?**].
- *Transport propagation*: duality propagates from hook vertices through the reduction graph Γ_N to every partition in the transport-closure (Proposition **??**).

1.14.0.0.2 Active frontier.

- *Type-A transport-to-transpose* (Conjecture **??**): the transport-closure of the hook vertices equals $\mathrm{Par}(N)$ at generic level.
- *General orbit duality* (Conjecture **??**): extends to all simple $\mathfrak{g}$ via Barbasch–Vogan/Spaltenstein duality.
- *DS–KD intertwining for arbitrary nilpotent* (Conjecture **??**): bar–cobar duality commutes with DS reduction at arbitrary f.

1.14.0.0.3 Key constraint. The difficulty is *not* the existence of quantum DS reduction for arbitrary f (Kac–Roan–Wakimoto [**?**]); it is proving that bar–cobar/Koszul duality commutes with arbitrary-nilpotent reduction, identifying the correct dual nilpotent, and determining the non-principal level transform.

1.15 E_1 MODULAR THEORY: THE ORDERED BAR COMPLEX AT ALL GENERA

The E_∞ modular theory (Theorems A–D+H, the shadow Postnikov tower, $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$) has an E_1 counterpart in which symmetry is replaced by ordering. The E_1 theory is developed as a standalone chapter (Chapter **??**), making the E_1/E_∞ parallelism architecturally visible. The following table records the parallel construction.

Object	E_∞ (*symmetric*)	E_1 (*ordered*)
Modular operad	$\mathcal{M}_{\mathsf{Com}}$: $\overline{\mathcal{M}}_{g,n}$	$\mathcal{M}_{\mathsf{Ass}}$: $\overline{\mathcal{M}}_{g,n}^{\mathrm{rib}}$
Feynman transform	$F\mathsf{Com}$	$F\mathsf{Ass}$ (Def. **??**)
Convolution	$\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ (Def. **??**)	$\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}E_1}$ (Def. **??**)
MC element	$\Theta_{\mathcal{A}} = D_{\mathcal{A}} - d_0$	$\Theta_{\mathcal{A}}^{E_1} = D_{\mathcal{A}}^{E_1} - d_0$
Arity-2 shadow	$\kappa(\mathcal{A})$ (scalar)	$r(z)$ (R-matrix)
Arity-3 shadow	$\mathfrak{C}(\mathcal{A})$ (cubic)	$r_3(z_1, z_2)$ (KZ associator)
Planted forests	$\mathbb{G}_{\mathrm{pf}}$ (unordered)	$\mathbb{G}_{\mathrm{pf}}^{\mathrm{pl}}$ (planar, Def. **??**)
Ambient algebra	$\mathfrak{g}_{\mathcal{A}}^{\mathrm{amb}}$	$\mathfrak{g}_{\mathcal{A}}^{\mathrm{amb},E_1}$ (Def. **??**)
Coinvariant map	$\mathrm{av}\colon \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}E_1} \twoheadrightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$; $\mathrm{av}(\Theta^{E_1}) = \Theta$	

1.15.0.0.1 Status of the E_1 five main theorems.

	Genus 0	*All genera*	*Reference*
$\mathbf{A}^{E_1}$: bar–cobar	**Proved**	**Proved**	Thms **??**, **??**
$\mathbf{B}^{E_1}$: inversion	**Proved**	**Proved**	Thms **??**, **??**
$\mathbf{C}^{E_1}$: complementarity	**Proved**	**Proved**	Thms **??**, **??**
$\mathbf{D}^{E_1}$: R-matrix	**Proved**	**Proved**	Thms **??**, **??**
$\mathbf{H}^{E_1}$: Hochschild	**Proved**	**Proved**	Thms **??**, **??**

1.15.0.0.2 Resolved conjectures.

- `conj:modular` (Vol II): promoted to theorem. The E_1 modular convolution $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}E_1}$ carries $\Theta_{\mathcal{A}}^{E_1}$ by the bar-intrinsic construction.
- `conj:DS` (Vol II, principal case): promoted to theorem for principal DS reduction at non-critical level. Hook-type in type A also covered.
- `conj:FG-shadow`: resolved at arities 2, 3, 4 (Theorem **??**). The E_∞ shadow IS the Σ_r-coinvariant of the E_1 shadow.

1.15.0.0.3 Remaining conjectural frontier.

- `conj:FG-shadow` at all arities: the full abelianisation spectral sequence from ^{ord} to requires analysis at infinite arity.

- `conj:bordered`: geometric realisation of the diagonal bicomodule via bordered ordered configuration spaces.
- `conj:DS` for arbitrary nilpotent f: requires Koszul-BRST commutation for non-principal reduction.

1.16 Structural upgrades

1.16.0.0.1 Shadow archetype classification theorem. Theorem **??** unifies the four shadow depth classes (**G/L/C/M**) into a single classification theorem with complete proofs for all primitive archetypes. Shadow depth is orthogonal to Koszulness: all four archetypes are chirally Koszul, yet their shadow depths differ.

1.16.0.0.2 Ran-coherent bar-cobar equivalence. Theorem **??** resolves the Ran-space formality gap identified in earlier audits: the bar-cobar quasi-isomorphism extends coherently from $\mathrm{Ran}^{\leq n}(X)$ to all of $\mathrm{Ran}(X)$ via the strong completion-tower theorem and the arity cutoff lemma.

1.16.0.0.3 Ambient complementarity FMP upgrade. Theorem **??** is upgraded from `Conjectured` to `ProvedHere`: the modular cyclic deformation complex $\mathrm{Def}^{\mathrm{mod}}_{\mathrm{cyc}}(\mathcal{A})$ is already a complete filtered cyclic dg Lie algebra, and the Lurie–Pridham correspondence + PTVV theorem give the (-1)-shifted symplectic formal moduli problem with Lagrangian maps unconditionally (under the standing perfectness/nondegeneracy hypotheses).

1.16.0.0.4 Shadow separation (Theorem ??). $\Theta_{\mathcal{A}} = \varprojlim \Theta^{\leq r}_{\mathcal{A}}$ in $\widehat{\mathfrak{g}^{\mathrm{mod}}_{\mathcal{A}}}$; gauge-equivalent MC classes have identical shadow towers. Separating witnesses: $\kappa(\mathcal{H}_1) = \kappa(\mathrm{Vir}_2)$ but $\mathfrak{C}_{\mathcal{H}} = 0 \neq \mathfrak{C}_{\mathrm{Vir}}$ (level 3); $(\kappa, \mathfrak{C})_{\mathcal{H}_0} = (\kappa, \mathfrak{C})_{\beta\gamma}$ but $\mathfrak{Q}_{\mathcal{H}_0} = 0 \neq \mathfrak{Q}_{\beta\gamma}$ (level 4). Shadow class detected by the vanishing pattern $(\mathrm{Sh}_3, \mathrm{Sh}_4, \mathrm{Sh}_5)$. $r_{\max}(\mathcal{A}^!) = r_{\max}(\mathcal{A})$ (Corollary **??**).

1.16.0.0.5 Shadow tautological classes (Theorem ??). $\tau_{g,n}(\mathcal{A}) := \sum_\Gamma |\mathrm{Aut}(\Gamma)|^{-1}\, \iota_{\Gamma,*}(\prod_e P_e)\, w^{\mathrm{cyc}}_\Gamma(\mathcal{A}) \in R^*(\overline{\mathcal{M}}_{g,n+1})$. Tautological by construction. $\tau_{g,2} = \kappa \cdot \pi^*\lambda_g$. Clutching-compatible via MC factorization. Additive under independent tensor products. For affine $V_k(\mathfrak{g})$: $\tau_{0,3} = (k+h^\vee)^{-1} \sum_\sigma f^{a_{\sigma(1)} a_{\sigma(2)} c} \kappa^{cd} f^{d a_{\sigma(3)} a_{\sigma(4)}} \cdot [\mathrm{pt}_\sigma]$ (Example **??**).

1.16.0.0.6 Analytic shadow realization (Corollary ??). For all $\mathcal{A}$ in the standard landscape, $\overline{B}(\mathcal{A}) \hookrightarrow \overline{B}^{\mathrm{an}}(\mathcal{A})$ densely; finite-arity shadows are algebraic; hence the algebraic and analytic shadow data coincide. Follows from HS-sewing (Theorem **??**).

1.17 Bridges to Volume II

Volume II develops the A_∞-chiral Hochschild theory in three space-time dimensions with the operad $\mathrm{SC}^{\mathrm{ch,top}}$. Homotopy–Koszulity of $\mathrm{SC}^{\mathrm{ch,top}}$ is proved in Volume II (via Kontsevich formality and transfer from the classical Swiss–cheese operad), so the bar–cobar adjunction for $\mathrm{SC}^{\mathrm{ch,top}}$-algebras is a Quillen *equivalence*. Volume II has *no remaining conjectural algebraic inputs*; its only conditional inputs are the standing analytic hypotheses (H1)–(H4). Five bridges connect the two volumes:

PROPOSITION 1.17.1 *(Bar-cobar bridge;* [proved elsewhere]*).* The $\mathrm{SC}^{\mathrm{ch,top}}$ bar-cobar Quillen equivalence of Volume II recovers the chiral bar-cobar adjunction of Theorem A (Theorem **??**) for boundary operators of the 3d theory. The closed color specializes to the BD chiral operad (Vol II, associated graded proposition).

Conjecture 1.17.2 *(Hochschild bridge;* [conjectured]*).* The bulk algebra of the 3d theory is the chiral Hochschild cochain complex $C^*_{\mathrm{ch}}(\mathcal{A})$, recovering Theorem H (Theorem **??**) via dimensional descent.

PROPOSITION 1.17.3 *(DK-YBE bridge;* [proved elsewhere]*).* The spectral braiding $r(z) = \int_0^\infty e^{-pz}\{a_\lambda b\}\,dp$ (the Laplace transform of the λ-bracket) recovers the DK-0 chain-level monodromy comparison (Theorem **??**).

PROPOSITION 1.17.4 *($\mathcal{W}$-algebra bridge at genus* 0*;* [proved elsewhere]*).* The Feynman m_k operations of the 3d theory, restricted to the $\mathcal{W}$-algebra family, match the bar differential computed in the $\mathcal{W}$-algebra chapters of Part II at genus 0. Extension to genus 1 is proved (Volume II, genus-one bridge theorem: $d^2_{\mathrm{fib}} = \kappa(\mathcal{A}) \cdot \omega_1$ via the Arnold defect on the torus); extension to $g \geq 2$ is proved algebraically (Theorem **??**: inductive genus determination via the bar-intrinsic construction), with the analytic comparison (Theorem **??**) established for all graph amplitudes on Σ_g by two-dimensional convergence (Proposition **??**: no UV renormalization in dimension 2). The remaining analytic input is HS-sewing (Definition **??**) for the mode-sum extension from $\mathcal{A}_{\mathrm{alg}}$ to $\mathcal{A}^{\mathrm{sew}}$.

Conjecture 1.17.5 *(BV functor bridge;* [conjectured]*).* Analytic hypotheses (H1)–(H4) of Volume II define the physics-to-algebra functor that realizes the $\mathrm{BV} = \mathrm{bar}$ identification at higher genus (MC5, Conjecture 2.2.7).

1.18 TOWARDS MODULAR HOMOTOPY THEORY FOR FACTORIZATION ALGEBRAS ON CURVES

The modular characteristic theorem (Theorem D, Theorem **??**) establishes the scalar logarithmic datum $\kappa(\mathcal{A})$. This section identifies the six components — five structural extensions and the Hochschild cohomology theorem — needed to pass from the proved modular Koszul core to modular homotopy theory for factorization algebras on curves — that is, to complete the nilpotence-periodicity correspondence (Remark **??**) from the scalar level to the full categorical level:

Label	Statement	Status	Reference
A_{mod}	Bar-cobar intertwined with Verdier,	**Proved**	Thm **??**
	functorial over $\overline{\mathcal{M}}_{g,n}$		
B_{mod}	Inversion on Koszul locus; coderived	Proved on Koszul locus;	Thm **??**,
	persistence off it	coderived persistence conjectural	§1.18.1
C_{mod}	Shifted symplectic complementarity	**Proved**	Thms **??**,
	(PTVV Lagrangian embedding)		**??**
Index	GRR: genus series $= \kappa(\mathcal{A}) \cdot (\hat{A}(ix) - 1)$	**Proved**	Thm 1.18.15
DK	DK-0/1/1$\frac{1}{2}$: chain-level, eval-locus, lattice;	DK-0/1/1$\frac{1}{2}$: proved (all types);	Thms **??**,
	DK-2/3: factorization DK;	DK-2/3: **proved** (eval-gen. core, all types, domain: $\mathcal{O}_{\mathrm{poly}}$;	**??**, **??**,
	DK-4/5: dg-shifted/triple bridge	uses Molev PBW [**?**]); DK-4: ML proved, alg. id. open; DK-5: conj.	**??**, **??**, **??**; Conj. **??**
H	Chiral Hochschild: $CH^*(\mathcal{W}^k(\mathfrak{g})) \cong \mathbb{C}[\Theta_1, \ldots, \Theta_r]$;	**Proved** (generic level,	Thms **??**,
	period 2 (rank 1), polynomial (rank ≥ 2);	critical level: ProvedElsewhere)	**??**, **??**;
	Koszul functoriality via Connes S		Thm **??**

Remark 1.18.1 *(Four levels of modular invariant).* The six components above implement a hierarchy of modular invariants of increasing categorical depth. The proved scalar level is the lowest; the full modular homotopy type is the highest:

Level	Invariant	Type	Status
0	$\kappa(\mathcal{A}) \cdot \hat{A}$-genus	Numbers F_g	**Proved** (Thm D)
1	$H^*(\overline{B}^{(g)}(\mathcal{A}), D_g)$	Graded vector spaces	**Resolved** at integrable levels (Thm **??**)
2	Variation of H^* over $\mathcal{M}_g$	Flat connection (KZ/Hitchin)	Open
3	Factorization and sewing	Chain-level modular functor (Thm **??**)	Structural

Theorem D is the *integrability condition*: $\mathrm{obs}_g = \kappa \cdot \lambda_g$ is a pure tautological class, free of boundary or non-tautological contributions, guaranteeing that the curvature of the genus-g bar complex is absorbable by a period correction. The corrected complex $(\overline{B}^{(g)}, D_g)$ with $D_g^2 = 0$ (Level 1) is the *derived fiber* of the factorization homology bundle $\int_{\Sigma_g} \mathcal{A}$ over $\mathcal{M}_g$; its variation (Level 2) recovers the monodromy representation of the mapping class group; its factorization structure (Level 3) recovers the full modular functor (Theorem **??**). The $\hat{A}$-genus is the *first Chern class* of this bundle — its Euler characteristic, not the bundle itself.

Smoking gun: for $\widehat{\mathfrak{sl}}_2$ at level k, $\kappa = 3(k+2)/4$ is one number, yet the Verlinde formula gives a bundle of rank $k+1$ at genus 1 (equation (**??**)), growing with g. Bar cohomology $H^0(\overline{B}^{(1)}(\widehat{\mathfrak{sl}}_{2,k}), D_1)$ should recover the Verlinde dimension — a concrete, computable test that Level 1 carries representation-theoretic data invisible to Level 0. See §**??**.

Resolution of genus-independence at integrable levels. Theorem **??** proves that bar cohomology dimensions are polynomial in $\lambda = k + h^\vee$, constant outside a finite exceptional set Σ_n. For $\mathfrak{sl}_2$ at degree 2: $\Sigma_2 = \{0\}$ (critical level only). Since integrable levels $k \geq 1$ give $\lambda \geq 3 > 0$, they are *generic* — not exceptional — and the fiberwise bar cohomology is genus-independent there (Proposition **??**). The integer conformal block dimension $\dim V_{g,k}$ relates to the normalized partition function Z_g via $\dim V = Z_g \cdot S_{00}^{2-2g}$ (Remark **??**).

The subsections below develop each component, separating what is established from what remains. For A_{mod}: the present proof establishes functorial compatibility of bar and cobar over $\overline{\mathcal{M}}_{g,n}$; whether this lifts to an equivalence of modular operads is a further question, not addressed here.

1.18.1 The coderived Ran-space formalism

The bar-cobar adjunction is most naturally an equivalence of ∞-categories — the categorical exp/log correspondence (Remark **??**):

$$\bar{B}_X\colon\ \mathrm{Alg}_{\mathrm{aug}}(\mathrm{Fact}(X)) \ \rightleftarrows\ \mathrm{CoAlg}_{\mathrm{conil}}(\mathrm{Fact}(X))\ :\Omega_X,$$

where $\mathrm{Fact}(X)$ denotes factorization algebras on $\mathrm{Ran}(X)$ (cf. Appendix **??**).

On the Koszul locus this is an equivalence: $\exp \circ \log = \mathrm{id}$ on the convergence domain. When curvature is present — that is, when the categorical logarithm acquires non-trivial monodromy — the correct ambient category is not the ordinary derived category but the *coderived category* in the sense of Positselski [**?**]: the analytic continuation that extends the exp/log correspondence past the convergence radius.

Curved objects produce acyclic-but-not-contractible complexes that the derived category erases too brutally; the coderived category retains the monodromy data that the ordinary derived category discards, just as the multi-valued logarithm retains branch information that a single-valued determination loses.

The provisional coderived category $\mathsf{D}^{\mathrm{co}}_{\mathrm{prov}}(X)$ (Definition **??**, Proposition **??**) provides a working substitute within the scope of this monograph. The Koszul locus — where bar-cobar inversion holds unconditionally (Theorem **??**) — is the locus where the coderived and derived categories agree.

What is established. Appendix **??** compares the strict, completed, and literature existence paradigms for bar-cobar on $\mathrm{Ran}(X)$. Theorem **??** provides the adjunction; Theorem **??** provides inversion on the Koszul locus. Appendix **??**, §**??** develops the coderived and contraderived categories on $\mathrm{Ran}(X)$: curved factorization coalgebras with CDG-factorization compatibility (Definition **??**), coacyclic factorization objects (Definition **??**), stratified conservative restriction via the injective characterization (Theorem **??**), and the factorization co-contra correspondence (Theorem **??**). The provisional coderived category embeds fully faithfully (Proposition **??**).

Now complete. The formerly conjectural off-Koszul bar-cobar inversion on $\mathrm{Ran}(X)$ is proved (Theorem **??**): the counit $\Omega_X\overline{B}_X(\mathcal{A}) \to \mathcal{A}$ is an isomorphism in $D^{\mathrm{co}}(\mathrm{CoFact}(X))$ without Koszulness. The proof follows the same three-step assembly as Theorem **??**: (i) on each stratum Ran_n, Positselski [**?**, Theorem 7.2] gives the coderived equivalence for the restricted CDG-coalgebra; (ii) factorization compatibility of the bar-cobar counit; (iii) conservative assembly via Theorem **??**. This closes structural gap H1 and completes Future 2.

1.18.2 The Lagrangian form of complementarity

Theorem C (Theorem **??**) establishes the direct-sum decomposition $Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!) = H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$ via the eigenspace decomposition of the Verdier involution. The natural strengthening is a Lagrangian-polarization theorem, now proved:

Theorem 1.18.2 *(Lagrangian complementarity;* [proved here]*).* For a modular Koszul pair $(\mathcal{A}, \mathcal{A}^!)$, the complex $C_g := R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$ carries two shifted symplectic structures, each admitting $Q_g(\mathcal{A})$ and $Q_g(\mathcal{A}^!)$ as complementary Lagrangians in the sense of Pantev–Toën–Vaquié–Vezzosi [**?**]:

(i) a $(-(3g-3))$-shifted symplectic structure from Verdier duality on the center local system (Proposition **??**);

(ii) a (-1)-shifted symplectic structure on the formal moduli $\mathrm{Def}_g(\mathcal{A})$ from the BV antibracket (Theorem **??**).

Remark 1.18.3 *(Degree clarification).* The original formulation of this result stated a single (-1)-shifted symplectic structure on C_g. The proved version reveals two structures of different degrees: the Verdier pairing gives $(-(3g-3))$-shifted on C_g itself, while the BV antibracket gives (-1)-shifted on the formal moduli. Both support the same Lagrangian polarization. See Remark **??** for the compatibility.

1.18.3 Completion kinematics and the modular cumulant transform

The completion-tower theorem (Theorem **??**) resolves the formal MC4 obstacle. What remains is a *kinematic* theory of the completed dual: the canonical primitive sector, the growth law of bar windows, and the entropy of completion. This subsection records the programme; the full definitions appear in §**??** (Chapter **??**) and the explicit calculations in §**??** (Chapter **??**).

Kinematics versus dynamics

The completed bar-cobar theory separates cleanly into two axes (Remark **??**):

- *Completion kinematics*: the primitive cumulant quotient $Q(\mathcal{A}) = \bar{\mathcal{A}}/\partial\bar{\mathcal{A}}$ (Definition **??**), the primitive generating series $G_{\mathcal{A}}(t) = \frac{1-t}{t}(\chi_{\mathcal{A}}(t) - 1)$ (Definition **??**), the completion Hilbert series $H_{\mathcal{A}}(t) = G_{\mathcal{A}}(t)/(1 - G_{\mathcal{A}}(t))$ (Definition **??**), the primitive defect $\Delta_{\mathcal{A}}(t) = G_{\mathcal{A}}(t) - G^{\mathrm{naive}}_{\mathcal{A}}(t)$ (Definition **??**), and the completion entropy $h_K(\mathcal{A}) = \log(\rho_{\mathcal{A}}^{-1})$ (Definition **??**). These depend only on the vacuum character, not on OPE coefficients or curvature.
- *Modular dynamics*: the coderivation $D_{\mathcal{A}}$, the curvature $\kappa(\mathcal{A})$, the universal MC class $\Theta_{\mathcal{A}}$ (Theorem **??**), and the dg-shifted Yangian kernel $r_{\mathcal{A}}(z)$. These depend on the full OPE structure.

The Virasoro involution $c \mapsto 26 - c$ changes the dynamic data but preserves the kinematic data: the same-family shadow Vir_{26-c} lives on the dynamic axis. Kinematically, even generic Virasoro has infinitely many primitive cumulants (the defect $\Delta_{\mathrm{Vir}}(t)$ begins $t^3 + 2t^5 + \cdots$).

The $\mathcal{W}_N$ entropy ladder

The completion entropy forms a monotone sequence (Proposition **??**):

$$h_K(\mathcal{W}_2) \approx 0.567 \;<\; h_K(\mathcal{W}_3) \approx 0.772 \;<\; h_K(\mathcal{W}_4) \approx 0.835 \;<\; \cdots \;<\; h_K(\mathcal{W}_\infty) \approx 0.872.$$

The $\mathcal{W}_\infty$ character admits a MacMahon factorization $\chi_{\mathcal{W}_\infty}(q) = \phi(q)\, M(q)$, where $M(q) = \prod_{n\geq 1}(1 - q^n)^{-n}$ is the plane-partition generating function. The $\mathcal{W}_\infty$ completion frontier is governed by plane-partition combinatorics.

The modular cumulant transform (conjectural target)

The *cumulant coalgebra* $\mathrm{Cum}_c(\mathcal{A}) := \hat{T}^c(sQ(\mathcal{A})^\vee)$ is the completed cofree coalgebra on the desuspended dual of the primitive cumulant quotient $Q(\mathcal{A}) = \bar{\mathcal{A}}/\partial\bar{\mathcal{A}}$ (Definition **??**).

Conjecture 1.18.4 *(Cumulant recognition;* [conjectured]*).* For admissible $\mathcal{A}$ satisfying reduced-weight finiteness and finite-window stabilization, $\mathrm{gr}_\rho\, \hat{B}(\mathcal{A}) \simeq \mathrm{Cum}_c(\mathcal{A})$ as completed curved dg coalgebras.

The platonic ideal of the completion programme is a single object

$$M(\mathcal{A}) = \big(\mathrm{Cum}_c(\mathcal{A}),\ D_{\mathcal{A}},\ \tau_{\mathcal{A}},\ r_{\mathcal{A}}(z),\ \Theta_{\mathcal{A}}\big)$$

whose five components are:

1. $\mathrm{Cum}_c(\mathcal{A})$: the completed cofree coalgebra on primitive cumulants (the kinematic core);
2. $D_{\mathcal{A}}$: the completed coderivation encoding genus-0 Koszul duality;
3. $\tau_{\mathcal{A}}$: the universal twisting morphism (the local dynamical field);
4. $r_{\mathcal{A}}(z) = \tau_{\mathcal{A}}|_{\deg 2}$: the ordered E_1/Yangian face, satisfying the A_∞ Yang–Baxter hierarchy;
5. $\Theta_{\mathcal{A}}$: the connected all-genera modular logarithm, the stable-graph exponential $\Theta_{\mathcal{A}} = \sum_{\Gamma \text{ connected}} \frac{\hbar^{g(\Gamma)}}{|\mathrm{Aut}(\Gamma)|}\Phi_\Gamma$, satisfying the modular quantum master equation $d\Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] + \hbar\,\Delta\Theta_{\mathcal{A}} = 0$.

Status. Components (1)–(2) are controlled by the completion-tower theorem and reduced-weight windows. Component (3) is the bar-cobar twisting morphism, proved on $\mathrm{CompCl}(\mathsf{F}_{\mathrm{ft}})$. Component (4) is the Yangian jet tower, accessible windowwise by the jet principle (Conjecture 1.18.5 below): reduced-weight-q bar windows determine Yangian jets through order z^{-q}. Component (5) is the principal open structural problem (MC2 is proved at all finite orders; the full modular QME is conjectural in the completed tensor product).

Conjecture 1.18.5 *(Jet principle;* [conjectured]*).* Reduced-weight-q bar windows $K_q(\mathcal{A})$ determine the dg-shifted Yangian MC kernel $r_{\mathcal{A}}(z) = \sum_{m\geq 0} r_m z^{-m-1}$ through jet order z^{-q}: that is, the truncation $r_{\mathcal{A}}(z) \bmod z^{-q-1}$ depends only on $\overline{B}(\mathcal{A})|_{K_q}$.

Six shadows. Every shadow the monograph computes is a projection of $M(\mathcal{A})$:

1. genus-0 face $\longrightarrow$ bar/cobar and Verdier duality;
2. ordered-boundary face $\longrightarrow$ RTT/Yangian/dg-shifted Yangian;
3. all-genera face $\longrightarrow$ modular homotopy theory;
4. scalar shadow $\longrightarrow \kappa(\mathcal{A})\lambda_g$;
5. spectral shadow $\longrightarrow \Delta_{\mathcal{A}}(x), \Pi_{\mathcal{A}}$;
6. Lagrangian shadow $\longrightarrow$ shifted-symplectic complementarity.

Conjecture 1.18.6 *(Grand completion;* [conjectured]*).* The modular cumulant transform $\mathcal{A} \mapsto M(\mathcal{A})$ extends finite-stage chiral Koszul duality to an equivalence between the completion closure of admissible chiral A_∞-algebras on curves and the homotopy theory of complete pronilpotent modular cumulant coalgebras, with genus-0 truncation = completed bar/cobar, ordered-boundary truncation = dg-shifted Yangian jet tower, and universal deformation theory = graph MC class $\Theta_{\mathcal{A}}$.

1.18.4 The analytic completion programme

The proved algebraic engine operates in the world of formal factorization algebras, cochain complexes, and dg categories. A genuine local-to-global field theory also requires analytic sewing (convergent partition functions, Hilbert-space completions, and positivity). Recent work of Moriwaki [**?**, **?**] constructs conformally flat factorization homology valued in IndHilb by left Kan extension from conformally flat disk algebras; for the Heisenberg VOA, the conformally flat 2-disk algebra on $\mathrm{Sym}\, A^2(D)$ (the symmetric algebra of the Bergman space) is identified with the ind-Hilbert completion of the affine Heisenberg vertex algebra. Adamo–Moriwaki–Tanimoto [**?**] prove conformal Osterwalder–Schrader axioms for a class of unitary full VOAs under energy/spectral growth and local C_1-cofiniteness.

The programme aims to bridge the algebraic engine to these analytic structures. Its objects are the *sewing envelope* $\mathcal{A}^{\mathrm{sew}}$ (the Hausdorff completion for the locally convex topology generated by sewing-amplitude seminorms), the *analytic bar coalgebra* $\overline{B}^{\mathrm{an}}(\mathcal{A})$ (graph-norm closure of the algebraic bar), and the *analytic shadow* $Q_g^{\mathrm{an}}(\mathcal{A}) := D^{\mathrm{co}}(\overline{B}_g^{\mathrm{an}}(\mathcal{A})\text{-comod})$. At genus g with curvature $m_0^{(g)} \neq 0$, the coderived passage of §1.18.1 is mandatory: ordinary cohomology fails, and the correct receptacle is the coderived analytic category.

Four target theorems define the programme (Chapter **??**, §**??**):

($\mathrm{A_{an}}$) *Heisenberg sewing theorem* (Theorem **??**): the sewing envelope of the algebraic Heisenberg VOA is exactly $\mathrm{Sym}\, A^2(D)$; the completed bar differential is the closure of the Gaussian collision operator on Bergman tensors; every closed amplitude is a Fredholm determinant on the one-particle Bergman space.

($\mathrm{B_{an}}$) *Lattice sewing envelope* (Conjecture **??**): every positive-definite even lattice equipped with an analytic theta-datum admits a canonical sewing envelope with charge-refined Hilbert sectors.

($\mathrm{C_{an}}$) *Analytic realization criterion* (Conjecture **??**): a unitary full VOA satisfying conformal OS, polynomial spectral growth, and HS-sewing admits a sewing envelope, a conformally flat 2-disk algebra, and a higher-genus coderived shadow.

($\mathrm{D_{an}}$) *Boundary bar duality* (Conjecture **??**): for an analytically Koszul $\mathcal{A}$, completed boundary modules at genus 0 are equivalent to analytic comodules over $\overline{B}^{\mathrm{an}}(\mathcal{A})$; at curved genus, the correct objects are analytic contramodules over the curved dual.

Status. Target ($\mathrm{A_{an}}$), the Heisenberg sewing theorem (Theorem **??**), is [proved here] for clauses (ii)–(iv) and [proved elsewhere] for clause (i) (Moriwaki [**?**]). Targets ($\mathrm{B_{an}}$)–($\mathrm{D_{an}}$) remain [conjectured]. The programme is recorded here to fix definitions and the precise relationship to the algebraic proved core.

1.18.5 The universal Maurer–Cartan class

The genus tower $\{\overline{B}^{(g)}(\mathcal{A})\}_{g\geq 0}$ (Theorem **??**) is controlled by a universal obstruction.

Theorem 1.18.7 *(Universal MC class;* [proved here]*).* For a modular Koszul chiral algebra $\mathcal{A}$ with simple Lie symmetry $\mathfrak{g}$, there exists a class

$$\Theta_{\mathcal{A}} \in \mathrm{MC}\Big(\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A}) \,\widehat{\otimes}\, R\Gamma\Big(\overline{\mathcal{M}}_{g,\bullet}, \mathbb{Q}\Big)\Big)$$

controlling the full genus tower as a single Maurer–Cartan deformation, with three properties:

(i) Its image under the scalar trace is the sequence of obstruction coefficients: $\mathrm{tr}(\Theta_{\mathcal{A}}) = \sum_{g\geq 1} \kappa(\mathcal{A}) \cdot \lambda_g$.

(ii) It is compatible with clutching: $\xi^*(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}} \star \Theta_{\mathcal{A}}$ under the boundary maps $\xi\colon \overline{\mathcal{M}}_{g_1,n_1+1} \times \overline{\mathcal{M}}_{g_2,n_2+1} \to \overline{\mathcal{M}}_{g,n}$.

(iii) Under Verdier duality: $\mathbb{D}(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}^!}$.

Proof. This is Theorem **??**, proved via the assembly of Theorem **??**: the cyclic L_∞-algebra $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ is constructed by Theorem **??**, the completed tensor product converges with clutching by Proposition **??**, and the tautological line support $o_g = \kappa\lambda_g$ is established by Theorem **??**. □

Remark 1.18.8 *(Scope).* The scalar shadow $\kappa(\mathcal{A}) \cdot \lambda_g$ is established (Theorem **??**). The clutching compatibility is implicit in the modular operad structure of the bar complex (Theorem **??**). At the one-channel level, Proposition **??** shows that these two geometric inputs would already force tautological-line support once they separate the relevant sector, and Proposition **??** reduces the remaining duality flank to a σ-stable Lagrangian two-plane on that sector. Proposition **??** then reduces the remaining H-level lift to perfect one-channel projector subcomplexes whose cross Verdier pairing is a PTVV quasi-isomorphism, and

Proposition **??** reduces that lift further to explicit one-channel coderivation subcomplexes in $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ and $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A}^!)$. Proposition **??** then reduces those subcomplexes further to finite low-bar-length cyclic coderivation seeds in $\mathrm{CoDer}^{\mathrm{cyc}}(\widehat{\overline{B}}_X(\mathcal{A}))[1]$ and $\mathrm{CoDer}^{\mathrm{cyc}}(\widehat{\overline{B}}_X(\mathcal{A}^!))[1]$. Proposition **??** compresses those finite seed sets further to one distinguished degree-2 cocycle on each side together with bar-length-≤ 3 correction packets and a finite pairing matrix. Proposition **??** then identifies the remaining packet with the three visible low-arity ingredients already supported by the current MC2 surface: the simple-pole bracket sector, the normalized double-pole pairing matrix, and the Killing l_3^η sector. Proposition **??** then reduces that visible packet further to a canonical transfer package on the one-channel seed spaces: one cyclic seed, one shared generator-seed lift producing the Killing l_3^η sector, and one functorial normalization splitting off the one-channel cocycle line. Proposition **??** then reduces that canonical package further to an explicit root-string transfer law on those seed spaces: the genus-2/genus-3 profile

$$O_2 = t^2(ae_{12} + bf_1 - mf_2), \qquad O_3^\eta = amt^3\eta,$$

together with obstruction-side recovery of (a, b, m) and the same coefficient-extraction normalization. Proposition **??** then reduces that explicit law further to a chart-existence/uniqueness statement: the ordered root-string chart is forced by the one-channel support graph and normalization data, up to rescaling of the three seed lines. Proposition **??** then reduces that chart statement further to intrinsic line detection: the seed, simple-pole, and Killing support lines must be canonically picked out by $l_{2,\mathrm{sp}}, \beta_g^{\mathrm{dp}}, \nu_g^{\mathrm{sp}}$, and the support of $(O_{2,g}, O_{3,g}^\eta)$. Proposition **??** then reduces that remaining line-detection step to automorphism rigidity: those support lines are the unique invariant lines for the one-channel support automorphism group compatible with the bracket, pairing, normalization, and obstruction profile. Proposition **??** then reduces that rigidity statement further to a finite stabilizer computation on the labeled one-channel support graph: the fixed vertices must be exactly the simple-pole, residual-kernel, and Killing support lines. Proposition **??** then reduces that stabilizer statement further to an explicit incidence-matrix / orbit-count computation on the visible one-channel graph: the relevant support lines are exactly the singleton orbits of the permutation group determined by the bracket, pairing, normalization, and support indicators. Proposition **??** then reduces that bounded permutation problem further to a universal three-case visible orbit table on the $m = 1, 2, 3$ root-string types, equivalently $\mathfrak{sl}_3, \mathfrak{sp}_4, \mathfrak{g}_2$. Proposition **??** then collapses that three-case verification to direct lookup/identification against one fixed labeled orbit table. Proposition **??** then collapses that fixed-table identification further to the minimal visible invariant signature packet forcing that table. Proposition **??** then collapses that invariant packet further to the universal signed seed-character law recovering it. Proposition **??** then collapses that character further to the reduced datum of two root-string signs and one normalization scalar. Proposition **??** then collapses that reduced datum further to one root-string parity sign plus one normalization scalar. Proposition **??** then collapses that parity-sign datum further to one chart-normalized seed scalar. The scalar-saturated class $\Theta_{\mathcal{A}}$ is now constructed for one-channel families (Theorem **??**): (a) the cyclic deformation complex $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ exists as a cyclic L_∞ algebra (Theorem **??**); (b) the Maurer–Cartan equation in the completed tensor product with tautological classes is solved at the scalar level by the conjunction of Proposition **??** and Theorem **??**. The non-scalar content is developed through the shadow Postnikov tower (Definition **??**): finite-order shadows through arity 4 are proved constructively, and the all-arity convergence is guaranteed by the bar-intrinsic construction (Theorem **??**; Theorem **??**). Scalar saturation (one-channel universality) is proved for all algebras in algebraic families with rational OPE coefficients (Theorem **??**), covering the entire standard Lie-theoretic landscape at all non-critical levels including admissible ones. The proof bypasses module-category semisimplicity via Whitehead reduction to a finite-dimensional linear system and algebraic semicontinuity of rank.

Homotopy template (Convention **??**): Type I (existence of a homotopy object). At H-level: a filtered cyclic L_∞ algebra $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ and an MC element $\Theta_{\mathcal{A}}$ with trace, clutching, and Verdier compatibility. The scalar shadow is $\kappa(\mathcal{A}) \cdot \lambda_g$ (proved, Theorem **??**). The full non-scalar class is Theorem **??** (Theorem 2.2.2).

Conjecture 1.18.9 *(Categorical modular Koszul duality;* [conjectured]*).* For each genus g and each modular Koszul chiral algebra $\mathcal{A}$, the curved bar-cobar adjunction at genus g induces an equivalence

$$\mathsf{D}^{\mathrm{co}}\big(\overline{B}^{(g)}(\mathcal{A})\text{-}\mathsf{comod}\big) \;\simeq\; \mathsf{D}^b\big(\mathcal{A}\text{-}\mathsf{mod}^{\Sigma_g}\big)$$

between the *coderived category* (§1.18.1) of curved $\overline{B}^{(g)}(\mathcal{A})$-comodules and the bounded derived category of $\mathcal{A}$-modules twisted by the Hodge data of Σ_g. This equivalence varies over $\mathcal{M}_g$ as a flat functor:

(i) At $g = 0$, it reduces to bar-cobar inversion (Theorem **??**).

(ii) Applied to integrable representations of $\widehat{\mathfrak{g}}_k$, the functor H^0 recovers the Tsuchiya–Ueno–Yamada space of conformal blocks (Remark **??**), and its monodromy gives the KZ/Hitchin connection.

(iii) The scalar shadow $c_1(\det \mathcal{V}_g) = \kappa(\mathcal{A}) \cdot \lambda_g$ is Theorem D; the full Chern character $\mathrm{ch}(\mathcal{V}_g)$ recovers the spectral discriminant $\Delta_{\mathcal{A}}$ (Remark **??**).

(iv) Under Verdier duality: $\mathsf{D}^{\mathrm{co}}(\overline{B}^{(g)}(\mathcal{A}^!)\text{-}\mathsf{comod}) \simeq \mathsf{D}^{\mathrm{co}}(\overline{B}^{(g)}(\mathcal{A})\text{-}\mathsf{comod})^{\mathrm{op}}$.

This is the *categorical lift* of Theorems A–D to all genera: Theorem B gives the equivalence, Theorem D gives its first Chern class, and the full equivalence is the modular functor of $\mathcal{A}$.

1.18.6 The discriminant as spectral invariant

The shared discriminant $\Delta(x) = (1-3x)(1+x)$ across $\mathfrak{sl}_2$, Virasoro, and $\beta\gamma$ systems (Theorem **??**) has a structural explanation. It is the *first nontrivial non-scalar characteristic class* of the modular Koszul object: where $\kappa(\mathcal{A})$ is a scalar measuring the curvature of d^2, the discriminant $\Delta_{\mathcal{A}}(x)$ records the branch geometry of the dual Hilbert series.

Distinct chiral theories can lie on the same modular spectral sheet — sharing the same Δ — even when their local operator content is entirely different. The underlying reason is functorial: Drinfeld–Sokolov reduction changes the growth pole (i.e. the leading OPE data) while preserving the discriminant family. This is compatible with the observation that $\Delta_{\mathcal{A}}$ depends only on the quadratic OPE data, which is the Koszul-dual-determining datum.

Theorem 1.18.10 *(Discriminant as spectral determinant — verified cases;* [proved here]*).* For $\mathcal{A} \in \{\widehat{\mathfrak{sl}}_2,\ \mathrm{Vir},\ \beta\gamma\}$, the bar-cohomology discriminant satisfies

$$\Delta_{\mathcal{A}}(x) \;=\; \det(1 - x\,T_{\mathrm{br}})$$

where T_{br} is a $d \times d$ matrix whose eigenvalues are the reciprocals of the branch points of the algebraic Koszul dual Hilbert series $P_{\mathcal{A}^!}(x)$, with d the degree of algebraicity. In all three cases $d = 2$, the branch points are $x = 1/3$ and $x = -1$, and $\Delta(x) = (1-3x)(1+x)$.

Proof. Each of the three Hilbert series involves $\sqrt{1-2x-3x^2}$ (Theorem **??**): $P_{\widehat{\mathfrak{sl}}_2}$ and P_{Vir} satisfy quadratic equations with discriminant $(1+x)(1-3x)$, while $P^2_{\beta\gamma} = (1+x)/(1-3x)$ has the same branch locus.

The branch points of any algebraic function $P(x)$ satisfying $a(x)P^2 + b(x)P + c(x) = 0$ are the zeros of $\mathrm{Disc}_P = b(x)^2 - 4a(x)c(x)$. For $\widehat{\mathfrak{sl}}_2$, the algebraic equation is $x(1+x)P^2 - (1+x)P + 1 = 0$ (Theorem **??**), giving

$$\mathrm{Disc}_P = (1+x)^2 - 4x(1+x) = (1+x)(1-3x).$$

The branch points are $x_1 = -1$ and $x_2 = 1/3$. Setting $\alpha_i = 1/x_i$, we obtain $\alpha_1 = -1$ and $\alpha_2 = 3$, and

$$\det(1 - x\,T_{\mathrm{br}}) = (1-\alpha_1 x)(1-\alpha_2 x) = (1+x)(1-3x) = \Delta(x).$$

Since P_{Vir} and $P_{\beta\gamma}$ involve the same radical $\sqrt{1-2x-3x^2}$, they share the same branch locus, hence the same Δ. □

THEOREM 1.18.11 *(Spectral discriminant — general case;* [proved here]*).* Let $\mathcal{A}$ be a Koszul chiral algebra whose Koszul dual Hilbert series $P_{\mathcal{A}^!}(x) = \sum_{n\geq 1} \dim(\mathcal{A}^!)_n\, x^n$ is either:

(a) *Rational*: $P_{\mathcal{A}^!}(x) = N(x)/D(x)$ with $\gcd(N, D) = 1$, $D(0) = 1$, and $\deg D = r$; or

(b) *Algebraic of degree $d \geq 2$*: satisfying an irreducible $f(x, y) \in \mathbb{Q}[x, y]$, $\deg_y f = d$, with discriminant $\Delta(x) = \mathrm{Disc}_y(f)$ normalized so that $\Delta(0) = 1$.

Define the *transfer matrix* T_{rec} as follows.

Rational case. The coefficients $a_n = \dim(\mathcal{A}^!)_n$ satisfy a constant-coefficient linear recurrence of order r (the degree of the denominator). Let T_{rec} be its companion matrix. Then $\Delta_{\mathcal{A}}(x) := D(x)$ and

$$\Delta_{\mathcal{A}}(x) \;=\; \det(1 - x\,T_{\mathrm{rec}}).$$

Algebraic case. The coefficients a_n satisfy a P-recursive recurrence of order d:

$$q_d(n)\,a_n + q_{d-1}(n)\,a_{n-1} + \cdots + q_0(n)\,a_{n-d} = 0 \tag{1.2}$$

where $q_i(n) \in \mathbb{Q}[n]$. Let $c_i = \lim_{n\to\infty} q_i(n)/n^{\deg q_d}$ be the leading asymptotic coefficient of q_i (so $c_d = 1$ after normalization). The asymptotic companion matrix is

$$T_{\mathrm{rec}} = \begin{pmatrix} -c_{d-1} & -c_{d-2} & \cdots & -c_0 \\ 1 & 0 & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & 1 & 0 \end{pmatrix} \in \mathrm{Mat}_{d\times d}(\mathbb{Q}).$$

Then the bar-cohomology discriminant satisfies

$$\Delta(x) \;=\; \det(1 - x\,T_{\mathrm{rec}}).$$

In both cases, the eigenvalues of T_{rec} are the reciprocals of the singularities (poles or branch points) of $P_{\mathcal{A}^!}$, and the spectral radius of T_{rec} equals $\dim \mathfrak{g}$ for Kac–Moody algebras (Theorem **??**).

Proof. Rational case. Write $D(x) = \prod_{i=1}^{r}(1-\alpha_i x)$ with $\alpha_i = 1/x_i$ the reciprocal poles. The partial-fraction decomposition of $P = N/D$ shows that $a_n = [x^n]P$ satisfies a constant-coefficient linear recurrence of order r with characteristic polynomial $\chi(t) = \prod(t - \alpha_i)$. The companion matrix T_{rec} has χ as its characteristic polynomial, so $\det(1 - x\,T_{\mathrm{rec}}) = \prod(1-\alpha_i x) = D(x) = \Delta_{\mathcal{A}}(x)$.

Algebraic case. The argument combines three classical results from analytic combinatorics.

Step 1: Algebraic ⇒ P-recursive. An algebraic power series is D-finite ([?], Proposition VI.1), hence its coefficients satisfy a P-recursive (holonomic) recurrence of order d, giving (1.2).

Step 2: Singularities of the generating function. Since $P(x)$ is algebraic of degree d with minimal polynomial $f(x, y) = 0$, its singularities as an analytic function are the branch points: the roots $x_1, \dots, x_m$ of $\Delta(x) = \mathrm{Disc}_y(f)$ ([?], Theorem VII.8).

Step 3: Poincaré–Perron theorem. For the P-recursive recurrence (1.2) with asymptotic companion matrix T_{rec}, the Poincaré–Perron theorem ([?], Theorem VIII.4) identifies the eigenvalues of T_{rec} with the asymptotic growth rates of the solutions: provided $c_0 \neq 0$ and the eigenvalues $\alpha_1, \dots, \alpha_d$ have distinct absolute values, the fundamental system of solutions satisfies $a_n^{(i)}/a_{n-1}^{(i)} \to \alpha_i$ as $n \to \infty$.

Step 4: Growth rates = reciprocals of branch points. By the transfer theorem for algebraic singularities ([?], Theorem VI.3), the contribution of a simple branch point x_j to the coefficients is $[x^n]\, P(x) \sim C_j \cdot x_j^{-n} \cdot n^{-3/2}$. The growth rates are therefore $\alpha_i = 1/x_i$, the reciprocals of the branch points.

Synthesis. Combining Steps 3 and 4, the eigenvalues of T_{rec} are $\alpha_i = 1/x_i$. Since $x_1, \dots, x_m$ are the roots of Δ (Step 2) and $\Delta(0) = 1$:

$$\det(1 - x\,T_{\mathrm{rec}}) = \prod_{i=1}^{d}(1 - \alpha_i x) = \prod_{i=1}^{d}\Big(1 - \frac{x}{x_i}\Big) = \Delta(x). \qquad \square$$

Remark 1.18.12 *(Scope and verification).* The rational case is unconditional (given rationality of P); the algebraic case additionally requires the Poincaré–Perron non-degeneracy condition ($c_0 \neq 0$, eigenvalues of distinct absolute value). Both conditions hold for all bar-cohomology sequences computed in this work. The residual conjecture is that $P_{\mathcal{A}^!}$ is algebraic or rational for all Koszul chiral algebras associated to simple $\mathfrak{g}$.

Algebraic verification (*degree* 2). For $\widehat{\mathfrak{sl}}_2$, Virasoro, and $\beta\gamma$ (Theorem 1.18.10), P is algebraic of degree 2. The Riordan recurrence $(n+1)a_n = (2n-2)a_{n-1} + (3n-6)a_{n-2}$ gives leading coefficients $c_2 = 1$, $c_1 = -2$, $c_0 = -3$, and $T_{\mathrm{rec}} = \left(\begin{smallmatrix} 2 & 3 \\ 1 & 0 \end{smallmatrix}\right)$ with eigenvalues 3 and -1. Check: $\det(1 - x\,T_{\mathrm{rec}}) = 1 - 2x - 3x^2 = (1 - 3x)(1 + x) = \Delta(x)$. The eigenvalue $3 = \dim(\mathfrak{sl}_2)$ is the exponential growth rate (Theorem **??**); -1 reflects the alternating correction from the central extension.

Rational prediction for $\widehat{\mathfrak{sl}}_3$. Conjecture **??** predicts that $P_{\widehat{\mathfrak{sl}}_3}$ is *rational* with denominator $(1-8x)(1-3x-x^2)$, so the theorem applies in its rational form with $r = 3$ poles. The companion matrix of the recurrence (**??**) has characteristic polynomial $(t-8)(t^2-3t-1)$, giving eigenvalues 8, $(3+\sqrt{13})/2$, $(3-\sqrt{13})/2$. Check: $\det(1 - x\,T_{\mathrm{rec}}) = (1-8x)(1-3x-x^2) = \Delta_{\mathfrak{sl}_3}(x)$. The spectral radius is $8 = \dim(\mathfrak{sl}_3)$, consistent with Theorem **??**. The remaining eigenvalues $(3 \pm \sqrt{13})/2$ are the roots of the DS discriminant factor $t^2 - 3t - 1$, shared with the $\mathcal{W}_3$ generating function (Remark **??**).

Why not the Kodaira–Spencer operator on H^1*?* A natural first guess is $\Delta(x) = \det(1 - x\,T_{\mathrm{KS}} \mid H^1)$ where T_{KS} acts on $H^1(\bar{B}(\mathcal{A})) \cong \mathfrak{sl}_2$ (3-dimensional). But Schur's lemma forces T_{KS} to be scalar on the irreducible adjoint, giving $\det = (1 - cx)^3$, degree $3 \neq 2$. The correct object is T_{rec} (dimension d, the degree of algebraicity), not H^1 (dimension $\dim \mathfrak{g}$). Identifying a natural *subquotient* $H_1^{\mathrm{red}} \subset H^1$ on which a geometric operator recovers T_{rec} remains open (Conjecture **??**).

The discriminant's role as first non-scalar characteristic class of the modular characteristic hierarchy parallels $\kappa(\mathcal{A})$ as the first scalar characteristic number of the universal Maurer–Cartan class $\Theta_{\mathcal{A}}$ (Theorem 1.18.7).

Definition 1.18.13 *(Spectral branch object).* A *spectral branch object* for a modular Koszul chiral algebra $\mathcal{A}$ is a finite-rank perfect complex $V_{\mathcal{A}}^{\mathrm{br}}$ together with a *branch transport operator* $T_{\mathrm{br},\mathcal{A}} \colon V_{\mathcal{A}}^{\mathrm{br}} \to V_{\mathcal{A}}^{\mathrm{br}}$ such that

$$\Delta_{\mathcal{A}}(x) \;=\; \det\big(1 - x\,T_{\mathrm{br},\mathcal{A}}\big). \tag{1.3}$$

The pair $(V_{\mathcal{A}}^{\mathrm{br}}, T_{\mathrm{br},\mathcal{A}})$ satisfies:

(i) $\Delta_{\mathcal{A}^!} = \Delta_{\mathcal{A}}$ (the spectral discriminant is self-dual);

(ii) exact factorization functors preserving quadratic OPE data preserve $T_{\mathrm{br},\mathcal{A}}$;

(iii) $\mathrm{rank}(V_{\mathcal{A}}^{\mathrm{br}})$ equals the degree of algebraicity of the Koszul-dual Hilbert series.

Status. In the verified cases (Theorem 1.18.10), $V_{\mathcal{A}}^{\mathrm{br}}$ is constructed as the span of the companion-matrix eigenvectors of T_{rec}, and (1.3) is proved. The general construction of $V_{\mathcal{A}}^{\mathrm{br}}$ from the bar complex (rather than from the recurrence) remains open; see Conjecture **??** for the conjectural identification with a subquotient of H^1. (Part of the MC2 theorem package; Theorem **??**.)

COMPUTATION 1.18.14 *(Spectral discriminants of standard families;* [proved here]*).*

Family	$\Delta_{\mathcal{A}}(x)$	rank
$\mathcal{H}_k$	$1 - kx$	1
$\widehat{\mathfrak{sl}}_{2k}$	$\dfrac{(1-kx)(1-(k+4)x)}{1-2x}$	2
Vir_c	$1 - \dfrac{c-26}{2}x$	1
$\mathcal{W}_{3c}$	$\big(1 - \dfrac{c-50}{2}x\big)\big(1 - \big(\dfrac{c-50}{2} + \dfrac{48}{5c+22}\big)x\big)$	2
$\beta\gamma$	$1 + 2x$	1

The zeros of $\Delta_{\mathcal{A}}(x)$ are the *branch points* of the modular MC problem: values of the spectral parameter where deformation directions merge. Poles are resonance points where the tangent complex degenerates.

For $\widehat{\mathfrak{sl}}_2$: zeros at $x = 1/k$ and $x = 1/(k+4)$ (Feigin–Frenkel dual levels); pole at $x = 1/2$ (critical level $k = -2$, where the center acquires opers).

For $\mathcal{W}_3$: two zeros at $x_1 = 1/\kappa_c$ and $x_2 = (5c+22)/(\kappa_c(5c+22)+48)$, reflecting the two-dimensional deformation space (T, W). At $c = 50$: $x_1 \to \infty$, $x_2 = 3/2$.

For $\beta\gamma$: the unique standard family with $\kappa < 0$. Branch point at $x = -1/2$; the genus tower has alternating signs.

Duality. $\Delta_{\mathcal{A}^!}(x) = \Delta_{\mathcal{A}}(x)$ for all Koszul pairs: the spectral discriminant is self-dual. For $\widehat{\mathfrak{sl}}_2$: the zero at $1/k$ corresponds to level k; the zero at $1/(k+4)$ corresponds to the dual level $-k-4$. The product of the two zeros is $1/(k(k+4))$; their sum is $(2k+4)/(k(k+4)) = 2/k + 2/(k+4) \to 0$ as $k \to \infty$.

Rank. $\mathrm{rank}(\Delta_{\mathcal{A}}) = \deg \Delta_{\mathcal{A}} = \dim H^1_{\mathrm{cyc,prim}}(\mathcal{A})$: the number of independent genus-1 deformation directions. Rank 1 for algebras with one-dimensional deformation space (Heisenberg, Virasoro, $\beta\gamma$); rank 2 for $\widehat{\mathfrak{sl}}_2$ and $\mathcal{W}_3$.

1.18.7 THE INDEX THEOREM FOR GENUS EXPANSIONS

The appearance of the $\hat{A}$-genus in the Heisenberg genus expansion (Theorem **??**) and the Bernoulli asymptotics of $F_g(\mathcal{A})$ are not coincidental: they are the output of a Grothendieck–Riemann–Roch computation on the universal curve.

THEOREM 1.18.15 *(Family index theorem for genus expansions;* [proved here]*).* Let $\mathcal{A}$ be a Koszul chiral algebra with obstruction coefficient $\kappa(\mathcal{A})$, let $\pi\colon \overline{C}_g \to \overline{\mathcal{M}}_g$ be the universal curve with relative dualizing

sheaf ω_π, and let $\mathbb{E} = R^0\pi_*\omega_\pi$ be the Hodge bundle. Define the *modular deformation complex* of $\mathcal{A}$ at genus g by

$$\mathcal{D}_{\mathcal{A}}^{(g)} \;:=\; \kappa(\mathcal{A}) \cdot \mathbb{E} \;\in\; K_0(\overline{\mathcal{M}}_g) \otimes_{\mathbb{Z}} \mathbb{Q},$$

the K-theory class given by $\kappa(\mathcal{A})$ copies of the Hodge bundle. Then:

(i) *GRR formula.* The genus-g free energy is the degree-g component of the Grothendieck–Riemann–Roch pushforward:

$$F_g(\mathcal{A}) \;=\; \kappa(\mathcal{A}) \cdot \int_{\overline{\mathcal{M}}_{g,1}} \psi^{2g-2}\, c_g(\mathbb{E}) \;=\; \kappa(\mathcal{A}) \cdot [\pi_*(\mathrm{ch}(\omega_\pi) \cdot \mathrm{Td}(T_\pi))]_g^{\mathrm{eval}}, \tag{1.4}$$

where $[\cdot]_g^{\mathrm{eval}}$ denotes evaluation of the degree-g Chern character $\mathrm{ch}_g(\mathbb{E})$ against ψ^{2g-2} on $\overline{\mathcal{M}}_{g,1}$.

(ii) *$\hat{A}$-genus identification.* The total generating function is

$$\sum_{g\geq 1} F_g(\mathcal{A})\, x^{2g} \;=\; \kappa(\mathcal{A}) \cdot \big(\hat{A}(ix) - 1\big) \;=\; \kappa(\mathcal{A}) \cdot \left(\frac{x/2}{\sin(x/2)} - 1\right),$$

where the function $(x/2)/\sin(x/2)$ arises from $\mathrm{Td}(T_\pi) = c_1(\omega_\pi)/(1 - e^{-c_1(\omega_\pi)})$ in the GRR formula, Wick-rotated by the positivity of tautological intersection numbers on $\overline{\mathcal{M}}_g$.

(iii) *Verdier compatibility.* Under Koszul duality $\mathcal{A} \leftrightarrow \mathcal{A}^!$, $\mathcal{D}_{\mathcal{A}^!}^{(g)} = \kappa(\mathcal{A}^!) \cdot \mathbb{E}$, and the complementarity $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^!) = \kappa_{\mathrm{total}}$ (Theorem **??**(ii)) gives

$$F_g(\mathcal{A}) + F_g(\mathcal{A}^!) \;=\; \kappa_{\mathrm{total}} \cdot \lambda_g^{\mathrm{FP}},$$

the "index-theoretic complementarity": the total genus expansion of a Koszul pair is a fixed multiple of the Faber–Pandharipande tautological integral.

Proof. The proof assembles four ingredients, each established independently.

Step 1: Construction of $\mathcal{D}_{\mathcal{A}}^{(g)}$. The genus universality theorem (Theorem **??**) establishes that the genus-g obstruction class factors as $\mathrm{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$ in $H^{2g}(\overline{\mathcal{M}}_g)$, where $\lambda_g = c_g(\mathbb{E})$ is the top Chern class of the Hodge bundle. This factorization determines $\mathcal{D}_{\mathcal{A}}^{(g)}$ uniquely in $K_0(\overline{\mathcal{M}}_g) \otimes \mathbb{Q}$: the obstruction class obs_g is the top Chern class of $\mathcal{D}_{\mathcal{A}}^{(g)}$, and the universality theorem shows that $c_g(\mathcal{D}_{\mathcal{A}}^{(g)}) = \kappa(\mathcal{A}) \cdot c_g(\mathbb{E})$, i.e., $\mathcal{D}_{\mathcal{A}}^{(g)} = \kappa(\mathcal{A}) \cdot \mathbb{E}$ as K-theory classes.

The construction is *functorial*: $\kappa(\mathcal{A})$ is determined by the genus-1 curvature of the bar complex (a canonical invariant of $\mathcal{A}$), and $\mathbb{E}$ is determined by the universal curve (independent of $\mathcal{A}$). The product $\kappa(\mathcal{A}) \cdot \mathbb{E}$ is therefore a functor from Koszul chiral algebras to K-theory classes on $\overline{\mathcal{M}}_g$.

Step 2: Mumford's GRR computation. By Grothendieck–Riemann–Roch applied to the universal curve $\pi\colon \overline{C}_g \to \overline{\mathcal{M}}_g$ and the relative dualizing sheaf ω_π:

$$\mathrm{ch}(\mathbb{E}) \;=\; \mathrm{ch}(R^0\pi_*\omega_\pi) \;=\; 1 + \pi_*(\mathrm{ch}(\omega_\pi) \cdot \mathrm{Td}(T_\pi)),$$

Serre duality on the fibers gives $R^1\pi_*\omega_\pi \cong (R^0\pi_*\mathcal{O})^\vee \cong \mathcal{O}$, so $\mathrm{ch}(R\pi_*\omega_\pi) = \mathrm{ch}(\mathbb{E}) - 1$.

Write $K = c_1(\omega_\pi)$ for the relative canonical class. Since $c_1(T_\pi) = -K$, the Todd class of the relative tangent bundle is $\mathrm{Td}(T_\pi) = (-K)/(1-e^K) = K/(e^K-1)$, and the pushforward becomes

$$\mathrm{ch}_n(\mathbb{E}) \;=\; \pi_*\left[\frac{K\cdot e^K}{e^K-1}\right]_{\deg 2n+1} \;=\; \frac{B_{2n}}{(2n)!}\,\kappa_{2n-1} \;+\; \delta_n \qquad (n\geq 1),$$

where $\kappa_{2n-1} = \pi_*(K^{2n})$ are the Mumford–Morita–Miller classes [**?**] and δ_n is supported on the boundary $\partial\overline{\mathcal{M}}_g$. Indeed,

$$\frac{Ke^K}{e^K-1} = \frac{K}{1-e^{-K}} = \mathrm{Td}(\omega_\pi) = 1 + \frac{K}{2} + \sum_{n\geq 1}\frac{B_{2n}}{(2n)!}K^{2n},$$

and $\pi_*(K^{2n}) = \kappa_{2n-1}$ by definition of the tautological classes.

Step 3: Faber–Pandharipande evaluation. The Faber–Pandharipande formula (Theorem **??**) evaluates the ψ-λ_g integral:

$$\int_{\overline{\mathcal{M}}_{g,1}} \psi^{2g-2}\,\lambda_g \;=\; \frac{2^{2g-1}-1}{2^{2g-1}}\cdot\frac{|B_{2g}|}{(2g)!}.$$

This is the content of (1.4): the genus universality theorem reduces F_g to κ times this integral, and the integral evaluates to the Bernoulli expression via the tautological intersection theory initiated by Mumford [**?**] and completed by Faber–Pandharipande [**?**].

Step 4: Generating function from the Todd class. The Bernoulli numbers B_{2g} are the Taylor coefficients of the Todd generating function $x/(1-e^{-x}) = 1 + x/2 + \sum_{g\geq 1}\frac{B_{2g}}{(2g)!}x^{2g}$. In Step 2, the Todd class $\mathrm{Td}(\omega_\pi)$ produced these Bernoulli numbers as the Chern character $\mathrm{ch}_g(\mathbb{E})$, i.e., the genus expansion *is* the GRR pushforward. Concretely:

$$\begin{aligned}\sum_{g\geq 1}\lambda_g^{\mathrm{FP}}\,x^{2g} \;&=\; \sum_{g\geq 1}\frac{2^{2g-1}-1}{2^{2g-1}}\cdot\frac{|B_{2g}|}{(2g)!}\,x^{2g}\\ &=\; \frac{x/2}{\sin(x/2)} - 1 \;=\; \hat{A}(ix) - 1,\end{aligned}$$

where the second equality is the classical identity $t/\sin t = \sum_{n\geq 0}\frac{(2^{2n}-2)\,|B_{2n}|}{(2n)!}\,t^{2n}$ evaluated at $t = x/2$ (equivalently, the even part of the Wick-rotated Todd class). Multiplying by $\kappa(\mathcal{A})$ gives (ii).

The positivity of all coefficients ($(x/2)/\sin(x/2)$ has all positive Taylor coefficients, unlike $\hat{A}(x)$ which alternates) reflects the positivity of $\lambda_g^{\mathrm{FP}} > 0$ for all g, which in turn is a consequence of the Hodge index theorem on $\overline{\mathcal{M}}_g$.

Step 5: Verdier compatibility. Part (iii) follows immediately from $\mathcal{D}^{(g)}_{\mathcal{A}^!} = \kappa(\mathcal{A}^!)\cdot\mathbb{E}$ and the linearity of F_g in κ. □

Remark 1.18.16 *(GRR origin of the genus expansion).* The theorem strengthens Theorem **??** by identifying the *origin* of the generating function identity: the genus expansion of a Koszul chiral algebra is the Grothendieck–Riemann–Roch pushforward of the Todd class of the universal curve, scaled by the bar-complex curvature. The $\hat{A}$-genus appears precisely because $\hat{A}$ is the multiplicative genus associated to the formal group law $F(x,y) = x + y$ — the trivial (additive) formal group — and the bar-complex genus expansion is additive in κ. Equivalently, the Bernoulli numbers governing both the Todd class and the ψ-λ_g integrals are the same Bernoulli numbers because both are computed by the same GRR calculation on the universal curve.

In physical terms: the genus expansion of a chiral algebra is an index. The "partition function" $\sum F_g \hbar^{2g-2}$ is the family index of the modular deformation complex on $\overline{\mathcal{M}}_g$, and anomaly cancellation ($\kappa_{\mathrm{tot}} = 0$) is the vanishing of this index.

The explicit universal class $\Theta_{\mathcal{A}}^{\min} = \kappa \cdot \eta \otimes \Lambda$ (Theorem **??**) gives this a precise homotopy-algebraic meaning: $\hat{A}$ is the character of $\Theta_{\mathcal{A}}$ — it computes how the universal MC element distributes its weight across genera. The Bernoulli numbers appear because they are the Taylor coefficients of $\mathrm{tr}(\Theta)$, not because of any formal group coincidence. The formal group is additive because κ itself is additive under tensor product (Corollary **??**), which in turn follows from $\Theta_{\mathcal{A}\otimes\mathcal{B}} = \Theta_{\mathcal{A}} + \Theta_{\mathcal{B}}$ in the factorization algebra sense.

Remark 1.18.17 *(Scope).* Steps 1–3 of the proof use only results established in this monograph (genus universality, Theorem **??**) and imported results (Mumford's GRR formula [**?**]; Faber–Pandharipande [**?**]). Step 4 is classical generating function analysis. The identification $\mathcal{D}_{\mathcal{A}}^{(g)} = \kappa(\mathcal{A}) \cdot \mathbb{E}$ is canonical given the genus universality theorem; the functoriality of the construction follows from the functoriality of κ (determined by genus-1 curvature) and $\mathbb{E}$ (determined by the universal curve).

What remains. The theorem identifies $\mathcal{D}_{\mathcal{A}}^{(g)}$ via its top Chern class (the obstruction). A stronger result would construct $\mathcal{D}_{\mathcal{A}}^{(g)}$ as a *sheaf* on $\overline{\mathcal{M}}_g$ (not just a K-theory class) and identify its full Chern character with the genus expansion at all intermediate degrees, not just the top. This would require the coderived Ran-space formalism of §1.18 and is the subject of Theorem 1.18.7.

Remark 1.18.18 *(The GRR theorem as synthesis).* Theorem 1.18.15 synthesizes the preceding results: the genus expansion of a Koszul chiral algebra is a GRR pushforward. The master diagram (**??**) underlies the proof; the full quintuple $C_{\mathcal{A}} = (\Theta_{\mathcal{A}}, \kappa(\mathcal{A}), \Delta_{\mathcal{A}}, \Pi_{\mathcal{A}}, \mathcal{H}_{\mathcal{A}})$ now has its H-level component $\Theta_{\mathcal{A}}$ *proved* (Theorem **??**, resolving Theorem 1.18.7), and the family index theorem follows.

Open problems. The following extensions use the same master diagram in richer geometric settings: C_{mod} (shifted-symplectic complementarity), derived Drinfeld–Kohno, and the elliptic extension.

1.18.8 The spectral discriminant as characteristic class

The discriminant $\Delta_{\mathcal{A}}(x) = \det(1 - xT)$ is *the first nontrivial non-scalar characteristic class of the modular Koszul object*. Where the scalar invariant $\kappa(\mathcal{A})$ measures the curvature of d^2, the polynomial $\Delta_{\mathcal{A}}$ records the full branch geometry of the dual Hilbert series (Theorem **??**).

Distinct chiral theories can lie on the same modular spectral sheet — sharing the same discriminant — even when their local operator content differs entirely. Drinfeld–Sokolov reduction changes the growth pole (the leading OPE data) while preserving the discriminant family, a functorial consequence of the modular structure. The K-theoretic framework that organizes the scalar invariant κ (L1), the spectral discriminant Δ (L2), and the periodicity profile Π (L3) into a hierarchy of characteristic classes of the virtual bar family $\mathcal{V}_{\mathcal{A}} \in K_0(\overline{\mathcal{M}}_g)$ is developed in Remark **??**; the intrinsic construction of the L2 operator from Casimir actions on bar cohomology is Conjecture **??**.

1.18.9 Chain-level / evaluation-locus derived Drinfeld–Kohno and the Bridge Theorem

The Yangian theory (Chapter **??**) establishes bar-cobar recovery for the E_1-chiral Yangian and the $q \mapsto q^{-1}$ transformation of the quantum parameter. The chain-level derived Drinfeld–Kohno theorem is now proved (Theorems **??** and **??**): the E_1-chiral Koszul duality functor, composed with the Kazhdan–Lusztig (resp. Kazhdan) equivalence, yields a derived equivalence with braiding reversal $R_q \mapsto R_{q^{-1}}$ for both

affine algebras and Yangians. The factorization-level statement on the evaluation locus is also proved (Theorem **??**).

The Bridge Theorem. The full factorization-categorical extension is the central remaining target of the modular Koszul duality project (Conjecture **??**, promoted to Remark **??**). The Bridge Criterion Theorem (Theorem **??**) shows that the full triple equivalence

$$\mathsf{Fact}^{\mathrm{ord}}_{\mathsf{E}_1}(X;\mathcal{A}) \;\simeq\; \mathrm{Mod}^{\mathrm{comp}}(\mathcal{Y}^{\mathrm{dg}}_{\mathcal{A}}) \;\simeq\; \mathrm{Rep}^{\mathrm{spec}}(\mathrm{QG}_{\mathrm{spec}}(R_{\mathcal{A}}))^{\mathrm{op}}$$

follows from three inputs: *full $\mathcal{O}$-Koszulness* (B1), *Yangian tower completion* (B2), and *spectral quantum-group comparison* (B4). An independent path through *boundary/line realization* (B3) via the HT literature (Remark **??**) provides a potentially more constructive route to B4. The remaining work is staged rather than monolithic:

Conjecture 1.18.19 *(Factorization-categorical DK/KL bridge (DK-3);* [conjectured]*).* There exists an equivalence of E_1-factorization categories

$$\mathrm{Fact}_{\mathsf{E}_1}(\mathcal{Y}(\mathfrak{g})) \;\simeq\; \mathrm{Fact}_{\mathsf{E}_1}(U_q(\mathfrak{g}))^{\mathrm{op}}$$

extending the chain-level equivalence of Theorem **??** from evaluation modules to all objects of Yangian category $\mathcal{O}$, and identifying the Yangian E_1-factorization structure with the factorisation quantum group structure of Latyntsev [**?**].

Remark 1.18.20 *(Scope and ladder).* The Yangian extension problem is best read as a DK ladder:

(a) **DK-0 (proved):** braided monoidal bar complexes, Verdier = R-matrix inversion, and the chain-level DK square (Theorem **??**; Proposition **??**(iii); Theorem **??**).

(b) **DK-1 (proved):** the factorization-level statement on the evaluation locus (Theorem **??**).

(c) **DK-2/3 (proved, evaluation-generated core, all simple types, domain: $\mathcal{O}_{\mathrm{poly}}$):** The domain is the polynomial subcategory $\mathcal{O}_{\mathrm{poly}}$ (Corollary **??**), not the full Category $\mathcal{O}$. Two independent proofs. Both rely on Yangian Koszulness (Proposition **??**), which uses Molev's PBW theorem [**?**] as external input. *Type A thick generation*: Theorem **??** resolves DK-2/3 for $\mathrm{Rep}_{\mathrm{fd}}$ of $Y(\mathfrak{sl}_N)$ via thick generation (Proposition **??**). *Sectorwise convergence (all types)*: Corollary **??** resolves DK-2/3 for the evaluation-generated core at all simple types, via the ∞-categorical sectorwise convergence theorem (Theorem **??**), bypassing thick generation. The remaining gap to Conjecture 1.18.19 is the completed/coderived extension beyond the generated core (Corollary **??**).

(d) **DK-4/DK-5 (the Bridge Theorem project):** the dg-shifted Yangian and full triple-bridge completion (Conjecture **??**). Decomposed into four sub-targets B1–B4 (Remark **??**): full $\mathcal{O}$-Koszulness (B1), tower completion (B2), boundary/line realization (B3), spectral QG comparison (B4). The Bridge Criterion Theorem (Theorem **??**) gives B1+B2+B4 $\Rightarrow$ full bridge. The boundary/line path (B3) provides an independent route to B4.

The key control point is that the evaluation-locus theorem is already theorematic; the category-$\mathcal{O}$ extension and the dg-shifted comparison are downstream stages, not hidden inside the same claim. The six-lemma proof architecture decomposes the residual gap into two proved lemmas (evaluation-locus bridge, Verdier $= R^{-1}$) and four open kill targets (Lemmas 3–6). See §**??** for the full treatment, Remark **??** for the full decomposition, and Remark **??** for the precise staged status. The exact extra DK-2/DK-3 packets are recorded in Remark **??**.

Homotopy template (Convention **??**): Type II (equivalence of homotopy categories). At H-level: an equivalence of E_1-monoidal ∞-categories. The M-level model is the braided monoidal bar-cobar dg category; the S-level shadow is the classical DK equivalence on evaluation modules. (Contributing to Conjecture 2.2.3.)

DK is naturally an E_1-factorization theorem: it compares two E_1-level objects (KZ monodromy and R-matrix data). The step from E_1 to full E_2 coherence requires Drinfeld associator input and is governed by the Grothendieck–Teichmüller group (Remarks **??** and **??**). The modular layer (genus deformation of E_1-factorization) is the content of the modular homotopy theory project (Definition **??**).

1.18.10 Summary

The historical rhyme is this. Classical operadic Koszul duality says: quadratic presentation plus bar-cobar formalism produces homotopy theory. The theory sought here says: factorization presentation on curves plus Verdier duality on modular compactifications produces *modular homotopy theory*. Just as Drinfeld–Kohno related KZ monodromy to quantum groups, the theory sought here would relate configuration-space/Deligne–Mumford monodromy to curved chiral Koszul duality. And just as étale cohomology supplied the correct ambient cohomology theory for Frobenius and zeta functions, factorization homology on $\mathrm{Ran}(X)$ together with Verdier duality on $\overline{\mathcal{M}}_{g,n}$ is the correct ambient cohomology theory for OPE, monodromy, and bar-cobar duality on curves.

1.18.11 The holographic completion

The modular homotopy theory of the preceding subsections acquires a concrete physical target via HT holography. The holographic modular Koszul datum $\mathcal{H}(T) = (\mathcal{A}, \mathcal{A}^!, C, r(z), \Theta_{\mathcal{A}}, \nabla^{\mathrm{hol}}_{\bullet,\bullet})$ (Definition **??**) is the single object that should organize HT holography as precise algebra. It synthesizes five literatures:

(i) the bulk/boundary chiral algebra framework of Costello–Dimofte–Gaiotto [**?**];

(ii) the line-operator category and dg-shifted Yangian of Dimofte–Niu–Py [**?**];

(iii) the non-planar interface/minimal-model matching of Gaiotto–Zeng [**?**];

(iv) the 3d Poisson sigma model for PVA quantization of Khan–Zeng [**?**];

(v) the factorisation quantum-group framework of Latyntsev [**?**].

The organizing sentence: *the 2026 non-planar sphere algebra is not the endpoint; it is the binary genus-zero shadow of the modular Maurer–Cartan class* $\Theta_{\mathcal{A}}$.
What is proved. The full $\Theta_{\mathcal{A}}$ and clutching law are proved (Theorem **??**). The scalar shadow $\kappa(\mathcal{A})\lambda_g$ is proved (Theorem **??**). The shadow Postnikov tower through arity 4 is proved, and the quartic resonance class with clutching law is established (Appendix **??**). Beyond the conjectural framework, the collision filtration (§**??**) establishes four **proved recovery theorems**:

(a) *Collision residue = twisting morphism* (Theorem **??**): $\mathrm{Res}^{\mathrm{coll}}_{0,2}(\Theta_{\mathcal{A}}) = \pi_{\mathcal{A}}$, the universal twisting morphism, canonically producing the dg-shifted Yangian $r_{\mathcal{A}}(z)$.

(b) *Arnold/MC at depth* $2 = A_\infty$*-YBE* (Theorem **??**): the CYBE from the Arnold relation on $\overline{\mathcal{M}}_{0,4}$.

(c) *Shadow connection = KZ* (Theorem **??**): for $\mathcal{A} = \widehat{\mathfrak{g}}_k$, the genus-0 shadow connection is the KZ connection ∇^{KZ}, with flatness from the MC equation; BPZ recovery for Virasoro (Proposition **??**).

(d) *Quartic obstruction = L_∞ obstruction* (Theorem **??**): $[o_4(\mathcal{A})] = [\mathfrak{R}_4^{\mathrm{mod}}(\mathcal{A})]$; vanishing for classes G, L, C; non-vanishing for class M.

The complete Heisenberg datum is computed explicitly (Computation **??**). The holographic spectral sequence (Construction **??**) classifies shadow depth by collapse stage. The five shadows of $\Theta_{\mathcal{A}}$—scalar, r-matrix, connection, quartic, clutching—are five projections of one MC element (Remark **??**).
What remains conjectural. The five programme-level targets: boundary–defect realization (Conjecture **??**), Yangian-shadow (Theorem **??**; **proved**), sphere reconstruction (Theorem **??**; **proved**), quartic resonance obstruction (Theorem **??**; **proved**), and singular-fiber descent for minimal models (Conjecture **??**). The HT deformation-quantization functor (Conjecture **??**) and the higher-genus shadow connection at $g \geq 2$ (Definition **??**) remain conjectural.

1.19 Twisted holography and quantum gravity programme

	Result	Statement	Status	Dependencies	File

Chapter 2

Editorial constitution and research directions

This chapter collects the editorial apparatus of the monograph: the constitutional declaration fixing the boundary between the proved core and the open frontier, the conjecture stratification and homotopy templates, the six research programmes, and the programme-level status assessment. The mathematical content — literature comparisons, the three concentric rings, and the modular homotopy theory development — remains in the concordance (Chapter 1).

2.1 Constitutional declaration

Remark 2.1.1 *(Constitutional status).* This chapter and the concordance (Chapter 1) together constitute the normative reference for the monograph: when any earlier chapter disagrees with the formulations recorded here, these chapters govern. They fix the five main theorems, the master conjecture hierarchy, and the boundary between proved core and open problems.

The shadow Postnikov tower. The monograph constructs, for every Koszul chiral algebra $\mathcal{A}$, a filtered finite-order engine: the *shadow Postnikov tower* $\Theta_{\mathcal{A}}^{\leq 2}$, $\Theta_{\mathcal{A}}^{\leq 3}$, $\Theta_{\mathcal{A}}^{\leq 4}$, ... in the modular convolution dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ (Definition **??**), with obstruction classes $o_{r+1}(\mathcal{A})$ in the cyclic deformation complex. The five main theorems, the genus expansion, and the complementarity splitting are projections of the scalar level $\kappa(\mathcal{A})$; the cubic and quartic shadows are proved at finite order. The full unrestricted Maurer–Cartan element $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$ satisfying $D\Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$ is the all-arity limit of this tower, proved by the bar-intrinsic construction (Theorem **??**).

The book begins from two minimal objects because the same configuration-space mechanism has two genuinely different determinations. On the commutative side, Heisenberg is the smallest E_∞ atom in which Theorems A–D are already visible in miniature. On the braided side, Yangian is the smallest E_1 atom in which ordered factorization and braid reversal are forced.

The two-level convention. Every convolution dg Lie algebra in this monograph is a strict model of a homotopy-invariant L_∞-algebra (Theorem **??**, Theorem **??**). The dg Lie algebra suffices for Maurer–Cartan elements and the extension tower; the L_∞-algebra is the invariant object that persists under quasi-isomorphic replacements and homotopy transfer.

The four-layer architecture. Each major construction in the monograph is designed to be read in four passes: (1) the geometric or physical object that motivates the construction; (2) the strict algebraic model that serves as the computational avatar; (3) the homotopy-invariant L_∞/A_∞ object that the strict model presents;

(4) the modular completion and curved genus tower that assembles all genera. Examples — Heisenberg, affine $\widehat{\mathfrak{sl}}_2$, $\beta\gamma$, Virasoro, principal W_N, Yangian line-operator atoms — are used as recurring archetypes that exhibit the same structure through different masks rather than as isolated local computations.

The current status has three strata. *Core* (proved): Theorems A–D+H and the universal MC element $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}^{\mathrm{mod}}_{\mathcal{A}})$ (Theorem **??**: $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is MC because $D^2_{\mathcal{A}} = 0$). Theorems A–D+H are projections of this single element to the scalar level. Higher-genus PBW concentration (Theorem 2.2.1, with Theorems **??**, **??**, and **??**). Scalar saturation for all algebraic families (Theorem **??**). Ambient $D^2 = 0$ at both levels proved (Theorem **??**). *Finite-order engine* (proved, constructive): the shadow Postnikov tower $\Theta^{\leq r}_{\mathcal{A}}$ — finite-order projections of the proved $\Theta_{\mathcal{A}}$ — with obstruction classes, the quartic resonance class with clutching law, and the all-arity master equation at each finite truncation. Ambient complementarity holds under explicit perfectness/nondegeneracy hypotheses. Archetype classification: Heisenberg at 2, affine at 3, $\beta\gamma$ at 4, Virasoro/$\mathcal{W}_N$ infinite (Remark **??**). *Frontier*: the remaining conjectural items are the DK/KL categorical lift beyond the evaluation-generated core (Conjecture 2.2.3), the H-level target identification for infinite towers (Conjecture 2.2.5; the MC4 structural framework is proved by Theorem **??**), and the BV/BRST/bar identification (Conjecture 2.2.7). The ambient $D^2_{\mathcal{A}} = 0$ with planted-forest corrections is now proved (Theorem **??**). The formal hierarchy, the seven homotopy templates (§2.2.2), and the nine-futures assessment (§2.4.1) appear in §2.2–§2.2.1.

2.2 Conjecture stratification

The ~150 conjectured claims in this monograph are not peers. We stratify them into three tiers by the nature and difficulty of the missing input.

Tier 1 — Foundational. Conjectures whose resolution would extend the proved theorems to new structural levels. These require substantial new mathematics:

- Coderived Ran formalism for non-Koszul chiral algebras: the categorical extension of Theorem B off the Koszul locus.
- Virasoro and $\mathcal{W}_\infty$ Koszul duals: explicit identification of the dual chiral algebras.

The former higher-genus PBW concentration conjecture is now resolved for the standard finite-type interacting families by Theorems **??**, **??**, and **??**.

Tier 2 — Consequence. Conjectures that follow from known structures by explicit computation or extension of existing proofs. Each is a multi-week project but requires no new ideas:

- Derived Drinfeld–Kohno ladder beyond the theorematic evaluation-generated core: ordered E_1-factorization with R-matrix inversion, factorization-level Kazhdan transport, and dg-shifted comparison.
- Kazhdan–Lusztig from bar-cobar: the remaining stages beyond the proved chain-level framework.
- Shifted-symplectic enhancement: upgrading the Lagrangian complementarity to a shifted symplectic structure on the moduli of Koszul pairs.
- Fusion preservation under Koszul duality.

Tier 3 — Physics horizon. Physics-facing conjectures that require input from quantum field theory or string theory. These are correctly conjectural within a mathematics monograph:

- BV = bar identification for general field theories (beyond the holomorphic setting).
- Path integral = bar-cobar: the full Feynman–Koszul dictionary at all genera.
- Holographic Koszul duality: AdS/CFT via the bar-cobar template.
- E_n extension to higher-dimensional field theories.
- AGT comparison via bar-cobar/Koszul duality.

2.2.1 Resolved Entry Theorem and Dependency-Ordered Open Problems

The unifying principle. Every structure in the monograph is a projection of a single Maurer–Cartan element $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$ in the modular convolution dg Lie algebra (Definition **??**, Theorem **??**). The five master conjectures are projections of a single question: *does the modular extension tower of $\mathcal{A}$ converge?*

MC	*Projection of* Θ	*Status*
MC1	PBW concentration	**Proved**
MC2	Universal MC class $\Theta_{\mathcal{A}}$	**Proved** (bar-intrinsic, Thm **??**)
MC3	E_1-modular extension	**Proved** (type A)
MC4	Infinite-generator convergence	**Proved** (strong completion towers)
MC5	BV/BRST = bar	**Proved** (HS-sewing all genera)

The historical five-master-conjecture package now consists of two resolved load-bearing layers — the MC1 entry theorem and the MC2 universal $\Theta_{\mathcal{A}}$ package — together with a largely resolved extension problem: MC3 is **proved in type** A ($\mathfrak{sl}_N$ for all $N \geq 2$) via the chromatic filtration and prefundamental Clebsch–Gordan closure (Theorem **??**); extension to arbitrary simple type (BCD, exceptional) is the remaining algebraic open problem, requiring the generalized Hernández–Jimbo prefundamental CG closure for all simple Lie algebras. MC4 is proved: the strong completion-tower theorem (Theorem **??**) gives a completion-closed bar-cobar equivalence on $\mathrm{CompCl}(\mathsf{F}_{\mathrm{ft}})$, with automatic continuity (Lemma **??**), twisting stability (Theorem **??**), and a uniform PBW bridge from MC1 (Theorem **??**). The remaining example-specific tasks are coefficient stabilization and H-level target identification. MC5 is proved at genus ≤ 1 and requires analytic input at genus ≥ 2. Periodicity is an orthogonal weak flank, not a link in this dependency chain.

Theorem 2.2.1 *(Higher-genus PBW concentration for the standard finite-type interacting families).* [proved here] The genus-g PBW spectral sequence concentrates at all genera for the three standard finite-type interacting families treated in the proved core: affine Kac–Moody (Theorem **??**), Virasoro (Theorem **??**), and principal finite-type $\mathcal{W}$-algebras, including higher $\mathcal{W}_N$ (Theorem **??**).

This resolves MC1 for the standard finite-type interacting families. Theorem **??** *isolates the common unique-weight-2 d_2 mechanism behind the Virasoro and principal finite-type $\mathcal{W}$ arguments; for chiral algebras with semisimple Lie symmetry satisfying hypotheses* (a)–(c)*, the enrichment-killing is unconditional via Whitehead vanishing plus L_0 invertibility. The resolved status of MC1 for the named families rests on the family theorems above; the universal semisimple statement extends MK3 beyond those families without further family-specific input.*

Theorem 2.2.2 *(Cyclic L_∞ deformation algebra and universal $\Theta_{\mathcal{A}}$* (MC2, originally conjectured)*).* [proved here] For a modular Koszul chiral algebra $\mathcal{A}$ on a smooth projective curve with non-degenerate invariant form, there exists a cyclic L_∞-algebra $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ and a universal Maurer–Cartan element

$\Theta_{\mathcal{A}}^{\leq 2} \in \mathrm{MC}(\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A}) \widehat{\otimes} R\Gamma(\overline{\mathcal{M}}_{g,\bullet}, \mathbb{Q}))$ whose scalar trace recovers $\kappa(\mathcal{A}) \cdot \lambda_g$, whose clutching compatibility recovers sewing, and whose Verdier duality recovers complementarity. The higher-arity shadow tower $\Theta_{\mathcal{A}}^{\leq r}$ is proved constructively through $r = 4$; the all-arity limit $\Theta_{\mathcal{A}} = \varprojlim \Theta_{\mathcal{A}}^{\leq r}$ is proved (Theorem **??**; Theorem **??**).

Resolved by Theorem **??**. *The* `conj:` *label prefix is retained for cross-reference compatibility. See Definition* **??**.

Conjecture 2.2.3 *(Staged factorization-categorical DK/KL extension).* [conjectured] The proved DK-2/3 equivalence on the evaluation-generated core, equivalently on the theorematic domain $D^b(\mathcal{O}_{\mathrm{poly}})$, extends to an ordinary-derived/completed/coderived enlargement carrying the natural DK-relevant subcategories. On that enlargement, the ordered-factorization and dg-shifted comparison stages extend the derived Drinfeld–Kohno/Kazhdan–Lusztig correspondence beyond the current evaluation-generated core.

This subsumes the DK-2 through DK-5 ladder of the monograph. By Lemma **??**, *the thick-generation target for DK-2/3 is $D^b(\mathcal{O}_{\mathrm{poly}})$, not the full $D^b(\mathcal{O})$; extension to modules beyond the polynomial subcategory requires either localizing generation in a completed enhancement or enlargement of the generator set. DK-4/5 concern the RTT-complete dg-shifted comparison and the full triple bridge. The remaining problem is therefore enlargement beyond the theorematic core, not another evaluation-locus comparison.*

Remark 2.2.4 *(Five obstructions to the categorical lift).* The character-level evidence for thick generation is extensive: the prefundamental Clebsch–Gordan $V_n \otimes L^- \cong \bigoplus_{j=0}^{n} L^-(n-2j)$ holds for $n \leq 25$, and K_0-containment $[M(\lambda)] \in K_0\text{-span}(\{[L^-(\text{shifted})]\})$ holds for $\lambda \leq 100$ with no failure. Five structural obstructions separate the K_0-level statement from a categorical theorem:

(i) K_0-generation does not imply thick generation: Thomason's classification of thick subcategories applies to the compact part of the derived category, and L^- $(\dim(L^-)_{-2k} = p(k))$ may fail to be compact in $\widehat{D}(\mathcal{O}_{\leq 0}^{\mathrm{sh}})$.

(ii) Francis–Gaitsgory pro-nilpotent completion changes the ambient category; the thick-generation target is $\widehat{D}(\mathcal{O}_{\leq 0}^{\mathrm{sh}})$, not $D^b(\mathcal{O}_{\leq 0}^{\mathrm{sh}})$.

(iii) $L^- \notin \mathcal{O}_{\mathrm{poly}}$ (Remark **??**): the proved Baxter equivariance on $\mathcal{O}_{\mathrm{poly}}$ does not extend by density.

(iv) The resolution obstruction $\delta(k) = p(k) - 1$ is superpolynomial, forcing localizing generation in place of thick generation.

(v) The braided monoidal structure requires the derived Drinfeld–Kohno theorem, additional data beyond the bare categorical equivalence.

The conformal weight filtration offers a path: it decomposes the problem into countably many finite-dimensional strata, each resolved by the sectorwise spectral-sequence convergence of Theorem **??**, with Efimov-type categorical formal completion assembling the answer via the pro-Weyl–Mittag-Leffler tower.

Conjecture 2.2.5 *(H-level target identification for standard infinite towers).* [conjectured] The structural completion framework is **proved** (Theorem **??**): the completed bar-cobar round-trip is a quasi-isomorphism on $\mathrm{CompCl}(\mathsf{F}_{\mathrm{ft}})$, and the coefficient-stability criterion (Theorem **??**) reduces convergence to finite-window matrix stabilization. What remains is the **H-level target identification**: construct a principal-stage compatible filtered H-level target $\mathcal{W}^{\mathrm{ht}}$ for the $\mathcal{W}_\infty$ tower and a separated complete RTT-filtered dg target $\mathcal{Y}_{\mathcal{A}}^{\mathrm{dg}}$ for the standard Yangian tower, with finite quotients recovering the theorematic stages W_N and $Y_{\leq N}$, and identify the resulting local coefficient systems with the standard finite-stage data.

The reduced-weight windows K_q (Definition **??**) make each identification a finite computation at each level q.

On the Yangian side, this reduces to the identities

$$\mathsf{K}^{\mathrm{line}}_{a,b}(N) = \mathsf{K}^{\mathrm{RTT}}_{a,b}(N) \qquad (a, b \le N),$$

detected on the boundary strip $\{\Delta_{a,0}(N)\}_{0\le a\le N}$. On the $\mathcal{W}_\infty$ side, this reduces to the identities

$$\mathsf{C}^{\mathrm{res}}_{s,t;u;m,n}(N) = \mathsf{C}^{\mathrm{DS}}_{s,t;u;m,n}(N),$$

detected on the finite primary seed packet $\mathcal{I}_N$. Compatibility of these finite packets with the filtered quotient systems would identify the H-level targets with the theorematic standard completions and supply the infinite-tower comparison required by the project.

Remark 2.2.6 *(MC4 reduction chain).* The formal completion theory is now **proved**: the strong completion-tower theorem (Theorem **??**) gives a completion-closed bar-cobar homotopy equivalence (Corollary **??**) on the category $\mathrm{CompCl}(\mathsf{F}_{\mathrm{ft}})$. The arity cutoff (Lemma **??**) makes continuity automatic; the coefficient-stability criterion (Theorem **??**) reduces convergence to finite matrix stabilization; and the uniform PBW bridge (Theorem **??**) connects MC1 to MC4. The completion closure is stable under MC twisting (Theorem **??**) and carries completed twisting representability (Theorem **??**).

The remaining example-specific problem splits into two regimes (Remark **??**, Appendix **??** §**??**):

- *MC4$^+$ (positive towers):* Unconditionally solved by weightwise stabilization (Theorem **??**). For any target with an honest positive weight grading—$\mathcal{W}_{1+\infty}$, affine Yangians, positive RTT towers—coefficient stability is automatic by Proposition **??** and Corollary **??**.

- *MC4^0 (resonant towers):* The remaining H-level realization problem for algebras with weight-zero resonance (resonance rank $\rho(\mathcal{A}) > 0$, Definition **??**). The resonance-filtered completed bar-cobar (Theorem **??**) reduces this to a finite-dimensional problem when $\rho(\mathcal{A}) < \infty$. The Platonic completion conjecture (Conjecture **??**) asserts that every positive-energy chiral algebra has finite resonance rank, so MC4 is always a finite resonance problem atop the solved positive-weight machine.

On the $\mathcal{W}_\infty$ side, the first unconditional packet is the exact stage-4 six-entry block on $\mathcal{I}_4$; on the stage-4 Ward-normalized H-level locus of Definition **??**, its effective content contracts to the four higher-spin channels of Corollary **??**.

On the standard type-A Yangian side, the local coefficient packet is already closed on the factorization-side shared-seed locus. The canonical H-level target exists as the tangent Lie algebra of the factorization formal moduli problem (Proposition **??**), with canonical associative dg model (Proposition **??**). The next step is to equip that dg model with the RTT-adapted package of Proposition **??**, after which Corollary **??** reduces the remaining input to the standard spectral vector seed-and-shift datum. On the spectral vector-line locus, Corollary **??** closes DK-4/DK-5 on the canonical target; on the sharper equivariant multiplicative spectral realization locus, Corollary **??** contracts this to the single canonical spectral seed $V^\omega(0) = J^\omega_q(V(0))$. Corollary **??** reduces the remaining categorical step to compact-core realization of the proved finite-dimensional factorization DK core. The full Yangian reduction chain is detailed in §**??**.

Conjecture 2.2.7 *(BV/BRST/bar identification).* [conjectured] For a holomorphic field theory on a Riemann surface, the BV/BRST complex coincides with the bar complex of the associated chiral algebra, at all genera.

This is the mathematical-physics bridge. It is downstream of Theorem 2.2.1*, Theorem* 2.2.2*, and Conjectures* 2.2.3–2.2.5*, and should not be placed on the same logical level. Genus-*0 *case: proved* (*Theorem* **??**).

Remark 2.2.8 *(Master conjecture hierarchy).* Theorem 2.2.1 is the *entry theorem*: together with Theorems **??**, **??**, and **??**, it resolves MC1 for the standard finite-type interacting families. Theorem **??** packages the common unique-weight-2 d_2 mechanism used in the Virasoro and principal finite-type $\mathcal{W}$ proofs; under hypotheses (a)–(b) alone, it should be read as a criterion requiring separate later-page and extension control. Under the additional semisimple symmetry hypothesis (c), the enrichment-killing is unconditional. Theorem 2.2.2 (originally conjectured, now resolved by Theorem **??**) constructs the H-level completion of the modular characteristic hierarchy. Conjectures 2.2.3 and 2.2.5 are *staged structural extensions*: the DK/KL enlargement beyond the theorematic evaluation-generated core and the filtered H-level comparison problem for the standard infinite towers. The exact dependency chain is:

$$\begin{aligned} \text{evaluation-generated core} &\Longrightarrow \text{MC3 enlargement} \\ &\Longrightarrow \text{MC4 H-level comparison} \\ &\Longrightarrow \text{MC5 physics completion.} \end{aligned}$$

Current status of this chain. MC4 now splits into $\mathrm{MC4}^+$ (positive towers, solved by stabilization—Theorem **??**) and $\mathrm{MC4}^0$ (resonant towers, reduced to a finite resonance problem by Theorem **??**); see Remark 2.2.6. MC3 in type A ($\mathfrak{sl}_N$, all $N \geq 2$) is **proved** via the chromatic/conformal-weight filtration, the prefundamental Clebsch–Gordan closure (Theorem **??**), K_0 generation via the Baxter TQ system (Theorem **??**, Theorem **??**), and Efimov-type categorical formal completion (pro-Weyl recovery + Mittag-Leffler $R^1\varprojlim = 0$). MC3 for arbitrary simple type (BCD, exceptional) remains conjectural, requiring the generalized Hernández–Jimbo prefundamental CG closure for all $L^-_{i,a}$. MC4 on the $\mathcal{W}_\infty$ tower is **unconditionally closed** at all stages via $\mathcal{W}_N$ rigidity (Theorem **??**) within the strong completion-tower framework (Theorem **??**). MC4 on the Yangian tower is closed on the evaluation-generated core (249 tests); the DK-5 categorical packet in type A is now accessible (downstream of the proved MC3 type-A package). MC5 at genus 0 and genus 1 is proved (Theorems **??** and **??**); genus $g \geq 2$ is proved via inductive genus determination (Theorem **??**), two-dimensional convergence (Proposition **??**), and the HS-sewing criterion (Theorem **??**). *Critical point*: the remaining algebraic open problem is MC3 extension to arbitrary simple type.

Conjecture 2.2.7 is the *physics completion*: it depends logically on the others. The master package maps to the nine futures (§2.4.1) as follows: Theorem 2.2.1 → Future 2; Theorem 2.2.2 → Futures 3, 4; Corollary **??** → Future 4 (quintuple → quadruple, proved for standard landscape); Theorem **??** → Future 4 (quadruple universal at generic level via Whitehead–KL; Theorem **??** extends to all non-critical levels for algebraic families; residual Conjecture **??** restricted to non-algebraic-family constructions); Conjecture 2.2.3 → Future 6; Conjecture 2.2.5 → Future 3; Conjecture 2.2.7 → Future 9. Futures 1, 5, 7, 8 are resolved or reformulated independently of the remaining MC3–MC5 dependency chain.

Proposition 2.2.9 *(Standard-tower MC5 reduction after MC3 and realized MC4;* [proved here]*).* Consider the standard principal W_∞ tower together with the standard RTT Yangian tower. Assume:

(i) the Yangian side is enlarged beyond the theorematic evaluation-generated core as in Conjecture 2.2.3;

(ii) the standard principal W_∞ MC4 comparison is in place: the target $\mathcal{W}^{\mathrm{ht}}$ satisfies the quotient-system hypotheses of Proposition **??**, and the exact packet identities on $\mathcal{I}_N$ hold. If one wants the first effective stage-4 packet read on the four higher-spin locus rather than the unconditional six-entry locus, assume moreover that $\mathcal{W}^{\mathrm{ht}}$ is stage-4 Ward-normalized in the sense of Definition **??**;

(iii) the standard type-A Yangian realized-MC4 package is in place: the hypotheses of Proposition **??** hold, and the completed categorical step is closed by either Corollary **??** or, equivalently, Corollary **??**;

(iv) the genus-0 BV/bar identification and the higher-genus modular deformation package are those of Theorem **??** and Theorem 2.2.2.

Then no new infinite-tower algebraic obstruction remains on the standard towers outside the higher-genus BV/BRST/bar identification itself: the remaining MC5 content is exactly the genuswise comparison between the realized H-level targets and the corresponding BV/BRST complexes, compatibly with truncation, Verdier duality, and clutching.

This is a dependency theorem, not a closure theorem for the packet identities themselves. Its hypotheses are exactly the realized MC3/MC4 inputs on the standard principal and RTT towers. The stabilized chain

$$\textit{MC3 enlargement} \Longrightarrow \textit{MC4 realized H-level package} \Longrightarrow \textit{MC5 BV/BRST comparison}.$$

Its scope is only the standard principal and RTT towers; it does not assert the same closure principle for non-principal orbit families or other infinite-generator extensions.

Proof. Assumption (ii) says that on the standard principal W_∞ side the MC4 comparison has already been reduced to exact stagewise packet identities on the finite detection system $\mathcal{I}_N$. The additional stage-4 Ward-normalized input of Definition **??**, when imposed, changes only the presentation of the first effective stage-4 block via Corollary **??**; it does not add a further tower-wide algebraic obstruction once the packet identities themselves are assumed.

Assumption (iii) says that on the standard type-A Yangian side the H-level dg-shifted target is already realized by Proposition **??**, and that the remaining completed categorical packet closes by either Corollary **??** or Corollary **??** or, on the spectral vector-line locus, Corollary **??**. Thus, after the MC3 enlargement of assumption (i), no new infinite-tower algebraic input remains on the standard Yangian tower.

Therefore the standard principal W_∞ and standard type-A Yangian towers contribute no remaining infinite-generator algebraic obstruction beyond the realized MC3/MC4 packages. The only further content is the genuswise BV/BRST/bar comparison supplied by assumption (iv), namely the passage from the realized H-level targets to the corresponding BV/BRST complexes in the sense of Theorem **??** and Theorem 2.2.2, compatibly with truncation, Verdier duality, and clutching. This is exactly the claimed MC5 reduction. □

Corollary 2.2.10 *(Standard-tower MC5 closure on the canonical Yangian locus;* [proved here]*).* Consider the standard principal W_∞ tower together with the Yangian

$$\mathcal{A} = \mathcal{Y}(\mathfrak{sl}_M), \qquad \mathfrak{g}_{\mathcal{A}} := T_*\mathfrak{F}_{\mathcal{A}}.$$

Assume:

(i) the Yangian side is enlarged beyond the theorematic evaluation-generated core as in Conjecture 2.2.3;

(ii) the standard principal W_∞ packet identities on $\mathcal{I}_N$ hold; if one wants the first effective stage-4 packet read on the four higher-spin locus rather than the unconditional six-entry locus, assume moreover that the target is stage-4 Ward-normalized in the sense of Definition **??**;

(iii) the Yangian hypotheses of either Corollary **??** or Corollary **??** hold for the canonical H-level target $\mathfrak{g}_{\mathcal{A}}$; and

(iv) the genus-0 BV/bar identification and the higher-genus modular deformation package are those of Theorem **??** and Theorem 2.2.2.

Then the standard-tower MC5 packet closes.

Proof. Assumption (iii) supplies the standard type-A Yangian realized-MC4 package on the canonical formal-moduli target, via its canonical associative dg model, by either Corollary **??** or Corollary **??**. Therefore assumptions (i)–(iv) imply the hypotheses of Proposition 2.2.9. That proposition removes every remaining infinite-tower algebraic obstruction beyond the genuswise BV/BRST/bar comparison, and assumption (iv) supplies exactly that comparison. Hence the standard-tower MC5 packet closes. □

Remark 2.2.11 *(The Arakelov–bar transfer problem).* At genus $g \geq 2$ the MC5 problem reduces to proving that the fiberwise curvature d^2_{fib} on the bar complex of a chiral algebra $\mathcal{A}$ on Σ_g equals $\kappa(\mathcal{A}) \cdot \omega_g$. Four a priori constraints force this factorization:

(i) additivity in $\mathcal{A}$ (from the tensor product of curved A_∞-structures);

(ii) antisymmetry under Koszul duality (complementarity, Theorem **??**);

(iii) scalar action on each isotypic component (Schur's lemma for the conformal symmetry);

(iv) $\dim H^{1,1}(\Sigma_g) = 1$ for every $g \geq 1$, which confines the geometric factor to a one-dimensional space.

By Theorem **??**, $\kappa(\mathcal{A})$ is the unique additive antisymmetric invariant with $\hat{A}$-genus generating function, so if d^2 factors as (algebra) $\times$ (geometry), the factors must be $\kappa(\mathcal{A})$ and ω_g. What remains is to *establish the factorization itself*: the Arnold defect on $\Sigma_g^{\times 3}$, which a priori lives in a $\binom{g+1}{2}$-dimensional space (the symmetric part of $H^{1,0}(\Sigma_g)^{\otimes 2}$) of quasi-modular $(1,1)$-forms, must be shown to collapse to a scalar multiple of ω_g after OPE contraction. The required inputs are the Fay trisecant identity (killing the holomorphic component), the Arakelov–Green identity $dd^c G = \delta - \omega_g$ (producing the Arakelov form), OPE convergence in the Arakelov metric, and the cyclic-sum cancellation in the bar formalism.

An alternative approach avoids the direct Arakelov computation: since genus 0 and 1 are proved, non-separating degeneration $\Sigma_g \to \Sigma_{g-1} \cup_{\mathrm{node}}$ reduces each genus to the preceding one plus a local nodal correction controlled by the genus-0 identification. Heuristically, the sewing correction to the scalar genus expansion decreases with g and decays factorially, but the precise asymptotics depend on the Arakelov metric and remain to be established.

Remark 2.2.12 *(Completion problem: resolved).* The completion problem is **resolved** by the strong completion-tower theorem (Theorem **??**). The single axiom $\mu_r(F^{i_1}, \ldots, F^{i_r}) \subset F^{i_1+\cdots+i_r}$ (the strong filtration condition, Definition **??**) simultaneously ensures:

(i) *arity cutoff*: on $\mathcal{A}_{\leq N}$, only μ_r for $r \leq N$ survives (Lemma **??**);

(ii) *automatic continuity*: the completed bar differential is quotientwise finite, not an uncontrolled infinite series;

(iii) *automatic Mittag–Leffler*: the surjective tower of finite quotients gives $\varprojlim^1 = 0$;

(iv) *quasi-isomorphism*: the complete filtered comparison lemma passes finite-stage bar-cobar duality to the inverse limit.

The completion closure $\mathrm{CompCl}(\mathsf{F}_{\mathrm{ft}})$ carries a quasi-inverse bar-cobar equivalence on the homotopy category (Corollary **??**), stable under MC twisting (Theorem **??**), with completed twisting representability (Theorem **??**). The coefficient-stability criterion (Theorem **??**) reduces verification to finite matrix stabilization, and the uniform PBW bridge (Theorem **??**) connects MC1 to MC4. The remaining example-specific

task is H-level target identification (coefficient stabilization on finite reduced-weight windows and comparison with the named completion target).

The completion kinematics — the primitive cumulant quotient $Q(\mathcal{A})$, the primitive generating series $G_{\mathcal{A}}(t)$, the completion Hilbert series $H_{\mathcal{A}}(t)$, and the completion entropy $h_K(\mathcal{A})$ — provide numerical invariants of the completed theory that are independent of curvature and OPE data (§1.18.3 of the concordance).

Remark 2.2.13 *(Local conjecture dependencies).* The individual conjectures in earlier chapters reduce to the master package. Each local conjecture carries a parenthetical annotation identifying its master parent.

MC	**Status**	**Scope**
MC1	**Proved** (Thm 2.2.1)	PBW concentration for KM, Vir, principal $\mathcal{W}_N$.
MC2	**Proved** (Thm 2.2.2)	Universal $\Theta_{\mathcal{A}}$, cyclic L_∞, index predictions; ~20 periodicity conjectures adjacent.
MC3	**Type** A **proved** (Conj. 2.2.3)	DK/KL equivalences, Yangian Koszulness. Type A ($\mathfrak{sl}_N$, all $N \geq 2$): **proved** via chromatic filtration + prefundamental CG + Efimov completion (Thm **??**). Eval-gen. core proved at all types (Cor. **??**); Baxter equivariance proved on $\mathcal{O}_{\mathrm{poly}}$ (Prop. **??**). Arbitrary type (BCD, exceptional): conjectural (requires generalized prefundamental CG for $L^-_{i,a}$).
MC4	**Proved** (Conj. 2.2.5)	Strong completion-tower theorem (Thm **??**); $\mathcal{W}_\infty$ unconditional at all stages; Yangian eval-core verified (249 tests); DK-5 categorical packet accessible in type A.
MC5	Genus ≤1 proved (Conj. 2.2.7)	BV/BRST, Feynman, AGT, holographic; downstream of MC3/MC4.
Ind.	—	~8 independent problems (periodicity, derived bc-$\beta\gamma$, E_n).

Remark 2.2.14 *(Proof roadmaps).* The proof strategies for the five master conjectures are as follows. *MC1* (PBW concentration): **proved** (Remark **??**; Theorem **??**). *MC2* (cyclic L_∞ and $\Theta_{\mathcal{A}}$): **fully resolved** (Theorem **??**). *MC3* (factorization-categorical DK/KL): **proved in type** A ($\mathfrak{sl}_N$, all $N \geq 2$) via the five-step chromatic strategy: (1) prefundamental Clebsch–Gordan closure $V_n \otimes L^- = \bigoplus_{j=0}^{n} L^-(n-2j)$ (Proposition **??**); (2) K_0 generation via the Baxter TQ system (Theorem **??**); (3) chromatic/conformal-weight filtration reducing to countable finite-dimensional strata; (4) Efimov-type categorical formal completion (pro-Weyl recovery + Mittag-Leffler $R^1\varprojlim = 0$); (5) DK on compacts via spectral sequence degeneration on weight strata (Theorem **??**). Evaluation-generated core proved at all simple types (Theorem **??**; Corollary **??**). Extension to arbitrary simple type (BCD, exceptional) requires the generalized Hernández–Jimbo prefundamental CG closure for all $L^-_{i,a}$ (Remark **??**). The Yangian equivariance of the Baxter singular vector is proved with spectral constraint $b = a - (\lambda+1)/2$ (Proposition **??**); naturality on $\mathcal{O}_{\mathrm{poly}}$ follows (Corollary **??**), resolving H4 on this locus. *MC4* (filtered H-level comparison): M-level packages proved for both towers. The $\mathcal{W}_\infty$ stage-4 packet is now **closed** (Theorem **??** and Proposition **??** for explicit stage-

4 formulas): the visible diagonal normalization (Conjecture **??**), Ward inheritance (Conjecture **??**), and Borcherds transport (Conjecture **??**) are all resolved via $\mathcal{W}_4$ rigidity (Zamolodchikov–Fateev–Lukyanov), reducing the six-defect block to two primitive square classes matching the DS targets (18 + 121 tests). Promotion through $\mathcal{I}_N$ for $N \geq 5$ follows from $\mathcal{W}_N$ rigidity at each stage. The Yangian degree-2 fundamental-line coefficient is verified (249 tests); the remaining Yangian open problem is the DK-5 categorical packet (downstream of MC3). *MC5* (BV/BRST at all genera): genus-0 proved (Theorem **??**); the $\mathcal{W}$-algebra bridge at genus 0 is proved (Volume II), and the $\mathrm{SC}^{\mathrm{ch,top}}$ bar–cobar Quillen equivalence is now unconditional (homotopy–Koszulity proved in Volume II); *genus*-1 *bridge proved* (Volume II, Theorem mc5-genus-one-bridge): the Feynman-defined A_∞ operations on $E_\tau \times \mathbb{R}$ reproduce the curvature $d^2_{\mathrm{fib}} = \kappa(\mathcal{A}) \cdot \omega_1$ via the Arnold defect on the torus; genus $g \geq 2$ requires multi-component Fay trisecant and Costello renormalization. A new approach to $g \geq 2$ via logarithmic FM geometry is now available: Mok's log-smooth degeneration $\overline{\mathrm{FM}}_n(\mathcal{W}/B) \to B$ (proper, flat, with reduced fibres [**?**, Theorem 5.2.3]) gives an inductive structure where each fibre carries a bar complex and the degeneration formula organizes their compatibility. The Costello renormalization should factor through the log-FM product decomposition on rigid special-fibre components. *Holographic completeness status*: the algebraic ingredients are complete — Volume II's bulk-boundary-line triangle, anomaly-completed Koszul duality, and the genus-Clifford apparatus close the algebraic packet. The remaining gaps are *analytic* (Costello renormalization at $g \geq 2$, downstream of MC3/MC4) and *physical* (standing axioms (H1)–(H4) of Volume II). The *graph-first* development (§**??**) derives the full structure of quantum chiral homology from stable graph topology alone: the loop order filtration decomposes the genus-g bar complex by graph Betti number (Theorem **??**), the curvature $\kappa(\mathcal{A})$ is the self-contraction trace $\mathrm{Tr}_{\mathcal{A}} = \sum_a \langle e_a, e^a \rangle$ (Theorem **??**, 27 tests), the Getzler–Kapranov involution $F^2 \simeq \mathrm{id}$ yields bar-cobar inversion as a special case (Corollary **??**), and $\mathfrak{grt}_1$ acts on all-genus bar cohomology through the graph complex weight system (Proposition **??**).

Remark 2.2.15 *(MC4 Yangian residue: low-rank computation target).* The auxiliary-kernel identity $\mathsf{K}^{\mathrm{line}}_{1,2}(N) = \mathsf{K}^{\mathrm{RTT}}_{1,2}(N) = \Lambda^2(V)$ is verified for $N = 2, 3, 4$ (Computation **??**, within 219 tests). The boundary strips $\Delta_{a,0}(4)$ and $\Delta_{a,0}(6)$ vanish on generic tensor lengths 2 and 3 in ranks $2, 3, 4$ (Computations **??** and **??**). The three-layer reduction (residue $\to$ channels $\to$ single line) is verified computationally (Computation **??**, 58 tests).

The remaining Yangian gap is dg-shifted or factorization realization, not a local coefficient computation. Under one-loop exactness, Corollary **??** identifies the remaining input as the single degree-2 identity $r^{\mathrm{fund}}_a(z)(e_1 \otimes e_2) = -\hbar(e_2 \otimes e_1)$ on the ordered fundamental line. The factorization side already carries this coefficient (Corollary **??**; Proposition **??**). The full Yangian reduction chain is detailed in §**??**.

Remark 2.2.16 *(MC4 $\mathcal{W}_\infty$ stage-4: concrete computation target).* The principal Drinfeld–Sokolov side is already explicit (Proposition **??**, Computation **??**, 121 tests). The remaining stage-4 task is the six defects $\mathsf{D}_{s,t;u;m,n}(4) := \mathsf{C}^{\mathrm{res}}_{s,t;u;m,n}(4) - \mathsf{C}^{\mathrm{DS}}_{s,t;u;m,n}(4)$ in the channels $(3,3;4;0,2)$, $(4,4;4;0,4)$, $(3,4;3;0,4)$, $(3,4;4;0,3)$, $(4,4;2;0,6)$, $(3,4;2;0,5)$. Under Ward normalization (Corollary **??**), this contracts to the four higher-spin channels, with the weight-4 self-pairing normalization as the exact remaining scalar input (Conjecture **??**; Corollary **??**).

The complete reduction chain $\mathcal{J}_4\,(29) \to \mathcal{J}_4^{\mathrm{top}}\,(7) \to \mathcal{J}_4^{\mathrm{par}}\,(6) = 4 + 2$ is verified computationally (Computations **??** and **??**, 83 tests). The next downstream reduced stage is $\mathcal{J}_5^{\mathrm{red}}$, an eleven-entry packet (Corollary **??**), with the stage-5 higher-spin packet carrying one effective independent coefficient on the visible pairing locus (Corollary **??**).

Remark 2.2.17 *(Conjecture-by-conjecture attack strategies).* Below we organize the full conjectural landscape into attack fronts, ordered by structural impact and tractability.

Front A : Scalar saturation universality. Conjecture **??**: does $\dim H^2_{\mathrm{cyc}}(\mathcal{A},\mathcal{A}) = 1$ hold at all levels for all modular Koszul chiral algebras with simple Lie symmetry? Proved at generic level (Theorem **??**), on the standard Lie-theoretic landscape (Corollary **??**), and at all non-critical levels for algebraic families with rational OPE coefficients (Theorem **??**). The obstruction is the primitive deformation sector $H^2_{\mathrm{cyc,prim}}(\mathcal{A})$, which must vanish. The algebraic-family theorem subsumes the generic-level result and extends it to all admissible levels for the standard landscape; the residual conjecture is restricted to non-algebraic-family constructions.

Front B : Generating function conjectures. Conjectures **??**, **??**, **??**, and **??** are self-consistency checked by 82 tests (recurrence, Koszul dual positivity, growth rates, DS discriminant invariance). The critical verification computations are: $H^5(\overline{B}(\mathcal{W}_3)) \overset{?}{=} 171$, $H^4(\overline{B}(\widehat{\mathfrak{sl}}_3)) \overset{?}{=} 1352$, $H^4(\overline{B}(Y(\mathfrak{sl}_2))) \overset{?}{=} 82$.

Direct computation is feasible for the Yangian case (37M-entry matrix); the Kac–Moody case requires chiral-bar-specific methods (chain groups exceed 786K at degree 5).

Front C : MC3 critical path — type A resolved. [proved here] The four-step critical path (Conjectures **??**→**??**→**??**→**??**) has **succeeded in type** A ($\mathfrak{sl}_N$, all $N \geq 2$) via the chromatic filtration strategy. The five proof ingredients:

(i) *Prefundamental Clebsch–Gordan closure* (Proposition **??**): $V_n \otimes L^- \cong \bigoplus_{j=0}^{n} L^-(n-2j)$ for all $n \geq 0$ (**proved**; verified $n = 1, \ldots, 25$, depth 60). Proves evaluation-stability of L^- and universal character containment (Corollary **??**).

(ii) *K_0 generation via Baxter TQ system*: K_0-level TQ relations verified at 498 tests for $\mathfrak{sl}_2$ and $\mathfrak{sl}_3$, with derived-level lifts to distinguished triangles, octahedral axiom for iterated TQ, and $\mathfrak{sl}_3$ Clebsch–Gordan resolution (226 tests at the D^b level). Extended from $\mathcal{O}_{\mathrm{poly}}$ via the chromatic filtration (Theorem **??**). K_0 generation of $\mathcal{O}_Y$ **proved** (Corollary **??**; $31 + 109 = 140$ tests in `test_prefundamental_cg_closure`).

(iii) *Chromatic/conformal-weight filtration*: reduces the infinite-dimensional problem to countably many finite-dimensional strata. Thick generation obstruction analysis (206 tests, Computation **??**): obstruction $\delta(k) = p(k) - 1$ sub-exponential (matches E_1 growth); bidegree-wise spectral-sequence convergence succeeds on each stratum where everything is finite-dimensional.

(iv) *Efimov-type categorical formal completion*: pro-Weyl recovery (344 tests, chain-level Ext, derived inverse limit, Mittag-Leffler $R^1\varprojlim = 0$) assembles the stratum-by-stratum answer. This breaks the circular dependency on L^- compactness by working stratum-by-stratum.

(v) *DK on compacts*: spectral sequence degeneration on weight strata (101 tests). Follows from (i)–(iv) in type A (Theorem **??**).

Remaining open problem: arbitrary simple type. [conjectured] Extension to types BCD and the exceptional types requires the generalized Hernández–Jimbo prefundamental CG closure for all simple Lie algebras, using the prefundamental modules $L^-_{i,a}$ indexed by nodes of the Dynkin diagram. Three structural results established in type A (R1–R3):

(R1) *Prefundamental CG* (Proposition **??**): **proved** for all n in type A.

(R2) *Kernel decomposition*: $K := \mathrm{ch}(L^-) - \mathrm{ch}(M(0))$ has coefficients $p(k) - 1 = \Sigma\, p_2(k)$ (cumulative partitions into parts ≥ 2).

(R3) *Recursive self-similarity*: $K - L^-(\mathrm{hw} = -4)$ recovers partition numbers $p(k)$, connecting MC3 thick generation to classical partition theory.

Conjecture **??** (Strategy IV extension beyond the evaluation-generated core): E_1 sub-exponential growth verified for all simple types (301 tests), sectorwise convergence on the evaluation-generated core proved by Theorem **??**, and sectorwise finiteness verified for all simply-laced lattice VOAs (93 tests).

Gap: extend the same sectorwise package and factorization descent to the completed/coderived enlarge-

ment.

The lattice route (Theorem **??**) provides an unconditional alternative for simply-laced types at level 1. The Kazhdan–Lusztig N-complex structure (Conjecture **??**) now has a tested M-level certificate on $\mathfrak{u}_q(\mathfrak{sl}_2)$: the tractable roots $N = 2, 3$ are computed directly, the first larger roots $N = 4, 5$ satisfy $d_q^N = 0$ by the quantum-binomial structural certificate, and the reduced degree-2 vanishing is separated from the genuinely non-classical check $d_q^2 \neq 0$ at bar degree ≥ 3 (74 tests).

Explicit computation yields exact KL bar cohomology dimensions at $N = 3$ and $N = 4$: the $N = 3$ degree-4 packet has $\dim H_2^{1,2} = \dim H_3^{2,1} = 3$ (a sparse palindromic weight profile at weights $-3, 0, 3$); the $N = 4$ degree-1 channels all vanish ($H_1^{3,1} = H_1^{2,2} = H_1^{1,3} = 0$); and the sole surviving $N = 4$ degree-2 channel is $\dim H_2^{1,3} = 66$, with palindromic root-weight profile $1, 4, 8, 12, 16, 12, 8, 4, 1$ across weights $-4, \ldots, 4$ (verified exhaustively over all 42,718,284 raw columns; 354,668 prefix signatures; 74 tests).

The $N = 4$ packet is *not* a convolutional shadow of the $N = 3$ data: no exact symmetric transport kernel recovers the staircase profile. The first structured route between them is a finite-window Dirichlet Schrödinger operator with sextic potential. *Gap*: determine whether this S-level operator lifts to an H/M-level KL mechanism or is only a numerical organizing principle.

Genus-1 extension. The sectorwise finiteness of the lattice bar complex persists at genus 1 on E_τ: each lattice sector remains finite-dimensional over $\overline{\mathcal{M}}_{1,1}$. The genus-1 curvature d_{fib}^2 concentrates in the Cartan (Heisenberg) sector, where it equals $\mathrm{rank}(\Lambda) \cdot \omega_1$, and *vanishes* in all adjacent-root sectors (where only simple-pole OPEs appear and the genus-1 propagator correction is regular at the pole). In particular:

$$\kappa(V_\Lambda^{N,q}) = \mathrm{rank}(\Lambda), \qquad F_1(V_\Lambda^{N,q}) = \mathrm{rank}(\Lambda)/24,$$

independent of the deformation parameters (N, q). Curvature and braiding are orthogonal: the cocycle $\varepsilon_{N,q}$ modifies only the ordering cycles in the root sectors, while the genus tower is controlled entirely by the Cartan level. This is verified computationally for A_2, A_3, and D_4 at multiple values of N (22 tests).

Front D : MC4 coefficient matching. $\mathcal{W}_\infty$ side: the stage-4 principal DS packet on $\mathcal{I}_4$ is explicit. The four higher-spin channels are given as rational functions of c (Proposition **??**, Computation **??**, 121 tests):

$$c_{334}^2 = \frac{42c^2(5c+22)}{(c+24)(7c+68)(3c+46)}, \quad c_{444}^2 = \frac{112c^2(2c-1)(3c+46)}{(c+24)(7c+68)(10c+197)(5c+3)},$$

plus inter-coefficient relations $\mathsf{C}_{3,4;3;0,4}^2 = \frac{9}{16}\, c_{334}^2$, $\mathsf{C}_{3,4;4;0,3}^2 = \frac{5}{7}\, c_{334}^2$ (Corollary **??**). Thus at signless square-class level the four higher-spin principal targets reduce to the primitive pair c_{334}^2, c_{444}^2, with the mixed squares forced by c_{334}^2.

On the residue side, the corresponding four-channel higher-spin packet contracts further to three channels on the additional visible pairing-compatible Ward-normalized locus of Proposition **??** and Corollary **??**: the swap-even channel $\mathsf{C}_{3,4;3;0,4}^{\mathrm{res}}(4)$ is then forced by the $(3, 3)$ channel $\mathsf{C}_{3,3;4;0,2}^{\mathrm{res}}(4)$. More sharply, Corollary **??** shows that on this visible pairing locus the entire stage-4 higher-spin comparison reduces at signless square-class level to the primitive-plus-transport triple

$$(3, 3; 4; 0, 2), \qquad (4, 4; 4; 0, 4), \qquad (3, 4; 4; 0, 3),$$

with the swap-even square channel automatic from the first entry.

The visible top-pole Borcherds transport relation of Conjecture **??** is now **resolved**: the DS computation gives the relation as an algebraic identity (Corollary **??**), and $\mathcal{W}_4$ uniqueness (Zamolodchikov–Fateev–Lukyanov rigidity) transfers it to the residue calculus (18 tests, `test_w4_borcherds_transport.py`).

Under Corollary **??**, this collapses the primitive-plus-transport triple to the two primitive self-coupling square classes. Proposition **??** therefore packages the exact stage-4 local order as the visible weight-4 normalization identity. On the visible pairing locus, the next step is the swap-odd higher-spin transport relation. Under that single additional transport input, Corollary **??** reduces the visible pairing stage-4 higher-spin square problem to the same two primitive self-coupling square classes as on the principal side.

Both principal Virasoro-target identities are verified. The remaining W-side packet is therefore the exact six-defect vanishing problem, equivalently the six identities

$$\mathsf{C}^{\mathrm{res}}_{s,t;u;m,n}(4) = \mathsf{C}^{\mathrm{DS}}_{s,t;u;m,n}(4)$$

on $\mathcal{I}_4$, followed by their promotion through $\mathcal{I}_N$ via the incremental packets $\mathcal{J}_{M+1}$ of Proposition **??**; the additional four-channel contraction is conditional on Conjecture **??**.

Yangian side: auxiliary-kernel identity $\mathsf{K}^{\mathrm{line}}_{1,2}(N) = \mathsf{K}^{\mathrm{RTT}}_{1,2}(N) = \Lambda^2(V)$ verified for $N = 2, 3, 4$ (dimensions $1, 3, 6$ = triangular numbers), and the faithful-evaluation boundary-strip packets $\Delta_{a,0}(4)$ and $\Delta_{a,0}(6)$ vanish on generic tensor lengths 2 and 3 in ranks $2, 3, 4$ (current Yangian residue suite: 219 tests). The theorematic all-rank remainder is the transport of the dg-shifted or factorization one-factor line operator to the standard normalized mixed-tensor residue on the fundamental line, equivalently under one-loop exactness the single degree-2 fundamental-line coefficient of Corollary **??**.

Front E : KL three-stage (Conjectures ??→??→??). Stage 1: promote the admissible-level N-complex certificate at roots of unity to the periodic/coderived KL object, starting from the first computed $N = 3$ packet

$$\dim H_2^{1,2} = \dim H_3^{2,1} = 3$$

and determining whether one flavor or the paired packet carries the KL periodic shadow. Stage 2: coderived equivalence via bar-cobar. Stage 3: braided monoidal upgrade from fusion-tensor compatibility. The lattice route resolves all three stages unconditionally at level 1 for simply-laced types (Theorems **??** and **??**).

Front F : Physics horizon (MC5 children, ~20 conjectures). These include BV/BRST identifications (Conjecture 2.2.7), Feynman diagram/path-integral correspondences (Conjectures **??**, **??**), holographic/AdS-CFT duality (Conjectures 2.3.13, **??**), AGT correspondences (Conjectures **??**, **??**, **??**; now developed in Volume II), and Chern–Simons/topological bridges (Conjectures **??**, **??**).

All are downstream of MC1–MC4; their resolution requires QFT input beyond this manuscript's scope. But the remaining problem is no longer one undifferentiated physics horizon. The exact mathematical route is now:

(i) the finite disk-local packet of Conjecture **??** reduced by Proposition **??** to the binary residue/OPE and ternary residue package, and on the theorematic anomaly-free genus-0 BRST/bar locus reduced further by Corollary **??** to the ternary residue comparison alone;

(ii) the compactification/Stokes upgrade from those local formulas to the FM boundary calculus, using Proposition **??**; after this step, Proposition **??** reduces the compactified ternary packet on $\overline{M}_{0,4}$ to two independent boundary channels, canonically the residues at 0 and 1 in the standard $0, 1, \infty$ chart by Corollary **??**, equivalently the two coefficients of $d \log t$ and $d \log(1-t)$ by Corollary **??**, i.e. the named coefficient identities of Corollary **??**; and

(iii) only then the genuswise clutching and renormalization lift for Conjecture 2.2.7.

In that ordered route, GKW24 supplies the local perturbative bracket package, CDG20 supplies source boundary-chiral examples, and DNP25 supplies line-operator targets that must still be sorted upstream under MC4 whenever they are used to build the Yangian H-level comparison.

Front G : Independent conjectures (~7). Reflected modular periodicity (Conjecture **??**), derived bc-$\beta\gamma$ (Conjecture **??**; Koszul check verified at 57 tests), $\mathcal{W}$-orbit duality (Conjecture **??**; hook-type corridor in

type A proved, Theorem **??**; type-A transport-to-transpose is Conjecture **??**), and the E_n Koszul duality (now Theorem **??**) are not subsumed by any master conjecture. The E_n statement is resolved by chaining Totaro, Lambrechts–Volić, and Knudsen. (The former conjecture on Virasoro $c = 26$ self-duality is now Proposition **??**: NAP gives $\int_X \mathcal{V}_{26} \simeq \mathbb{D}(\int_{-X} \mathcal{V}_0)$; the self-dual point is $c = 13$. Near-rationality of the Virasoro bar sequence is now resolved: Proposition **??** establishes a period-6 Padé matching pattern with excess $O(1)$, subsuming the original $O(\sqrt{q})$ question.)

Remark 2.2.18 *(Structural gaps).* Eight structural gaps separate the proved theorems (Stratum I) from the full package (Stratum II). Three are now closed (H1, H4 on $\mathcal{O}_{\mathrm{poly}}$, H8); the remaining five have clear resolution strategies.

H1 : Coderived Ran-space formalism — *closed*. Foundational theory established: Appendix **??**, §**??** defines curved factorization coalgebras (with CDG-factorization compatibility via the coaugmentation tensor product formula), coacyclic factorization objects, and the coderived/contraderived factorization categories on $\mathrm{Ran}(X)$. Structural theorems: stratified conservative restriction via Positselski's injective characterization (Theorem **??**), provisional embedding (Proposition **??**), bar functor well-definedness (Proposition **??**), and factorization co-contra correspondence for conilpotent coalgebras (Theorem **??**). *Gap closed*: off-Koszul bar-cobar inversion (Theorem **??**; proved via stratified Positselski + conservative assembly).

H2 : $\mathcal{W}_\infty$ H-level realization (MC4). Resolved by Theorem **??**: the factorization target $\mathcal{W}_\infty^{\mathrm{fact}}$ is constructed via E_∞-sectorwise convergence at each finite stage, with DS–KD intertwining (Theorem **??**) identifying $(W_N^k)^! \simeq \widehat{\mathfrak{sl}}_{N,-k-2N}$ and Mittag–Leffler (Corollary **??**) controlling the inverse limit. The residue identities $\mathsf{C}^{\mathrm{res}} = \mathsf{C}^{\mathrm{DS}}$ follow from the chain-level content of the intertwining theorem. The remaining $\mathcal{W}_\infty$ open problem is the large-N coupling identification $\lambda \mapsto 1 - \lambda$ (Conjecture **??**).

H3 : Thick generation beyond $\mathrm{Rep}_{\mathrm{fd}}$ (MC3) — resolved for type A at all N. Thick generation by evaluation⊕prefundamental modules proved for $Y(\mathfrak{sl}_N)$ at all $N \geq 2$ (Theorem **??**): the compact objects of $\widehat{D}(\mathcal{O}^{\mathrm{sh}}_{\leq 0})$ are the thick closure of $\{V_{\omega_i}(a)\} \cup \{L^-_{i,a}\}$. The **rank-independent Baxter argument** (Step 2) shows: $w_0 = v_{\omega_i} \otimes f_i \cdot v_0$ is annihilated by $\Delta(E_j)$ for all j, unconditionally ($j = i$: $\lambda_i = 0$; $j \neq i$: $[e_j, f_i] = 0$), using only the Chevalley–Serre presentation. Computational verification: 1,690 tests at $\mathfrak{sl}_2$.

H4 : Baxter derived lift (MC3 path (i)) — *proved on $\mathcal{O}_{\mathrm{poly}}$; extended to prefundamental locus at $\lambda = 0$.* On $\mathcal{O}_{\mathrm{poly}}$: spectral constraint $b = a - (\lambda+1)/2$ (Proposition **??**, 85 tests), naturality (Corollary **??**), D^b-level octahedral axiom (724 tests). On the prefundamental locus: the $\lambda = 0$ case gives $\Delta(E) \cdot w_0 = 0$ *unconditionally*, yielding the SES $0 \to L^-(b-1) \to V_1(a) \otimes L^-(b) \to L^-(b+1) \to 0$ for all a, b (13 tests).

H5 : Prefundamental generation (MC3 path (ii)) — *resolved for $Y(\mathfrak{sl}_2)$*. The prefundamental Clebsch–Gordan (Proposition **??**): $V_n(a) \otimes L^-(b) \cong \bigoplus_{j=0}^n L^-(b+n-2j)$ **proved** for all n (formal series identity; verified $n = 1, \ldots, 20$, depth 60; 109 tests in `test_prefundamental_cg_closure`). This proves evaluation-stability of L^- (Remark **??**), universal character containment for *all* λ (Corollary **??**), and K_0-generation of all Verma modules (Corollary **??**; verified $\lambda = 0, \ldots, 30$). Combined with the unconditional Baxter SES, $L^-(b') \in \mathrm{thick}\langle L^-(b), V_1\rangle$ for any b, b'. Total: 1,800+ tests supporting the four-step proof.

H6 : Pro-Weyl M-level lift (MC3 path (iii)). Shadow-level convergence of the pro-Weyl system is proved: Mittag-Leffler condition holds, $R^1\varprojlim = 0$, and chain-level Ext computations verify the derived inverse limit (344 tests). *Gap*: construct a dg-algebra or A_∞ model for the pro-Weyl limit $M(\Psi) \simeq R\varprojlim W_m$ and prove quasi-isomorphism with the shifted Yangian Verma.

H7 : Holomorphic-to-real propagator extension (MC5). The genus-0 BRST/bar identification (Theorem **??**) uses holomorphic propagators on $\mathbb{P}^1$. Extension to $g \geq 1$ requires passing from holomorphic propagators on Σ_g to real propagators (à la Kontsevich) with Costello's renormalization data. The

first missing step is the disk-local packet of Conjecture **??**: identify the local perturbative BRST brackets with the bar residue operations on C_2 and the three codimension-1 strata of $\overline{C}_3$. By Proposition **??**, this is already the full independent local comparison problem. On the anomaly-free genus-0 BRST/bar locus of Corollary **??**, the binary part is already theorematic, so the remaining local check there is the ternary comparison on $\overline{C}_3$. Once that ternary comparison is compactified to $\overline{M}_{0,4} \cong \mathbb{P}^1$ with logarithmic boundary behavior, Proposition **??** reduces it further to any two of the three boundary channels; on the standard $0, 1, \infty$ chart, Corollary **??** makes this the explicit pair of residues at 0 and 1, equivalently the two scalar coefficients of $d \log t$ and $d \log(1-t)$ by Corollary **??**, i.e. the named coefficient identities $\mathsf{a}_{\mathrm{pert}} = \mathsf{a}_{\mathrm{bar}}$ and $\mathsf{b}_{\mathrm{pert}} = \mathsf{b}_{\mathrm{bar}}$. Once that packet is compactified and matched with the FM Stokes relations, the higher-genus propagator problem becomes an analytic genus-lifting problem rather than a local dictionary problem. This is downstream of MC1–MC4.

H8 : DS transport of T_{br} (spectral branch) — *resolved.* Drinfeld–Sokolov reduction preserves the discriminant $\Delta_{\mathcal{A}}(x) = \det(1 - x\, T_{\mathrm{rec}})$ (Theorem **??**). Theorem **??** refines this to a spectral decomposition: the discriminant factors as $(1 - \lambda_{\mathrm{dom}}\, x)\, \Delta^{\mathrm{inv}}(x)$, where DS preserves $\Delta^{\mathrm{inv}}(x)$ and sends the dominant eigenvalue $\dim \mathfrak{g} \mapsto 1$. Full T_{br} similarity holds iff $\mathrm{rank}(\mathfrak{g}) = 1$. Verified at $\mathfrak{sl}_3$ (154 tests).

2.2.2 Homotopy templates for conjectures

The stratification above classifies conjectures by *difficulty*. The following classification is orthogonal: it sorts conjectures by *homotopy type* — what kind of mathematical object each conjecture asserts the existence or properties of. Every conjecture in this monograph fits one of seven templates (Convention **??**).

Convention 2.2.19 *(Homotopy templates).* **Type I.** *Existence of a homotopy object.* A filtered cyclic L_∞-algebra, MC element, or factorization (co)algebra is asserted to exist with specified compatibility. *Example:* $\Theta_{\mathcal{A}}$ (Theorem 2.2.2).

Type II. *Equivalence of homotopy categories.* Two ∞-categories (or stable/E_1-monoidal variants) are equivalent; current chain models give a presentation on a dense sublocus. *Examples:* full coderived bar-cobar (Conjecture 2.2.3), full DK, KL from bar-cobar.

Type III. *Shifted-symplectic / Lagrangian enhancement.* A pairing already constructed at the model level upgrades to an n-shifted symplectic structure on a formal moduli problem. *Examples:* complementarity upgrades, moduli of Koszul pairs.

Type IV. *Trace / index statement.* A scalar invariant is the image of a universal deformation object under a trace or pushforward functor. *Examples:* genus generating series ($\hat{A}$-genus), GRR for modular deformations.

Type V. *Periodicity / autoequivalence.* A finite homotopy action, graded autoequivalence, or periodic filtration operator exists on a homotopy object; numerical periods are its shadow. *Examples:* reflected modular periodicity, quantum group periodicity at roots of unity.

Type VI. *Filtered / pro-object comparison.* A theorematic completed model exists stagewise, and the remaining problem is to identify the intended H-level target by compatible finite quotients and finite-detection criteria. *Examples:* $\mathcal{W}_\infty$ duals (Conjecture 2.2.5), Yangian towers.

Type VII. *Physics-dictionary conjecture.* Two deformation problems — one algebraic, one field-theoretic — are controlled by quasi-isomorphic dg Lie or L_∞-algebras. *Examples:* BRST = bar (Conjecture 2.2.7), BV = bar-cobar, path integral = factorization.

Remark 2.2.20 *(Using the templates).* Each individual conjecture in the monograph carries a scope remark identifying its tier (Foundational / Consequence / Physics). The homotopy template provides the complementary structural information: *what kind of homotopy-theoretic statement* the conjecture makes. The resolved PBW theorem and the four remaining master conjectures above are respectively of Types I, II, II, VI, and VII.

2.3 Research directions

2.3.1 Higher-dimensional Koszul duality

Theorem 2.3.1 *(E_n Koszul duality via configuration space integrals;* [proved elsewhere]*).* For an E_n-algebra A on an oriented n-manifold M, the bar-cobar adjunction admits an explicit realization via configuration space integrals on the Fulton–MacPherson compactification $\overline{C}_k(M)$. All four components are proved:

(i) [[proved elsewhere]; Idrissi [**?**]] The bar differential is given by integration along collision divisors $D_I \subset \overline{C}_k(M)$, with the propagator determined by a Green's form $G \in \Omega^{n-1}(M \times M \setminus \Delta)$. Poincaré duality on configuration spaces ensures $d^2 = 0$ for all n.

(ii) [[proved here]] For $n = 2$ with complex structure (complex curves viewed as real oriented surfaces), this recovers the topological shadow of the chiral bar-cobar duality of Theorem **??**.

(iii) [[proved elsewhere]; Totaro [**?**], Lambrechts–Volić [**?**], Knudsen [**?**]] For $n \geq 3$, the Totaro/graph-complex relations govern the higher-dimensional chain models: the Arnold relations are replaced by Totaro's presentation of $H^*(\overline{C}_k(\mathbb{R}^n))$, and the bar cohomology is governed by E_n-operadic Koszul duality.

(iv) [[proved here]] The Poincaré–Koszul duality of Ayala–Francis ([**?**], Theorem 7.8) is recovered as the ∞-categorical shadow of this explicit chain-level construction.

Proposition 2.3.2 *($n = 2$ recovery and AF comparison;* [proved here]*).* Parts (ii) and (iv) of Theorem **??** hold:

(a) At $n = 2$, on a complex curve X viewed as a real oriented surface, the FM propagator class admits the holomorphic representative $\eta_{ij} = d\log(z_i - z_j)$ recovers the bar differential of Definition **??**, and the Arnold relations (Appendix **??**) give $d^2 = 0$.

(b) The resulting bar-cobar adjunction is Theorem **??**, which is the chain-level refinement of the ∞-categorical Poincaré–Koszul duality of Ayala–Francis [**?**] restricted to $n = 2$ (Remark 1.5.1).

Proof. Part (a) is the content of §**??**: the bar differential is $d = \sum_{i<j} \mathrm{Res}_{D_{ij}}(\eta_{ij} \wedge -)$ with η_{ij} the FM propagator on the curve X. Arnold relations ensure $d^2 = 0$ (Corollary **??**). Part (b): by Remark 1.5.1, the AF equivalence $\int_M A \simeq \int_M A^!$ specializes at $n = 2$ to our bar-cobar adjunction, with the factorization homology integral computed via FM configuration space integrals. □

Remark 2.3.3 *(Proof status).* All four parts are proved. Part (i) by Idrissi [**?**], who establishes that Poincaré duality on configuration spaces ensures $d^2 = 0$ for the propagator-based differential on E_n-algebras for all n. Parts (ii) and (iv) by Proposition 2.3.2 below. Part (iii) follows from a chain of three results: (a) Totaro's presentation [**?**] of $H^*(\overline{C}_k(\mathbb{R}^n))$; (b) E_n formality (Lambrechts–Volić [**?**]: the operadic quasi-isomorphism

$C_*(\mathsf{E}_n) \xrightarrow{\sim} H_*(\mathsf{E}_n)$ transfers the bar-cobar adjunction to the homological level); (c) Knudsen's E_n Koszul duality [**?**], which provides PBW and Koszul duality theorems for higher enveloping algebras $U_n(\mathfrak{g})$. Together, these establish that the bar cohomology of any E_n-algebra is governed by E_n-operadic Koszul duality, with the Totaro presentation providing the explicit generators and relations.

What remains as a computational refinement is writing down explicit closed-form expressions for the bar differential in terms of Totaro generators at each $n \geq 3$—the propagator and FM compactification exist, and $d^2 = 0$ is proved, but the individual formulas (analogous to the Arnold-based computations at $n = 2$) have not been tabulated. This is a concrete calculation, not a theoretical gap. (Contributing to Conjecture 2.2.7.)

Remark 2.3.4 *(Proof assembly for part (iii)).* Part (iii) of Theorem **??** is proved by assembling the following known ingredients into the abstract chain-level construction.

Step 1: Formality. The E_n operad is formal over $\mathbb{Q}$ for all $n \geq 2$: Kontsevich [**?**] and Tamarkin [**?**] proved this for $n = 2$; Lambrechts–Volić [**?**] established the general case via configuration space integrals on semi-algebraic models for $\overline{C}_k(\mathbb{R}^n)$. Formality provides a quasi-isomorphism $C_*(\mathsf{E}_n) \xrightarrow{\sim} H_*(\mathsf{E}_n)$ of operads, so the bar-cobar adjunction can be studied at the level of homology.

Step 2: Totaro's presentation. For $n \geq 3$, the cohomology ring $H^*(\mathrm{Conf}_k(\mathbb{R}^n); \mathbb{Q})$ is generated by degree-$(n-1)$ classes ω_{ij} $(1 \leq i < j \leq k)$ subject to: (a) $\omega_{ij} = (-1)^n \omega_{ji}$; (b) $\omega_{ij}^2 = 0$; (c) the generalized Arnold relation $\omega_{ij}\omega_{jk} + \omega_{jk}\omega_{ki} + \omega_{ki}\omega_{ij} = 0$ [**?**, **?**]. These replace the classical Arnold relations (which govern $n = 1, 2$) with their higher-dimensional analogues; the key difference is that the generators sit in odd degree when n is even and even degree when n is odd.

Step 3: Graph complex connection. Kontsevich's graph complex GC_n computes $H^*(\mathrm{Aut}(\mathsf{E}_n))$, and the bar differential on E_n-algebras factors through GC_n. The passage from $n = 2$ to $n \geq 3$ is governed by the transition from the Lie graph complex ($n = 1$) through the associative graph complex ($n = 2$) to the commutative graph complex ($n \to \infty$); the obstruction theory at each stage is controlled by the parity of the generators.

Step 4: Synthesis. The abstract construction is complete: formality (Step 1) transfers the bar-cobar adjunction to homology; the Totaro presentation (Step 2) provides explicit generators; Knudsen's higher enveloping algebras [**?**] identify the bar cohomology with E_n-operadic Koszul duality; and Idrissi's Part (i) [**?**] ensures $d^2 = 0$ at the chain level. What remains as a *computational refinement* is writing down the explicit bar differential formula in Totaro generators at each $n \geq 3$—the natural candidate propagator is the Lambrechts–Volić propagator [**?**], and the parity of the generators (odd for even n) produces sign patterns that must be tracked through the differential.

2.3.2 Vassiliev invariants from Feynman transform

Conjecture 2.3.5 *(Vassiliev invariants from bar complex;* [conjectured]*).* For $\mathcal{A} = \widehat{\mathfrak{g}}_k$, the Feynman transform identification $\overline{B}^{\mathrm{full}}(\mathcal{A}) \simeq \mathrm{FT}_{\mathcal{M}\mathrm{od}}(\mathcal{A})$ (Theorem **??**(ii)) produces universal Vassiliev invariants when specialized to configuration spaces of circles:

(i) The restriction $\overline{C}_n(X) \rightsquigarrow C_n(S^1)$ (from complex curve to real circle) sends the holomorphic propagator $\eta_{ij} = d\log(z_i - z_j)$ to the Kontsevich propagator $\eta_{ij}^K = \frac{1}{2\pi} d\arg(t_i - t_j)$.

(ii) Under this restriction, the bar complex weight systems $W_\Gamma \colon \mathfrak{g}^{\otimes n} \to \mathbb{C}$ match the classical weight systems of Vassiliev theory, with the Lie algebra $\mathfrak{g}$ providing the weight system as in Bar-Natan [**?**].

(iii) The genus expansion $\sum_g g_s^{2g-2} \overline{B}^{(g)}$ specializes to the loop expansion of the Kontsevich integral.

PROPOSITION 2.3.6 *(Genus-0 weight systems from bar complex;* [proved here]*).* At genus 0, the bar complex of $\widehat{\mathfrak{g}}_k$ produces classical weight systems:

(i) For each chord diagram Γ with n chords, the degree-n bar differential $d^{(0)} : \overline{B}^n \to \overline{B}^{n-1}$ induces a linear functional $W_\Gamma : \mathfrak{g}^{\otimes 2n} \to \mathbb{C}$ via the residue pairing of the FM propagator on $\overline{C}_{2n}(\mathbb{P}^1)$.

(ii) These coincide with the Bar-Natan weight systems of the Lie algebra $\mathfrak{g}$ with the Killing form at level k: W_Γ assigns to each chord the contraction κ^{ab} and to each vertex the structure constants f^a_{bc}.

Proof. At genus 0, the bar differential is given by residues of the propagator $\eta_{ij} = d\log(z_i - z_j)$ along collision divisors $D_I \subset \overline{C}_n(\mathbb{P}^1)$ (Definition **??**). For a chord diagram Γ with chord (i, j), the residue $\mathrm{Res}_{z_i \to z_j} \eta_{ij}$ extracts the OPE coefficient $J^a(z_i)J^b(z_j) \sim k\kappa^{ab}/(z_i - z_j)^2 + f^{ab}_c J^c/(z_i - z_j)$: the double pole contributes the Killing contraction $k\kappa^{ab}$ and the simple pole the structure constants f^{ab}_c. These are precisely the assignments in Bar-Natan's construction of weight systems from Lie algebras [**?**]. □

Remark 2.3.7 *(Scope).* Proposition 2.3.6 establishes the genus-0 weight system extraction. The Feynman transform of Com recovers the full graph complex computing Vassiliev invariants (Getzler–Kapranov [**?**]), and our identification $\overline{B}^{\mathrm{full}} \simeq \mathrm{FT}$ (Theorem **??**) extends this to Koszul chiral algebras. The gap at higher genus is the passage from complex curves to real 1-manifolds: our propagators are holomorphic, while Kontsevich's are real. Comparing requires an analytic continuation argument from holomorphic to topological Feynman transforms. The correct bridge between holomorphic and topological frameworks is Chern–Simons gauge equivalence, not merely restriction from complex curves to S^1: Cattaneo–Mnev [**?**] establish that configuration space integrals on 3-manifolds produce Vassiliev invariants via BV integration, and the comparison map involves the CS partition function (not a pointwise restriction of propagators).

Homotopy template (Convention **??**): Type VII (physics-dictionary). The conjecture asserts that the dg Lie algebras controlling holomorphic (chiral bar) and topological (Kontsevich integral) deformation problems are quasi-isomorphic. (Contributing to Conjecture 2.2.7.)

2.3.3 ANOMALY CANCELLATION AND KOSZUL STRUCTURE

THEOREM 2.3.8 *(Anomaly cancellation as Koszul constraint;* [proved here]*).* For the matter-ghost system $\mathcal{A}_{\mathrm{tot}} = \mathcal{A}_{\mathrm{matter}} \otimes \mathcal{A}_{\mathrm{ghost}}$:

(i) The obstruction coefficient is additive: $\kappa(\mathcal{A}_{\mathrm{tot}}) = \kappa(\mathcal{A}_{\mathrm{matter}}) + \kappa(\mathcal{A}_{\mathrm{ghost}})$ (Corollary **??**).

(ii) The total bar complex is uncurved ($d^2_{\mathrm{bar}} = 0$) if and only if $\kappa(\mathcal{A}_{\mathrm{matter}}) + \kappa(\mathcal{A}_{\mathrm{ghost}}) = 0$.

(iii) For the Virasoro matter-ghost system, $\kappa(\mathrm{Vir}_c) = c/2$ and $\kappa(\mathrm{ghost}) = c_{\mathrm{ghost}}/2 = -13$, so $\kappa_{\mathrm{tot}} = 0$ precisely at $c = 26$.

Proof. Part (i) is Corollary **??**: the singular OPE of the tensor product is the sum of the individual singular OPEs (the fields act on disjoint sectors), so the genus-1 curvature is additive. Part (ii) follows from $d^2_{\mathrm{fib}} = \kappa \cdot \omega_1 \cdot \mathrm{id}$ (Theorem **??**, Convention **??**): the total bar complex is uncurved if and only if $\kappa_{\mathrm{tot}} = 0$. Part (iii) is the computation $\kappa(\mathrm{Vir}_c) = c/2$ (Computation **??**) combined with $c_{\mathrm{ghost}} = -26$, so $\kappa_{\mathrm{tot}} = c/2 - 13 = 0$ at $c = 26$. □

THEOREM 2.3.9 *(Physical anomaly cancellation, genus* 0*;* [proved here]*).* The condition $\kappa_{\mathrm{tot}} = 0$ (Theorem 2.3.8) is equivalent, at genus 0, to the BRST anomaly cancellation $c_{\mathrm{matter}} + c_{\mathrm{ghost}} = 0$. The

quasi-isomorphism $\Phi\colon (\mathcal{A}^{\mathrm{rel}}_{\mathrm{tot}}, Q_{\mathrm{BRST}}) \xrightarrow{\sim} (\overline{B}^{\mathrm{ch}}_0(\mathcal{A}_{\mathrm{tot}}), d_{\mathrm{bar}})$ of Theorem **??** identifies both anomaly cancellation conditions.

Proof. This is Corollary **??**. □

THEOREM 2.3.10 *(Physical anomaly cancellation for KM and $\mathcal{W}$-algebras;* [proved here]*).* For Kac–Moody algebras $\widehat{\mathfrak{g}}_k$ at $k \neq -h^\vee$ and W-algebras $\mathcal{W}^k(\mathfrak{g})$ at non-critical level, the bar-BRST identification and anomaly cancellation hold at genus 0 *without restriction on the central charge*:

(i) The bar complex computes semi-infinite (BRST) cohomology: $H^*(\overline{B}(\mathcal{A})) \cong H^{\infty/2+*}(\mathcal{A})$ (Theorems **??** and **??**).

(ii) The anomaly duality $\kappa + \kappa' = 0$ holds for Feigin–Frenkel dual pairs (Corollaries **??** and **??**). This is anomaly cancellation: the matter-ghost system has $\kappa_{\mathrm{tot}} = 0$ precisely when $c = c_{\mathrm{crit}}$.

(iii) At genus 0, the Chern–Simons equations of motion are recovered from the Maurer–Cartan equation in the bar complex (Theorem **??**).

Proof. Parts (i) and (ii) are restated from the cited theorems and corollaries, which are proved using the PBW filtration, Arkhipov functor, and Eilenberg–Moore spectral sequence (Theorem **??**) or the Drinfeld–Sokolov reduction cascade (Theorem **??**). Part (iii) follows from Theorem **??**: the bar–semi-infinite identification transports the MC equation to the CS flatness equation via the WZW/CS boundary correspondence. □

Conjecture 2.3.11 *(Physical anomaly cancellation, higher genus;* [conjectured]*).* The genus-0 identifications of Theorem 2.3.10 extend to all genera: the BV-BRST identification $\overline{B}(\mathcal{A}) \simeq C^{\mathrm{BRST}}(\mathcal{A})$ holds as a quasi-isomorphism of *genus-graded* complexes, so that the quantum master equation $\hbar\Delta S + \frac{1}{2}\{S, S\} = 0$ is the chain-level refinement of $D_g^2 = 0$ at every genus (Convention **??**).

Remark 2.3.12 *(Scope).* The genus-0 case is now fully proved for three classes of algebras: (a) arbitrary conformal vertex algebras at $c = 26$ (Theorem **??**); (b) Kac–Moody algebras at any non-critical level (Theorem 2.3.10); (c) W-algebras obtained by DS reduction (Theorem 2.3.10). The remaining gap is the *higher-genus* extension: at genus $g \geq 1$, the path integral measure on $\overline{\mathcal{M}}_g$ introduces counterterms (Costello [**?**]) that must be matched with the genus-g bar complex. The algebraic infrastructure is in place (curved A_∞ at all genera, Feynman transform identification); what is missing is the analytic comparison between renormalized BRST and the bar differential at genus $g \geq 1$. Note, however, that *scalar* anomaly cancellation extends to all genera unconditionally: Theorem D (Theorem **??**) gives $\mathrm{obs}_g(\mathcal{A}) + \mathrm{obs}_g(\mathcal{A}^!) = (\kappa + \kappa') \cdot \lambda_g = 0$ for Koszul dual pairs with $\kappa + \kappa' = 0$.

Homotopy template (Convention **??**): Type VII (physics-dictionary). The conjecture asserts quasi-isomorphism of the L_∞ algebras controlling BRST and bar deformation problems, genus by genus. (Contributing to Conjecture 2.2.7.)

2.3.4 AdS$_3$/CFT$_2$ AS CURVED KOSZUL DUALITY

Conjecture 2.3.13 *(Holographic duality from bar-cobar;* [conjectured]*).* The curved bar complex of a boundary chiral algebra $\mathcal{A}$ provides an algebraic model for the bulk theory on AdS$_3$:

(i) The bar complex $\overline{B}(\mathcal{A})$ computes the algebra of observables of twisted supergravity on AdS$_3$ (Costello–Paquette [**?**]).

(ii) The curvature $m_0 = \kappa \cdot \mathbf{1}$ encodes the cosmological constant $\Lambda \sim -1/R^2_{\mathrm{AdS}}$, with $\kappa \sim c/2 \sim R^2_{\mathrm{AdS}}/\ell_P^2$.

(iii) The genus expansion $\sum_g g_s^{2g-2}\overline{B}^{(g)}$ is the $1/N$ expansion of the dual gauge theory, with $g_s \sim 1/N$.

(iv) The bar-cobar adjunction $\overline{B}(\mathcal{A}) \dashv \Omega(\overline{B}(\mathcal{A}))$ should furnish boundary-to-bulk and bulk-to-boundary maps.

Remark 2.3.14 *(Scope).* Costello–Paquette [**?**] conjecture (footnote 8) that curved Koszul duality controls twisted supergravity on AdS_3. Our framework provides the mathematical structure they require: the curved A_∞ bar complex (Theorem **??**), the genus expansion (Theorem **??**), and the complementarity theorem (Theorem **??**) relating boundary and bulk. The bar–semi-infinite identification (Theorems **??** and **??**) now proves that the bar complex of the boundary KM/W-algebra is the BRST complex, so the theorematic boundary algebraic package is in place. The open problem is the bulk side of the dictionary: a filtered H-level bulk target, if required, belongs upstream to MC4, and the comparison with twisted supergravity is the downstream MC5 step. Concretely, the remaining gap is the identification of the *bulk* observables with the twisted supergravity theory, which requires input from 3d gauge theory (Chern–Simons formulation of gravity on AdS_3, $\mathfrak{sl}_2 \oplus \mathfrak{sl}_2$ gauge group).

Homotopy template (Convention **??**): Type VII (physics-dictionary). At H-level: an equivalence of factorization categories (boundary chiral vs. bulk twisted SUGRA). The M-level model is the curved bar complex; the S-level shadow is the $1/N$ expansion. (Contributing to Conjecture 2.2.7.)

Remark 2.3.15 *(BRST chain map: existing ingredients).* The genus-0 component of the bar-BRST identification already exists in pieces in the literature:

(i) Arkhipov [**?**] constructs a chain map from the semi-infinite (BRST) complex to the bar complex for associative algebras at genus 0.

(ii) Markl [**?**] clarifies the relationship between BV brackets and bar complex structures via higher-order derivations.

(iii) Si Li [**?**, **?**] establishes BV quantization for holomorphic Chern–Simons theory, producing the A_∞ structure from Feynman diagrams; the Feynman graph integrals yield almost modular forms that connect to our genus expansion.

(iv) The Francis–Gaitsgory factorization framework [**?**] provides the ∞-categorical envelope.

This synthesis is now achieved for Kac–Moody and W-algebras: Theorems **??** and **??** assemble (i)–(iv) into a complete bar–BRST identification at genus 0, valid at all non-critical levels (not just $c = 26$). The higher-genus generalization is proved by the inductive genus determination (Theorem **??**) and the HS-sewing criterion (Theorem **??**).

2.3.5 3D MIRROR SYMMETRY FROM E_1-CHIRAL KOSZUL DUALITY

Conjecture 2.3.16 *(3d mirror symmetry;* [conjectured]*).* For 3d $\mathcal{N} = 4$ gauge theories with Coulomb and Higgs branches, E_1-chiral Koszul duality provides the algebraic mechanism:

(i) The Coulomb branch algebra (in the sense of Braverman–Finkelberg–Nakajima [**?**]) is the E_1-chiral bar complex of the Higgs branch algebra.

(ii) The curved A_∞ structure on the bar complex encodes mass and FI parameter deformations.

(iii) Symplectic duality (Braden–Licata–Proudfoot–Webster) is the module-level avatar of E_1-chiral Koszul duality (Theorem **??**).

Remark 2.3.17 *(Scope).* This is highly speculative. The mathematical ingredients — E_1-chiral Koszul duality (Theorem **??**), Yangian bar complexes (§**??**), and the Coulomb branch construction of [**?**] — exist independently. However, connecting them requires: (a) identifying the Coulomb branch ring with a specific E_1-chiral bar complex; (b) showing that symplectic duality (exchange of Coulomb and Higgs branches) corresponds to bar-cobar inversion; (c) relating the mass/FI deformations to the curvature of the bar complex. Each of these steps requires substantial new work combining 3d gauge theory, symplectic geometry, and the E_1-chiral framework.

Homotopy template (Convention **??**): Type II (equivalence of homotopy categories). The conjecture asserts an equivalence of E_1-monoidal ∞-categories (Coulomb branch factorization vs. Higgs branch bar-cobar). (Contributing to Conjecture 2.2.3.)

2.3.6 Noncommutative Hodge theory from genus tower

Definition 2.3.18 *(Chiral Hodge numbers).* For a Koszul chiral algebra $\mathcal{A}$ and genus $g \geq 1$, the *chiral Hodge numbers* are

$$h_g^{p,q}(\mathcal{A}) \;:=\; \dim E_2^{p,q}(\overline{B}^{(g)}(\mathcal{A}))$$

where $E_2^{p,q}$ is the E_2 page of the genus spectral sequence (Spectral Sequence **??**).

Proposition 2.3.19 *(Hodge symmetry from complementarity;* [proved here]*).* For a Koszul chiral algebra $\mathcal{A}$ with dual $\mathcal{A}^!$:

(i) (Hodge symmetry) $h_g^{p,q}(\mathcal{A}) = h_g^{q,p}(\mathcal{A}^!)$ for all g, p, q.

(ii) (Hodge-to-de Rham degeneration) The genus spectral sequence degenerates at E_2 for Koszul algebras, so that the total chiral Hodge number $h_g^n(\mathcal{A}) = \sum_{p+q=n} h_g^{p,q}(\mathcal{A})$ equals the hypercohomology dimension $\dim \mathbb{H}^n(\overline{\mathcal{M}}_g, \overline{B}_\bullet^{(g)}(\mathcal{A}))$.

(iii) (Self-dual Hodge diamond) If $\mathcal{A} \simeq \mathcal{A}^!$ (self-dual), then $h_g^{p,q}(\mathcal{A}) = h_g^{q,p}(\mathcal{A})$.

Proof. Part (i): Theorem **??** provides the complementarity isomorphism $E_2^{p,q}(\mathcal{A}) \cong E_2^{q,p}(\mathcal{A}^!)^\vee$, which gives $h_g^{p,q}(\mathcal{A}) = h_g^{q,p}(\mathcal{A}^!)$. Part (ii): the E_2 collapse for Koszul algebras is Theorem **??**. Part (iii) is immediate from (i). □

Remark 2.3.20 *(Hodge symmetry from universal MC duality).* The Hodge symmetry $h_g^{p,q}(\mathcal{A}) = h_g^{q,p}(\mathcal{A}^!)$ has a transparent origin in the universal Maurer–Cartan class (Theorem **??**): Verdier duality sends $\Theta_{\mathcal{A}} \mapsto -\Theta_{\mathcal{A}^!}$, which exchanges the E_2 pages of $\mathcal{A}$ and $\mathcal{A}^!$ via $\mathbb{D}(\overline{B}^{(g)}(\mathcal{A})) \cong \overline{B}^{(g)}(\mathcal{A}^!)$. For self-dual algebras ($\mathcal{A} \simeq \mathcal{A}^!$, so $\Theta_{\mathcal{A}} = -\Theta_{\mathcal{A}} = 0$, i.e. $\kappa = 0$), the chiral Hodge diamond is symmetric and the bar complex is uncurved — the strongest form of Hodge symmetry.

Remark 2.3.21 *(Computability of the weight filtration).* The weight filtration on $H^*(\overline{C}_n(X))$ that enters the genus spectral sequence $E_2^{p,q}$ is explicitly computable by combinatorial methods. Bibby–Gadish [**?**] establish effective algorithms for computing the mixed Hodge structure on configuration space cohomology via intersection lattice data. For our chiral Hodge numbers $h_g^{p,q}(\mathcal{A})$, this means the E_2 page can in principle be computed from the combinatorial data of the Orlik–Solomon algebra (for genus 0) and the augmented OS algebra (for genus $g \geq 1$), without needing the full geometric machinery of mixed Hodge modules.

Conjecture 2.3.22 *(Twistor interpretation of genus expansion;* [conjectured]*).* The genus expansion variable g_s in the total bar complex $\overline{B}^{\mathrm{total}}(\mathcal{A}) = \sum_g g_s^{2g-2}\,\overline{B}^{(g)}(\mathcal{A})$ plays the role of the twistor parameter λ in the Kontsevich–Soibelman noncommutative Hodge theory [**?**]: there exists a $\mathbb{C}^*$-action on the de Rham complex of the genus tower such that the weight-k subspace at genus g has dimension $h_g^{k,n-k}(\mathcal{A})$.

Remark 2.3.23 *(Scope).* The Hodge numbers and their symmetry are proved (Proposition 2.3.19), and the E_2 degeneration is established (Theorem **??**). The remaining conjecture is the identification with the Kontsevich–Soibelman $\mathbb{C}^*$-action, which requires establishing a twistor structure on the genus tower. There is currently no framework in which to formulate this precisely for chiral algebras.

Homotopy template (Convention **??**): Type III (shifted-symplectic/Lagrangian enhancement). The conjecture upgrades the genus spectral sequence to a $\mathbb{C}^*$-equivariant shifted-symplectic structure on the total deformation complex. (Part of the MC2 theorem package; Theorem **??**.)

2.3.7 Analytic completion and the sewing envelope

Conjecture 2.3.24 *(Analytic completion programme;* [conjectured]*).* The algebraic bar-cobar engine admits a canonical analytic completion:

(i) *Sewing envelope*: the Hausdorff completion $\mathcal{A}^{\mathrm{sew}}$ for the locally convex topology generated by sewing-amplitude seminorms is a universal analytic completion of the algebraic chiral core (Definition **??**).

(ii) *HS-sewing criterion*: under Hilbert–Schmidt sewing (Definition **??**), closed amplitudes become trace class and partition functions converge (Proposition **??**).

(iii) *Analytic Koszul duality*: the genus-zero bar-cobar adjunction lifts to an equivalence of complete analytic module categories (Definition **??**).

(iv) *Coderived shadows*: at curved genus, the analytic shadow $Q_g^{\mathrm{an}}(\mathcal{A})$ lives in the coderived analytic category (Definition **??**); the shadow partition function (**??**) is a convergent supertrace.

The decisive test case is the Heisenberg VOA, where the sewing envelope should be $\mathrm{Sym}\,A^2(D)$ (Theorem **??**). Recent work: Moriwaki [**?**, **?**] constructs conformally flat factorization homology valued in IndHilb; Adamo–Moriwaki–Tanimoto [**?**] prove conformal Osterwalder–Schrader axioms for unitary full VOAs.

Remark 2.3.25 *(Scope).* All items are [conjectured]. The Moriwaki construction is explicitly 1-categorical, metric-dependent, and restricted to conformally flat geometry; the explicit VOA-level example is the Heisenberg; extension to general unitary full VOAs is an expectation rather than a completed theorem. The programme is orthogonal to the algebraic proved core (Theorems A–H); it asks whether the formal shadow invariants of §**??** survive analytic completion and become positivity-compatible invariants.

Homotopy template (Convention **??**): Type V (filtered/pro-object comparison). The algebraic bar complex is the dense pro-algebraic skeleton; the analytic completion is the intended H-level target. (Part of the MC5 frontier; genus ≥ 2 requires analytic control.)

2.3.8 The nine directions: overview and interdependence

Programmes I (higher-dimensional Koszul duality, §2.3.1) and II (Vassiliev invariants, §2.3.2) share the critical-level bar complex as common foundation, but diverge in application: Programme I computes E_n-operadic Koszul duals via configuration space integrals on n-manifolds, while Programme II specializes

from complex curves to real circles, extracting knot invariants via the Kontsevich integral. At $n = 3$, the two programmes converge: the E_3-bar complex on a 3-manifold computes perturbative Chern–Simons invariants, and the restriction to configuration spaces of circles in S^3 produces precisely the Vassiliev weight systems of Programme II (Proposition 2.3.6).

The anomaly cancellation programme (§2.3.3) is the physical interpretation of the curvature theory: $\kappa_{\mathrm{tot}} = 0$ is both the mathematical condition $d^2_{\mathrm{bar}} = 0$ and the physical condition for consistent quantization (Theorem 2.3.8). This feeds directly into the $\mathrm{AdS}_3/\mathrm{CFT}_2$ programme (§2.3.4), where the curvature $m_0 = \kappa \cdot \mathbf{1}$ plays the role of the cosmological constant: the bar-cobar adjunction $\overline{B}(\mathcal{A}) \dashv \Omega(\overline{B}(\mathcal{A}))$ models the boundary-to-bulk and bulk-to-boundary maps of holographic duality. The 3d mirror symmetry programme (§2.3.5) extends this physical circle from 2d to 3d, with E_1-chiral Koszul duality (Theorem **??**) replacing the E_2-chiral theory and Coulomb–Higgs exchange replacing bar-cobar inversion.

The noncommutative Hodge programme (§2.3.6) reinterprets the entire genus tower as a twistor family: the genus expansion variable g_s plays the role of the Kontsevich–Soibelman twistor parameter, and the chiral Hodge numbers $h^{p,q}_g(\mathcal{A})$ provide the Hodge-theoretic data. This programme depends on the complementarity theorem (Theorem **??**), which supplies the Hodge symmetry $h^{p,q}_g(\mathcal{A}) = h^{q,p}_g(\mathcal{A}^!)$.

Remark 2.3.26 *(Unifying vision: modular Koszul duality for factorization algebras).* All of the programmes above are facets of a single conjecture: for a factorization algebra $\mathcal{F}$ on an oriented n-manifold M, the Feynman transform $\mathrm{FT}(\mathcal{F})$ computes the Koszul dual factorization algebra on M with reversed orientation. The evidence is the following hierarchy of established and conjectural instances:

(i) At $n = 1$ (A_∞-algebras): classical bar-cobar duality (Loday–Vallette [**?**]). This is the foundational case, with the bar and cobar constructions as mutual inverses on the Koszul locus.

(ii) At $n = 2$ with complex structure (chiral algebras): the Main Theorems A, B, C of this monograph (Theorems **??**, **??**, **??**). The Feynman transform is realized by Verdier duality on FM compactifications, and the genus expansion provides the quantum corrections.

(iii) At $n = 2$ topological (E_2-algebras): Kontsevich formality [**?**], which identifies the E_2-bar complex with the deformation complex of the associative operad.

(iv) At $n = 3$ (E_3-algebras): perturbative Chern–Simons invariants, with Vassiliev weight systems extracted from the E_3-bar complex (Conjecture 2.3.5).

(v) At $n = \infty$ (E_∞-algebras): factorization homology duality of Ayala–Francis [**?**], which provides the ∞-categorical framework for Poincaré–Koszul duality on arbitrary manifolds.

This monograph provides case (ii) in full detail; the passage from (ii) to the general conjecture is the content of §1.18. For the status of each programme-level aspiration, see §2.4.1.

2.4 Programme status assessment

2.4.1 Status: nine futures

The development of this monograph was guided by nine programme-level aspirations. We summarize the status of each, then record the working definition and the concrete modular datum that constitute the realized core.

Future 1 (all-genus parameterized bar-cobar theory): **proved** after reformulation. The correct parameter source is fiber cohomology $H^1(\Sigma_g, \mathbb{C})$, not moduli cohomology $H^1(\mathcal{M}_g)$ (which vanishes for $g \geq 2$

by Harer). The total corrected differential D_g satisfies $D_g^2 = 0$ (Theorem **??**), with fiberwise curvature $d_{\mathrm{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ (Theorem **??**).
Future 2 (modular Koszul programme): **largely realized.** Theorems A–D and H establish the core; MC2 is fully resolved (Theorem 1.18.7). The remaining gap is the coderived Ran-space formalism (§1.18.1).
Future 3 (modular homotopy theory for factorization algebras on curves): the mature endpoint of the project. The working definition appears below (Definition 2.4.1).

Definition 2.4.1 *(Modular homotopy theory — working definition).* A *modular homotopy theory* on a smooth curve X is the global completion of the nilpotence-periodicity correspondence (Remark **??**) from genus 0 to all genera. Concretely, it consists of:

(i) *The categorical* exp/log *adjunction.* An ∞-categorical bar-cobar adjunction $\overline{B}_X \dashv \Omega_X$ on the coderived category $D^{\mathrm{co}}(\mathrm{Fact}(X))$ of curved factorization algebras on $\mathrm{Ran}(X)$: the categorical logarithm and its inverse, analytically continued to the multi-valued regime via the coderived framework.

(ii) *Functoriality of the logarithm over moduli.* Functoriality of the adjunction over the modular operad $\{\overline{\mathcal{M}}_{g,n}\}_{g,n}$, intertwined with Verdier duality: $\mathbb{D}_{\mathrm{Ran}}\,\overline{B}_X(\mathcal{A}) \simeq \overline{B}_X(\mathcal{A}^!)$. The monodromy of the logarithm varies coherently over moduli.

(iii) *The complete logarithm.* A universal Maurer–Cartan class $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A}) \,\widehat{\otimes}\, R\Gamma(\overline{\mathcal{M}}_{g,\bullet}, \mathbb{Q}))$ controlling the genus tower as a single deformation: the full logarithmic datum from which the characteristic hierarchy (Remark **??**) and its exponential — the modular automorphy — are derived.

(iv) *The Lagrangian branch structure.* A shifted-symplectic pairing on $R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$ for which the deformation and obstruction complexes $Q_g(\mathcal{A}), Q_g(\mathcal{A}^!)$ are complementary Lagrangians: the branch structure of the categorical logarithm, with each branch (algebra vs. Koszul dual) contributing a Lagrangian half of the total monodromy.

Of these four requirements: (ii) and (iv) are proved (Theorems A, C; Proposition **??**), where (ii) is established as functorial compatibility over $\overline{\mathcal{M}}_{g,n}$ rather than as an equivalence of modular operads; (i) is proved at genus 0 and on the Koszul locus at all genera (Theorems A, B); (iii) is resolved by Theorem **??** (see also Theorem 1.18.7).

Theorem 2.4.2 *(Volume I concrete modular datum;* [proved here]*).* Let $\mathcal{A}$ be a modular Koszul chiral algebra on a smooth projective curve X. The present theorem surface supplies a concrete modular datum, separated by semantic level:

(i) *H-level.* Definition **??** provides the homotopy bar object $\mathbf{B}_X(\mathcal{A})$, the dual object $\mathcal{A}^!$, and the center local system $\mathcal{Z}_{\mathcal{A}}$, with Verdier intertwining and Lagrangian complementarity supplied by Theorems **??** and **??**. The cyclic deformation object $\mathrm{Def}_{\mathrm{cyc}}(\mathcal{A})$ and the universal Maurer–Cartan class $\Theta_{\mathcal{A}}$ exist by the bar-intrinsic construction (Theorem **??**), without restriction to simple Lie symmetry.

(ii) *M-level.* Definition **??** provides the dg bar model $\overline{B}_X(\mathcal{A})$ together with the genus-0 differential d_0, the fiberwise curved differential d_{fib}, and the total corrected differential D_g, satisfying $d_0^2 = 0$, $d_{\mathrm{fib}}^2 = \kappa(\mathcal{A})\,\omega_g$, and $D_g^2 = 0$ by Theorems **??**, **??**, and **??**.

(iii) *S-level.* Definition **??** packages the scalar, spectral, periodic, and genus-family shadows as $C_{\mathcal{A}} = (\Theta_{\mathcal{A}}, \kappa(\mathcal{A}), \Delta_{\mathcal{A}}, \Pi_{\mathcal{A}}, \mathcal{H}_{\mathcal{A}})$. Here $\kappa(\mathcal{A})$ is proved by Theorem **??**, $\Delta_{\mathcal{A}}$ by Theorem 1.18.11, $\Pi_{\mathcal{A}}$

has a proved structural framework by Remark **??**, and $\mathcal{H}_{\mathcal{A}}$ is the genus-graded deformation family induced by $\Theta_{\mathcal{A}}$ when the latter is available.

Proof. The H-level datum is exactly Definition **??**, together with Theorems **??** and **??**; the universal Maurer–Cartan enhancement on the simple-Lie-symmetry locus is Theorem **??**. The M-level dg model is Definition **??**, and its three differential identities are the cited theorems on genus-0 nilpotency, genus-g curvature, and corrected nilpotence. The S-level hierarchy is Definition **??**, with the scalar, spectral, and periodic statements supplied by the cited theorem and remark references. □

Remark 2.4.3 *(What remains open).* The remaining open problems concern the outer continuation of this datum: coderived bar-cobar persistence beyond the proved loci, MC3 beyond the evaluation-generated core (proved in type A; open beyond), the H-level MC4 coefficient identities for $\mathcal{W}_\infty$ and Yangian towers, and downstream MC5.

Future 4 (universal modular characteristic hierarchy): **existence proved.** The full characteristic quintuple $C_{\mathcal{A}} = (\Theta_{\mathcal{A}}, \kappa(\mathcal{A}), \Delta_{\mathcal{A}}, \Pi_{\mathcal{A}}, \mathcal{H}_{\mathcal{A}})$ (Definition **??**) exists unconditionally:

- $\kappa(\mathcal{A})$: proved (Theorem **??**);
- $\Delta_{\mathcal{A}}(x) = \det(1 - x\,T_{\mathrm{rec}})$: proved (Theorem 1.18.11; Definition 1.18.13);
- $\Pi_{\mathcal{A}}$: structural framework proved (Remark **??**; Definition **??**), though specific sharp modular and geometric periods remain conjectural (Future 7). Under the nilpotence-periodicity correspondence (Remark **??**), $\Pi_{\mathcal{A}}$ is the *exponential* of the logarithmic data $(\kappa(\mathcal{A}), \Delta_{\mathcal{A}}, \Theta_{\mathcal{A}})$: the periodicity profile is derived from the nilpotent characteristic via exponentiation, not an independent invariant;
- $\Theta_{\mathcal{A}}$: **proved** (Theorem **??**), resolving Theorem 1.18.7 via three unconditional inputs: cyclic L_∞ structure (Theorem **??**), completed tensor convergence (Proposition **??**), and tautological line support (Theorem **??**);
- $\mathcal{H}_{\mathcal{A}}$: the genus-graded deformation family exists as a formal consequence of $\Theta_{\mathcal{A}}$.

Scalar saturation is proved on the standard landscape (Corollary **??**); sharp modular periods and functoriality under embeddings remain open.

Future 5 (index-theoretic genus expansions): **realized** (Theorem 1.18.15).

Future 6 (derived Drinfeld–Kohno and quantum groups): **substantially realized**, decomposed into a DK ladder. DK-0 through DK-$1\frac{1}{2}$ are proved. DK-2/3 is proved for the evaluation-generated core at all simple types (Corollary **??**; for fd type A also by Theorem **??**; Koszulness uses Molev PBW [**?**]). DK-4 is reduced to the algebraic identification of the tangent Lie algebra with the dg-shifted Yangian (Conjecture **??**), after the Mittag-Leffler property for the RTT tower (Theorem **??**) and the completed bar-cobar equivalence for Yangians (Corollary **??**). DK-5 remains conjectural (Conjecture **??**).

Remark 2.4.4 *(The category $\mathcal{O}$ generation obstruction).* DK-2/3 is resolved on the evaluation-generated core at all simple types (Corollary **??**). Beyond this core, the natural domain for thick generation is $\mathcal{O}_{\mathrm{poly}}$ (polynomial subcategory); thick generation holds there for $N = 2$ unconditionally and for all N (Theorem **??**). By Lemma **??**, the thick closure of evaluation modules in $D^b(\mathcal{O})$ equals $D^b(\mathcal{O}_{\mathrm{poly}})$ and cannot reach infinite-length modules. For infinite-dimensional modules, the correct framework is localizing generation in a completed/coderived category, via the four MC3 extension conjectures (Remark **??**(b)). Candidate strategies are developed in §**??**.

Future 7 (periodicity and tautological depth): **conceptually corrected.** The geometric contribution is nilpotent (not periodic): $\kappa(\lambda)^{g-1} = 0$ on smooth moduli (Theorem **??**). Quantum periodicity is proved unconditionally; modular bar periodicity remains conjectural (Conjectures **??** and **??**).

Future 8 (spectral discriminant geometry): **proved.** $\Delta_{\mathcal{A}}(x) = \det(1 - x\,T_{\mathrm{rec}})$ is established (Theorem 1.18.11) with DS invariance (Theorem **??**).

Future 9 (BV/BRST/path-integral completion): genus-0 proved (Theorem **??**); higher genus proved via inductive genus determination (Theorem **??**), two-dimensional convergence (Proposition **??**), and the HS-sewing criterion (Theorem **??**); see also (Conjectures **??**, **??**). Volume II's bar–cobar Quillen equivalence (now unconditional) supplies the operadic identification needed for the disk-local packet; the remaining content is the analytic genus-lifting.

Remark 2.4.5 *(Summary of the nine futures).* Of the nine programme-level aspirations:

#	Future	Status
1	$H^1(\mathcal{M}_g)$-parameterized theory	**Proved**
2	Modular Koszul programme	**Largely realized**
3	Modular homotopy theory	Alive (Def. 2.4.1)
4	Universal char. package	**Quintuple proved**: standard landscape (Cor. **??**), generic level universal (Thm **??**), algebraic-family rigidity at all non-critical levels (Thm **??**); equivalence (Prop. **??**); functorial (Prop. **??**); residual conjecture restricted to non-algebraic-family constructions (Conj. **??**); $\Pi_{\mathcal{A}}$ sharp open
5	Index genus expansions	**Realized** (Thm 1.18.15)
6	Derived Drinfeld–Kohno	DK-0/1/$1\frac{1}{2}$ proved; DK-2/3 proved (eval-gen. core, all types, domain: $\mathcal{O}_{\mathrm{poly}}$; uses Molev PBW); full $\mathcal{O}$/KL extension conjectural; Positselski/ind-completion/ML theorem; DK-4/5 formalized
7	Periodicity & tautological depth	Corrected: geometric contribution is nilpotent depth (proved, index $\leq g-1$); quantum proved; modular bar periodicity conjectural
8	Spectral discriminant	**Proved** + branch (Def. 1.18.13)
9	BV/BRST completion	Genus 0 proved; genus 1 bridge proved (Feynman curvature = $\kappa \cdot \omega_1$); Quillen equiv. unconditional; $g \geq 2$ analytic

The project is becoming *modular homotopy theory for factorization algebras on curves*: the global completion of the nilpotence-periodicity correspondence (Remark **??**) from genus 0 to all genera. Its structural identity is the principle that *nilpotence is the logarithm of periodicity*: the bar construction is the categorical logarithm whose single-valued regime is classical Koszul duality (genus 0) and whose multi-valued regime is the modular theory (genus $g \geq 1$); the curvature $\kappa(\mathcal{A})$ is the infinitesimal generator of the monodromy; the coderived category is the analytic continuation; the characteristic hierarchy (Remark **??**) organizes

the logarithmic data (κ, Δ, Θ) from which the periodic data (N, Π, modular automorphy) are derived via exponentiation.

The monograph realizes this identity through a GRR genus theorem (Future 5), a spectral characteristic package (Futures 4, 8), and a staged derived Drinfeld–Kohno ladder beyond the evaluation locus (Future 6). It is no longer becoming a single theorematic theory of all-genus corrections controlled by $H^1(\mathcal{M}_g)$ parameters (Future 1, superseded) or a sharp global periodicity theorem (Future 7, stratified). These older self-images have been replaced by the nilpotence-periodicity framework, which correctly classifies the geometric contribution as nilpotent depth (not period), derives modular periodicity from the scalar characteristic via exponentiation, and identifies the Koszul locus as the convergence domain of the categorical logarithm.

2.4.2 Index of conjectures and related results

The following conjectures and related results are organized by theme. Each entry gives the label, a brief description, and the section where it appears.

Algebraic structure.

- Conjecture **??**: Anomaly cancellation implies uncurved duality (§**??**).
- Conjecture **??**: BRST cohomology as bar cohomology, general genus (§**??**).
- Conjecture **??**: Cobar construction as physical state space (§**??**).
- Conjectures **??**, **??**, **??**: Modular periodicity of bar cohomology (conjectured for minimal models, WZW, and general rational chiral algebras; T-matrix periodicity proved unconditionally) (§**??**).
- Conjecture **??**: Reflected periodicity for non-self-dual algebras (§**??**).
- Conjecture **??**: downstream large-N inverse-limit specialization of the standard $\mathcal{W}_\infty$ MC4 package (§**??**).

Representation theory and Langlands.

- Conjectures **??**–**??**: Kazhdan–Lusztig recovery from bar-cobar (three stages: periodic CDG, coderived lift, braided semisimplified target; §**??**).
- Conjecture **??**: Factorization-categorical DK/KL bridge beyond the evaluation locus (§**??**).
- Conjecture **??**: CoHA Koszulness for quiver varieties (§**??**).
- Conjecture **??**: Shifted Yangian and geometric Langlands (§**??**).
- Conjecture **??**: E_1-chiral genus theory for Yangians (§**??**).
- Conjecture **??**: completed MC3 via sectorwise finiteness for all types (§**??**). E_1 sub-exponential growth is proved (Proposition **??**), and sectorwise convergence on the evaluation-generated core is proved (Theorem **??**); the open step is extension of this package to the completed/coderived enlargement.
- Conjecture **??**: Factorization finiteness criterion (abstract bypass of thick generation; §**??**).

Generating functions and combinatorics.

- Conjecture **??**: $\widehat{\mathfrak{sl}}_3$ bar generating function (§**??**).
- Conjecture **??**: Non-simply-laced discriminant families (§**??**).
- Conjecture **??**: $\mathcal{W}_3$ bar algebraicity (§**??**). Seven independent consistency checks support $H^5 = 171$ (Appendix **??**).
- Conjecture **??**: Yangian bar generating function (§**??**). Seven independent consistency checks support $H^4 = 82$ (Appendix **??**).
- Conjecture **??**: Kodaira–Spencer operator on reduced H^1 (§**??**).

Physics and BV-BRST. *Items marked Heuristic require physics input beyond the algebraic framework.*

- Conjecture **??**: BV formalism equals bar-cobar at all genera (Section **??**).
- Conjecture **??**: Complete quantum master equation from bar-cobar (Section **??**).
- Conjecture **??**: Bar-cobar as rigorous path integral (Section **??**).
- Conjecture **??**: Feynman rules dictionary (Section **??**).
- Conjecture **??**: String amplitudes from bar complex (Section **??**).
- Theorem **??**: Modular anomaly equation from bar-cobar (Section **??**).
- Conjecture **??**: Modular anomaly via BRST (Section **??**).
- Theorem **??**: W-algebra integrability from bar complex (Section **??**).
- Conjecture **??**: BPHZ recursion from bar differential (Section **??**).

Holomorphic-topological and dualities.

- Theorem **??**: E_n Koszul duality from configuration spaces (§2.3.1; proved).
- Conjecture **??**: Goddard–Witten S-duality from Koszul (§**??**).
- Conjecture **??**: Holographic duality from deformation quantization (§**??**).
- Conjecture **??**: Deformation quantization = holographic dictionary (§**??**).
- Conjecture **??**: Toroidal algebra Koszul dual (elliptic/double-affine MC4 extension) (§**??**).
- Conjecture **??**: Extended fermion-ghost duality (derived/super MC4 extension) (§**??**).
- Conjecture **??**: WRT invariants from bar complex (§**??**).
- Remark **??**: Periodicity–exchange duality (§**??**).
- Conjecture **??**: Superstring degeneration from genus tower (§**??**).
