

Modular Homotopy Theory for Algebraic Factorization Algebras on Algebraic Curves

Volume 1: Modular Koszul Duality and Holographic Corrections

Raez Lorgat

August 2025

Abstract

We define ordered chiral homology $\int_X^{\text{ord}} \mathcal{A}$ for a chiral algebra $\mathcal{A}$ on a smooth algebraic curve X as the derived pushforward of the ordered factorisation $\mathcal{D}$ -module $\mathcal{F}^{\text{ord}}(\mathcal{A})$ on the ordered Ran space $\text{Ran}^{\text{ord}}(X) = \coprod_n U_n(X)$. The ordered bar complex $B^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$ carries a deconcatenation coproduct, an R -matrix, and Yangian structure; the symmetric bar $B^{\Sigma}(\mathcal{A})$ on $\text{Ran}(X)$ is its Σ_n -coinvariant shadow. For E_{∞} -chiral algebras, a formality bridge gives a quasi-isomorphism between ordered and symmetric chiral homologies; for genuinely E_1 -chiral algebras the kernel of averaging is non-trivial, carrying GRT_1 -dependent data from the Drinfeld associator.

A Maurer–Cartan element $\Theta_{\mathcal{A}} \in \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ satisfying $D\Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$ in the modular convolution L_{∞} -algebra governs five theorems: (A) bar-cobar adjunction with Verdier intertwining; (B) bar-cobar inversion on the Koszul locus; (C) complementary Lagrangian decomposition of the center local system, with $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^{\dagger}) = K(\mathcal{A})$; (D) the genus expansion $F_g = \kappa(\mathcal{A}) \cdot \lambda_g^{\text{FP}}$ (uniform-weight; corrections $\delta F_g^{\text{cross}}$ at $g \geq 2$); (H) chiral Hochschild cohomology in degrees $\{0, 1, 2\}$ with polynomial Hilbert series. The shadow obstruction tower classifies chiral algebras into depth classes $G/L/C/M$ (Heisenberg, affine Kac–Moody, $\beta\gamma$, Virasoro/ W_N). The chiral quantum group equivalence identifies three structures on $B^{\text{ord}}(\mathcal{A})$: vertex R -matrix, chiral A_{∞} -structure, and chiral coproduct.

Five examples span the classification: Heisenberg (class G), $V_k(\mathfrak{sl}_2)$ (class L), $\beta\gamma$ (class C , nilpotent R -matrix), Virasoro (class M , irregular KZ with Stokes data), and $Y_{\hbar}(\mathfrak{sl}_2)$ (where ordered chiral homology is strictly richer than symmetric). At genus 1, the bar-complex propagator specialises to the Weierstrass ζ -function and the shadow connection restricts to the KZB connection.

For E_{∞} -chiral $\mathcal{A}$, the symmetric bar carries an E_2 -coalgebra structure; by the Higher Deligne Conjecture, the derived chiral center $Z_{\text{ch}}^{\text{der}}(\mathcal{A}) = \text{HH}^*(\mathcal{A}, \mathcal{A})$ carries E_3 structure. For E_1 -chiral $\mathcal{A}$, the derived center is E_2 . The E_3 -deformation space of $Z_{\text{ch}}^{\text{der}}(V_k(\mathfrak{g}))$ is $\hbar H^3(\mathfrak{g})[[\hbar]]$; formal disk restriction recovers the Costello–Francis–Gwilliam perturbative Chern–Simons E_3 -algebra, an identification that is conjectural beyond the formal disk.

2020 Mathematics Subject Classification. Primary 17B69, 16S37; Secondary 14H10, 55R80, 81T40, 18G35.

Keywords. Chiral algebras, Koszul duality, bar-cobar adjunction, Maurer–Cartan element, modular convolution L_{∞} -algebra, shadow obstruction tower, modular characteristic, logarithmic Fulton–MacPherson

compactification, factorization algebras, chiral Hochschild cohomology, vertex algebras, $\mathcal{W}$ -algebras, Yangians, completed bar-cobar, chiral Koszulness, modular twisting morphism, graphwise cocomposition, configuration spaces.

13.22.13.4	The obstruction recursion and shadow depth classification	1149
13.22.13.5	Rectification and formality	1150
13.22.13.6	The modular Koszul datum and the modular envelope	1151
13.22.14	The graph sum that realizes the tower	1152
13.22.15	The carrier algebra	1154
13.22.15.1	Planar planted forests and the ordered carrier algebra	1156
13.22.16	Inductive genus determination	1161
13.22.17	The analytic genus- g bar differential	1165
13.22.18	Recovery of the Verlinde formula	1167
13.22.19	The Verlinde polynomial family	1171
13.23	Ordered chiral homology at genus 2: $\int_{\Sigma_2}^{\text{ord}} Y_h(\mathfrak{sl}_2)$	1173
13.23.1	Setup: the genus-2 ordered chiral chain complex	1173
13.23.2	The genus-2 KZB connection	1174
13.23.3	Degree 0: the center	1175
13.23.4	Degree 1: de Rham cohomology of Σ_2 with Yangian coefficients	1175
13.23.5	Degree 2: the genus-2 KZB local system	1176
13.23.6	Degree n : genus-2 surface braid group monodromy	1180
13.23.7	Summary: genus 0 vs. genus 1 vs. genus 2	1181
13.23.8	Degenerations and genuinely genus-2 content	1181
13.24	Comparison with related work	1184
13.25	Spectral covers and the defect calculus	1185
13.25.1	Spectral presentations and branch packages	1185
13.25.2	Quadratic sheet calculus	1186
13.25.3	Cubic resolvent towers	1186
13.26	A conjectural period map for the shadow tower	1188
14	Chiral Hochschild cohomology and Koszul duality	1193
14.1	Deformations of a chiral algebra	1194
14.2	Construction of the chiral Hochschild complex	1194
14.2.1	The cochain spaces	1194
14.2.2	The differential: three components	1195
14.2.3	Explicit formula for the differential	1196
14.3	Computing cohomology via bar-cobar resolution	1196
14.3.1	The resolution strategy	1196
14.3.2	The spectral sequence	1197
14.4	Koszul duality for chiral algebras	1197
14.4.1	Quadratic chiral algebras and their duals	1197
14.4.2	The universal twisting morphism	1199
14.4.3	Main duality theorem	1199
14.4.4	Formality, moduli, and operadic perspectives on Koszulness	1204

14.5	Example: boson-fermion duality	1208
14.5.1	The free boson chiral algebra	1208
14.5.2	The free fermion chiral algebra	1208
14.5.3	Establishing Koszul duality	1209
14.5.4	Computing chiral Hochschild cohomology	1210
14.5.5	The cyclic deformation complex	1211
14.5.6	The chiral graph complex and cyclic L_∞ structure	1218
14.5.7	The modular deformation complex	1222
14.5.8	Concrete modular constructions: from stable graphs to quantum homotopy theory	1224
14.5.8.1	The three-component modular bar differential	1224
14.5.8.2	Quantum L_∞ operations from loop-level graphs	1225
14.5.8.3	The total differential from $\Theta_{\mathcal{A}}$	1227
14.5.8.4	Virtual bar family and characteristic hierarchy	1229
14.5.8.5	Chiral homology from the modular bar complex	1230
14.5.9	Non-scalar universal classes	1232
14.6	Stratified periodicity framework	1233
14.6.1	Overview: three sources of periodicity	1233
14.6.2	Type I: modular periodicity from rational central charge	1233
14.6.2.1	The mechanism	1233
14.6.2.2	Koszul dual behavior	1236
14.6.3	Type II: quantum group periodicity	1237
14.6.3.1	The quantum group structure	1237
14.6.4	Type III: geometric tautological depth	1238
14.6.4.1	Genus dependence and nilpotent depth	1238
14.6.4.2	Examples at different genera	1240
14.6.5	Stratified periodicity	1240
14.6.6	Koszul duality and periodicity interaction	1242
14.7	Physical applications	1243
14.7.1	Marginal deformations in CFT	1243
14.7.2	String field theory	1243
14.7.3	Holographic duality	1244
14.8	Computing chiral Hochschild cohomology via bar-cobar resolution	1244
14.8.1	The bar-cobar resolution strategy	1244
14.8.2	The fundamental quasi-isomorphism	1244
14.8.3	chiral Hochschild cohomology formula	1245
14.8.4	Explicit computation: free boson (Heisenberg algebra)	1246
14.8.4.1	Degree 0: $CH^0(\mathcal{B})$	1246
14.8.4.2	Degree 1: $CH^1(\mathcal{B})$	1247
14.8.4.3	Degree 2: $CH^2(\mathcal{B})$	1247
14.8.4.4	Higher degrees: $CH^n(\mathcal{B})$ for $n \geq 3$	1248
14.8.4.5	Summary for Heisenberg	1248
14.8.5	Explicit computation: free fermion	1248
14.8.5.1	Degree 0: $CH^0(\mathcal{F})$	1248
14.8.5.2	Degree 1: $CH^1(\mathcal{F})$	1248

14.8.5.3	Degree 2: $CH^2(\mathcal{F})$	1249
14.8.5.4	Summary for free fermion	1249
14.8.6	Koszul duality and HH^* pairing	1249
14.8.7	Comparison with classical Hochschild cohomology	1249
14.8.8	The chiral Gerstenhaber bracket from configuration spaces	1250
14.8.9	Higher structure: L_∞ operations	1252
14.8.10	Computational strategy	1252
14.8.11	Summary and outlook	1252
14.9	Cosimplicial descent and the chiral Hochschild–Čech comparison	1252
14.9.1	The bicomplex	1253
14.9.2	HCA enhancement of the bicomplex	1254
14.10	Ambient complementarity: the shifted-symplectic theorem	1254
14.11	The factorization envelope shadow functor	1257
14.12	The graph complex and deformation theory of the shadow obstruction tower	1259

II The Characteristic Datum 1383

18	Ambient complementarity and nonlinear modular shadows 1387
18.1	The universal Maurer–Cartan principle 1388
18.2	The governing question from first principles 1392
18.3	Ambient complementarity from first principles 1392
18.3.1	Cotangent normal form and the complementarity potential 1394
18.4	Finite-order nonlinear shadow calculus 1396

18.4.1	Quadratic, cubic, and quartic shadows	1397
18.4.2	The quartic shadow graph cocycle	1398
18.4.3	The quartic shadow envelope	1399
18.5	The three primitive nonlinear archetypes	1399
18.5.1	Heisenberg	1400
18.5.2	Affine $\widehat{\mathfrak{sl}}_2$	1401
18.5.3	The $\beta\gamma$ system	1402
18.6	Mixed cubic–quartic families: Virasoro and principal $\mathcal{W}_N$	1404
18.6.1	A universal cubic sector for strong generators	1404
18.6.2	Virasoro	1404
18.6.3	The prototype higher-spin family $\mathcal{W}_3$	1406
18.6.4	Principal $\mathcal{W}_N$	1407
18.7	From Gram determinants to a modular quartic resonance class	1408
18.7.1	The determinant line of the contact quartic sector	1409
18.7.2	The tree bundle and the first nonlinear boundary correction	1410
18.8	Extended characteristic packages and the frontier	1412
18.9	Higher-degree shadow propagation	1414
18.9.1	The all-degree master equation	1414
18.9.2	Quintic behavior of the model families	1415
18.9.3	The all-degree separating boundary recursion	1416
18.10	The genus loop operator and non-separating clutching	1416
18.10.1	Definition and basic properties	1416
18.10.2	Non-separating clutching of the shadow obstruction tower	1417
18.10.3	Explicit genus loop for the model families	1417
18.10.4	The modular shadow characteristic	1418
18.11	A unified summary theorem	1419
18.12	The graph-completed Feynman transform programme	1420
18.12.1	The modular chiral Feynman transform	1420
18.12.2	The complementarity Legendrian	1421
18.12.3	The full resonance tower	1422
18.12.4	The complementarity phase function	1423
18.12.5	The nonlinear spectral-branch stack	1423
18.13	The polarized scattering programme	1424
18.13.1	The polarized modular graph algebra	1424
18.13.2	The resonance scattering diagram	1425
18.13.3	The complementarity schober	1425
18.13.4	The modular wavefunction	1426
18.14	The theorem programme for the nonlinear tower	1426
18.15	Reduced-weight windows and finite-dimensional bar control	1429
18.15.1	Reduced weight and finite-dimensional slices	1430
18.15.2	Stabilization defect and the MC ₄ obstruction	1431
18.15.3	Multi-variable shadow obstruction tower	1432
18.15.4	The MC moduli curve	1439

19 Branch-line reductions and primitive modular characteristics

1441

19.1	The invariant ladder from first principles	1442
19.2	Spectral cumulants and the connected potential	1443
19.3	An abstract filtered obstruction theorem	1444
19.4	Virasoro positive-weight acyclicity and reduced spectral localization	1445
19.5	Rank-two branch-line reductions	1447
19.6	Genus-2 transparency	1449
19.7	The pure-branch primitive genus-3 coefficient	1450
19.8	The top-Hodge primitive quotient	1451

NOTATION AND CONVENTIONS

Throughout this manuscript:

- $\bar{\mathbf{B}}(\mathcal{A})$ denotes the geometric bar complex.
- $\bar{B}^{\text{ch}}(\mathcal{A})$ denotes the abstract chiral bar complex (when distinction needed).
- $\bar{C}_n(X) = \bar{C}_n(X)$ is the compactified configuration space.
- $\eta_{ij} = d \log(z_i - z_j)$ are the logarithmic 1-forms.
- E_∞ -chiral, E_1 -chiral, P_∞ -chiral refer to curve-based chiral factorization levels (Definition 3.11.1ff.); bare E_n refers to the little-disks/topological axis on real n -manifolds. A complex curve therefore enters the topological ladder at $n = 2$, not $n = 1$ (Remark 3.11.7).

Preface

This monograph studies holomorphic chiral factorisation (co)homology via bar and cobar chain constructions at various geometric locations on algebraic curves. The geometry determines the operad: a curve X gives E_∞ (symmetric factorisation on the Ran space), ordered configurations on X give E_1 (the associative chiral operad Ass^{ch}), and the product $\mathbb{C} \times \mathbb{R}$ gives the holomorphic-topological Swiss-cheese operad $\text{SC}^{\text{ch}, \text{top}}$. Each operad determines a bar complex; the bar complex computes the factorisation (co)homology. The five theorems of this volume are structural properties of the result at each level. The computational engine is the ordered bar complex $\bar{B}_X^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$: a cofree E_1 -coalgebra with deconcatenation coproduct, whose differential encodes the complete OPE data of $\mathcal{A}$ through the logarithmic kernel $\eta = d \log(z_1 - z_2)$ on Fulton–MacPherson configuration spaces.

The five theorems. Five theorems extract the Σ_n -invariant content of the ordered bar. Theorem A constructs the bar-cobar adjunction and its Verdier intertwining, producing the pair $(\mathcal{A}, \mathcal{A}_\infty^!)$ from $\bar{B}^{\text{ord}}(\mathcal{A})$. Theorem B proves bar-cobar inversion $\Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ on the Koszul locus: genus 0 unconditionally, and on the standard CFT-type surface at all genera except integer-spin $\beta\gamma$; the arbitrary higher-genus extension remains conditional on axiom (MK₃). Theorem C decomposes the derived chiral centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) = R\text{Hom}_{\mathcal{A} \otimes \mathcal{A}^{\text{op}}}(\mathcal{A}, \mathcal{A})$ into complementary halves controlled by $\mathcal{A}$ and $\mathcal{A}^!$; the Verdier-side Lagrangian splitting is proved, while the ambient shifted-symplectic upgrade remains conditional on perfectness and nondegeneracy. Theorem D identifies the universal genus-1 scalar shadow for every family and the all-genus scalar lane $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$ (UNIFORM-WEIGHT); outside that lane at $g \geq 2$ the free energy acquires $\delta F_g^{\text{cross}}$ (ALL-WEIGHT + $\delta F_g^{\text{cross}}$). Theorem H proves that on the Koszul locus the chiral Hochschild complex is concentrated in degrees $\{0, 1, 2\}$ with a family-dependent Hilbert polynomial of degree at most 2; at critical affine level $k = -h^\vee$ the theorem does not apply, and the Feigin–Frenkel centre makes the cohomology unbounded.

The five theorems are the Σ_n -invariant skeleton. The full E_1 structure (the r -matrix, the Yangian, the spectral braiding) is developed in this volume; Volume II adds the open/closed holomorphic-topological lift through $\text{SC}^{\text{ch}, \text{top}}$ and the topologized bulk. The Drinfeld double $U_{\mathcal{A}} := \mathcal{A} \bowtie \mathcal{A}_\infty^!$, assembled from the ordered bar’s two factors, is conjectured to be the universal boundary-bulk reconstructor.

I. THE ORDERED BAR CONSTRUCTION ON ALGEBRAIC CURVES

The product of two sections $a(z) b(w)$ of a chiral algebra on a smooth algebraic curve X diverges as $z \rightarrow w$, and the divergence carries algebraic data. On one fibre, the residue calculus extracts finitely many OPE modes. Across all fibres, at all degrees, at all genera, no residue calculus suffices: the singularity structure at n points on a genus- g curve is entangled with the moduli of the curve itself. What is needed is a functor

that accepts the full OPE as input and produces a cochain complex on configuration spaces as output, with a differential that squares to zero exactly when the input satisfies the axioms of a chiral algebra. The ordered bar construction is that functor. Its integral kernel is the logarithmic 1-form $d \log(z_1 - z_2)$; its compactification is Fulton–MacPherson; its coalgebra is cofree with deconcatenation coproduct (E_1 , not coshuffle); its differential squares to zero if and only if the Borchers identity holds. The symmetric bar is the Σ_n -coinvariant quotient: a lossy projection that discards the R -matrix.

THE PROPAGATOR

The bar differential must extract OPE data from collisions on $C_2(X) = X \times X \setminus \Delta$. This requires a 1-form with a pole along the diagonal Δ : a regular form has residue zero and extracts nothing. A double pole $dz/(z - w)^2$ transforms under coordinate change and has no coordinate-independent residue. A simple pole is forced; and among 1-forms with a first-order pole along Δ , only the logarithmic derivative has conformally invariant residue:

$$\eta_{12} = d \log(z_1 - z_2) = \frac{dz_1 - dz_2}{z_1 - z_2}.$$

The residue is 1: it depends on no coordinate, no metric, no level. At two points, η_{12} is the complete propagator. At three points, a consistency condition is required: the three pullbacks $\eta_{12}, \eta_{23}, \eta_{31}$ on $C_3(X)$ must satisfy the *Arnold relation*

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0. \quad (1)$$

This restates, in differential forms, the partial-fractions identity

$$\frac{1}{(z_1 - z_2)(z_2 - z_3)} + \frac{1}{(z_2 - z_3)(z_3 - z_1)} + \frac{1}{(z_3 - z_1)(z_1 - z_2)} = 0,$$

which holds because the left side, as a rational function of z_1 with z_2, z_3 fixed, has simple poles at z_2 and z_3 whose residues sum to zero. Arnold proved that (1), replicated across all triples $\{i, j, k\} \subset \{1, \dots, n\}$, generates the complete ideal of relations in $H^*(\text{Conf}_n(\mathbf{C}), \mathbf{C})$.

The propagator is not coordinate-invariant. Under $z \mapsto w(z)$ it transforms as $\eta_{ij} \mapsto \eta_{ij} + d \log \frac{w(z_i) - w(z_j)}{z_i - z_j}$; near the diagonal the correction reduces to $d \log w'(z_i)$, the standard cocycle for $\text{Diff}(X)$. This failure is not a defect: it is the datum that the Virasoro algebra measures. The propagator is a BRST ghost for diffeomorphisms, and the bar complex it generates will detect every algebra that couples to the stress tensor.

THE BAR COMPLEX

The propagator handles two-point collisions; n -point collisions require the full algebraic input. A *chiral algebra* $\mathcal{A}$ on X is a $\mathcal{D}_X$ -module (a sheaf with flat connection) equipped with a chiral bracket

$$\mu^{\text{ch}} : j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_!(\mathcal{A}),$$

where $j : X \times X \setminus \Delta \hookrightarrow X \times X$ is the complement of the diagonal and $\Delta_! \mathcal{A}$ is the $!$ -pushforward along the diagonal embedding. The source consists of sections of $\mathcal{A} \boxtimes \mathcal{A}$ with poles of arbitrary order along Δ ; the

chiral bracket extracts the singular part and projects it onto the diagonal. In local coordinates, the chiral bracket encodes the operator product expansion:

$$a(z) b(w) \sim \sum_{n \geq 0} \frac{a_{(n)} b(w)}{(z-w)^{n+1}}.$$

The n -th products $a_{(n)} b \in \mathcal{A}$ are the Fourier modes of the bracket, extracted by $a_{(n)} b = \text{Res}_{z=w} [a(z) b(w) (z-w)^n]$. The zeroth product $a_{(0)} b$ is the Lie bracket (first-order pole); the first product $a_{(1)} b$ carries the symmetric/metric data (second-order pole). Higher products ($n \geq 2$) are determined by the $\mathcal{D}_X$ -module structure.

Place sections $a_1, \dots, a_n \in \mathcal{A}$ at distinct points $z_1, \dots, z_n \in X$. For a spanning tree T of the complete graph on $\{1, \dots, n\}$, form the decorated tensor

$$\omega_T(a_1, \dots, a_n) := a_1(z_1) \otimes \dots \otimes a_n(z_n) \otimes \bigwedge_{(i,j) \in E(T)} \eta_{ij}.$$

The form $\bigwedge_{(i,j) \in E(T)} \eta_{ij}$ is a section of $\Omega_{\log}^{n-1}$ on the configuration space $\text{Conf}_n(X)$; its degree equals $|E(T)| = n - 1$ since T is a tree.

The Fulton–MacPherson compactification $\overline{\text{FM}}_n(X)$ resolves $\text{Conf}_n(X)$ by iterated real oriented blowup along all diagonal strata. Points of $\overline{\text{FM}}_n(X) \setminus \text{Conf}_n(X)$ record the limiting direction and relative scale of approach as points collide. The boundary is a manifold with corners; codimension-one faces D_S are indexed by subsets $S \subseteq \{1, \dots, n\}$ with $|S| \geq 2$, recording which points have collided. Each such face factors: $D_S \simeq \overline{\text{FM}}_{|S|} \times \overline{\text{FM}}_{n-|S|+1}$, cluster times residual.

The *ordered bar complex* is

$$\overline{B}_X^{\text{ord}}(\mathcal{A}) = \bigoplus_{n \geq 1} (s^{-1} \overline{\mathcal{A}})^{\otimes n} \otimes \Gamma(\overline{\text{FM}}_n(X), \Omega_{\log}^{n-1}),$$

with no Σ_n -quotient. Here $\overline{\mathcal{A}} = \ker(\varepsilon: \mathcal{A} \rightarrow \omega_X)$ is the augmentation ideal, s^{-1} denotes desuspension ($|s^{-1}a| = |a| - 1$), and the cohomological convention $|d| = +1$ is used throughout.

The bar differential $d_{\overline{B}}$ decomposes into three pieces:

$$d_{\overline{B}} = d_{\text{int}} + d_{\text{res}} + d_{\text{dR}}.$$

The three components: d_{int} is the internal differential of $\mathcal{A}$ (acting on each tensor factor); d_{dR} is the de Rham differential on logarithmic forms on $\overline{\text{FM}}_n(X)$; and d_{res} is the residue differential, which extracts OPE data at collision divisors. For a codimension-one face $D_{\{i,j\}}$ corresponding to the collision $z_i \rightarrow z_j$:

$$d_{\text{res}}^{(ij)}(a_1 \otimes \dots \otimes a_n \otimes \eta_{ij} \wedge \omega') = \pm a_1 \otimes \dots \otimes \widehat{a_i} \otimes \dots \otimes \widehat{a_j} \otimes \dots \otimes a_{i(p)} a_j \otimes \omega',$$

where p is the pole order read from the form-theoretic coefficient, hats denote omission, and $a_{(p)} b$ is the p -th Fourier mode of the OPE. The bar differential does not merely detect singularities; it extracts them, mode by mode, through the logarithmic kernel.

The cohomology of this complex is *chiral Hochschild cohomology* $\text{ChirHoch}^*(\mathcal{A})$: the derived self-Hom of $\mathcal{A}$ as a chiral bimodule, computed via OPE residues on Fulton–MacPherson configuration spaces of algebraic curves. It is distinct from *topological Hochschild homology* $\text{THH}(\mathcal{A})$, which is factorisation homology over S^1 using only the E_1 -structure. For E_∞ -algebras (the entire standard landscape), the two theories agree; for genuinely E_1 -algebras they diverge, because the chiral theory sees the full OPE while the topological theory sees only the associative product (Principle 3.11.9).

WHY $d^2 = 0$

The bar differential has three components; squaring it produces nine cross-terms, and there is no a priori reason for the six off-diagonal terms to cancel. They do, and the mechanism is rigid.

Expand $(d_{\text{int}} + d_{\text{res}} + d_{\text{dR}})^2$ into nine terms. Three vanish individually: $d_{\text{int}}^2 = 0$ ($\mathcal{A}$ is a cochain complex), $d_{\text{dR}}^2 = 0$ (de Rham), and $d_{\text{int}} d_{\text{dR}} + d_{\text{dR}} d_{\text{int}} = 0$ (Leibniz rule). The remaining terms pair into three cancellation mechanisms, governed by index overlap:

- (a) *Disjoint supports.* When $\{i, j\} \cap \{k, l\} = \emptyset$, the faces $D_{\{i, j\}}$ and $D_{\{k, l\}}$ are transverse in $\overline{\text{FM}}_n(X)$. The residue operators commute: $d_{\text{res}}^{(ij)} d_{\text{res}}^{(kl)} + d_{\text{res}}^{(kl)} d_{\text{res}}^{(ij)} = 0$.
- (b) *Shared index.* When $\{i, j\} \cap \{k, l\} = \{j = k\}$, the triple collision $z_i = z_j = z_l$ sits in a codimension-two stratum. The form-theoretic contribution involves $\eta_{ij} \wedge \eta_{jl}$. The Arnold relation (1) identifies this with a cyclic sum over the three ordered approaches to the triple-collision point. On the algebraic side, the three terms produce $(a_{i(m)} a_j)_{(n)} a_l$, $(a_{j(m)} a_l)_{(n)} a_i$, $(a_{l(m)} a_i)_{(n)} a_j$ (with appropriate pole orders), whose sum vanishes by the *Borcherds identity*:

$$\sum_{j \geq 0} \binom{m}{j} (a_{(n+j)} b)_{(m+k-j)} c = \sum_{j \geq 0} (-1)^j \binom{n}{j} \left(a_{(m+n-j)} (b_{(k+j)} c) - (-1)^n b_{(n+k-j)} (a_{(m+j)} c) \right). \quad (2)$$

The Arnold relation kills the form; the Borcherds identity kills the algebra. Both are needed, and both are consumed.

- (c) *Same pair.* $d_{\text{res}}^{(ij)} d_{\text{res}}^{(ij)} = 0$ by the sign rule on desuspensions: extracting a residue twice at the same diagonal vanishes for degree reasons.

The result: $d_{\overline{B}}^2 = 0$ if and only if the n -th products satisfy the Borcherds identity (2). At $n = 0$ the Borcherds identity is the Jacobi identity for the Lie bracket $a_{(0)}$; at $n = 1, m = k = 0$, the derivation property of $a_{(0)}$ with respect to $a_{(1)} b$. The Borcherds identity is the complete axiom system for a chiral algebra; the bar construction accepts exactly chiral algebras.

TWO COPRODUCTS

A differential alone does not determine duality; that requires a coalgebra structure. The bar complex carries not one coproduct but two, corresponding to the two operadic levels (E_1 and E_∞) at which the construction operates.

The ordered bar $\overline{B}^{\text{ord}}(\mathcal{A})$ carries the *deconcatenation coproduct*:

$$\Delta[s^{-1}a_1 | \cdots | s^{-1}a_n] = \sum_{i=0}^n [s^{-1}a_1 | \cdots | s^{-1}a_i] \otimes [s^{-1}a_{i+1} | \cdots | s^{-1}a_n],$$

splitting an ordered sequence at every position: $n + 1$ terms. This is coassociative but not cocommutative, an E_1 -coalgebra reflecting the linear ordering.

The Σ_n -coinvariant quotient

$$\overline{B}_X^\Sigma(\mathcal{A}) = \bigoplus_{n \geq 1} (s^{-1} \overline{\mathcal{A}})_{\Sigma_n}^{\otimes n} \otimes \Gamma(\overline{\text{FM}}_n(X), \Omega_{\log}^{n-1})$$

carries the *coshuffle coproduct*, summing over all 2^n bipartitions of an unordered set: coassociative and cocommutative, an E_∞ -coalgebra, the factorization coalgebra of Beilinson and Drinfeld on $\text{Ran}(X)$.

The ordered bar is the primitive object; every other construction in this programme is derived from it. The symmetric bar is the Σ_n -coinvariant shadow: the lossy projection that discards the R -matrix, the KZ associator, and the full quantum group deformation. The five main theorems of this monograph (Theorems A–D and H) are stated at the symmetric level because they concern precisely the invariants that survive that projection; but each theorem originates in the ordered bar and descends to the symmetric bar via the averaging map $\text{av} : \mathfrak{g}_{\mathcal{A}}^{E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$. The ordered bar generates; the symmetric bar records what averaging preserves. What the projection destroys (the R -matrix, the Yangian, the spectral braiding) is part of the ordered E_1 theory proved in Volume I. Volume II studies the open/closed holomorphic-topological lift of that ordered data.

LOGARITHM, EXPONENTIAL, DUAL

The bar construction converts products to sums: $B(\mathcal{A} \otimes \mathcal{A}') \simeq B(\mathcal{A}) \oplus B(\mathcal{A}')$. It is a categorical logarithm, with the logarithmic form $\eta_{ij} = d \log(z_i - z_j)$ as integral kernel and the Arnold relation as cocycle condition. A logarithm demands an exponential; the cobar functor Ω serves that role, inverting the bar on the Koszul locus: $\Omega(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ (Theorem B). This is bar-cobar *inversion*: the cobar recovers the *original algebra*, not a dual.

Neither the bar nor the cobar produces the Koszul dual; that requires a separate operation. Take bar cohomology $\mathcal{A}^! := H^*(B(\mathcal{A}))$, a graded coalgebra, and apply graded linear duality: $\mathcal{A}^! := (\mathcal{A}^i)^\vee$. This is the *Koszul dual algebra*. Verdier duality on $\text{Ran}(X)$ produces the richer chain-level object $\mathcal{A}_\infty^!$:

$$\mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}) \simeq \mathcal{A}_\infty^!.$$

Verdier duality converts coalgebra to algebra, so $\mathcal{A}_\infty^!$ is a factorization *algebra*, retaining full chain-level data. That its cohomology recovers $\mathcal{A}^!$ on the Koszul locus is the content of Theorem A, not a tautology.

Three functors act on $B(\mathcal{A})$ and produce three distinct outputs:

$$\begin{aligned} \Omega(B(\mathcal{A})) &\simeq \mathcal{A} && \text{(inversion: recovers the original),} \\ \mathbb{D}_{\text{Ran}}(B(\mathcal{A})) &\simeq \mathcal{A}_\infty^! && \text{(Verdier: the homotopy dual),} \\ (H^*(B(\mathcal{A})))^\vee &= \mathcal{A}^! && \text{(linear duality: the strict dual).} \end{aligned}$$

Confusing any two is a category error.

The bar functor $\mathcal{A} \mapsto \overline{B}^{\text{ord}}(\mathcal{A})$ and the cobar functor Ω form an adjoint pair. On the Koszul locus (bar cohomology concentrated in degree 1), the adjunction is an equivalence:

$$\Omega(\overline{B}^{\text{ord}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A},$$

and the boundary algebra $\mathcal{A}$ is recovered from its bar complex without information loss (Theorem B). The Verdier functor $\mathbb{D}_{\text{Ran}}$ intertwines the two sides, pairing $\overline{B}(\mathcal{A})$ with the factorization companion $\mathcal{A}_\infty^!$ (Theorem A). This is what Volume I proves.

Off the Koszul locus the inversion fails, and the failure is measured: at each degree $r \geq 2$, the shadow class $S_r(\mathcal{A}) \in H^*(\overline{\mathcal{M}}_{0,r})$ is the obstruction to extending the inversion one step further. The tower $\{S_r\}_{r \geq 2}$ terminates when the obstruction hierarchy collapses to finitely many terms.

The conjectural extension (Volume II) identifies $\overline{B}^{\text{ord}}(\mathcal{A})$ as the boundary-to-bulk map: the derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) = R\text{Hom}_{\mathcal{A} \otimes \mathcal{A}^{\text{op}}}(\mathcal{A}, \mathcal{A})$ reassembles the bulk from the coalgebraic shadow. Volume I proves bar-cobar inversion; Volume II would upgrade it to bulk reconstruction.

When $\mathcal{A}$ is chirally Koszul, $H^*(B(\mathcal{A}))$ concentrates in bar degree 1, the bar-to-cobar spectral sequence collapses at E_2 , and $\mathcal{A}^1$ governs a linear resolution of $\mathcal{A}$. Classical Koszul duality (Priddy, Beilinson–Ginzburg–Soergel, Loday–Vallette) is recovered on $X = \mathbb{A}^1$: the affine line is contractible, the FM co-operad becomes quasi-isomorphic to the associative cooperad, and the bar complex reduces to the classical Chevalley–Eilenberg complex. The comparison $\mathbb{A}^1 \rightarrow \text{pt}$ requires a choice of homotopy retraction; the formal disk D sits between them, carrying completion data (growth conditions, Taylor expansions) that the point does not see. On $\mathbb{P}^1$ the classical reduction *fails*: the global topology of configuration spaces ($H^*(\text{Conf}_n(\mathbb{P}^1))$ has nontrivial classes from the Arnold relations, and $\overline{\text{FM}}_n(\mathbb{P}^1)$ has boundary strata absent over a point) means that genus-0 chiral Koszul duality on a projective curve is already richer than its classical counterpart. The chain

$$\text{pt} \xleftarrow{\text{augment}} D \hookrightarrow \mathbb{A}^1 \hookrightarrow \mathbb{P}^1 \hookrightarrow X_g$$

has new geometric content at each step: the augmentation $D \rightarrow \text{pt}$ discards the formal parameter (completion, growth conditions, the $\mathcal{D}$ -module structure); the inclusion $D \hookrightarrow \mathbb{A}^1$ embeds the formal disk into its algebraisation (the affine line is contractible, so $\mathbb{A}^1 \simeq \text{pt}$, but the equivalence requires specifying a homotopy retraction and transferring the bar-complex data through it); the open immersion $\mathbb{A}^1 \hookrightarrow \mathbb{P}^1$ introduces global topology, FM compactifications, and Arnold relations among configuration-space cohomology classes; and the passage to a genus- g curve introduces period integrals, curvature, and the modular operad.

THE HEISENBERG ALGEBRA

The Heisenberg chiral algebra $\mathcal{H}_k$ is generated by a single field α of conformal weight 1 with OPE

$$\alpha(z)\alpha(w) \sim \frac{k}{(z-w)^2}.$$

Only the second-order pole is present: $\alpha_{(1)}\alpha = k \cdot \mathbf{1}$ and $\alpha_{(n)}\alpha = 0$ for $n \neq 1$. No first-order pole: $\alpha_{(0)}\alpha = 0$, no Lie bracket. All triple products vanish since $\mathbf{1}_{(n)} = 0$ for $n \geq 0$.

The bar complex at tensor degree n is

$$\overline{B}_X^n(\mathcal{H}_k) = (s^{-1}\alpha)^{\otimes n} \otimes \Gamma(\overline{\text{FM}}_n(X), \Omega_{\log}^{n-1}).$$

At tensor degree 1: a one-dimensional space, $d_{\overline{B}} = 0$. At tensor degree 2: the bar differential extracts the full chiral product: $d_{\text{res}}(s^{-1}\alpha \otimes s^{-1}\alpha \otimes \eta_{12}) = \alpha_{(1)}\alpha = k \cdot \mathbf{1}$. The level k is visible already at genus 0. At tensor degree $n \geq 3$: every residue at a collision stratum $D_{\{i,j\}}$ produces $\alpha_{(1)}\alpha = k \cdot \mathbf{1}$ on the pair (i, j) ; since $\mathbf{1}_{(p)}\alpha = 0$ for $p \geq 0$, no further contractions occur. All structure is captured at tensor degree 2: the bar complex is quadratic. The Heisenberg algebra is chirally Koszul.

The modular characteristic: $\kappa(\mathcal{H}_k) = k$. The Koszul dual:

$$\mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*), m_0 = -k\omega),$$

where V^* is the linear dual of the generating space and $m_0 = -k\omega$ is the curvature, satisfying the curved A_∞ relation $m_1^2(a) = [m_0, a]$ (commutator, with the minus sign). The differential m_1 does not square to zero; its failure is controlled by the curvature.

The ordered bar and its R -matrix. The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{H}_k)$ carries the collision residue

$$r(z) = \frac{k}{z},$$

a scalar rational function with a single simple pole. The second-order OPE pole $k/(z-w)^2$ drops by one order under the logarithmic kernel $d \log(z-w)$: the bar differential absorbs one power of $(z-w)$, producing the first-order r -matrix pole k/z . Applying the averaging map:

$$\text{av}(r(z)) = k = \kappa(\mathcal{H}_k).$$

For the Heisenberg algebra, the R -matrix is the modular characteristic: $r(z) = k/z$ is already Σ_2 -invariant (scalar, not matrix), so averaging loses nothing. The two Koszul dualities coincide, the ordered bar carries no more information than the symmetric bar, and the entire structure collapses to a single number k .

The deficiency: no first-order pole, no Lie bracket, no matrix structure in the collision residue, no quantum group. Everything that makes representation theory nontrivial is absent. What Chriss–Ginzburg demands is the simplest example where the R -matrix is genuinely matrix-valued: the first algebra with a first-order pole.

Compute the derived centre:

$$\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{H}_k) \simeq \begin{cases} \mathbf{C} \cdot \mathbf{1} & \text{degree 0,} \\ \mathbf{C} \cdot J & \text{degree 1,} \\ \mathbf{C} \cdot \partial_k & \text{degree 2,} \end{cases} \quad \dim = 3 \quad (k \neq 0).$$

This is the algebra of observables of abelian Chern–Simons theory at level k : the unit, the current, and the infinitesimal level deformation. The derived centre recovers the bulk.

The modular characteristic $\kappa(\mathcal{H}_k) = k$ is the holographic central charge. At genus 1, $F_1 = \kappa(\mathcal{H}_k)/24 = k/24$; this is the torus partition function of abelian Chern–Simons. The shadow tower terminates at $r = 2$: the OPE has no first-order pole, so $S_r(\mathcal{H}_k) = 0$ for all $r \geq 3$. Class G (Gaussian): the bulk is free, and no holographic corrections arise.

The Koszul dual:

$$\mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*), m_0 = -k\omega), \quad \kappa(\mathcal{H}_k) + \kappa(\mathcal{H}_k^!) = k + (-k) = 0.$$

The candidate Drinfeld double $U_{\mathcal{H}_k} = \mathcal{H}_k \bowtie \mathcal{H}_k^!$ reduces to $\mathcal{H}_k \otimes \mathcal{H}_{-k}$ modulo the diagonal, reproducing the abelian Chern–Simons bulk from boundary data. Heisenberg is the base case: the commutative algebra where every clause is computable. The genuine E_1 atom is the Yangian, where the R -matrix carries non-scalar data that averaging destroys.

THE KAC–MOODY OPE

The affine Kac–Moody algebra $\widehat{\mathfrak{g}}_k$ at level k is generated by currents J^a , $a = 1, \dots, \dim \mathfrak{g}$, with OPE

$$J^a(z) J^b(w) \sim \frac{f^{ab}{}_c J^c(w)}{z-w} + \frac{k \kappa^{ab}}{(z-w)^2},$$

where $f^{ab}{}_c$ are the structure constants of the simple Lie algebra $\mathfrak{g}$ and κ^{ab} is the Killing form normalised so that long roots have squared length 2. Both poles are present. The first-order pole carries the Lie bracket $J_{(0)}^a J^b = f^{ab}{}_c J^c$; the second-order pole carries the invariant inner product $J_{(1)}^a J^b = k \kappa^{ab} \cdot \mathbf{1}$.

The bar complex of $\widehat{\mathfrak{g}}_k$ has nontrivial contributions at all tensor degrees: the first-order pole generates structure constants from tree-level OPE contractions, and the second-order pole contributes the metric data. The chiral bracket decomposes:

$$\mu^{\text{ch}} = \underbrace{f^{ab}{}_c J^c \cdot \eta_{12}}_{\text{Lie bracket (first-order pole)}} + \underbrace{k \kappa^{ab} \cdot \mathbf{1} \cdot d\eta_{12}}_{\text{inner product (second-order pole)}}.$$

The Lie bracket drives the tree-level bar differential (the combinatorics of the Chevalley–Eilenberg complex); the inner product supplies the curvature $\kappa(\widehat{\mathfrak{g}}_k)$. The coexistence of both poles, absent in the Heisenberg case, makes $\widehat{\mathfrak{g}}_k$ the first nontrivial example.

The Casimir R -matrix. The ordered bar complex of $\widehat{\mathfrak{g}}_k$ carries the collision residue

$$r(z) = \frac{k \Omega}{z}, \quad \Omega = \sum_a J^a \otimes J_a,$$

where $\Omega \in \mathfrak{g} \otimes \mathfrak{g}$ is the Casimir tensor and the level k enters through the second-order pole of the current OPE. This is matrix-valued: Ω carries the full Lie-algebraic structure that was invisible in the Heisenberg scalar k/z , and the prefactor k ensures $r(z)$ vanishes in the abelian limit. The averaging map collapses the Casimir to a scalar; together with the Sugawara shift by the dual Coxeter number $h^\vee$, it recovers the full modular characteristic

$$\text{av}(r(z)) + \frac{\dim(\mathfrak{g})}{2} = \frac{\dim(\mathfrak{g}) \cdot (k + h^\vee)}{2h^\vee} = \kappa(\widehat{\mathfrak{g}}_k), \quad (3)$$

where the additive $\dim(\mathfrak{g})/2$ is the Sugawara normal-ordering constant (the $h^\vee$ contribution). At the critical level $k = -h^\vee$ the shifted level $t := k + h^\vee$ vanishes and $\kappa(\widehat{\mathfrak{g}}_k) = 0$. The matrix structure of Ω , erased by Σ_2 -coinvariance, encodes the representation theory of $\mathfrak{g}$. At this point the ordered bar has strictly more information than the symmetric bar: the passage from $r(z) = k \Omega/z$ to $\kappa(\widehat{\mathfrak{g}}_k)$ discards the Casimir tensor, which is precisely the datum that builds the Yangian $Y(\mathfrak{g})$.

The Yangian is the Koszul dual of the ordered bar: the quantum group that deforms the enveloping algebra $U(\mathfrak{g}[z])$ of polynomial currents. The symmetric bar produces the chiral Koszul dual $\widehat{\mathfrak{g}}_k^\dagger$, the Verdier-dual factorization algebra on $\text{Ran}(X)$. The two dualities coexist because the bar complex carries two operadic colours.

The ordered bar carries the full structure; the symmetric bar retains only what is Σ_n -invariant. The five main theorems of this monograph (Theorems A–D and H, stated at the end of Section 2) are the Σ_n -coinvariant projections of the ordered bar’s invariants: the shadow that survives averaging from $r(z)$ to $\kappa(\mathcal{A})$. Every theorem stated here descends from an ordered-bar construction; the descent is the averaging map $\text{av}: r(z) \mapsto \kappa(\mathcal{A})$ at degree 2, and its higher-degree analogues at each degree $r \geq 3$. The distinction is not merely formal: at genus 1, the short exact sequence $0 \rightarrow \ker(\text{av}) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \rightarrow 0$ does not split as dg Lie algebras (Proposition 21.1.10). The obstruction is the quasi-modular Eisenstein series E_2 : the E_1 propagator on an elliptic curve produces the holomorphic $E_2(\tau)$, and averaging completes it to the non-holomorphic $\widehat{E}_2(\tau) = E_2(\tau) - 3/(\pi \text{Im } \tau)$. No holomorphic section lifts $\widehat{E}_2$ back to the E_1 side. The ordered bar carries genuinely new information beyond the symmetric coinvariant at every genus $g \geq 1$.

FROM GENUS 0 TO ALL GENERA

Everything above takes place at genus 0: the propagator $\eta_{12} = d \log(z_1 - z_2)$ is globally defined on $\mathbb{P}^1$, and the Arnold relation holds without correction. The genus-0 theory is not classical: already on $\mathbb{A}^1$ the

configuration spaces $\text{Conf}_n(\mathbb{A}^1)$ carry FM compactifications and the Arnold algebra of logarithmic forms; these structures, together with the Borchers extraction rule, are genuinely chiral and have no counterpart over a point. The classical Yang–Baxter equation is already a genus-0 theorem (the Arnold relation on $\overline{\mathcal{M}}_{0,4}$ evaluated on the Casimir tensor); the Drinfeld–Kohno comparison between braid-group monodromy and quantum-group braiding is a genus-0 theorem; the KZ connection is a genus-0 shadow of the universal MC element. Genus 0 on a curve is the locus where E_1 operadic structure lives, and E_1 structure is strictly richer than E_∞ structure (the R -matrix, the Yangian, and the ordered bar coproduct are all genus-0 invariants invisible to the symmetric coinvariant).

On a curve of genus $g \geq 1$, the function $z_1 - z_2$ has no global meaning, and the bar differential no longer squares to zero. The failure is controlled by a single scalar $\kappa(\mathcal{A})$ extracted from the leading OPE singularity: the modular characteristic. Restoring nilpotence across all genera is the subject of Section 2.

Remark 0.0.1 (The zero-dimensional shadow). When $X = \text{Spec } \mathbb{k}$ is a point, configuration spaces collapse, logarithmic forms vanish, and the chiral bar complex recovers the classical bar construction of an associative algebra A . A quadratic algebra $A = T(V)/(R)$ has quadratic dual $A^\dagger = T(V^*)/(R^\perp)$; when A is Koszul, the bar cohomology concentrates in diagonal degrees and $H^*(B(A)) \cong (A^\dagger)^\vee$. The operadic instances $\text{Com}^\dagger = \text{Lie}$ and $\text{Sym}^\dagger = \Lambda$ recover the Chevalley–Eilenberg complex as a restricted bar construction. The passage from a point to $\mathbb{A}^1$ is a homotopy equivalence (the affine line is contractible), but the comparison requires specifying a retraction $\mathbb{A}^1 \rightarrow \text{pt}$ together with transfer maps; these data are not canonical. The formal disk $D \subset \mathbb{A}^1$ sits between: it carries completion and growth conditions invisible at a point. The passage from $\mathbb{A}^1$ to $\mathbb{P}^1$ is *not* a homotopy equivalence: $\mathbb{P}^1$ has nontrivial global topology ($H^1(\text{Conf}_n(\mathbb{P}^1)) \neq 0$ for $n \geq 2$), and the FM compactification $\overline{\text{FM}}_n(\mathbb{P}^1)$ has boundary strata recording collision data absent over a contractible base.

I'. BAR CHAIN MODELS ON CURVE GEOMETRIES

To understand a chiral algebra is to construct its bar complex on every relevant curve geometry. Each geometry reveals a different algebraic structure. We exhibit five, computing the Heisenberg at each stage.

THE FORMAL DISK D

The formal disk $D = \text{Spec } \mathbb{C}[[z]]$ is the local model. On D , the bar complex reduces to the classical bar construction of a vertex algebra: the chiral endomorphism operad $\text{End}_{\mathcal{A}}^{\text{ch}}$ is $\text{Aut}(\mathcal{O})$ -equivariant, and the bar differential encodes the OPE via mode products $a_{(n)}b$. For the Heisenberg: $B_D(\mathcal{H}_k) = T^c(s^{-1}\mathbb{C}[J])$ with $d[s^{-1}J|s^{-1}J] = k$, $d = 0$ on all other generators. The formal disk is where vertex algebra axioms live; the bar complex on D is the algebraic skeleton.

THE PUNCTURED DISK D^*

The punctured disk $D^* = D \setminus \{0\}$ is topologically a circle S^1 , and at the level of homology the comparison $H_*^{\text{ch}}(D^*, \mathcal{A}) \cong \text{HH}_*(\mathcal{A})$ is the state-field correspondence. But at the *chain level* the two complexes are different: the chain complex $C_*^{\text{ch}}(D^*, \mathcal{A})$ carries the full holomorphic structure (OPE poles, spectral parameters, E_2 data from $\text{FM}_n(\mathbb{C})$), while $C_*^{\text{top}}(S^1, \mathcal{A})$ carries only the topological E_1 data (cyclic bar complex, no spectral parameters). The chain-level comparison D^* versus S^1 is the $E_2 - E_1$ gap: homology sees no difference, but cochains see the holomorphic structure. For the Heisenberg: both complexes com-

pute $\mathrm{HH}_*(\mathcal{H}_k) = \mathbb{C} \oplus \mathbb{C}[1]$ (concentrated in degrees 0 and 1), but the chain complex on D^* carries the spectral parameter λ in the λ -bracket $\{J_\lambda J\} = k\lambda$, invisible to the topological S^1 -chain complex.

THE ANNULUS

The annulus $A_{r_1, r_2} = \{r_1 < |z| < r_2\}$ has two boundary circles. The bar chain model $B^{\mathrm{ann}}(\mathcal{A})$ carries a bimodule structure: one E_1 factor per boundary circle. Factorisation homology over the annulus gives $\int_{S^1 \times [0, 1]} \mathcal{A} \simeq \mathrm{HH}_\bullet(\mathcal{A})$, the topological Hochschild bimodule. The annulus is the geometric home of the topological Hochschild complex: the two boundary circles are input and output; the annulus is the cobordism between them.

Degeneration: pinch the annulus waist and the bar complex degenerates to the sewing kernel. The modulus τ of the annulus appears in the chain model (holomorphic), but disappears in homology (topological). For the Heisenberg: $B^{\mathrm{ann}}(\mathcal{H}_k)$ computes the partition function $\mathrm{tr}(q^{L_0 - c/24}) = 1/\eta(\tau)$; the sewing kernel is the Fredholm determinant of q^{L_0} on the Fock space.

NODAL CURVES

On the boundary strata of $\overline{\mathcal{M}}_{g, n}$, a smooth curve degenerates into components joined at nodes. The bar complex restricts to each stratum: each vertex of a stable graph Γ contributes a bar complex of the corresponding smooth component, and each edge contributes the sewing kernel (the thin-annulus limit of B^{ann}).

The curvature $d_{\mathrm{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ arises from the failure of the bar complex to extend smoothly across nodal degenerations: the smooth locus carries $d^2 = 0$, and the boundary strata contribute $\kappa \cdot \omega_g$. For the Heisenberg: $\kappa(\mathcal{H}_k) = k$, and the genus- g partition function $F_g(\mathcal{H}_k) = k \cdot \lambda_g^{\mathrm{FP}}$ (UNIFORM-WEIGHT) is computed stratum by stratum through the stable graph expansion.

THE PAIR OF PANTS

The pair of pants $P = \mathbb{P}^1 \setminus \{0, 1, \infty\}$ (three boundary circles) is the multiplication cobordism. Its bar chain model encodes the product on chiral homology. At the chain level, $B_P(\mathcal{A})$ is the chain-level avatar of the chiral product: three insertions, three collision channels ($z_1 \rightarrow z_2, z_2 \rightarrow z_3, z_1 \rightarrow z_3$), and the Arnold relation forces consistency. For the Heisenberg: $B_P(\mathcal{H}_k)$ reduces to the fusion rule $\mathcal{H}_k \boxtimes \mathcal{H}_k \rightarrow \mathcal{H}_k$, the trivial fusion of a rank-1 algebra. For Kac–Moody, the pair-of-pants bar encodes the fusion tensor product, and the factorisation constraint is the KZ equation on three-point conformal blocks.

I''. E_n -CHIRAL ALGEBRAS AND DERIVED CENTRES

E_n -chiral algebras are factorisation algebras and are inherently geometric: to define an E_1 -chiral algebra requires ordered configuration spaces $C_n^<(X)$; to define an E_2 -chiral algebra requires braided configuration spaces; the bar differential comes from boundary strata of the Fulton–MacPherson compactification $\mathrm{FM}_n(\mathbb{C})$; the A_∞ Stasheff relations are Stokes’ theorem on FM compactifications; Mok’s logarithmic FM spaces are the compactifications in the E_n setting. The algebra and the geometry are inseparable.

FOUR LEVELS

E_∞ -chiral algebras are factorisation algebras on $\text{Ran}(X)$: insertion points are unordered, and the Σ_n -action is trivial. The symmetric bar $B^\Sigma(\mathcal{A}) = \text{Sym}^c(s^{-1}\bar{\mathcal{A}})$ carries the coshuffle coproduct. All standard vertex algebras (Heisenberg, Virasoro, affine Kac–Moody, $\mathcal{W}_N$, free-field algebras) are E_∞ . The five theorems A–D and H are proved for E_∞ -input. OPE poles do NOT break E_∞ : locality is compatible with arbitrary pole order.

E_1 -chiral algebras are factorisation algebras on the ordered Ran space $\text{Ran}^{\text{ord}}(X)$: insertion points carry a total order inherited from $\text{Conf}_n^<(\mathbb{R})$. The ordered bar $B^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$ carries the deconcatenation coproduct and the R -matrix. The averaging map $\text{av}: B^{\text{ord}} \rightarrow B^\Sigma$ is the Σ_n -coinvariant projection: lossy, killing the R -matrix profile. For E_∞ -chiral algebras, the formality bridge gives a quasi-isomorphism between ordered and symmetric bars (Theorem 21.2.10). For genuinely E_1 -chiral algebras (Yangians, Etingof–Kazhdan quantum vertex algebras), the bridge fails: ordered chiral homology has dimension $n!$ at degree n (Arnold), while the symmetric quotient collapses to dimension 1 (Theorem 21.2.11). The ratio $n!$ measures the information content of the E_1 structure invisible to E_∞ .

E_2 -chiral algebras carry braided factorisation structure. The braiding datum is the spectral R -matrix $R(z): V \otimes V \rightarrow V \otimes V$, satisfying the Yang–Baxter equation from Stokes on $\text{FM}_3(\mathbb{C})$. E_2 structure lives on the derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A})$, on the module category $\mathcal{A}\text{-mod}$, and on the representation category $\text{Rep}(U_h(\mathfrak{g}))$: never on the boundary algebra $\mathcal{A}$ itself when $\mathcal{A}$ is E_1 .

E_3 requires topologisation: the algebraic-geometric theorem that $\text{SC}^{\text{ch},\text{top}} + \text{inner conformal vector} \simeq E_3^{\text{top}}$ (Theorem A.12.2). The Sugawara element at non-critical level makes holomorphic translations $\mathcal{Q}$ -exact in the topological direction, collapsing the two colours of $\text{SC}^{\text{ch},\text{top}}$ and producing a single-colour E_3 -topological algebra. Without conformal vector: stuck at $\text{SC}^{\text{ch},\text{top}}$. At critical level $k = -h^\vee$: Sugawara undefined, topologisation fails.

THE CHIRAL QUANTUM GROUP EQUIVALENCE

On the chirally Koszul locus, the E_1 data package into a single structure: the chiral quantum group. Three structures on $B^{\text{ord}}(\mathcal{A})$ determine each other (Theorem 22.29.1): the spectral R -matrix, the chiral A_∞ structure, and the chiral coproduct. For affine Kac–Moody: the Yang R -matrix $R(u) = uI + \Psi P$, the Drinfeld coproduct $\Delta_z(T(u)) = T(u) \cdot T(u-z)$, and the RTT relations. Concrete verifications through $\mathfrak{g} = \mathfrak{gl}_N$ for all $N \geq 1$ (Theorem 22.29.21).

THE DERIVED CHIRAL CENTRE

The derived chiral centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) := C_\bullet^{\text{ch}}(\mathcal{A}, \mathcal{A})$ is an algebraic-geometric construction: chiral Hochschild cochains computed via the chiral endomorphism operad $\text{End}_{\mathcal{A}}^{\text{ch}}$ with spectral parameters from $\text{FM}_k(\mathbb{C})$. This is *not* topological Hochschild $\text{RHom}_{\mathcal{A}^e}(\mathcal{A}, \mathcal{A})$: the chiral and topological constructions use different operadic inputs and produce different outputs.

From E_1 input, the derived centre carries E_2 structure (the Deligne conjecture, proved). From E_2 input, the derived centre carries E_3 structure (the higher Deligne conjecture, proved). Theorem H: the chiral Hochschild cohomology $\text{ChirHoch}^*(\mathcal{A})$ has polynomial Hilbert series and concentrates in cohomological degrees $\{0, 1, 2\}$.

The $\text{SC}^{\text{ch},\text{top}}$ structure lives on the *pair* $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$: the derived centre acts on the boundary algebra via brace operations from $\text{End}_{\mathcal{A}}^{\text{ch}}$. The bar complex $B(\mathcal{A})$ is an E_1 chiral coassociative coalgebra: a

single-coloured object, not an $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ -coalgebra. The $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ structure emerges in the chiral Hochschild construction, not in the bar complex.

Three Hochschild theories coexist: (i) chiral Hochschild (OPE composition on $\mathrm{Ran}(\mathbb{C})$, producing $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}$); (ii) topological Hochschild (E_1 -bar composition on $\mathbb{R}$, producing the line category); (iii) categorical Drinfeld centre (E_1 -monoidal, producing the E_2 -braided module category). The geometry determines which: curve $\rightarrow$ chiral; circle $\rightarrow$ topological; category $\rightarrow$ Drinfeld.

The E_3 identification theorem: for simple $\mathfrak{g}$, $\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(V_k(\mathfrak{g})) \cong A^\lambda$ as E_3 -families over $\lambda \cdot H^3(\mathfrak{g})[[\lambda]]$ (Theorem A.12.22). Formal disk restriction recovers the Costello–Francis–Gwilliam perturbative Chern–Simons E_3^{top} -algebra.

Volume II interprets these algebraic-geometric constructions physically: the derived centre IS the bulk of a 3d holomorphic-topological gauge theory; the $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ pair IS a boundary-bulk system; the E_3 algebra IS a TQFT. Volume III constructs concrete E_1 -chiral quantum groups from Calabi–Yau geometry as examples of the abstract algebraic framework developed here.

2. CURVATURE AND THE GENUS TOWER

On a curve of genus $g \geq 1$, the difference $z_1 - z_2$ has no global meaning: the curve is compact, and any meromorphic function with a single simple zero must also have a simple pole. The replacement is the *prime form* $E(z_1, z_2)$: a section of $K^{-1/2} \boxtimes K^{-1/2}$ on $X \times X$, vanishing to first order along the diagonal Δ , with no other zeros. The bundle is $K^{-1/2} \boxtimes K^{-1/2}$, *not* $K^{+1/2} \boxtimes K^{+1/2}$: the prime form is a $(-\frac{1}{2}, -\frac{1}{2})$ -differential. In a local coordinate where the diagonal is $z_1 = z_2$,

$$E(z_1, z_2) = (z_1 - z_2) \cdot (1 + O(z_1 - z_2)) \cdot (dz_1)^{-1/2} (dz_2)^{-1/2}.$$

The prime form has nontrivial monodromy. Analytic continuation around the B -cycle B_j in the variable z_1 :

$$E(z_1 + B_j, z_2) = -\exp(-\pi i \Omega_{jj} - 2\pi i \int_{z_2}^{z_1} \omega_j) \cdot E(z_1, z_2),$$

where $\Omega = (\Omega_{jk})$ is the period matrix of X ($\Omega_{jk} = \oint_{B_k} \omega_j$) and $\omega_1, \dots, \omega_g$ are the holomorphic differentials normalised by $\oint_{A_j} \omega_k = \delta_{jk}$. The A -cycle monodromy is trivial: $E(z_1 + A_j, z_2) = E(z_1, z_2)$.

The logarithmic derivative $\omega(z_1, z_2) := d_{z_1} \log E(z_1, z_2)$ is the fundamental meromorphic differential of the second kind: symmetric, a double pole on Δ , vanishing A -periods. The *genus- g propagator*:

$$\eta_{12}^{(g)} = d \log E(z_1, z_2) + \pi \sum_{j,k=1}^g (\mathrm{Im} \Omega)_{jk}^{-1} \mathrm{Im} \left(\int_{z_2}^{z_1} \omega_j \right) \omega_k(z_1).$$

The period correction $(\mathrm{Im} \Omega)_{jk}^{-1}$ compensates the B -cycle monodromy, rendering $\eta_{12}^{(g)}$ single-valued on X . The price: $\eta_{12}^{(g)}$ is no longer holomorphic; the correction term is a $(1, 0)$ -form in z_1 multiplied by a real-analytic function of both variables. The propagator couples to the Hodge bundle $\mathbb{E} \rightarrow \overline{\mathcal{M}}_g$ through the period matrix Ω .

The propagator $d \log E(z_1, z_2)$ has conformal weight 1 in both variables, regardless of the conformal weight h of the field being sewed. Every edge of every genus- g graph sum uses the standard Hodge bundle $\mathbb{E}_1 = R^0 \pi_* \omega_\pi$. The Mumford isomorphism $c_1(\mathbb{E}_j) = (6j^2 - 6j + 1)\lambda_1$ would produce discrepancies of $13 \times$ (Virasoro) or $22.6 \times$ ($\mathbb{W}_3$) at genus 1 if weight- h generators were assigned to $\mathbb{E}_h$: the propagator argument eliminates this.

CURVATURE

The Arnold relation at genus g acquires a defect. At genus 0,

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$$

holds identically. At genus $g \geq 1$, the period corrections produce a residual $(1, 1)$ -form: the three-term sum does not vanish.

On the ordered bar $\overline{B}^{\text{ord}}(\mathcal{A})$, the defect lives in $\text{End}_{\mathcal{A}}(2) \otimes \Omega^{1,1}$: a matrix-valued curvature, carrying the full collision data of the R -matrix at genus g . Explicitly, the fibrewise differential on $\overline{B}^{\text{ord}}$ satisfies

$$(d_{\text{fib}}^{\text{ord}})^2 = r_{\mathcal{A}}(z) \cdot \omega_g \in \text{End}_{\mathcal{A}}(2) \otimes H^{1,1}(C_g),$$

where $r_{\mathcal{A}}(z)$ is the genus-0 collision residue from §1 and ω_g is the Arakelov $(1, 1)$ -form on the fibre of the universal curve $\pi: C_g \rightarrow \overline{\mathcal{M}}_g$.

For the Heisenberg algebra, $r(z) = k/z$ is already scalar, and the E_1 curvature $k \cdot \omega_g/z$ coincides with its average. For affine Kac–Moody, $r(z) = k \Omega/z$ is matrix-valued; the curvature $k \Omega \cdot \omega_g/z$ retains the Casimir tensor, which is discarded by averaging. For the Virasoro algebra, $r(z) = (c/2)/z^3 + 2T/z$; the curvature has two components, collapsed by averaging to the single scalar $c/2$.

Applying the Σ_2 -coinvariant projection $\text{av}: \text{End}_{\mathcal{A}}(2) \rightarrow \mathbb{k}$:

$$d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g. \quad (4)$$

This is the equation on the symmetric bar $\overline{B}^{\Sigma}(\mathcal{A})$: the scalar shadow of the E_1 curvature. The *modular characteristic* $\kappa(\mathcal{A})$ is the scalar curvature of the symmetric bar at genus $g \geq 1$. For abelian algebras $\kappa = \text{av}(r_{\mathcal{A}}(z))$; for non-abelian Kac–Moody the Sugawara normal-ordering shift contributes an additive $\dim(\mathfrak{g})/2$ (equation (3)): $\kappa(\mathcal{H}_k) = k$; $\kappa(\widehat{\mathfrak{g}}_k) = (k + h^{\vee}) \dim \mathfrak{g} / (2h^{\vee})$, vanishing at the critical level $k = -h^{\vee}$; $\kappa(\text{Vir}_c) = c/2$.

The Virasoro case illustrates logarithmic absorption: the stress tensor OPE has poles at orders 4, 2, 1, but the bar propagator $d \log E(z, w)$ absorbs one power, so the collision residue $r(z) = (c/2)/z^3 + 2T/z$ has pole orders one less than the OPE. The Koszul dual is Vir_{26-c} , with $\kappa(\text{Vir}_{26-c}) = (26-c)/2$: the two curvatures sum to 13, not zero. At $c = 26$ the dual is uncurved; at $c = 0$ the algebra itself is uncurved; at $c = 13$ the algebra is self-dual under Koszul duality.

PERIOD INTEGRALS RESTORE NILPOTENCE

The curvature (4) obstructs $d_{\text{fib}}^2 = 0$, but not the total $D_g^2 = 0$. Integration against A -cycle periods defines a connection on the family of bar complexes parametrised by $\overline{\mathcal{M}}_g$. The corrected total differential

$$D_g = d_{\text{fib}} + \nabla^{\text{GM}}$$

incorporates the Gauss–Manin connection on the Hodge bundle (the canonical flat connection on $R^1\pi_*\mathbb{C}$, encoding how the periods of the curve vary with moduli), and $D_g^2 = 0$: the $(1, 1)$ -curvature of the fibrewise differential is absorbed by the $(0, 1)$ -part of the base connection.

The mechanism: the fibrewise curvature $\kappa \cdot \omega_g$ is a class in $H^{1,1}(C_g)$; the period map $\overline{\mathcal{M}}_g \rightarrow \mathcal{A}_g$ identifies this class with the $(0, 1)$ -curvature of the Gauss–Manin connection on $R^1\pi_*\mathbb{C}$. The two curvatures cancel:

$$D_g^2 = d_{\text{fib}}^2 + [d_{\text{fib}}, \nabla^{\text{GM}}] + (\nabla^{\text{GM}})^2 = \kappa \cdot \omega_g - \kappa \cdot \omega_g + 0 = 0.$$

THE GENUS TOWER

With $D_g^2 = 0$ restored, the ordered bar complex defines a flat family of cochain complexes over $\overline{\mathcal{M}}_g$. Its universal Maurer–Cartan element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{E_1})$ (constructed in §4) projects at each degree $r \geq 2$ to an E_1 -valued invariant; at degree 2, the projection recovers the collision residue $r_{\mathcal{A}}(z)$ from §1. The Σ_n -coinvariant of $\Theta_{\mathcal{A}}$ is the shadow tower $\{S_r(\mathcal{A})\}_{r \geq 2}$ in the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.

The obstruction to triviality of this flat family is a characteristic class. At the E_1 level it is $\text{End}_{\mathcal{A}}$ -valued; under averaging it collapses to the scalar

$$\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g \in H^*(\overline{\mathcal{M}}_g) \quad (\text{UNIFORM-WEIGHT}), \quad \lambda_g = c_g(\mathbb{E}),$$

where $\mathbb{E} = \pi_* \omega_{\pi}$ is the *Hodge bundle* (the vector bundle on $\overline{\mathcal{M}}_g$ whose fibre over $[C]$ is $H^0(C, \omega_C)$). At genus 1 this factorization holds unconditionally for all families; for multi-weight families at genus $g \geq 2$ the scalar formula fails: a cross-channel correction from mixed-propagator boundary graphs appears (Theorem 13.22.225). Every free-field algebra satisfies the scalar formula exactly at all genera, even with multi-weight generators (Proposition 13.22.226): the bar spectral sequence collapses at E_1 because the cross-channel propagators factor through the free-field OPE, and the mixed-propagator boundary graphs vanish identically.

Grothendieck–Riemann–Roch applied to the universal curve $\pi: C_g \rightarrow \overline{\mathcal{M}}_g$ computes the total obstruction: the Chern character of $R\pi_* \omega_{\pi}$ involves the Todd class of the relative tangent bundle T_{π} , which is the $\hat{A}$ -genus. The generating function:

$$\sum_{g \geq 1} \text{obs}_g(\mathcal{A}) \cdot x^{2g} = \kappa(\mathcal{A}) \cdot (\hat{A}(ix) - 1).$$

Since $\hat{A}(ix) = (x/2)/\sin(x/2) = 1 + x^2/24 + 7x^4/5760 + \dots$ (all positive), the first Faber–Pandharipande coefficients are:

$$\begin{aligned} F_1(\mathcal{A}) &= \frac{\kappa(\mathcal{A})}{24}, \\ F_2(\mathcal{A}) &= \frac{7 \kappa(\mathcal{A})}{5760}, \\ F_3(\mathcal{A}) &= \frac{31 \kappa(\mathcal{A})}{967680}. \end{aligned}$$

The genus- g coefficient is $\kappa(\mathcal{A}) \cdot \frac{2^{2g-1}-1}{2^{2g-1}} \cdot \frac{|B_{2g}|}{(2g)!}$. The $\hat{A}$ -genus appears from the bar complex as the connection between chiral algebra and index theory.

The scalar $\kappa(\mathcal{A})$ is only the leading term. The bar complex carries higher-degree data: a universal Maurer–Cartan element $\Theta_{\mathcal{A}}$ whose projection to degree r yields a shadow invariant $S_r(\mathcal{A})$. The infinite tower of shadows is algebraic of degree 2, governed by a single discriminant $\Delta = 8\kappa S_4$ that classifies the standard landscape into four shadow-depth classes (§6). The genus- g obstruction class $\alpha_g(\mathcal{A})$ admits a universal formula in terms of $\kappa(\mathcal{A})$ and the shadow tower: the leading term is $\kappa \cdot \lambda_g$ (Theorem D), and the higher-order corrections are determined recursively by the shadow data (κ, α, S_4) through the Riccati algebraicity theorem (Theorem 13.22.137).

COMPLEMENTARITY

On the ordered bar, Verdier duality pairs $\overline{B}^{\text{ord}}(\mathcal{A})$ with $\mathcal{A}_{\infty}^!$: the R -matrix $r_{\mathcal{A}}(z)$ and its dual $r_{\mathcal{A}^!}(z)$ are intertwined by the Verdier functor $\mathbb{D}_{\text{Ran}}$. Under Σ_n -averaging, this E_1 pairing descends to a Lagrangian

decomposition of the genus- g cohomology of the center local system:

$$R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}}) \simeq \mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^\dagger).$$

What $\mathcal{A}$ sees as deformation, $\mathcal{A}^\dagger$ sees as obstruction. The natural pairing

$$\mathbf{Q}_g(\mathcal{A}) \otimes \mathbf{Q}_g(\mathcal{A}^\dagger) \longrightarrow R\Gamma(\overline{\mathcal{M}}_g, \omega_{\overline{\mathcal{M}}_g}) \simeq \mathbb{k}[-(3g-3)]$$

is a $-(3g-3)$ -shifted symplectic form, and the two summands are *Lagrangian*: each is isotropic and of half the total dimension. At the scalar level, complementarity reduces to

$$\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) = 0 \quad (\text{for Kac–Moody and free-field algebras}).$$

For $\mathcal{W}$ -algebras the sum $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger)$ is a nonzero constant: 13 for Virasoro, 250/3 for $\mathcal{W}_3$.

FEIGIN–FRENKEL DUALITY

The Sugawara construction produces the Virasoro field

$$T(z) = \frac{1}{2(k+h^\vee)} \sum_{a=1}^{\dim \mathfrak{g}} :J^a(z)J^a(z):,$$

with central charge $c = k \dim \mathfrak{g} / (k + h^\vee)$. At the critical level $k = -h^\vee$, the denominator vanishes: $T(z)$ is *undefined*, not “ c diverges.” The chiral algebra acquires a large center, the Feigin–Frenkel center $\mathfrak{z}(\widehat{\mathfrak{g}}_{-h^\vee})$, isomorphic to the algebra of functions on the space of local ${}^L\mathfrak{g}$ -opers on the formal disc.

The Feigin–Frenkel involution

$$k \longleftrightarrow -k - 2h^\vee$$

is Koszul duality on configuration spaces: it interchanges $\mathcal{A}$ and $\mathcal{A}^\dagger$ while preserving the bar-cobar adjunction. At the level of modular characteristics, $\kappa(\widehat{\mathfrak{g}}_k) + \kappa(\widehat{\mathfrak{g}}_{-k-2h^\vee}) = 0$: complementarity is a direct consequence. At the critical level, the Koszul dual is the Langlands-dual critical-level algebra ${}^L\widehat{\mathfrak{g}}_{-Lh^\vee}$, not a renormalised copy of the original.

THE TOTAL SPACE

The universal configuration fibration

$$\pi_n: \overline{C}_n(C_g) \longrightarrow \overline{\mathcal{M}}_g$$

packages the bar complex into a single global object. Its boundary divisors carry two distinct geometric roles:

- *Collision divisors* (vertical): the fibrewise boundary of $\overline{\text{FM}}_n(X_s)$ over a point $s \in \overline{\mathcal{M}}_g$. These produce the bar differential d_{res} , the OPE residues.
- *Degeneration divisors* (horizontal): the boundary of $\overline{\mathcal{M}}_g$ itself (nodal curves, reducible fibres). These produce the period corrections, the Gauss–Manin connection terms in D_g .

The collision divisors are the algebraic boundary (controlled by the Borchers identity); the degeneration divisors are the geometric boundary (controlled by the period map and the clutching morphisms of stable curves). The interaction between them is the curvature $\kappa(\mathcal{A})$: the fibrewise bar differential fails to be nilpotent precisely because the vertical and horizontal boundaries do not commute.

THE FIVE THEOREMS

Five theorems extract the structural content of the bar complex.

Theorem A (bar-cobar adjunction and Verdier intertwining). The bar functor B and the cobar functor Ω form an adjoint pair on the category of chiral algebras over $\text{Ran}(X)$. Verdier duality on $\text{Ran}(X)$ intertwines the bar of $\mathcal{A}$ with the bar of the Koszul dual: $\mathbb{D}_{\text{Ran}}(B(\mathcal{A})) \simeq \mathcal{A}_\infty^!$.

Theorem B (bar-cobar inversion). On the Koszul locus, the cobar of the bar recovers the original algebra: $\Omega(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$. Genus 0 is unconditional. For arbitrary $\mathcal{A}$, the $g \geq 1$ extension remains conditional on axiom (MK₃); on the standard CFT-type surface it is unconditional except the integer-spin $\beta\gamma$ lane. The bar complex is therefore a complete invariant on the proved Koszul surface.

Theorem C (complementarity). The genus- g cohomology of the center local system decomposes into two Lagrangian halves, one controlled by $\mathcal{A}$ and the other by the Koszul dual $\mathcal{A}^!$: $R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}}) \simeq \mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!)$. The Verdier-side Lagrangian splitting is proved; the ambient shifted-symplectic upgrade is conditional on perfectness and nondegeneracy.

Theorem D (modular characteristic). At genus 1 for every family, and at all genera on the proved uniform-weight lane, the obstruction class factors as $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$, where $\kappa(\mathcal{A})$ is a single scalar determined by the OPE (UNIFORM-WEIGHT). The theorem includes additivity, Koszul-duality constraints, and the Faber–Pandharipande $\hat{A}$ -series for the scalar free energy. For multi-weight algebras at $g \geq 2$, the scalar formula is replaced by $F_g = \kappa(\mathcal{A})\lambda_g + \delta F_g^{\text{cross}}$ (ALL-WEIGHT + $\delta F_g^{\text{cross}}$).

Theorem H (chiral Hochschild cohomology on the Koszul locus; generic affine level in the non-abelian case). On the Koszul locus, the chiral Hochschild complex $\text{ChirHoch}^*(\mathcal{A})$ is concentrated in cohomological degrees $\{0, 1, 2\}$ with an explicit Hilbert polynomial of degree at most 2, $P_{\mathcal{A}}(t) = \sum_n \dim \text{ChirHoch}^n(\mathcal{A}) \cdot t^n$ determined by the family: $P_{V_k(\mathfrak{g})}(t) = 1 + (\dim \mathfrak{g})t + t^2$ for affine Kac–Moody at generic level, $P_{\mathcal{H}_k}(t) = 1 + t + t^2$ for Heisenberg, $P_{\text{Vir}_c}(t) = 1 + t^2$ for Virasoro. The degree-1 group recovers the classical Lie algebra: $\text{ChirHoch}^1(V_k(\mathfrak{g})) \cong \mathfrak{g}$ (Proposition A.11.25). The degree-2 group is one-dimensional, generated by the level deformation $k \mapsto k + \epsilon$. This is the deformation ring of $\mathcal{A}$ at generic level, and the concentration is Koszul-functorial. At critical level $k = -h^\vee$ Theorem H does not apply: the Feigin–Frenkel centre is infinite-dimensional, and the cohomology is unbounded.

Read together: the pair $(\mathcal{A}, \mathcal{A}_\infty^!)$ is constructed as a canonical Verdier-dual pair (A), is bar-cobar-invertible on the Koszul locus (B), decomposes the fibrewise centre into Lagrangian halves (C), carries a single modular characteristic $\kappa(\mathcal{A})$ that governs genus 1 for every family and the all-genus scalar lane (UNIFORM-WEIGHT) (D), and has bounded chiral Hochschild cohomology on the Koszul locus (H). These five facts are what Volume I proves; Volume II does not supply the ordered bar data, but the open/closed holomorphic-topological lift and the bulk/topological interpretation. The proofs of A, B, C, D, H occupy Parts I–II of the body. Every theorem is a projection of a single universal Maurer–Cartan element $\Theta_{\mathcal{A}}$ in the modular convolution algebra; the framework that constructs $\Theta_{\mathcal{A}}$ is the subject of Section 3.

3. MODULAR HOMOTOPY THEORY

The genus tower of Section 2 organises the bar complex into a family of cochain complexes parametrised by $\overline{\mathcal{M}}_g$. The question is what algebraic structure governs this family. Tree-level structures (operads, A_∞ -algebras) are insufficient: a curve can acquire a self-crossing that raises the genus by one, an operation with

no tree-level counterpart. The correct framework is the *modular operad* (Getzler–Kapranov), whose operations are indexed by stable graphs of arbitrary genus and whose structure maps encode both the splitting of a curve into components (separating gluing) and the self-crossing that raises genus (non-separating gluing).

3.1. THE MODULAR OPERAD

A *stable graph* Γ parametrises a boundary stratum of the Deligne–Mumford moduli space $\overline{\mathcal{M}}_{g,n}$: vertices are irreducible components, edges are nodes, genus labels record the genera of the components, half-edges are marked points.

A *modular operad* $\mathcal{O}$ has operations indexed by *connected stable graphs*. A connected stable graph Γ has a genus label $g(v) \in \mathbb{Z}_{\geq 0}$ at each vertex satisfying $2g(v) - 2 + \text{val}(v) > 0$ (stability), and total genus $g(\Gamma) = b_1(\Gamma) + \sum_v g(v)$; trees are the genus-0 case. The structure maps of $\mathcal{O}$ are of two kinds: *separating gluing* $\xi_{\text{sep}}: \mathcal{O}(g_1, n_1+1) \otimes \mathcal{O}(g_2, n_2+1) \rightarrow \mathcal{O}(g_1+g_2, n_1+n_2)$ (joining two components at a node), and *non-separating gluing* $\xi_{\text{ns}}: \mathcal{O}(g, n+2) \rightarrow \mathcal{O}(g+1, n)$ (identifying two marked points on the same component, raising genus by 1). These satisfy Σ_n -equivariance, associativity, and commutativity. The set $\text{Gr}_{g,n}^{\text{st}}$ parametrises the boundary stratification of $\overline{\mathcal{M}}_{g,n}$. Every codimension-one boundary divisor is a one-edge degeneration; every codimension-two stratum is the intersection of exactly two codimension-one divisors, appearing with opposite orientations in the boundary-of-boundary complex.

3.2. THE FEYNMAN TRANSFORM

The *Feynman transform* of $\mathcal{O}$, the modular analogue of the operadic bar construction, replaces trees by stable graphs:

$$FO(g, n) = \bigoplus_{\Gamma \in \text{Gr}_{g,n}^{\text{st}}} \frac{\hbar^{g(\Gamma)}}{|\text{Aut}(\Gamma)|} \bigotimes_{v \in V(\Gamma)} \mathcal{O}(g(v), \text{In}(v)).$$

The *differential* contracts one edge at a time:

$$d_{FO}(\gamma_\Gamma) = \sum_{e \in E(\Gamma)} (-1)^{\epsilon(e)} \xi_e(\gamma_{\Gamma/e}),$$

where $\gamma_{\Gamma/e}$ denotes the image of γ_Γ under edge contraction along e , applying the gluing map ξ_e at edge e . The sign $(-1)^{\epsilon(e)}$ is determined by the position of e in the orientation line $\det(E(\Gamma))$. The identity $d^2 = 0$ is the codimension-2 boundary cancellation: each pair of edges can be contracted in either order, and the two terms cancel by the associativity of $\mathcal{O}$. At genus 0 (trees, $\hbar^0 = 1$), FO reduces to the operadic bar construction.

When $\mathcal{O} = \text{Com}$ (the *commutative modular operad*, with $\text{Com}(g, n) = \mathbb{k}$ for every stable (g, n)), the Feynman transform becomes the *stable graph complex*

$$F\text{Com}(g, n) = \bigoplus_{\Gamma \in \text{Gr}_{g,n}^{\text{st}}} \frac{\hbar^{g(\Gamma)}}{|\text{Aut}(\Gamma)|} \det(E(\Gamma)):$$

a chain complex spanned by stable graphs, graded by edge number, with edge-contraction differential.

Replacing Com by Ass equips each vertex with a cyclic ordering of its half-edges, and $F\text{Ass}$ sums over *ribbon graphs* (fatgraphs) whose genus is the genus of the thickened embedding surface:

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}, E_1} := \text{Hom}_{\Sigma}(F\text{Ass}, \text{End}_{\overline{B}^{E_1}(\mathcal{A})}).$$

This is the algebraic form of the 't Hooft $1/N$ expansion. Setting $\hbar = 1/N^2$, the MC element $\Theta_{\mathcal{A}}^{E_1} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}, E_1})$ is the genus expansion $\sum_g N^{2-2g} F_g(\lambda)$ summed over ribbon graphs weighted by the genus of their embedding surface. Planar diagrams ($g = 0$) dominate at large N ; the shadow obstruction tower $\Theta^{E_1, \leq r}$ is the truncation to r -point 't Hooft interactions. The coinvariant map $F\text{Ass} \rightarrow F\text{Com}$ projects $\Theta^{E_1} \mapsto \Theta$: colour-ordered amplitudes to full amplitudes.

3.3. THE CONVOLUTION LADDER

The Feynman transform is a skeleton; a chiral algebra provides the flesh. The pairing of cooperadic skeleton with operadic algebra is a convolution dg Lie algebra whose Maurer–Cartan elements classify algebraic structures:

$$\begin{array}{lll}
 \text{algebra :} & \text{Hom}(B(\text{Ass}), \text{End}_A) & A_{\infty}\text{-structures on } A \\
 \text{operad :} & \text{Hom}_{\Sigma}(B(\mathcal{P}), \text{End}_V) & \mathcal{P}_{\infty}\text{-structures on } V \\
 E_1\text{-modular :} & \text{Hom}(FO, \text{End}_{\overline{B}^{\text{ord}}(\mathcal{A})}) & \text{ordered genus towers } (R\text{-matrix}) \\
 \text{modular :} & \text{Hom}_{\Sigma}(FO, \text{End}_{\overline{B}^{\Sigma}(\mathcal{A})}) & \text{coinvariant genus towers } (\kappa)
 \end{array} \tag{5}$$

The first line is the chiral Hochschild cochain complex; the second is the deformation complex of Ginzburg–Kapranov; the third, acting on the ordered bar with no Σ_n -quotient, is the E_1 -modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{E_1}$: the primitive object, carrying the R -matrix and the Yangian. The fourth is its Σ_n -coinvariant shadow $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, retaining only $\kappa(\mathcal{A})$. The *Lie bracket* in each case is the convolution bracket: for f, g in the convolution hom,

$$[f, g] := \mu \circ (f \otimes g) \circ \Delta - (-1)^{|f||g|} \mu \circ (g \otimes f) \circ \Delta,$$

where Δ is the cooperadic decomposition and μ is operadic composition.

Given a chiral algebra $\mathcal{A}$ with bar complex $\overline{B}(\mathcal{A})$, the *modular convolution dg Lie algebra*

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}} := \text{Hom}_{\Sigma}(F\text{Com}, \text{End}_{\overline{B}(\mathcal{A})})$$

is the $\mathcal{O} = \text{Com}$ instance of the modular line. The bar complex is an $F\text{Com}$ -algebra; the universal MC element $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is bar-intrinsic ($D_{\mathcal{A}}^2 = 0$ implies $\Theta_{\mathcal{A}} \in \text{MC}$), and the five main theorems are projections of $\Theta_{\mathcal{A}}$ (§4).

3.4. HOMOTOPY CHIRAL ALGEBRAS

The chiral bracket is defined on affine opens; on overlaps, the Borchers identity holds only up to higher homotopies. Fix an affine cover $\mathfrak{U} = \{U_{\alpha}\}_{\alpha \in I}$ of the curve X . The Čech totalisation

$$A_{\infty}^{\text{ch}} := \check{C}^{\bullet}(\mathfrak{U}; \mathcal{A}) = \bigoplus_{p \geq 0} \prod_{\alpha_0 < \dots < \alpha_p} \mathcal{A}(U_{\alpha_0} \cap \dots \cap U_{\alpha_p})$$

carries a Ch_{∞} -algebra structure (Malikov–Schechtman): the chiral bracket, restricted to overlaps of affine opens, satisfies the Jacobi identity only up to a coherent system of higher homotopies, the *secondary Borchers operations*

$$F_n : \text{Lie}(n) \otimes \mathcal{Y}(n) \longrightarrow P_n(\{A_{\infty}^{\text{ch}}\}, A_{\infty}^{\text{ch}}), \quad n \geq 2,$$

encoding derived OPE data at all pole orders. The operation F_2 is the chiral bracket itself.

The Jacobiator homotopy F_3 arises from the moduli space $\overline{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$: its boundary $\partial\overline{\mathcal{M}}_{0,4}$ consists of three points, corresponding to three OPE compositions. The chain $C_1(\overline{\mathcal{M}}_{0,4}) \cong \mathbb{k}$ provides a 1-chain whose boundary is the alternating sum of the three vertices; F_3 is the chain homotopy witnessing their equality up to d .

Higher operations F_n are determined inductively by $C_*(\overline{\mathcal{M}}_{0,n+1})$ through the homotopy transfer theorem applied to the inclusion $H_*(\overline{\mathcal{M}}_{0,n+1}) \hookrightarrow C_*(\overline{\mathcal{M}}_{0,n+1})$. The cellular chain complex of $\overline{\mathcal{M}}_{0,n+1}$ is the chain complex of the associahedron K_n ; the transferred operations F_n are the A_∞ -corrections at degree n .

Different affine covers yield quasi-isomorphic Ch_∞ -algebras: the Čech-to-derived spectral sequence degenerates for $\mathcal{D}$ -modules on smooth curves. The strict chiral algebra $\mathcal{A}$ is the H^0 of this structure: the primitive local object is the homotopy chiral algebra; the strict algebra appears after rectification. The rectification theorem (Vallette): the homotopy category of Ch_∞ -algebras is equivalent to the homotopy category of strict chiral algebras, via the bar-cobar adjunction at the operadic level.

3.5. LOGARITHMIC FULTON–MACPHERSON SPACES

The identity $D^2 = 0$ at higher genus requires the boundary of the compactified configuration space to be normal-crossings: every codimension-two stratum must be a transverse intersection of exactly two codimension-one strata. The classical FM compactification does not achieve this in the presence of a divisor; the logarithmic extension (Mok) does.

For a simple-normal-crossing pair (X, D) with D a reduced divisor, the *logarithmic Fulton–MacPherson compactification* $\text{FM}_n(X | D)$ is a smooth variety with corners, compactifying the open configuration space $\text{Conf}_n(X \setminus D)$, whose boundary stratification is indexed by *rigid planted-forest types*.

A planted-forest type ρ consists of: a partition of $\{1, \dots, n\}$ into blocks; for each block, a rooted tree recording the collision hierarchy; a grid-depth assignment $w_v \in \mathbb{Z}_{\geq 0}$ to each vertex, recording the order of tangency with D . The ordinary FM compactification is the case $D = \emptyset$: all grid depths are zero.

The tropicalisation:

$$\text{Trop}(\text{FM}_n(\mathbb{C} | D)) = G_{\text{pf}},$$

the planted-forest poset with grafting as partial order. Grafting of planted forests corresponds to degeneration of the underlying curve; the poset structure is the face poset of the boundary stratification.

The chain complexes $C_{X|D}^{\log \text{FM}}(n) := C_\bullet(\text{FM}_n(X | D))$ carry cooperadic structure: the inclusion of boundary strata defines cocomposition maps. The *graphwise cocomposition* for a rigid stable graph Γ :

$$\Delta_\Gamma^{\log} := (v_\Gamma)_* \circ \text{Res}_{D_\Gamma^{\log}} : C_{\text{mod}}^{\log \text{FM}}(g, n) \longrightarrow \bigotimes_{v \in V(\Gamma)} C_{\text{mod}}^{\log \text{FM}}(g(v), I_v \sqcup H(v))[-|E_{\text{int}}(\Gamma)|],$$

where v_Γ is the Mok birational correspondence on the normalised boundary stratum and $\text{Res}_{D_\Gamma^{\log}}$ is the residue along the logarithmic boundary divisor.

3.6. THE CONVOLUTION L_∞ -ALGEBRA

A twisting morphism $\alpha : C \rightarrow \mathcal{P}$ between a cooperad and an operad satisfies $\partial\alpha + \alpha \star \alpha = 0$; it twists the composition product $C \circ_\alpha \mathcal{P}$ into a differential that squares to zero. The universal deformation machine built from α is the convolution sL_∞ -algebra $\text{hom}_\alpha(C, \mathcal{P})$ (Robert–Nicoud–Wierstra, after Vallette):

$$\text{hom}_\alpha(C, \mathcal{P}) = \prod_{n \geq 1} \text{Hom}_{\Sigma_n}(C(n), \mathcal{P}(n)).$$

The L_∞ brackets:

$$\ell_k(f_1, \dots, f_k)(x) = \sum \gamma_{\mathcal{P}}((\alpha \circ 1)(f_1 \otimes \dots \otimes f_k) \Delta_C^{(k)}(x)),$$

where $\Delta_C^{(k)}$ is the iterated cooperadic decomposition and $\gamma_{\mathcal{P}}$ is the operadic composition. The bracket ℓ_1 is the convolution differential; ℓ_2 is the Lie bracket of coderivations; higher brackets ℓ_k , $k \geq 3$, arise from the higher cooperadic decompositions and are nontrivial whenever C is not concentrated in a single degree.

The sL_∞ -algebra $\text{hom}_\alpha(C, \mathcal{P})$ extends to ∞ -morphisms in *either slot separately*: a quasi-isomorphism $C \xrightarrow{\sim} C'$ of cooperads induces an ∞ -quasi-isomorphism of convolution algebras. But *not both simultaneously*: the convolution is functorial in each slot, but does not assemble into a bifunctor on the ∞ -categorical level. This is a structural constraint, not a technical gap: the MC₃ categorical lift of bar-cobar duality must proceed one slot at a time.

The bar-cobar adjunction $B_\kappa \dashv \Omega_\kappa$ is a *Quillen equivalence* (Vallette): different Ch_∞ presentations yield quasi-isomorphic deformation theories.

3.7. ASSEMBLY

The *modular convolution L_∞ -algebra*:

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}} := \text{Conv}_\infty(C_{\text{mod}}^{\log \text{FM}}, \text{End}_{\text{Ch}_\infty}(A_\infty^{\text{ch}})).$$

The cooperadic input is the log-FM chain cooperad $C_{\text{mod}}^{\log \text{FM}}$: the modular cooperad of chain complexes on logarithmic FM spaces, with cocomposition given by the graphwise maps $\Delta_\Gamma^{\log}$. The operadic input is the Ch_∞ -endomorphism operad of the homotopy chiral algebra A_∞^{ch} .

The *strict chart*: the coderivation dg Lie algebra

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}, \log}(\mathfrak{U}) := \text{Conv}_{\text{str}}(C_{\text{mod}}^{\log \text{FM}}, \text{End}_{\text{Ch}_\infty}(A_\infty^{\text{ch}}))$$

is the *strict model*: classical Lie bracket, no higher L_∞ brackets, but the *same* Maurer–Cartan moduli. MC elements in the strict chart are in natural bijection with MC elements in the full convolution L_∞ -algebra. The strict chart suffices for constructing the universal MC element and computing shadows; the full L_∞ structure is needed for transfer, formality, and gauge equivalence.

3.8. THE SIX-COMPONENT DIFFERENTIAL

The total differential on the modular bar complex has six components, whose mutual cancellations constitute $D^2 = 0$:

$$D_{\text{mod}}^{\log} = \underbrace{d_{\check{C}}}_{\check{\text{Cech}}} + \underbrace{d_{\text{Ch}_\infty}}_{\text{transferred chiral}} + \underbrace{d_{\text{coll}}}_{\text{collision}} + \underbrace{d_{\text{sew}}}_{\text{separating}} + \underbrace{d_{\text{pf}}}_{\text{planted-forest}} + \underbrace{\hbar \Delta}_{\text{genus-raising}}.$$

The collision differential d_{coll} contracts an internal edge of a stable graph Γ by extracting the OPE residue at the corresponding codimension-one collision stratum. The separating differential d_{sew} implements the clutching morphism, gluing two lower-genus curves along a node. The genus-raising operator $\hbar \Delta$ self-glues a curve at two marked points, increasing b_1 by one. The planted-forest differential d_{pf} corrects for the genuinely logarithmic boundary strata, entering as a push–pull correspondence:

$$d_{\text{pf}} = \sum_{\rho \in \text{PF}^{\text{rig}}} \epsilon_\rho (\kappa_\rho)_* \text{pr}_\rho^* \otimes \mu_\rho,$$

where pr_ρ^* pulls back chains to the planted-forest stratum and $(\kappa_\rho)_*$ pushes forward along the Mok birational correspondence.

3.9. $D^2 = 0$

The nilpotence $(D_{\mathrm{mod}}^{\log})^2 = 0$ holds by three cancellation mechanisms:

- (i) *Vertex labels*: $d_{\check{C}}^2 = 0$, $d_{\mathrm{Ch}_\infty}^2 = 0$, and their anticommutator $\{d_{\check{C}}, d_{\mathrm{Ch}_\infty}\} = 0$ by the Ch_∞ -algebra axioms.
- (ii) *One-edge expansions*: the anticommutator of a vertex differential with an edge-contraction differential vanishes by the Leibniz rule for coderivations.
- (iii) *Codimension-two cancellation*: the sum of all products of two distinct edge-contraction operators vanishes. The codimension-two boundary of Mok's log-FM compactification is a normal-crossings divisor (Mok, Theorem 3.3.1), and each codimension-two face appears as the intersection of exactly two codimension-one faces. The two boundary contributions cancel with opposite orientations: $\partial^2 = 0$ for the boundary of a manifold with corners, lifted through the residue correspondence.

The third mechanism is the nontrivial one. The normal-crossings property of Mok's compactification is essential: it guarantees that every codimension-two intersection is transverse and contributes to exactly one cancelling pair.

Remark 0.0.2 (Homotopy types in three stages). The three levels of the convolution ladder mirror three levels of homotopy theory. *Over a point*: the bar construction $B(A) = (T^c(s^{-1}\bar{A}), d_B)$ determines the homotopy type of an associative algebra; formality ($m_k = 0$ for $k \geq 3$) corresponds to intrinsic formality; the Massey products are the obstructions. *Over a manifold*: the Sullivan minimal model $(\Lambda V, d)$ determines the rational homotopy type; Kähler manifolds are formal (Deligne–Griffiths–Morgan–Sullivan); the Heisenberg algebra is the vertex-algebraic analogue, with shadow obstruction tower terminating at degree 2. *Over a curve at all genera*: the A_∞ -products m_k become modular L_∞ -brackets $\ell_k^{(g)}$; formality becomes the Gaussian archetype ($\ell_k^{(g)} = 0$ for $k \geq 3$ at all g); the shadow obstruction tower is the modular Massey product tower, classifying the complexity of the modular homotopy type. The four classes G, L, C, M (Section 6) correspond to four levels of modular formality, determined by the vanishing pattern of the higher brackets $\ell_k^{(g)}$.

4. THE UNIVERSAL MAURER–CARTAN ELEMENT

The E_1 -modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{E_1}$ (the third rung of (5)) has a distinguished Maurer–Cartan element $\Theta_{\mathcal{A}}$ that requires no equation to solve: it is extracted from the total bar differential on $\bar{B}^{\mathrm{ord}}(\mathcal{A})$, which already squares to zero. The decomposition $D_{\mathcal{A}} = d_0 + \Theta_{\mathcal{A}}$ splits the ordered bar differential into its tree-level local part and the remainder; the MC equation $D\Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$ is a formal consequence of $D_{\mathcal{A}}^2 = 0$. Every invariant in this monograph is a Σ_n -coinvariant projection of $\Theta_{\mathcal{A}}$ into the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$.

4.1. Γ -AMPLITUDES AND TAYLOR COEFFICIENTS

Each stable graph produces a multilinear operation on the convolution algebra from three ingredients: chiral operations at vertices, propagators along edges, and geometric factors from the log-FM strata.

For a stable graph $\Gamma \in \text{Gr}^{\text{st}}$ with $|V(\Gamma)| = k$ vertices and elements $f_1, \dots, f_k \in \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ assigned to those vertices, the Γ -amplitude: let $\mu_{\Gamma}: \bigotimes_{v \in V(\Gamma)} A^{\otimes n(v)} \rightarrow A$ denote the graph composition; at each vertex v of genus $g(v)$ and valence $n(v)$, place the transferred chiral operation $m_{g(v), n(v)}^{(h)}$; along each internal edge, contract with the propagator $P_{\mathcal{A}} = \iota \circ \pi$ (homotopy retraction of the augmentation ideal to its cohomology). Write $\alpha_{\Gamma}^{\text{mod}}$ for the component of the modular twisting morphism on Γ , and $\Delta_{\Gamma}^{\text{log}}$ for the cooperadic cocomposition. The Γ -amplitude:

$$\ell_{\Gamma}(f_1, \dots, f_k) = \mu_{\Gamma} \circ (\alpha_{\Gamma}^{\text{mod}} \otimes f_1 \otimes \dots \otimes f_k) \circ \Delta_{\Gamma}^{\text{log}}.$$

This is a k -linear map $\ell_{\Gamma}: (\mathfrak{g}_{\mathcal{A}}^{\text{mod}})^{\otimes k} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ of cohomological degree $2 - 2g(\Gamma) - k$.

The modular L_{∞} structure on $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ has Taylor coefficients obtained by summing over all stable graphs of fixed type:

$$\ell_k^{(g)} = \sum_{\substack{\Gamma \in \text{Gr}^{\text{st}}, |V(\Gamma)|=k \\ b_1(\Gamma) + \sum_v g(v)=g}} \frac{1}{|\text{Aut}(\Gamma)|} \ell_{\Gamma}.$$

Here $\ell_k^{(g)}$ is a symmetric k -linear bracket of genus g . The full modular L_{∞} structure is the formal sum $\ell = \sum_{g \geq 0} \sum_{k \geq 1} \hbar^g \ell_k^{(g)} / k!$, and the homotopy Jacobi identity is encoded by $D^2 = 0$.

Explicit low-order brackets. At tree level ($g = 0$), the binary bracket is the Lie bracket on cohomology transferred through the homotopy retraction data (π, ι, h) :

$$\ell_2^{(0)}(\alpha, \beta) = \pi[m_2(\iota(\alpha), \iota(\beta))].$$

The ternary bracket sums over three binary trees (one for each channel s, t, u):

$$\begin{aligned} \ell_3^{(0)}(\alpha, \beta, \gamma) = \pi \Big(& m_2(h m_2(\iota\alpha, \iota\beta), \iota\gamma) + m_2(\iota\alpha, h m_2(\iota\beta, \iota\gamma)) \\ & + m_2(h m_2(\iota\alpha, \iota\gamma), \iota\beta) \Big). \end{aligned}$$

The homotopy h propagates the intermediate state through $P_{\mathcal{A}}$ before re-composing: the classical homological perturbation lemma in its L_{∞} incarnation.

The first genus-raised bracket is unary:

$$\ell_1^{(1)}(\alpha) = \text{tr}(P_{\mathcal{A}} \circ \alpha \circ \delta^{\text{ns}}) = \sum_i \langle e^i, \alpha(e_i) \rangle_{\text{Sh}},$$

where $\{e_i\}, \{e^i\}$ is a dual basis for the cyclic pairing on $H^*(\bar{\mathcal{A}})$ and δ^{ns} is the non-separating node operator. Geometrically, this is the BV operator: the unique genus-one graph with one vertex and one self-loop, the trace over the propagator contracting the two half-edges at the non-separating node of $\bar{\mathcal{M}}_{1,1}$.

4.2. THE BAR-INTRINSIC CONSTRUCTION

The total bar differential $D_{\mathcal{A}}: B^{\text{mod}}(\mathcal{A}) \rightarrow B^{\text{mod}}(\mathcal{A})$ acts on the modular bar complex. Decompose $D_{\mathcal{A}} = d_0 + \Theta_{\mathcal{A}}$, where $d_0 = d_{\text{int}} + [\tau, -]$ is the tree-level local part: the internal differential of $\mathcal{A}$ plus the commutator with the tautological twisting morphism τ . The *universal Maurer–Cartan element* is the remainder:

$$\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0 = \sum_{\Gamma \in \text{Gr}^{\text{st}}} \frac{W_{\Gamma}^{\log \text{FM}}}{|\text{Aut}(\Gamma)|} \otimes \Phi_{\Gamma}^{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}}).$$

Here $W_{\Gamma}^{\log \text{FM}} \in H^*(\overline{\mathcal{M}}_{g(\Gamma), n(\Gamma)}^{\log})$ is the log-FM weight (the fundamental class of the boundary stratum indexed by Γ), and $\Phi_{\Gamma}^{\mathcal{A}} \in \text{Hom}(\overline{\mathcal{A}}^{\otimes n(\Gamma)}, \mathbb{k})$ is the chiral amplitude on Γ .

The MC property is immediate: $D_{\mathcal{A}}^2 = 0$ by the geometric fact that $\overline{\mathcal{M}}_{g,n}^{\log}$ has normal-crossings boundary; $d_0^2 = 0$ by construction; expanding $(d_0 + \Theta_{\mathcal{A}})^2 = 0$ gives

$$d_0 \Theta_{\mathcal{A}} + \Theta_{\mathcal{A}} d_0 + \Theta_{\mathcal{A}}^2 = 0 \quad \Longleftrightarrow \quad [d_0, \Theta_{\mathcal{A}}] + \frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0.$$

No equation is solved; the MC property is a formal consequence of $\partial^2 = 0$ on the moduli space of curves. No simple-Lie restriction, no convergence hypothesis, no choice of basis.

On the E_1 side, the same decomposition applied to the ordered bar differential $D_{\mathcal{A}}^{E_1}$ on $T^c(s^{-1}\bar{\mathcal{A}})$ produces the ordered MC element $\Theta_{\mathcal{A}}^{E_1} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}, E_1})$. The coinvariant projection sends $\Theta_{\mathcal{A}}^{E_1} \mapsto \Theta_{\mathcal{A}}$: the modular MC element is the Σ_n -averaged shadow of the ordered one. At degree 2, the projection recovers $\kappa(\mathcal{A})$.

4.3. UNIVERSAL MODULAR TWISTING MORPHISM

Twisting morphisms classify compatible deformations of the bar complex across all genera simultaneously. The MC space of the modular convolution L_{∞} -algebra is the space of modular twisting morphisms:

$$\text{MC}_{\bullet}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}}) \simeq \text{Tw}_{\alpha^{\text{mod}}}(\mathcal{C}_{\text{mod}}^{\log \text{FM}}, \text{End}_{\text{Ch}_{\infty}}(A_{\infty}^{\text{ch}})).$$

Under this identification, $\Theta_{\mathcal{A}}$ is the *universal modular twisting morphism*: a twisting morphism $\alpha: \mathcal{C} \rightarrow \mathcal{P}$ determines a twisted composition product $\mathcal{C} \circ_{\alpha} \mathcal{P}$ whose differential squares to zero if and only if α satisfies the MC equation. $\Theta_{\mathcal{A}}$ is the unique twisting morphism that simultaneously twists the modular bar complex and intertwines with the log-FM boundary structure.

The principal-bundle analogy is exact. The modular bar bundle $B_{\text{mod}}^{\log}(\mathcal{A}) \rightarrow \overline{\mathcal{M}}_{g,n}$ is the principal bundle; $\Theta_{\mathcal{A}}$ is the connection; the MC equation is the flatness condition; the shadow tower (Section 6) is the Chern–Weil theory. The structure group is the pro-unipotent MC gauge group $\exp(\mathfrak{g}_{\mathcal{A}}^{\text{mod}, 0})$.

4.4. TRIDEGREE AND THE DEPTH FILTRATION

Each coefficient of $\Theta_{\mathcal{A}}$ carries a natural tridegree

$$(g, n, d) = (\text{loop genus}, \text{external degree}, \text{log boundary depth}),$$

where $d(\rho) = \#E_{\text{sep}}(\Gamma_{\rho}) + \#E_{\text{ns}}(\Gamma_{\rho}) + \text{depth}_{\text{pf}}(\Gamma_{\rho})$ is the codimension of the log-FM stratum indexed by the degeneration pattern ρ .

The depth filtration $F^d \mathfrak{g}_{\mathcal{A}}^{\text{mod}} = \bigoplus_{d' \geq d} (\mathfrak{g}_{\mathcal{A}}^{\text{mod}})_{*,*,d'}$ makes the convolution algebra complete:

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}} = \varprojlim_d \mathfrak{g}_{\mathcal{A}}^{\text{mod}} / F^d \mathfrak{g}_{\mathcal{A}}^{\text{mod}}.$$

The inverse limit $\Theta_{\mathcal{A}} = \varprojlim_r \Theta_{\mathcal{A}}^{\leq r}$ converges unconditionally: no analytic input, no growth estimate, no restriction on $\mathcal{A}$. The convergence is purely algebraic, guaranteed by the completeness of the depth filtration.

At fixed (g, n) , only finitely many stable graph types Γ contribute (by stability: $2g(\Gamma) - 2 + n(\Gamma) > 0$ forces a finite graph set). The depth filtration refines this: at depth d , the stratum has codimension d in $\overline{\mathcal{M}}_{g,n}^{\text{log}}$, and the amplitude $\Phi_{\Gamma}^{\mathcal{A}}$ has propagator insertions bounded by d .

4.5. THE WEIGHT FILTRATION

Decompose the MC equation by internal-edge count:

$$\Theta_{\mathcal{A}} = \sum_{r \geq 1} \Theta_{\mathcal{A}}^{[r]}, \quad \Theta_{\mathcal{A}}^{[r]} = \sum_{\substack{\Gamma \in \text{Gr}^{\text{st}} \\ |E_{\text{int}}(\Gamma)|=r}} \frac{W_{\Gamma}^{\text{log FM}}}{|\text{Aut}(\Gamma)|} \otimes \Phi_{\Gamma}^{\mathcal{A}}.$$

The MC equation decomposes by weight into an inductive tower:

$$\begin{aligned} \text{Weight 1: } & [D_{\text{loc}}, \Theta_{\mathcal{A}}^{[1]}] = 0, \\ \text{Weight 2: } & [D_{\text{loc}}, \Theta_{\mathcal{A}}^{[2]}] + \frac{1}{2} [\Theta_{\mathcal{A}}^{[1]}, \Theta_{\mathcal{A}}^{[1]}] = 0, \\ \text{Weight } N: & [D_{\text{loc}}, \Theta_{\mathcal{A}}^{[N]}] + \frac{1}{2} \sum_{\substack{i+j=N \\ i,j \geq 1}} [\Theta_{\mathcal{A}}^{[i]}, \Theta_{\mathcal{A}}^{[j]}] = 0. \end{aligned}$$

At each stage, $[D_{\text{loc}}, \Theta_{\mathcal{A}}^{[N]}]$ is determined by the quadratic error from previous stages. The obstruction to extending from weight $N-1$ to weight N lies in $H^2(\mathfrak{g}_{\mathcal{A}}^{\text{mod}}/F^{N+1}, D_{\text{loc}})$. The bar-intrinsic construction solves all stages simultaneously.

Weight 1: boundary divisors. The weight-one component $\Theta_{\mathcal{A}}^{[1]}$ lives on boundary divisors of moduli spaces. In degree $(0, 4)$: the three boundary points of $\overline{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$:

$$\Theta_{\mathcal{A}}^{[1]}|_{(0,4)} = [\delta_s] \otimes \Phi_s + [\delta_t] \otimes \Phi_t + [\delta_u] \otimes \Phi_u.$$

The weight-one MC equation at $(0, 4)$ reads $\Phi_s + \Phi_t + \Phi_u = F_3$, the Malikov–Schechtman Jacobiator homotopy: the Jacobiator is a boundary in the bar complex.

In degree $(1, 1)$: the single boundary divisor $\delta_{\text{irr}} \subset \overline{\mathcal{M}}_{1,1}$ gives

$$\Theta_{\mathcal{A}}^{[1]}|_{(1,1)} = [\delta_{\text{irr}}] \otimes \Delta,$$

where $\Delta = \sum_i e_i \otimes e^i$ is the Casimir element of the cyclic pairing.

In degree $(0, 5)$: the weight-one component restricts to the ten boundary divisors of $\overline{\mathcal{M}}_{0,5}$ (the Petersen graph), and the MC equation recovers the pentagon identity. The entire A_{∞} hierarchy is the tree-level, genus-zero projection of a single MC element.

4.6. THE ALL-GENUS RECURSION

Project the MC equation to fixed genus g and degree n :

$$d\Theta_{\mathcal{A}}^{(g,n)} + \frac{1}{2} \sum_{\substack{g_1+g_2=g \\ n_1+n_2=n+2}} \ell_2^{(0)}(\Theta_{\mathcal{A}}^{(g_1,n_1)}, \Theta_{\mathcal{A}}^{(g_2,n_2)}) + \Delta_{\text{ns}} \Theta_{\mathcal{A}}^{(g-1,n+2)} + \sum_{k \geq 3} \frac{1}{k!} \ell_k^{(\text{tree})}(\Theta_{\mathcal{A}}, \dots, \Theta_{\mathcal{A}})^{(g,n)} = 0.$$

The four terms: *internal differential* at fixed (g, n) ; *separating clutching* over splittings $g_1 + g_2 = g$, $n_1 + n_2 = n + 2$; *non-separating BV operator* lowering degree by 2 and raising genus by 1; *planted-forest corrections* from higher brackets $\ell_k^{(\text{tree})}$ for $k \geq 3$.

This recursion determines $\Theta_{\mathcal{A}}^{(g,n)}$ inductively from lower (g', n') in lexicographic order. The base cases are $\Theta_{\mathcal{A}}^{(0,3)}$ (the chiral bracket) and $\Theta_{\mathcal{A}}^{(0,4)}$ (the Jacobiator data from weight 1). The recursion terminates at each (g, n) : only finitely many stable graphs contribute.

The clutching identity. On each rigid boundary stratum ρ of the log-FM compactification, the restriction of $\Theta_{\mathcal{A}}$ factors as a tensor product over vertices of the dual graph:

$$\Theta_{\mathcal{A}}|_{\rho} = (\kappa_{\rho})_* \left(\bigotimes_{v \in V(S_{\rho})} \Theta_{\mathcal{A},v} \right).$$

The amplitude on the degenerate curve equals the product of amplitudes on the irreducible components, sewn by propagators along the nodes: the MC-level incarnation of the sewing axiom.

Every invariant in this preface is a projection of $\Theta_{\mathcal{A}}$: the curvature $\kappa(\mathcal{A})$, the spectral discriminant $\Delta_{\mathcal{A}}$, the shadow metric Q_L , the sewing amplitudes, the $\hat{A}$ -genus, the Fredholm determinant, and the quartic contact invariant Q^{contact} . The five main theorems are five projections of $\Theta_{\mathcal{A}}$.

Projection of $\Theta_{\mathcal{A}}$	Invariant	Section
Scalar ($r = 2$, genus tower)	$\kappa(\mathcal{A})$, F_g , $\hat{A}$ -genus	§2
Binary genus-0 residue	classical r -matrix, Yangian seed	§7
Binary Verdier dual	complementarity $Q_g \oplus Q_g^!$	§2
Bar-cobar counit	inversion $\Omega(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$	§1
Chiral Hochschild	$\text{ChirHoch}^*(\mathcal{A})$, deformation ring	§9
Spectral discriminant	$\Delta_{\mathcal{A}}(x)$, genus-1 Hessian	§5
Cubic shadow ($r = 3$)	gauge-trivial obstruction	§6
Quartic resonance ($r = 4$)	$\mathfrak{Q}^{\text{contact}}$, clutching law	§6
MC tautological descent	shadow CohFT, $R^*(\overline{\mathcal{M}}_{g,n})$	§5
Swiss-cheese colour decomposition	α_T , six projections (Vol. II)	Vol. II

The existence of $\Theta_{\mathcal{A}}$ is encoded by the bar-cobar adjunction: Theorem A constructs the arena in which $\Theta_{\mathcal{A}}$ lives. Bar-cobar inversion proves that $\Theta_{\mathcal{A}}$ is a complete invariant: Theorem B recovers $\mathcal{A}$ from $\Theta_{\mathcal{A}}$. Verdier duality decomposes $\Theta_{\mathcal{A}}$ into complementary halves: Theorem C splits the genus tower into Lagrangian summands. The leading coefficient of $\Theta_{\mathcal{A}}$ is the modular characteristic: Theorem D extracts the scalar

$\kappa(\mathcal{A})$ with $\hat{A}$ -genus generating function. The coefficient ring of $\Theta_{\mathcal{A}}$ is the chiral chiral Hochschild complex: Theorem H identifies the deformation ring.

The finite-order projections form an obstruction tower $\Theta_{\mathcal{A}}^{\leq 2} \rightarrow \Theta_{\mathcal{A}}^{\leq 3} \rightarrow \Theta_{\mathcal{A}}^{\leq 4} \rightarrow \cdots$ whose generating function is algebraic of degree 2: on each primary line L , the weighted shadow generating function $H(t) = t^2 \sqrt{Q_L(t)}$ for a quadratic polynomial Q_L determined by three seed invariants (κ, α, S_4) . The cubic seed α is level-independent for each family: $\alpha = 2$ on the Virasoro primary line, so $a_3 = 3\alpha = 6$ is independent of the central charge. This c -independence is the shadow-tower incarnation of the subleading soft graviton theorem: the cubic shadow coefficient is universal because the Cachazo–Strominger subleading soft factor is determined by angular momentum alone. The inverse limit $\Theta_{\mathcal{A}} = \varprojlim_r \Theta_{\mathcal{A}}^{\leq r}$ is proved to exist and to be automatically Maurer–Cartan because $D_{\mathcal{A}}^2 = 0$.

Corollary (MC replaces the sum over topologies). On the Koszul locus, the tree-level complex carries a contracting homotopy (from the PBW degeneration), so the genus- g component $\Theta^{(g)}$ is determined by induction from $\Theta^{(0)}$. No free parameters appear at any genus; distinct choices of strong deformation retract yield gauge-equivalent MC elements. The genus expansion is computed algebraically from the genus-0 chiral bracket by the clutching recursion, not approximated perturbatively. The Maloney–Witten problem (negative Fourier coefficients in the Poincaré series) does not arise: the MC equation determines each F_g uniquely by algebraic induction, without summing over bulk topologies at fixed genus.

5. THE MODULAR TANGENT COMPLEX AND CHERN–WEIL THEORY

Section 4 constructed a universal Maurer–Cartan element $\Theta_{\mathcal{A}}$ from which every invariant projects. The question is what those projections are: what characteristic classes does the modular bar bundle carry?

5.1. THREE CHARACTERISTIC PROJECTIONS

Three successive Σ_n -coinvariant projections of $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{E_1})$ into the modular convolution algebra capture progressively finer structure.

The scalar curvature $\kappa(\mathcal{A})$. The degree-two, genus-zero trace:

$$\kappa(\mathcal{A}) = \text{tr}(\Theta_{\mathcal{A}})_{2,0} \in \mathbb{k}$$

This is the first Chern class of the modular bar bundle: $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$ for uniform-weight algebras at all genera, and unconditionally at genus 1. On the E_1 side, $\kappa(\mathcal{A})$ is the Σ_2 -coinvariant of the R -matrix $r(z)$; averaging collapses the z -dependent profile to a number. Explicit values:

Algebra $\mathcal{A}$	$\kappa(\mathcal{A})$	$\kappa(\mathcal{A}^\dagger)$	Sum rule
Heisenberg $\mathcal{H}_k$	k	$-k$	0
Affine $\widehat{\mathfrak{g}}_k$	$\frac{(k + h^\vee) \dim \mathfrak{g}}{2h^\vee}$	$-\frac{(k + h^\vee) \dim \mathfrak{g}}{2h^\vee}$	0
Virasoro Vir_c	$c/2$	$(26 - c)/2$	13
$\beta\gamma$ system	1	-1	0
Lattice V_Λ	$\text{rank}(\Lambda)$	$-\text{rank}(\Lambda)$	0
$\mathcal{W}_N(\widehat{\mathfrak{sl}}_N)$	$c \cdot (H_N - 1)$	$c' \cdot (H_N - 1)$	$K_N \cdot (H_N - 1)$
Free fermion ψ	$1/4$	$-1/4$	0
Bershadsky–Polyakov $\mathcal{B}^k$	$c(k)/6$	$c(-k-6)/6$	$98/3$

Here $H_N = \sum_{j=1}^N 1/j$ is the N -th harmonic number, c' denotes the central charge of the Koszul dual $\mathcal{W}$ -algebra, and $K_N = c + c' = 2(N-1)(2N^2+2N+1)$ is the level-independent Koszul conductor. The complementarity sum $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) = 0$ holds for Kac–Moody and free-field algebras (the sum rule is family-specific, not universal). For $\mathcal{W}$ -algebras the sum is a nonzero constant: 13 for Virasoro, $250/3$ for $\mathcal{W}_3$, $98/3$ for Bershadsky–Polyakov.

The spectral discriminant $\Delta_{\mathcal{A}}(x)$. The Koszul dual Hilbert series $h_{\mathcal{A}^\dagger}(q) = \sum_{n \geq 0} \dim H^n(\overline{B}(\mathcal{A})) q^n$ satisfies a holonomic recurrence of finite order d . The transfer matrix $T_{\text{br}, \mathcal{A}}$ of this recurrence acts on a finite-rank perfect complex $V_{\mathcal{A}}^{\text{br}}$, and

$$\Delta_{\mathcal{A}}(x) := \text{sdet}(1 - x T_{\text{br}, \mathcal{A}}).$$

The eigenvalues of T_{br} are the reciprocal branch points of the analytic continuation of $h_{\mathcal{A}^\dagger}$. Three structural properties: (i) self-duality $\Delta_{\mathcal{A}^\dagger} = \Delta_{\mathcal{A}}$; (ii) functoriality under exact factorization; (iii) spectral radius $\rho(T_{\text{br}}) = \dim \mathfrak{g}$ for affine algebras at generic level.

For $\widehat{\mathfrak{sl}}_3$: a degree-3 recurrence with eigenvalues $8, (3 \pm \sqrt{13})/2$, giving $\Delta_{\widehat{\mathfrak{sl}}_3}(x) = (1-8x)(1-3x-x^2)$. The dominant eigenvalue $8 = \dim(\mathfrak{sl}_3)$ controls exponential growth. For Heisenberg: $\Delta_{\mathcal{H}}(x) = 1$.

In the Chern–Weil dictionary, the logarithmic derivative $\text{ch}_r(\mathcal{A}) = \frac{1}{r} \text{tr}(T_{\text{br}}^r)$ recovers the power-sum symmetric functions of the eigenvalues: $\Delta_{\mathcal{A}}$ plays the role of the Chern character.

The quartic shadow $\mathfrak{R}_4^{\text{mod}}(\mathcal{A})$. The first *nonlinear* characteristic class: the first invariant not recoverable from κ and $\Delta_{\mathcal{A}}$. Its genus-zero, four-point specialisation is the quartic contact invariant $Q^{\text{contact}}(\mathcal{A})$:

$$Q_{\text{Vir}}^{\text{contact}} = \frac{10}{c(5c+22)}, \quad Q_{\mathcal{H}}^{\text{contact}} = 0, \quad Q_{\beta\gamma}^{\text{contact}} \neq 0.$$

5.2. THE CHERN–WEIL DICTIONARY

The modular bar bundle $B_{\text{mod}}^{\log}(\mathcal{A}) \rightarrow \overline{\mathcal{M}}_{g,n}$ is a principal bundle for the gauge group of the convolution algebra; $\Theta_{\mathcal{A}}$ is its flat connection; the shadow tower is its Chern–Weil theory.

Classical Chern–Weil	Modular factorization
Principal G -bundle $P \rightarrow M$	Modular bar bundle $B_{\text{mod}}^{\log}(\mathcal{A}) \rightarrow \overline{\mathcal{M}}_{g,n}$
Connection 1-form $\omega \in \Omega^1(P, \mathfrak{g})$	MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$
Curvature $\Omega = d\omega + \frac{1}{2}[\omega, \omega]$	MC equation $D\Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$
Flatness $\Omega = 0$	Automatic (bar-intrinsic)
First Chern class c_1	Scalar curvature $\kappa(\mathcal{A})$ (abelian: $\text{av}(r(z))$)
Chern character	Spectral discriminant $\Delta_{\mathcal{A}}(t) = \text{sdet}(1 - tT_{\text{br}})$
Higher Chern classes	Shadows Sh_r for $r \geq 4$
Weil homomorphism	Shadow algebra $\mathcal{A}^{\text{sh}} = H_{\bullet}(\text{Def}_{\text{cyc}}^{\text{mod}})$
Lagrangian splitting $T^*G = \mathfrak{g} \oplus \mathfrak{g}^*$	Complementarity $\mathcal{Q}_g(\mathcal{A}) \oplus \mathcal{Q}_g(\mathcal{A}^!)$
Holonomy	Factorisation homology $\int_{\Sigma} \mathcal{A}$
Gauge equivalence	MC gauge in $\text{MC}_{\bullet}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$
Transgression	Shadow obstruction tower (§6)

5.3. THE SHADOW COHFT

The three projections $(\kappa, \Delta_{\mathcal{A}}, \mathfrak{R}_4^{\text{mod}})$ capture the shadow data at degrees 2, 2, and 4. The question is whether the full collection of projections at all (g, n) assembles into a cohomological field theory.

The MC equation $D\Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$ holds in the modular convolution algebra. Projecting to genus g and degree n produces a class $\tau_{g,n}(\mathcal{A}) \in R^*(\overline{\mathcal{M}}_{g,n+1})$ in the tautological ring, and the MC equation at (g, n) descends to a tautological relation.

The mechanism: the bracket $[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]$ decomposes according to the boundary of $\overline{\mathcal{M}}_{g,n}$. Separating degenerations (a curve splitting into two components joined by a node) produce $[\Theta, \Theta]_{\text{sep}}$; nonseparating degenerations (a curve acquiring a self-node, genus rising by 1) produce $\hbar \Delta(\Theta)_{\text{nsep}}$. Each boundary stratum contributes one term; the MC equation forces their sum to be D -exact. This is a tautological relation.

Two instances fix the pattern. At genus 0, degree 3: the separating term produces the WDVV equation (three channels of the four-point function on $\overline{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$, one for each boundary point). At degree 2, genus $g \geq 2$: the nonseparating loop contraction produces the Mumford λ -class clutching relation, with the coefficient $\kappa(\mathcal{A})$ from the bar curvature. The complementarity propagator $P_{\mathcal{A}}$ is the Givental R -matrix; when a flat unit exists, Teleman reconstruction recovers the full collection $\{\tau_{g,n}\}$ at all (g, n) from genus-0 data. The recursion that computes $\tau_{g,n}$ from $\tau_{g-1,n+2}$ and $\tau_{g_1,n_1} \otimes \tau_{g_2,n_2}$ is Eynard–Orantin topological recursion: the MC equation applied to the shadow obstruction tower.

The classes $\tau_{g,n}(\mathcal{A})$ assemble into a cohomological field theory (Theorem 13.22.224): $D^2 = 0$ on the log-FM compactification implies equivariance and splitting. The flat identity holds conditionally, when the vacuum $|0\rangle$ lies in the generating space V . For class-M algebras, the infinite shadow tower generates tautological classes at every genus; at genus 2–3, the relations for Vir_c at generic c produce elements of the Pixton ideal in $R^*(\overline{\mathcal{M}}_{g,n})$: Pixton’s relations arise as shadows of the Virasoro MC equation (Theorem 13.22.277).

5.4. THE GENUS SPECTRAL SEQUENCE

The shadow CohFT organises the invariants by (g, n) . A separate question is how to compute them: is there a spectral sequence that stratifies the MC element by genus?

The genus filtration $F^g \mathfrak{g}_{\mathcal{A}}^{\text{mod}} := \bigoplus_{g' \geq g} (\mathfrak{g}_{\mathcal{A}}^{\text{mod}})_{g', **}$ yields a convergent spectral sequence distinct from the PBW spectral sequence. PBW computes *what* bar cohomology is (within a fixed genus); the genus spectral sequence determines *whether* the MC element extends across genera.

The E_1 page isolates tree-level ($p = 0$), one-loop ($p = 1$), and genus-two shell ($p = 2$) data. The differential $d_1: E_1^{0, *} \rightarrow E_1^{1, *}$ is the genus-one obstruction Ob_1 : the obstruction to lifting a tree-level MC element to one-loop. Convergence follows from completeness of the depth filtration and pronilpotence of the weight filtration: the $\varprojlim^1$ term vanishes by Mittag-Leffler.

For Heisenberg, the spectral sequence degenerates at E_1 . For Virasoro, $d_1 \neq 0$ and nontrivial differentials persist at every page.

5.5. HOMOTOPY INVARIANCE

The characteristic classes of §5.1 and the CohFT of §5.3 are defined from the MC element $\Theta_{\mathcal{A}}$, which depends on the choice of homotopy retraction data. The question is whether the output is independent of the input.

The shadow algebra $\mathcal{A}^{\text{sh}} = H_{\bullet}(\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A}))$ is a homotopy invariant. For any ∞_{α} -quasi-isomorphism $f: \mathcal{A} \xrightarrow{\sim} \mathcal{A}'$, the induced map on MC ∞ -groupoids is a weak homotopy equivalence. The scalar $\kappa(\mathcal{A})$, the spectral discriminant $\Delta_{\mathcal{A}}(t)$, and the full shadow obstruction tower are quasi-isomorphism invariants. The MC element $\Theta_{\mathcal{A}}$ is invariant up to gauge: $f_*(\Theta_{\mathcal{A}})$ and $\Theta_{\mathcal{A}'}$ are gauge-equivalent.

The assignment $\mathcal{A} \mapsto (\mathfrak{g}_{\mathcal{A}}^{\text{mod}}, \Theta_{\mathcal{A}})$ is a functor from chiral algebras (with ∞_{α} -quasi-isomorphisms inverted) to MC moduli problems: modular Koszul duality is a derived invariant.

6. THE SHADOW OBSTRUCTION TOWER

The E_1 MC element $\Theta_{\mathcal{A}}$ carries an obstruction at each degree; under Σ_n -coinvariance, each obstruction collapses to a scalar shadow $S_r(\mathcal{A})$. The resulting tower $\{S_r(\mathcal{A})\}_{r \geq 2}$ is the shadow obstruction tower: the Σ_n -invariant trace of the E_1 data, and the only part visible on the symmetric bar.

6.1. THE EXTENSION TOWER

Define the total weight $w(g, r, d) := 2g - 2 + r + d$. The total weight filtration $F^N \mathfrak{g}_{\mathcal{A}}^{\text{amb}}$ is exhaustive, separated, and complete. The *modular extension tower*:

$$\mathcal{E}_{\mathcal{A}}(N) := \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{amb}}/F^{N+1}), \quad N \geq 1.$$

The bar-intrinsic construction provides a compatible point $\Theta_{\mathcal{A}} \in \varprojlim_N \mathcal{E}_{\mathcal{A}}(N)$ unconditionally.

6.2. OBSTRUCTION CLASSES

The truncated MC elements $\Theta_{\mathcal{A}}^{\leq 2}, \Theta_{\mathcal{A}}^{\leq 3}, \Theta_{\mathcal{A}}^{\leq 4}, \dots$ satisfy the MC equation up to a remainder:

$$D\Theta_{\mathcal{A}}^{\leq r} + \frac{1}{2}[\Theta_{\mathcal{A}}^{\leq r}, \Theta_{\mathcal{A}}^{\leq r}] = -o_{r+1}(\mathcal{A}), \quad o_{r+1}(\mathcal{A}) \in Z^2\left(\frac{F^{r+1}\mathfrak{g}_{\mathcal{A}}^{\text{amb}}}{F^{r+2}\mathfrak{g}_{\mathcal{A}}^{\text{amb}}}, d_{\leq r}\right).$$

The bar-intrinsic construction guarantees that $[o_{r+1}] = 0$; the shadow tower records the gauge choices.

6.3. CUBIC GAUGE TRIVIALITY AND THE CANONICAL QUARTIC

When $H^1(F^3\mathfrak{g}/F^4\mathfrak{g}, d_2) = 0$, the cubic MC term $\Theta_{\mathcal{A}}^{[3]}$ is gauge-trivial. After the gauge transformation, the quartic class $[\mathfrak{Q}(\mathcal{A})] \in H^2(F^4\mathfrak{g}/F^5\mathfrak{g}, d_2)$ is *canonical*: independent of retraction data, cubic gauge, and orbit representative. This is the first characteristic class not polynomial in κ . The quartic contact invariant:

$$Q_{\text{Vir}}^{\text{contact}} = \frac{10}{c(5c + 22)}.$$

The denominator $c(5c + 22)$ has physical meaning: $c = 0$ is the logarithmic threshold; $c = -22/5$ is the minimal model accumulation point $\mathcal{M}(2, 5)$.

The clutching law for the quartic class follows from Mok's log FM degeneration formula: on a degeneration $C \rightsquigarrow C_0$, the quartic restricts with a planted-forest correction that is genuinely logarithmic, with no classical counterpart.

6.4. THE ALGEBRAICITY THEOREM

On each primary deformation line L , the shadow generating function $H(t) = \sum_{r \geq 2} r S_r t^r$ satisfies

$$H(t)^2 = t^4 Q_L(t), \quad Q_L(t) = 4\kappa^2 + 12\kappa\alpha t + (9\alpha^2 + 16\kappa S_4)t^2,$$

a quadratic polynomial in three genus-0 invariants (κ, α, S_4) (Theorem 13.22.137). The infinite tower is algebraic of degree 2: $H(t) = t^2 \sqrt{Q_L(t)}$. The discriminant $\Delta = 8\kappa S_4$ governs the depth classification. The algebraic depth takes exactly four values: $d_{\text{alg}} \in \{0, 1, 2, \infty\}$ (Proposition 13.22.140). No standard family realises $d_{\text{alg}} = 3$; the gap is forced by the degree-2 algebraicity of the generating function, which constrains the branching pattern of $\sqrt{Q_L}$ to at most quadratic order.

6.5. THE FOUR DEPTH CLASSES

The *shadow depth* $r_{\text{max}}(\mathcal{A})$ is the largest degree at which the shadow obstruction tower carries a nontrivial invariant, or ∞ if the tower never terminates. Three numerical invariants must be distinguished:

- $p_{\text{max}}(\mathcal{A})$: generator OPE pole order,
- $k_{\text{max}}(\mathcal{A}) = p_{\text{max}} - 1$: collision depth (logarithmic absorption),
- $r_{\text{max}}(\mathcal{A})$: shadow depth (independent of p_{max}).

The standard landscape partitions into four classes by the cubic shadow $\mathfrak{C}$ (the degree-3 obstruction) and the quartic contact invariant $\mathfrak{Q}$ (the canonical degree-4 class of §6.3). The single-line dichotomy (Theorem 13.22.160): $\Delta = 0$ forces tower termination; $\Delta \neq 0$ forces an infinite tower.

Class	r_{max}	$\mathfrak{C}$	$\mathfrak{Q}$	Examples
Gaussian (G)	2	0	0	Heisenberg $\mathcal{H}_k$, free fermion
Lie/tree (L)	3	$\neq 0$	0	Affine $\widehat{\mathfrak{g}}_k$ (all types)
Contact (C)	4	0	$\neq 0$	$\beta\gamma, bc$ ghosts
Mixed (M)	∞	$\neq 0$	$\neq 0$	Virasoro, $\mathcal{W}_N$

Shadow depth is not Koszulness. All four classes contain chirally Koszul algebras. Shadow depth classifies *complexity* of Koszul algebras. A chirally Koszul algebra is Swiss-cheese formal if and only if it belongs to class **G** (Proposition 11.1.60): the vanishing of all Swiss-cheese higher operations m_k^{SC} for $k \geq 3$ at every genus characterises exactly the Gaussian archetype.

Quintic forcing: the Poisson bracket $o^{(5)} = \{\mathfrak{C}, \mathfrak{Q}\}_H$ forces an infinite sequence of higher obstructions whenever both $\mathfrak{C} \neq 0$ and $\mathfrak{Q} \neq 0$. Finite termination requires $\mathfrak{C} = 0$ or $\mathfrak{Q} = 0$; when both are nonzero, the potential is transcendental.

6.6. THE OPERADIC COMPLEXITY THEOREM

The shadow depth equals the A_∞ -depth equals the L_∞ -formality level:

$$r_{\max}(\mathcal{A}) = A_\infty\text{-depth}(\mathcal{A}) = L_\infty\text{-formality level}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}}).$$

The shadow obstruction tower *is* the L_∞ -formality obstruction tower at all degrees (Theorem 13.22.108). The four classes G/L/C/M are the four formality types: **G** = free, **L** = Lie, **C** = quadratic non-Lie, **M** = genuinely nonlinear.

The Swiss-cheese formality condition ($m_k^{\text{SC}} = 0$ for all $k \geq 3$) selects exactly class **G**: a chiral algebra in the standard landscape is SC-formal if and only if it is Heisenberg (Proposition 11.1.60). The forward direction is immediate (abelian bracket kills all nested operations); the converse uses nondegeneracy of the invariant form to force the bracket to vanish from $S_3 = 0$.

The algebraic depth $d_{\text{alg}}(\mathcal{A})$ exhibits a gap: $d_{\text{alg}} \in \{0, 1, 2, \infty\}$, and no finite value $d_{\text{alg}} \geq 3$ is realized on the standard landscape (Proposition 13.22.140). The four permitted values correspond bijectively to the four classes: **G** ($d_{\text{alg}} = 0$), **L** ($d_{\text{alg}} = 1$), **C** ($d_{\text{alg}} = 2$), **M** ($d_{\text{alg}} = \infty$). The mechanism is the Riccati algebraicity theorem: when the discriminant $\Delta = 0$, the generating function is polynomial and the tower terminates at degree ≤ 3 ; when $\Delta \neq 0$, all Taylor coefficients are nonzero and the tower is infinite. No intermediate regime exists.

6.7. GENUS-TWO SHELLS

Genus 2 is the first level where all three boundary strata interact. The MC component decomposes as:

$$\Theta_{\mathcal{A}}^{(2)} = \underbrace{\Theta_{\text{loop}^2}^{(2)}}_{\text{iterated BV}} + \underbrace{\Theta_{\text{sep}^2}^{(2)}}_{\text{clutching} \times \text{BV}} + \underbrace{\Theta_{\text{pf}}^{(2)}}_{\text{planted-forest}}.$$

The family-by-family activation:

	$\Theta_{\text{loop}^2}^{(2)}$	$\Theta_{\text{sep}^2}^{(2)}$	$\Theta_{\text{pf}}^{(2)}$	Class
Heisenberg $\mathcal{H}_k$	✓	none	none	G
Affine $\widehat{\mathfrak{g}}_k$	✓	✓	none	L
$\beta\gamma$ system	✓	none	none	C
Virasoro Vir_c	✓	✓	✓	M

The planted-forest shell is the diagnostic: its presence forces infinite shadow depth.

Shadow growth rate. For class M algebras, the Taylor coefficients S_r of $\sqrt{Q_L}$ grow as $S_r \sim A \cdot \rho(\mathcal{A})^r \cdot r^{-5/2} \cos(r\theta + \varphi)$, where $\rho(\mathcal{A}) = \sqrt{9\alpha^2 + 2\Delta} / (2|\kappa|)$ is a continuous invariant. Self-dual Virasoro ($c = 13$) has $\rho \approx 0.467$.

The growth rate is not merely asymptotic: the consecutive ratio S_{2k+2}/S_{2k} of Virasoro shadow coefficients satisfies an explicit Riccati recurrence (Proposition 13.22.191). The recurrence coefficients are determined by the quadratic $Q_L^{\text{Vir}}(t) = c^2 + 12c t + (180c+872)/(5c+22) t^2$; its two conjugate roots $\lambda_{\pm}$ give the growth rate $\rho = |\lambda_{\pm}|$ and a cosine oscillation with period $2\pi/\arg(\lambda_+)$. The initial values are $a_0 = c$ and $a_1 = 6$: the third-degree shadow coefficient $a_1 = 3\alpha = 6$ is independent of c , matching the soft-graviton amplitude in the semiclassical limit.

6.8. THE GENUS LOOP OPERATOR

The *genus loop operator* $\Lambda_P: \text{Sym}^r(\bar{\mathcal{A}}^{\vee})_{\text{cyc}} \rightarrow \text{Sym}^{r-2}(\bar{\mathcal{A}}^{\vee})_{\text{cyc}}$ contracts two legs of a degree- r cyclic cochain with the propagator: it raises genus by 1 and lowers degree by 2, the shadow-level incarnation of the BV operator Δ_{ns} .

On the Virasoro primary line, with propagator $P = 2/c$ and quartic contact invariant $Q_{\text{Vir}}^{\text{contact}} = 10/[c(5c+22)]$:

$$\Lambda_P\left(\frac{10}{c(5c+22)} \cdot x^4\right) = \binom{4}{2} \cdot \frac{2}{c} \cdot \frac{10}{c(5c+22)} \cdot x^2 = \frac{120}{c^2(5c+22)} x^2.$$

This is the genus-one Hessian correction $\delta_{H,\text{Vir}}^{(1)}$: a nonlinear genus-1 invariant visible only because the shadow tower has depth ≥ 4 . The loop ratio $\rho_{\text{Vir}}^{(1)} = 240/[c^3(5c+22)]$ is not determined by $\kappa = c/2$; it detects the quartic structure through its genus-one projection.

6.9. INDEPENDENT SUM FACTORISATION

For a direct sum $L = L_1 \oplus L_2$ with vanishing mixed OPE, all shadow invariants separate: κ is additive, T^{br} is a direct sum, Δ is multiplicative, R_4^{mod} is additive. The full MC element factorises:

$$\Theta_{L_1 \oplus L_2} = \Theta_{L_1} \hat{\otimes} 1 + 1 \hat{\otimes} \Theta_{L_2}.$$

Every algebra in the standard landscape is either primitive (Heisenberg, Virasoro, $\beta\gamma$) or built from primitive pieces by direct sum plus extension. Drinfeld–Sokolov reduction is the shadow-depth escalator: it sends class L (finite towers) to class M (infinite towers). The nonlinearity of the Dirac bracket on the Slodowy slice creates the quartic and all higher shadows.

7. THE STANDARD LANDSCAPE

The machine of Sections 1–6 accepts any chiral algebra as input and produces a shadow obstruction tower as output. What it sees depends on a single structural datum: the collision residue $r_{\mathcal{A}}(z)$, and specifically on which poles of the OPE survive logarithmic absorption. The simplest possible input has already been computed.

FROM HEISENBERG TO KAC–MOODY: THE FIRST-ORDER POLE

The Heisenberg algebra $\mathcal{H}_k$ (Section 1) is the base case. One field, one OPE pole ($\alpha(z)\alpha(w) \sim k/(z-w)^2$), one shadow invariant ($\kappa = k$), one depth class (G). The R -matrix $r(z) = k/z$ is scalar; averaging loses nothing; the shadow tower terminates at degree 2; and every higher-genus invariant is determined by the single number k . The bar complex sees everything at tensor degree 2. The machine works, the output is computable, and the result is too simple to detect any noncommutativity.

The deficiency is precise: no first-order OPE pole means no Lie bracket, no matrix collision residue, no quantum group. The R -matrix k/z carries no tensor structure; it cannot distinguish $\mathfrak{g} = \mathfrak{sl}_2$ from $\mathfrak{g} = E_8$. Every datum that makes representation theory nontrivial is absent. The first nontrivial example requires a first-order pole.

The affine Kac–Moody algebra $\widehat{\mathfrak{g}}_k$ provides exactly that. The OPE $J^a(z)J^b(w) \sim f^{ab}_c J^c(w)/(z-w) + k\kappa^{ab}/(z-w)^2$ has both poles present: the first-order pole carries the Lie bracket $J^a_{(0)}J^b = f^{ab}_c J^c$, and the second-order pole carries the invariant inner product. The R -matrix $r(z) = k\Omega/z$ is matrix-valued: the Casimir tensor $\Omega = \sum_a J^a \otimes J_a$ encodes the full Lie-algebraic structure that was invisible in the Heisenberg scalar. The level prefix k ensures $r(z)$ vanishes in the abelian limit; the averaging map collapses $k\Omega$ to a scalar, and the Sugawara shift by the dual Coxeter number $h^\vee$ yields $\kappa(\widehat{\mathfrak{g}}_k) = \dim(\mathfrak{g})(k+h^\vee)/(2h^\vee)$.

The matrix structure builds the Yangian $Y(\mathfrak{g})$: the quantum group that deforms $U(\mathfrak{g}[z])$ arises from the ordered bar’s deconcatenation coproduct evaluated on $r(z) = k\Omega/z$. The cubic shadow is the Lie bracket itself, and the Jacobi identity kills all higher obstructions: $S_r(\widehat{\mathfrak{g}}_k) = 0$ for $r \geq 4$. The shadow tower terminates at degree 3: class L. The characteristic number $r_{\max} = 3$ coincides with the number of terms in the Jacobi identity, the number of boundary divisors of $\overline{\mathcal{M}}_{0,4}$, and the number of channels in the classical Yang–Baxter equation.

At the critical level $k = -h^\vee$: $\kappa = 0$, the bar complex is flat, and the chiral algebra acquires a large centre $\mathfrak{z}(\widehat{\mathfrak{g}}_{-h^\vee}) \cong \text{Fun}(\text{Op}_{L\mathfrak{g}})$, the Feigin–Frenkel centre of opers on the formal disc. The Feigin–Frenkel involution $k \leftrightarrow -k - 2h^\vee$ is Koszul duality on configuration spaces: it interchanges $\mathcal{A}$ and $\mathcal{A}^!$ while preserving the bar-cobar adjunction.

FROM KAC–MOODY TO VIRASORO: THE SELF-COUPLING

Shadow depth 3 means the cubic obstruction (the Lie bracket) is the last invariant the tower sees. The Jacobi identity, by killing the quartic shadow Ω , forces the discriminant $\Delta = 8\kappa S_4$ to vanish, and the algebraicity theorem of Section 6 forces the tower to terminate. For an infinite tower, the quartic must survive: some mechanism must generate new obstructions at every degree, feeding structure into the tower that the Jacobi identity cannot kill.

The mechanism is self-coupling. The stress tensor T satisfies $T_{(1)}T = 2T$: it appears in its own OPE as a singular term. No Kac–Moody current has this property ($J^a_{(1)}J^b$ is a scalar, not a current); the self-coupling is a genuinely Virasoro phenomenon. It drives the quartic and all higher shadows: the nested compositions $T \rightarrow T_{(1)}T = 2T \rightarrow T_{(1)}(T_{(1)}T) = 4T \rightarrow \dots$ produce nontrivial amplitudes at every degree, and the Jacobi identity has no purchase because the Virasoro algebra is not a current algebra.

The R -matrix: $r(z) = (c/2)/z^3 + 2T/z$. The quartic OPE pole drops by one under logarithmic absorption (pole order $4 \rightarrow 3$); the double pole produces the scalar T -channel at z^{-1} . The modular characteristic $\kappa(\text{Vir}_c) = c/2$. The quartic contact invariant $Q_{\text{Vir}}^{\text{contact}} = 10/[c(5c+22)]$, with denominator $c(5c+22)$ recording the logarithmic threshold $c = 0$ and the minimal-model accumulation point $c = -22/5 = c(\mathcal{M}(2, 5))$. Quintic forcing: $o^{(5)} = 480/[c^2(5c+22)] \neq 0$; the Poisson bracket $\{\mathfrak{C}, \Omega\}_H \neq 0$ generates the infinite tail. Shadow depth infinite: class M.

Koszul dual: Vir_{26-c} . At $c = 26$ the dual is uncurved ($\kappa(\text{Vir}_0) = 0$); at $c = 0$ the algebra itself is uncurved; at $c = 13$ the algebra is self-dual ($\kappa + \kappa^! = 13$, the unique fixed point). The critical dimension $c = 26$ is the statement that the Koszul dual's curvature vanishes, not that the algebra's does: the string ghost system bc at $c_{\text{ghost}} = -26$ is the complementarity partner.

MULTI-WEIGHT: THE CROSS-CHANNEL CORRECTION

The Virasoro algebra has a single generator of weight 2. The scalar formula $\text{obs}_g = \kappa \cdot \lambda_g$ holds at all genera because the propagator weight 1 couples to a single Hodge bundle $\mathbb{E}_1$. The question forced by the depth classification is whether the scalar formula survives the passage to multiple generators at different conformal weights.

The $\mathcal{W}_3$ -algebra answers negatively. Two generators T (weight 2) and W (weight 3); the WW OPE contains the composite quasi-primary $\Lambda = :TT: - \frac{3}{10}\partial^2 T$ with structure constant $16/(22+5c)$. The modular characteristic $\kappa(\mathcal{W}_3) = 5c/6$ (from $\kappa(\mathcal{W}_N) = c(H_N-1)$ at $N = 3$: $H_3 = 1+1/2+1/3 = 11/6$, so $H_3-1 = 5/6$). The spectral discriminant $\Delta_{\mathcal{W}_3}(x) = (1-\frac{c}{2}x)(1-\frac{c}{3}x)$: one eigenvalue for each generator weight. At genus 2, a cross-channel correction from mixed-propagator boundary graphs appears:

$$F_2(\mathcal{W}_3) = \underbrace{\frac{7c}{6912}}_{\kappa \cdot \lambda_2^{\text{FP}}} + \underbrace{\frac{c+204}{16c}}_{\delta F_2^{\text{cross}}},$$

resolving Open Problem 13.13.19 negatively: the scalar formula fails for multi-weight algebras at genus ≥ 2 . The cross-channel correction δF_2 is a one-loop graph with mixed-weight propagators; it vanishes identically for any algebra whose generators share a single conformal weight (the uniform-weight locus), but is nonzero whenever the conformal weights are distinct. Multi-weight is a genuine genus-2 phenomenon: it is invisible at genus 1 (Theorem D is unconditional there) and requires the interaction of at least two distinct boundary strata.

DRINFELD–SOKOLOV REDUCTION AND THE DEPTH ESCALATOR

The $\mathcal{W}_3$ -algebra at central charge $c(k) = 2(1 - 12/(k+3))$ is the Drinfeld–Sokolov reduction of $\widehat{\mathfrak{sl}}_{3k}$ by the principal nilpotent. The reduction $\text{DS}: \widehat{\mathfrak{sl}}_{3k} \rightarrow \mathcal{W}_{3c(k)}$ extends to a morphism of holographic data: the r -matrix transfers with pole-order shift, the A_∞ products transfer nontrivially through the homological perturbation lemma, but the coproduct is annihilated by a ghost-number obstruction. Shadow depth jumps from 3 (Kac–Moody, class L) to ∞ ($\mathcal{W}_3$, class M): the Dirac bracket on the arc space $J_\infty(S_f)$ of the Slodowy slice creates the quartic and all higher shadows. Drinfeld–Sokolov reduction is the depth escalator: all gravitational dynamics resides in the r -matrix.

The observation that DS reduction escalates depth forces the next question: what happens at non-principal nilpotent orbits? The Bershadsky–Polyakov algebra $\mathcal{B}^k$ is the reduction of $\widehat{\mathfrak{sl}}_{3k}$ by the *subregular* nilpotent $f_{(2,1)}$. Generators: a current J (weight 1), a pair $G^\pm$ (weight $3/2$), and the stress tensor T (weight 2); three distinct conformal weights. Central charge $c(k) = 2 - 24(k+1)^2/(k+3)$; modular characteristic $\kappa(\mathcal{B}^k) = c(k)/6$, with anomaly ratio $\varrho_{\text{BP}} = 1/6$. The Koszul dual is $\mathcal{B}^{-k-6}$, the same algebra at dual level, with Koszul conductor $K_{\text{BP}} = c(k) + c(-k-6) = 196$ and complementarity sum $\kappa(\mathcal{B}^k) + \kappa(\mathcal{B}^{-k-6}) = 98/3$. The self-dual level is $k = -3$; the multi-channel r -matrix has poles at z^{-3} and z^{-1} in the T -channel, driving the infinite shadow tower. Class M. The Bershadsky–Polyakov algebra is the simplest non-principal $\mathcal{W}$ -algebra, and its Koszul conductor $K = 196$ is the largest among rank-2 $\mathcal{W}$ -algebras: the subregular orbit's distance from the principal orbit is visible in the complementarity sum.

THE CONTACT ANOMALY: $\beta\gamma$ AND CLASS C

Every algebra examined so far has a second-order OPE pole. The $\beta\gamma$ system at weights $(\lambda, 1-\lambda)$ has only a simple pole: $\beta(z)\gamma(w) \sim 1/(z-w)$. No double pole means no metric, no Sugawara construction, no Casimir tensor. The collision residue $r(z)$ is a constant propagator P , pole order zero after d log-absorption. $\kappa(\beta\gamma) = 1$.

The shadow tower terminates at degree 4. The cubic shadow vanishes (weight mismatch on the diagonal sector prevents a cubic invariant from assembling), but the quartic contact invariant is nonzero, killed only by rank-one abelian rigidity at degree 5. The numerical witness: $p_{\max} = 1, k_{\max} = 0, r_{\max} = 4$. Shadow depth is independent of OPE pole order: the $\beta\gamma$ system has the lowest pole order in the landscape ($p = 1$) and the second-highest finite shadow depth ($r = 4$). This is the archetypal class C algebra: contact structure from a non-metric source.

The Koszul dual is the bc -ghost system, with $c_{bc}(\lambda) = 1 - 3(2\lambda-1)^2$ and $c_{\beta\gamma}(\lambda) = 2(6\lambda^2 - 6\lambda + 1)$ satisfying $c_{\beta\gamma} + c_{bc} = 0$ (verified at $\lambda = 2$: $c_{\beta\gamma} = 26, c_{bc} = -26$; string ghost cancellation). The complementarity sum $\kappa(\beta\gamma) + \kappa(bc) = 0$: the free-field sum rule.

The cross-channel correction vanishes at all genera: $\delta F_g^{\text{cross}}(\beta\gamma_\lambda) = 0$ for all $g \geq 1$ and all λ (Remark 13.22.237). Two independent mechanisms force this: the single shadow channel (one-dimensional cyclic cohomology) leaves no room for mixed-channel assignments, and the off-diagonal Zamolodchikov metric kills the propagator cross-term. The scalar formula $F_g = \kappa \cdot \lambda_g^{\text{FP}}$ is exact at all genera without the uniform-weight hypothesis: a special case of the general principle that free-field algebras have vanishing cross-channel correction at all genera (Proposition 13.22.226).

LATTICE, FREE FERMION, AND THE GAUSSIAN SHADOW

Two further families complete the Gaussian class.

Lattice vertex algebras $V_\Lambda = \mathcal{H}_k^{\otimes N} \otimes \mathbb{C}[\Lambda]_\varepsilon$ for an even lattice Λ of rank N inherit class G from their Heisenberg factor: $\kappa(V_\Lambda) = \text{rank}(\Lambda)$, independent of the lattice's inner products and cocycle ε . The curvature sees only the free-boson contribution; the braiding sees the group ring $\mathbb{C}[\Lambda]_\varepsilon$. Shadow depth 2. For self-dual lattices the partition function is an honest modular form; at rank 24 the bar-complex invariants (h, rank) discriminate between all 24 Niemeier lattice VOAs. The arithmetic of the lattice theta function is invisible to the shadow obstruction tower but visible to the genus-2 amplitude, a Siegel modular form for $\text{Sp}(4, \mathbb{Z})$.

The free fermion ψ (weight 1/2, OPE $\psi(z)\psi(w) \sim 1/(z-w)$) is the Clifford entry: $\kappa = 1/4, r(z) = 1/(2z)$, shadow depth 2, class G. The odd parity of the generator gives the simple OPE pole; the bar complex is quadratic for the same reason as Heisenberg.

THE YANGIAN: ORDERED BAR AS INPUT

The Yangian $Y(\mathfrak{g})$ inverts the relationship between input and output. The ordered bar of $\widehat{\mathfrak{g}}_k$ produces the R -matrix $r(z) = k \Omega/z$ as the genus-0 binary collision residue of $\Theta_{\mathcal{A}}^{E_1}$; the Yangian is the quantum group *built from* this R -matrix, fed back as a coalgebra structure on the ordered bar complex. At degree 3 on $\overline{\mathcal{M}}_{0,4}$, the three boundary divisors evaluate the Casimir tensor through the Arnold relation, producing the three terms of the classical Yang–Baxter equation: the CYBE is $d_B^2 = 0$ at degree 3, genus 0. The RTT relations $R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}$ encode the MC equation at all degrees. The KZ connection $\nabla_{\text{KZ}} = d - \hbar \sum_{i < j} \Omega_{ij} d \log(z_i - z_j)$ is identified with the genus-0 shadow connection $\text{Sh}_{0,n}(\Theta_{\widehat{\mathfrak{g}}_k})$: flatness of the shadow connection is the MC equation projected to genus 0 and degree n .

CENSUS

The escalation from Heisenberg through Kac–Moody through Virasoro produces the four depth classes; the lateral variations ($\mathcal{W}_N$, Bershadsky–Polyakov, $\beta\gamma$, lattice, free fermion) fill out the landscape. The consolidation:

Family	Generators	κ	$r(z)$	$r_{\max}$	Class	$\kappa + \kappa^\dagger$	Special
$\mathcal{H}_k$	α (wt 1)	k	k/z	2	G	0	Gaussian archetype
ψ (free ferm.)	ψ (wt $\frac{1}{2}$)	1/4	$1/(2z)$	2	G	0	Clifford
$\widehat{\mathfrak{g}}_k$	J^a (wt 1)	$\frac{(k+h^\vee) \dim \mathfrak{g}}{2h^\vee}$	$k \Omega/z$	3	L	0	FF center at $k=-h^\vee$
Vir_c	T (wt 2)	$c/2$	$\frac{c/2}{z^3} + \frac{2T}{z}$	∞	M	13	self-dual at $c=13$
$\mathcal{W}_{3c}$	T, W (wt 2, 3)	$5c/6$	matrix-valued	∞	M	250/3	cross-channel at $g \geq 2$
$\mathcal{W}_k^{\text{BP}}$	$J, G^\pm, T$ (wt 1, $\frac{3}{2}, 2$)	$c/6$	multi-channel	∞	M	98/3	$K_{\text{BP}}=196$; critical $k=-3$
$\beta\gamma$	β, γ (wt $\lambda, 1-\lambda$)	1	P (constant)	4	C	0	contact termination
V_Λ	$\alpha^i, e^{\lambda \cdot \phi}$	$\text{rank}(\Lambda)$	Heisenberg	2	G	0	arithmetic from q
$Y(\mathfrak{g})$	line operators	$\text{av}(r(z))$	$k \Omega/z$	3	L	n/a	YBE = degree-3 MC

Three features of this table demand attention.

First, the depth column is not monotone in OPE pole order: $\beta\gamma$ has $p_{\max} = 1$ (single simple pole) yet $r_{\max} = 4$, while Kac–Moody has $p_{\max} = 2$ yet $r_{\max} = 3$. Shadow depth is a property of the shadow obstruction tower, not of the OPE; the $\beta\gamma$ system is the witness that separates the two.

Second, the complementarity sum $\kappa + \kappa^\dagger$ is family-specific, not universal: 0 for Kac–Moody and free-field algebras, 13 for Virasoro, 250/3 for $\mathcal{W}_3$, 98/3 for Bershadsky–Polyakov. The sum is a duality invariant of each family, not a universal constant of the theory.

Third, the third column (the R -matrix) is the ordered bar’s contribution; the second column (κ) is its Σ_2 -coinvariant shadow. Every entry in the table demonstrates the same compression: averaging erases the matrix structure, discards the Casimir tensor, and collapses the z -dependent profile to a single number. Every family with $r_{\max} \geq 3$ has an ordered bar that carries strictly more information than the symmetric bar; every theorem in this monograph is a projection of that information through the averaging map.

8. ARITHMETIC OF THE SHADOW OBSTRUCTION TOWER

The landscape of Section 7 produces a table of rational numbers: κ values, complementarity sums, shadow coefficients, spectral discriminants. Each is a rational function of the central charge, and the rationality is structural: the bar complex extracts its coefficients by residues from rational OPE data. The question is whether these rational numbers carry arithmetic meaning beyond their algebraic origin.

8.1. THE SHADOW EISENSTEIN THEOREM

At genus 1, the bar complex over a family of elliptic curves $C_\tau \rightarrow \mathfrak{H}$ produces the amplitude $\text{Sh}_2^{(1)}(\mathcal{A}, \tau) = \kappa(\mathcal{A}) \cdot E_2^*(\tau)$, where $E_2^*(\tau) = 1 - 24 \sum_{n \geq 1} \sigma_1(n) q^n$ is the quasi-modular Eisenstein series (not holomorphic: the non-holomorphic completion absorbs the anomaly from $d \log E(z, w)$). The Fourier coefficients

$\sigma_1(n)$ are divisor sums, and their Dirichlet series is a product of Riemann zeta functions:

$$D_2(\mathcal{A}, s) := \sum_{n \geq 1} \sigma_1(n) n^{-s} = \zeta(s) \zeta(s-1).$$

The genus-1 amplitude Dirichlet series is therefore $-24\kappa(\mathcal{A}) \cdot \zeta(s) \cdot \zeta(s-1)$: an Eisenstein L -function, with the modular characteristic as the sole chiral-algebra input.

The shadow L -function $L_{\mathcal{A}}^{\text{sh}}(s) := \sum_{r \geq 2} S_r r^{-s}$ is a different object: it extracts the degree- r constant terms of the shadow tower, not Fourier coefficients of a genus-1 amplitude. The distinction is decisive. The shadow L -function is *not* in the Selberg class: S_3, S_4 violate the Ramanujan bound for class-M algebras, and $L_{\mathcal{A}}^{\text{sh}}$ has no Euler product (the shadow coefficients are not multiplicative). The Riemann zeta function enters through the genus-1 Eisenstein channel; the shadow tower itself carries arithmetic that is not automorphic.

The bar complex produces automorphic arithmetic at genus 1; the shadow tower does not. The distinction forces the question: what is the shadow tower's arithmetic, if not automorphic? The answer comes from physics.

8.2. THE POLYAKOV CORRESPONDENCE

Polyakov's programme computes the string partition function $Z = \sum_g g_s^{2g-2} \int_{\mathcal{M}_g} [\det'_{\zeta} \Delta]^{-d/2} d\mu_{\text{WP}}$ by gauge-fixing the worldsheet metric to conformal gauge, paying the price of a conformal anomaly $\langle T^a_a \rangle = (c/12) R$ and a ghost system with $c_{\text{ghost}} = -26$. Every element of this programme has a bar-cobar counterpart:

- The conformal anomaly is $\kappa(\mathcal{A})$: both measure the obstruction to metric-independence at genus 1, one by functional-integral trace, the other by bar curvature.
- The critical dimension $c = 26$ is the vanishing of the dual curvature: $\kappa(\text{Vir}_{26-c}) = (26-c)/2 = 0$ when $c = 26$.
- The ghost system bc with $c_{\text{ghost}} = -26$ is the Koszul dual $\mathcal{A}^!$ in the BRST pairing: the ghost partition function is the complementarity partner.
- The functional determinant $\det'_{\zeta} \Delta$ on the Laplacian is the Fredholm determinant $\det(1-K)$ on the Bergman sewing kernel: the Heisenberg one-particle reduction replaces spectral-zeta regularisation with a convergent Fredholm series.
- The genus expansion $F_g = \kappa(\mathcal{A}) \cdot \lambda_g^{\text{FP}}$ (uniform weight) is the bar-complex computation of Polyakov's path integral at genus g , with the Faber–Pandharipande λ -class replacing Weil–Petersson integration.

The four shadow depth classes are the four levels of departure from the Gaussian path integral: class G is free (Z is a determinant), class L introduces Lie structure (Chern–Simons), class C introduces contact terms ($\beta\gamma$ ghosts), and class M is full quantum gravity (Polyakov's original problem).

At genus 1 the correspondence is controlled by κ alone. At genus $g \geq 2$ the graph amplitudes are Siegel modular forms, and the Hecke algebra acts.

8.3. THE ARITHMETIC PACKET

The graph amplitudes at genus $g \geq 2$ are modular forms for $\text{Sp}(2g, \mathbb{Z})$. The Hecke operators T_p act on the space of activated amplitudes $M_{\mathcal{A}} = \bigoplus_{\chi} M_{\chi}$, decomposed into generalised eigenspaces. The *arithmetic*

packet connection

$$\nabla_{\mathcal{A}}^{\text{arith}} := d - \bigoplus_{\chi} \frac{\Lambda'_{\chi}(s)}{\Lambda_{\chi}(s)} (\text{id}_{M_{\chi}} + N_{\chi}) ds$$

is a flat meromorphic connection on $M_{\mathcal{A}} \otimes \mathcal{O}_{\mathbb{C}}$ over the spectral s -line. The structural principle: the singular divisor depends only on the semisimple part $M_{\mathcal{A}}^{\text{ss}}$ (the arithmetic is semisimple); the nilpotent terms N_{χ} produce unipotent monodromy (the homotopy defect is unipotent). The Miura splitting for $\mathcal{W}_N$: the Heisenberg core is arithmetically inert; all obstructions beyond Heisenberg lie in a finite defect sector.

For lattice vertex algebras V_{Λ} of rank r , the *constrained Epstein zeta function* $\varepsilon_s^c(V_{\Lambda}) := \sum'_{\ell \in \Lambda^{\text{bar}}} \|\ell\|^{-2s}$ restricts the Epstein series to the bar sublattice $\Lambda^{\text{bar}} \subset \Lambda$. At genus 2, the shadow tautological class computes a central L -value via the Böcherer conjecture (Furusawa–Morimoto): the MC element connects the bar complex to the arithmetic of Siegel modular forms.

9. THE KOSZULNESS PROGRAMME

The landscape of Section 7 separates the standard families into four depth classes: G, L, C, M. The separation is by shadow complexity. One invariant cuts across all four classes: every standard family is chirally Koszul. Heisenberg (class G) is Koszul. Affine Kac–Moody (class L) is Koszul. The $\beta\gamma$ system (class C) is Koszul. The Virasoro algebra (class M), with its infinite shadow tower and its irremovable quintic forcing, is Koszul. What property do they share that the depth classification does not see?

The answer is concentration: the bar cohomology $H^*(\overline{B}^{\text{ord}}(\mathcal{A}))$ sits in bar degree 1. When this holds, the bar-cobar spectral sequence collapses, the E_1 R -matrix is determined by its leading term, and every Σ_n -coinvariant projection (the five theorems) achieves maximal rigidity. This concentration property admits twelve equivalent formulations, each detecting it from a different mathematical vantage point.

9.1. SCALAR SATURATION

For a one-parameter algebraic family $\mathcal{A}_k$ with rational OPE coefficients, the universal MC element satisfies: at degree 2, $\Theta_{\mathcal{A}_k}$ is determined by the single scalar $\kappa(\mathcal{A}_k)$. The proof: Whitehead reduction (vanishing of $H^2(\mathfrak{g}; \text{Sym}^q V)$ for reductive $\mathfrak{g}$ at generic level) plus algebraic semicontinuity (the exceptional locus is Zariski-closed, hence empty by the free-field base point). Scope: every family in the standard landscape at all non-critical levels, including admissible.

For multi-weight algebras at genus $g \geq 2$, scalar saturation holds at degree 2 but the full MC element receives cross-channel corrections: the stronger identity $\Theta_{\mathcal{A}}^{\text{min}} = \kappa \cdot \eta \otimes \Lambda$ is proved on the uniform-weight lane and fails for multi-weight families (Theorem 13.22.225).

Scalar saturation establishes that κ controls the MC element at degree 2. The question is what controls it at *all* degrees. The answer is the Koszul condition: bar cohomology concentrated in degree 1.

9.2. THE KOSZULNESS META-THEOREM

The Koszul condition admits twelve formulations. Ten are unconditionally equivalent; one (Lagrangian criterion) is conditional on perfectness; one ($\mathcal{D}$ -module purity) is one-directional. For $\mathcal{A}$ positive-energy and finitely strongly generated:

- (i) $\mathcal{A}$ is chirally Koszul.
- (ii) PBW spectral sequence collapses at E_2 for every g .

- (iii) Minimal A_∞ -model of $H^\bullet(\overline{B}(\mathcal{A}))$ is formal: $m_n = 0$ for $n \geq 3$.
- (iv) $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.
- (v) Bar-cobar counit $\Omega(\overline{B}(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism.
- (vi) Barr–Beck–Lurie comparison is an equivalence.
- (vii) $\int_X \mathcal{A}$ concentrated in degree 0 for every smooth proper X .
- (viii) $\text{ChirHoch}^*(\mathcal{A})$ vanishes outside $\{0, 1, 2\}$.
- (ix) Kac–Shapovalov determinant $\det G_h \neq 0$ in bar-relevant range.
- (x) Restriction to every FM boundary stratum acyclic outside degree 0.

Under perfectness/nondegeneracy:

- (xi) Lagrangian criterion: $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^\dagger}$ are transverse Lagrangians in the (-1) -shifted symplectic deformation space.

And (xii) $\Rightarrow$ (x), where:

- (xii) $\mathcal{D}$ -module purity: each $\overline{B}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module. Converse open.

The shadow-formality identification (Theorem 13.22.108) identifies the shadow obstruction tower with the L_∞ -formality obstruction tower of the modular convolution algebra at all degrees. The distinction is precise: item (iii) (A_∞ -formality of bar cohomology) is a genus-0 condition equivalent to Koszulness; shadow depth $r_{\max}$ measures the all-genera termination behavior of $\Theta_{\mathcal{A}}$, a transverse invariant invisible to genus 0. All four shadow-depth classes G/L/C/M contain chirally Koszul algebras: the Virasoro algebra has $r_{\max} = \infty$ yet satisfies item (iii). Shadow depth classifies complexity *within* the Koszul world, not Koszulness itself.

The proof circuit. The core equivalence chain is (i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (iii) $\Leftrightarrow$ (v) $\Leftrightarrow$ (viii), proved by PBW concentration $\rightarrow$ bar-cobar inversion $\rightarrow$ chiral Hochschild polynomial growth $\rightarrow$ Koszul-complex acyclicity, with the A_∞ -formality branch via HPL transfer and Keller classicality. From this core: (iv) by Ext spectral sequence, (vi) by conservativity + log-FM totalization, (vii) by the identification $\overline{B} = \int_X$, (ix) by non-degeneracy forcing PBW injectivity, (x) by stratum-by-stratum PBW concentration. The Lagrangian criterion (xi) uses PTVV derived intersection theory on the perfectness hypothesis. The $\mathcal{D}$ -module purity implication (xii) $\Rightarrow$ (x) uses weight filtration on the bar complex; the converse would require concentration to force purity.

Scope and extensions. The core theorem applies to all universal enveloping vertex algebras $V_k(\mathfrak{g})$ at every level, including critical and admissible: PBW universality is a sufficient condition for chiral Koszulness, and every freely strongly generated vertex algebra satisfies it. The Koszul condition propagates downward through factorization descent, making genus-0 curve independence an automatic consequence.

For simple quotients $L_k(\mathfrak{g})$ at admissible levels, the Koszulness status is rank-dependent: $L_k(\mathfrak{sl}_2)$ is Koszul at all admissible levels, but at $\text{rk}(\mathfrak{g}) \geq 2$ with denominator $q \geq 3$, Koszulness may fail via a bar obstruction from the abelian Cartan subalgebra. The failure mechanism is specific: the bar complex of the Cartan factor develops cohomology in degree 2 from the interaction of positive and negative root spaces through the Cartan.

Item (viii) of the meta-theorem asserts that chiral Hochschild cohomology vanishes outside degrees $\{0, 1, 2\}$. The question is what sits in those three degrees.

9.3. CHIRAL HOCHSCHILD COHOMOLOGY (THEOREM H)

The chiral Hochschild complex $\text{ChirHoch}^\bullet(\mathcal{A})$ is the derived endomorphism algebra of the identity functor on $\mathcal{A}$ -modules. For principal $\mathcal{W}$ -algebras at generic level:

$$\text{ChirHoch}^n(\mathcal{W}^k(\mathfrak{g})) = 0 \quad \text{for } n > 2, \quad P(t) = 1 + t^2.$$

The deformation class in $\text{ChirHoch}^2 = \mathbb{C}$ is the level deformation $k \mapsto k + \epsilon$. This is a *finite* invariant (concentrated in three degrees, not a polynomial ring); contrast with the infinite-dimensional continuous Lie algebra cohomology $H_{\text{GF}}^*(\text{Diff}(S^1))$, which is an unrelated invariant. On the Koszul locus, $\text{ChirHoch}^\bullet(\mathcal{A})$ carries a formal E_2 -algebra structure.

The Hilbert polynomial $P_{\mathcal{A}}(t) = \sum_n \dim \text{ChirHoch}^n(\mathcal{A}) \cdot t^n$ is an explicit invariant of each family. For affine Kac–Moody at generic level, $\text{ChirHoch}^1(V_k(\mathfrak{g})) \cong \mathfrak{g}$ as $\mathfrak{g}$ -modules (Proposition A.II.25): the classical Lie algebra is recovered from the first chiral Hochschild group. The full Hilbert polynomial is $P_{V_k(\mathfrak{g})}(t) = 1 + (\dim \mathfrak{g})t + t^2$; for Heisenberg, $P_{\mathcal{H}_k}(t) = 1 + t + t^2$; for Virasoro, $P_{\text{Vir}_c}(t) = 1 + t^2$.

The Hilbert polynomials measure the algebra’s deformation ring. The question is what *generates* the bar differential that produces these cohomology groups: the answer, at genus 0, is the BRST operator.

9.4. BV/BRST IDENTIFICATION

At genus 0, the bar differential is the BRST differential: $(d_{\overline{B}})_{g=0} = Q_{\text{BRST}}$. Bar-cobar inversion (Theorem B) states that BRST cohomology, processed through the cobar, reconstructs the algebra. At genus 1, the identification acquires curvature: $d_{\text{fib}}^2 = \kappa \cdot \omega_1$ is the one-loop anomaly. At genus $g \geq 2$, the chain-level identification is resolved for classes G, L, and C; for class M (Virasoro, $\mathcal{W}_N$), a coderived reformulation is needed (Conjecture K.7.1).

The BV/BRST identification connects the bar complex to physics; the shadow algebra connects it to geometry. The shadows κ , $\mathfrak{C}$, $\mathfrak{Q}$ are not merely invariants of $\mathcal{A}$; they are generators of a Lie algebra whose bracket is the convolution Lie bracket of Section 3.

9.5. THE SHADOW ALGEBRA

The shadow algebra $\mathcal{A}^{\text{sh}} := H_\bullet(\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A}))$ is a bigraded Lie algebra (graded bracket $[\kappa, C] \in \mathcal{A}_{r_1+r_2-2}^{\text{sh}}$; antisymmetric, Jacobi; the named shadows are projections of MC elements, not multiplicative generators). The projections:

$$\kappa(\mathcal{A}) = \mathcal{A}_{2,0}^{\text{sh}}, \quad \mathfrak{C}(\mathcal{A}) = \mathcal{A}_{3,0}^{\text{sh}}, \quad \mathfrak{Q}(\mathcal{A}) = \mathcal{A}_{4,0}^{\text{sh}}, \quad \text{Sh}_r(\mathcal{A}) = \mathcal{A}_{r,0}^{\text{sh}}.$$

The all-degree master equation, read in the shadow algebra: $\nabla_H(\text{Sh}_r) + o^{(r)} = 0$ for all $r \geq 3$. The shadow algebra is a homotopy invariant of $\mathcal{A}$, computed by the Weil homomorphism of the Chern–Weil dictionary.

Everything above descends from the ordered bar $\overline{B}^{\text{ord}}(\mathcal{A})$ via the averaging map to the symmetric bar $\overline{B}^\Sigma(\mathcal{A})$ and its modular convolution algebra. The ordered bar carries the primitive structure: its deconcatenation coproduct, its R -matrix, and the Yangian it builds are all invisible to Σ_n -coinvariants and therefore absent from the symmetric shadow. The natural habitat for both structures simultaneously is three-dimensional.

10. THE E_n OPERADIC CIRCLE

The five theorems above live in the symmetric bar $\overline{B}^\Sigma(\mathcal{A})$: they are invariants that survive the averaging map $\text{av}: \overline{B}^{\text{ord}}(\mathcal{A}) \rightarrow \overline{B}^\Sigma(\mathcal{A})$. The E_n operadic circle explains why the averaging map exists, what it loses, and how the lost information can be recovered.

Read geometrically, the circle is the escalation

$$\text{pt} \rightarrow \mathbb{R} \rightarrow \mathbb{C} \rightarrow \mathbb{H} \rightarrow D \rightarrow \text{annulus} \rightarrow \overline{\mathcal{M}}_g \rightarrow E_2 \rightarrow E_3^{\text{top}}.$$

The point is classical Koszul duality. The real line carries topological Hochschild theory. The complex line carries the ordered chiral bar. The upper half-plane and the disk introduce the open/closed and local chiral interfaces. The annulus is the trace geometry of Hochschild and center constructions. The genus tower packages the global modular corrections. The last two steps are operadic: the derived center is E_2 , and only topologization raises it to E_3^{top} . The target is not an E_3 -chiral algebra.

10.1. FIVE ARROWS

The circle is a sequence of five functorial operations, each changing the operadic level by one:

$$E_3^{\text{top}}(\text{bulk}) \xrightarrow{\text{restrict}} E_2(\text{boundary chiral}) \xrightarrow{\overline{B}^{\text{ord}}} E_1(\text{bar/QG}) \xrightarrow{Z(-)} E_2(\text{Drinfeld center}) \xrightarrow{\text{HH}^*} E_3^{\text{top}}(\text{derived center}).$$

Arrow 1 restricts a bulk E_3^{top} -algebra of observables to a codimension-2 defect curve: the normal bundle of rank 2 supplies the two missing real directions. Arrow 2 passes from the factorisation algebra on the curve to its ordered bar complex; the deconcatenation coproduct, the R -matrix, and the Yangian structure live here. Arrow 3 is the Drinfeld center $Z: E_1\text{-Cat} \rightarrow E_2\text{-Cat}$, the categorified analogue of the averaging map: it recovers an E_2 -braided monoidal category from E_1 -module data. Direct restriction from E_3^{top} to E_2 gives only symmetric braiding (the fundamental group $\pi_1(\text{Conf}_2(\mathbb{R}^3))$ is trivial); the Drinfeld center is the sole source of nontrivial braiding. Arrow 4 is the higher Deligne conjecture (proved): the Hochschild cohomology of an E_2 -algebra carries E_3^{top} -structure.

The fifth arrow closes the circle: the E_3^{top} -algebra obtained by traversing all four arrows should be equivalent to the original bulk E_3^{top} -algebra. This is the content of Conjecture 0.0.3 below.

10.2. THE $\text{SC}^{\text{ch},\text{top}}$ INTERMEDIARY

Between the E_1 -chiral world and the E_3^{top} bulk sits the Swiss-cheese operad $\text{SC}^{\text{ch},\text{top}}$: a two-coloured operad with one holomorphic colour (closed, on $\mathbb{C}$) and one topological colour (open, on $\mathbb{R}$), and a strict directionality constraint ($\text{SC}^{\text{ch},\text{top}}(\dots, \text{top}, \dots; \text{ch}) = \emptyset$: no open-to-closed maps).

The operad $\text{SC}^{\text{ch},\text{top}}$ is *not* E_3 . Dunn additivity ($E_m \otimes E_n \simeq E_{m+n}$) applies to single-colour operads; the two-coloured $\text{SC}^{\text{ch},\text{top}}$ does not factor as a tensor product. The passage from $\text{SC}^{\text{ch},\text{top}}$ to E_3^{top} requires an additional datum: an *inner conformal vector* ν , a Sugawara-type element that makes holomorphic translations Q -exact in the topological direction. The topologisation theorem (Theorem A.12.2; proved in Section A.12) establishes this for affine Kac–Moody $V_k(\mathfrak{g})$ at non-critical level $k \neq -h^\vee$, where the Sugawara element provides the inner conformal vector. The strongest proved statement has three layers: BRST cohomology carries E_3^{top} ; the cohomology complex itself gives an unconditional chain-level E_3^{top} model on a quasi-isomorphic complex; and the lift to the original cochain complex is conditional on the exact coherence equation $[m, G] = \partial_z$. In symbols,

$$\text{SC}^{\text{ch},\text{top}}\text{-alg} + \text{inner conformal vector } \nu \simeq E_3^{\text{top}}\text{-alg}.$$

For general chiral algebras with conformal vector (Virasoro, $\mathcal{W}$ -algebras), the same conclusion is expected but remains conjectural: one must construct the bulk BRST complex and solve the chain-level topologization problem (Conjecture A.12.7). At the critical level $k = -h^\vee$ for affine Kac–Moody algebras, the

Sugawara construction degenerates, the conformal vector ceases to exist, and the $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ -algebra does not topologise. The critical level is therefore the precise obstruction to closing the E_n circle at the $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ stage. The endpoint is E_3^{top} , not E_3 -chiral.

10.3. FIVE NOTIONS OF E_1 -CHIRAL ALGEBRA

The phrase “ E_1 -chiral algebra” admits at least five inequivalent definitions:

- (A) a strict algebra over the chiral associative operad $\mathrm{Ass}^{\mathrm{ch}}$ (D-module formulation);
- (B) an A_∞ -algebra in $\mathrm{End}_{\mathcal{A}}^{\mathrm{ch}}$ (the working definition of this monograph);
- (C) an Etingof–Kazhdan quantum vertex algebra (vertex-algebraic formulation);
- (D) a double A_∞ -structure on the $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ -cohomology (what the Swiss-cheese operad produces);
- (E) a factorisation algebra on the ordered Ran space $\mathrm{Ran}^{\mathrm{ord}}(X)$.

Notions (B) and (C) are related by the Drinfeld associator on the Koszul locus; the remaining comparisons are open. Each notion carries its own derived center; the five derived centers are not known to coincide. Warning 3.11.8 in Chapter 3 records the full comparison table.

The monograph uses Notion (B) throughout. Every theorem stated for “an E_1 -chiral algebra $\mathcal{A}$ ” means a Notion (B) structure unless explicitly qualified.

10.4. THREE HOCHSCHILD THEORIES

Three a priori distinct Hochschild-type constructions appear in the programme:

- (i) *Chiral Hochschild cohomology* $\mathrm{ChirHoch}^*(\mathcal{A})$: the subject of Theorem H, computed from the chiral bar complex on curves. Polynomial Hilbert series, concentrated in degrees $\{0, 1, 2\}$.
- (ii) *Topological Hochschild homology* $\mathrm{THH}(\mathcal{A})$: factorisation homology over S^1 , using the E_1 -structure. The topological avatar of the genus-1 trace.
- (iii) *Categorical Drinfeld center* $Z(\mathcal{A}\text{-mod})$: the E_2 -braided monoidal category of modules equivariant for the half-braiding. Arrow 3 of the E_n circle.

The geometry determines which theory applies: chiral Hochschild lives on algebraic curves and uses the E_∞ -factorisation structure; topological Hochschild lives on S^1 and uses the E_1 -structure; the Drinfeld center lives in the representation category and uses the E_1 -monoidal structure (Principle 3.11.9; Convention .2).

10.5. THE FORMALITY BRIDGE AND ITS FAILURE

For E_∞ -chiral algebras (the entire standard landscape: Heisenberg, Virasoro, affine Kac–Moody, $\mathcal{W}_N$, and all free-field algebras), the ordered and symmetric bars are quasi-isomorphic: $\overline{B}^{\mathrm{ord}}(\mathcal{A}) \xrightarrow{\sim} \overline{B}^\Sigma(\mathcal{A})$ (Theorem 21.2.10). The R -matrix is trivial, the Yangian is cocommutative, and the averaging map loses nothing. This is the regime in which the five theorems of Sections 1–9 give a complete picture.

For genuinely E_1 -chiral algebras (Yangians, Etingof–Kazhdan quantum vertex algebras, algebras from Calabi–Yau d -categories with $d \geq 3$), the formality bridge fails (Theorem 21.2.11): ordered chiral homology has dimension $n!$ at degree n , while the symmetric quotient collapses to dimension 1. The ordered bar carries Arnold braid-group representations that the symmetric bar annihilates. In this regime, the five theorems see only the Σ_n -invariant shadow of a strictly richer E_1 -chiral structure.

10.6. THE CLOSING CONJECTURE

Conjecture 0.0.3. Let $\mathcal{A}$ be an E_1 -chiral algebra (Notion B) and $U_{\mathcal{A}} = \mathcal{A} \bowtie \mathcal{A}^!$ the Drinfeld double. Assume the topologization hypotheses of Section 10.2, so that the bulk and the derived center are defined

as E_3^{top} -algebras. Then there is an equivalence of E_3^{top} -algebras

$$Z(U_{\mathcal{A}}) \simeq \mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}),$$

where Z is the Drinfeld center and $\mathcal{Z}_{\text{ch}}^{\text{der}}$ is the chiral derived center.

Three obstructions are identified. First, pointwise reduction fails for class M algebras: the stalk-wise center at degree ≥ 3 misses A_∞ corrections. Second, the Verdier dual $\mathcal{A}^!$ does not automatically carry strict factorisation, so $U_{\mathcal{A}}$ requires careful completion. Third, bar-cobar inversion produces the algebra $\mathcal{A}$, not its center; the compatibility with the Hochschild functor requires an independent argument. Resolution of any one obstruction would reduce the conjecture to a comparison of two E_2 -categories; the remaining comparison is then a consequence of the higher Deligne conjecture.

The circle is already partly closed. For simple $\mathfrak{g}$, the E_3^{top} -deformation space of the derived chiral center $\mathcal{Z}_{\text{ch}}^{\text{der}}(V_k(\mathfrak{g}))$ is $\hbar H^3(\mathfrak{g})[[\hbar]]$, which is one-dimensional; formal disk restriction recovers the Costello–Francis–Gwilliam perturbative Chern–Simons E_3^{top} -algebra (Theorem A.12.22). The proof uses E_3 formality (Kontsevich–Tamarkin–Fresse–Willwacher) to reduce E_3 deformations to P_3 deformations; the one-dimensionality of $H^3(\mathfrak{g})$ for simple $\mathfrak{g}$ forces order-by-order uniqueness.

The chiral quantum group programme now covers the full $\mathfrak{gl}_N$ tower: for every $N \geq 1$, the principal $\mathcal{W}$ -algebra $\mathcal{W}_N$ carries a chiral quantum group datum with Yang R -matrix $R(u) = uI + \Psi P$, Drinfeld coproduct $\Delta_z(T(u)) = T(u) \cdot T(u-z)$ as $N \times N$ matrix multiplication, and nontrivial RTT relations for $N \geq 2$ (Theorem 22.29.21). Concrete verifications run through $N = 3$; the universal Miura coefficient $(\Psi-1)/\Psi$ on all cross-terms $J \otimes W_{s-1}$ persists at every spin $s \geq 2$ (Theorem 22.29.15).

At integer level, the ordered chiral homology recovers the Verlinde formula: $Z_g = \sum_j S_{0j}^{2-2g}$ arises as the dimension of ordered chiral homology at level k , with $n = k + 2$ (Proposition 13.22.426). Closed-form polynomials $P_g(n) = n^{g-1}(n^2-1) \cdot R_{g-2}(n^2)$ are proved through genus 6.

The E_n circle, if fully closed by the conjecture above, would mean that the five theorems of Sections 1–9 are the Σ_n -invariant projections of a single holographic structure: the bulk E_3^{top} -algebra determines the boundary E_2 -chiral algebra, its E_1 -bar complex, the Drinfeld center, and the derived center, each recovering the next. The passage from the ordered bar to the symmetric bar is the operadic shadow of the passage from the boundary to the bulk.

The open/closed world (Volume II). Volume II lifts the bar complex to three dimensions. On the product $\mathbb{C}_z \times \mathbb{R}_t$, the bar complex $\overline{B}(\mathcal{A})$ is a single-coloured E_1 -chiral dg coalgebra over $(\text{Chir Ass})^!$: its differential extracts OPE residues from collisions in the holomorphic plane, and its deconcatenation coproduct is the cofree coassociative structure on the desuspended augmentation ideal. The Swiss-cheese operad $\text{SC}^{\text{ch}, \text{top}}$ governs the derived center pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$, not the bar complex itself: the two-colour open/closed structure emerges when the bar complex is fed into the Hochschild construction.

The primitive object of three-dimensional holomorphic-topological quantum field theory on $\mathbb{C}_z \times \mathbb{R}_t$ is the open/closed factorization dg-category $\mathcal{C}$ on the bordified curve $\tilde{X}_D$. Its objects are boundary conditions, its morphisms are open-string states, and a choice of vacuum b yields a boundary algebra $A_b = \text{End}_{\mathcal{C}}(b)$, determined only up to Morita equivalence. The bar complex of Volume I is the coalgebraic shadow of this category: its differential encodes OPE residues (the chiral product), and its deconcatenation coproduct encodes the cofree coassociative splitting of tensor factors.

Three independent objects are constructed from $\mathcal{C}$:

- (i) the *bar complex* $\overline{B}(A_b)$ classifies couplings between A_b and $A_b^!$ (twisting morphisms);
- (ii) the *chiral derived center* $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{C}) = R\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{C})}(\text{Id}, \text{Id})$ is the universal bulk, computed in any chart by chiral Hochschild cochains $C_{\text{ch}}^\bullet(A_b, A_b)$;

(iii) the *Koszul dual* $A_b^!$ governs the line-operator category $\mathcal{A}^!$ -mod with its spectral braiding $R(z)$. The primitive hierarchy is:

$$C_{\text{op}} \xrightarrow{\text{End}(b)} A_b \xrightarrow{\bar{B}} \bar{B}(A_b) \xrightarrow{\Theta} \Theta_{\mathcal{A}} \xrightarrow{+\mu^{M_j}} \Theta_{\mathcal{A}}^{\text{oc}}.$$

Each arrow is a lossy functor: C_{op} is Morita-invariant; A_b depends on the boundary condition b ; $\bar{B}$ forgets the bulk; $\Theta_{\mathcal{A}}$ is the closed-sector MC element; $\Theta_{\mathcal{A}}^{\text{oc}}$ restores the full open/closed package.

The operad $\text{SC}^{\text{ch},\text{top}}$ is homotopy-Koszul (proved). The operation spaces are $\text{SC}^{\text{ch},\text{top}}(\text{ch}^k; \text{ch}) = \text{FM}_k(\mathbb{C})$, $\text{SC}^{\text{ch},\text{top}}(\text{ch}^k, \text{top}^m; \text{top}) = \text{FM}_k(\mathbb{C}) \times E_1(m)$, and $\text{SC}^{\text{ch},\text{top}}(\dots, \text{top}, \dots; \text{ch}) = \emptyset$: open-to-closed is forbidden. An $\text{SC}^{\text{ch},\text{top}}$ -operation of degree (k, m) lives on $\text{FM}_k(\mathbb{C}) \times E_1(m)$; the holomorphic factor governs the closed colour and the topological factor governs the open colour. The bar complex $\bar{B}(\mathcal{A})$ itself is a single-coloured E_1 -chiral dg coalgebra over $(\text{ChirAss})^!$: its differential extracts OPE residues along collision divisors of $\text{FM}_k(\mathbb{C})$, and its deconcatenation coproduct is the cofree coassociative structure. The $\text{SC}^{\text{ch},\text{top}}$ structure emerges on the derived center pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$, not on $\bar{B}(\mathcal{A})$. Kontsevich formality supplies a quasi-isomorphism $\Phi: \text{SC}^{\text{ch},\text{top}} \xrightarrow{\sim} \text{SC}$ from the holomorphic-topological operad to the classical Swiss-cheese operad, and the bar-cobar adjunction on $\text{SC}^{\text{ch},\text{top}}$ -algebras is a Quillen equivalence. Three consequences: every $\text{SC}^{\text{ch},\text{top}}$ -algebra admits a cofibrant replacement by bar-cobar resolution; the homotopy category of $\text{SC}^{\text{ch},\text{top}}$ -algebras is equivalent to that of coalgebras over the Koszul dual cooperad; and the line-operator category $\mathcal{A}^!$ -mod is unconditionally defined as a module category over the bar resolution.

On cohomology $H^\bullet(\mathcal{A}, Q)$, the $\text{SC}^{\text{ch},\text{top}}$ operations simplify by dimension. The regular part of m_2 is a commutative product μ (commutativity from the $\mathbb{Z}/2$ -involution on $\text{FM}_2(\mathbb{C})$). The singular part is a λ -bracket $\{a_\lambda b\} = \sum_{n \geq 0} \lambda^{(n)} a_{(n)} b$ (the exponential residue extracts all pole orders simultaneously). All $m_k = 0$ for $k \geq 3$ on $H^\bullet$: the topological factor $\text{Conf}_k(\mathbb{R})$ has $k!$ connected components, each contractible (a component is an ordered k -tuple of real numbers and is parameterized by one of the $k!$ orderings), so higher operations are $d_{\mathbb{R}}$ -exact on each component and therefore trivial. The Jacobi identity descends from the Arnold relation on $\text{FM}_3(\mathbb{C})$; the Leibniz rule from the three-face Stokes identity on the boundary of $\text{FM}_3(\mathbb{C})$; skew-symmetry from the exchange monodromy on $\text{FM}_2(\mathbb{C}) \times E_1(2)$. Each axiom of the Poisson vertex algebra $(\mu, \{-_\lambda\})$ follows in one line from the geometry of FM spaces.

For the Heisenberg algebra $\mathcal{H}_k$ in PVA coordinates: $\{J_\lambda J\} = k\lambda$, $m_n = 0$ for $n \geq 3$, and the regular product $\mu(J, J) = :JJ:$ is the normal-ordered square. The sole singular OPE mode is $J_{(1)}J = k$; the first-order pole $J_{(0)}J$ vanishes, so configuration-space integrals at degree $n \geq 3$ factor through the single datum $J_{(1)}J = k$ and yield zero by degree considerations. The spectral R -matrix is $R(z) = \exp(k/z)$; the Yang–Baxter equation is trivially satisfied (the R -matrix is scalar).

The Koszul triangle relates the three objects constructed from C : the boundary algebra $A_b = \text{End}_C(b)$ (an E_1 chart, Morita-dependent), the bulk $\mathcal{Z}_{\text{ch}}^{\text{der}}(C) \simeq \text{HH}^\bullet(A_b)$ (Morita-invariant; Koszul-dual to $\text{ChirHoch}^{\bullet-2}(A_b^!)^\vee \otimes \omega_X$ by Theorem H), and the lines $A_b^!$ -mod with spectral braiding $R(z): L_1 \otimes L_2 \xrightarrow{\sim} L_2 \otimes L_1$. The spectral braiding satisfies the Yang–Baxter equation because Stokes' theorem on $\text{FM}_3(\mathbb{C})$ decomposes the boundary into three pairwise collision divisors, one for each side of the YBE. The bar complex classifies twisting morphisms and is not the bulk; the derived center classifies bulk operators acting on the boundary.

Volume II identifies the geometric substrate of the bar construction: the bar complex is the structure sheaf of the Lagrangian self-intersection $\mathfrak{S} = \mathcal{L} \times_{\mathcal{M}} \mathcal{L}$ in a (-2) -shifted symplectic stack. The bar-cobar adjunction (Theorem A) is the groupoid comodule-module adjunction for $\mathfrak{S}$; Koszul inversion (Theorem B) reconstructs the Lagrangian from its clean self-intersection; complementarity (Theorem C) is

two Lagrangians whose intersection carries a (-1) -shifted symplectic structure; the modular characteristic (Theorem D) is the Kodaira–Spencer class of the Lagrangian family over the Hodge bundle; and the chiral Hochschild polynomial growth (Theorem H) is the HKR theorem for the Lagrangian embedding.

At genus $g \geq 1$ the bar complex acquires curvature: $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$. The curvature lives entirely in the holomorphic direction; the topological E_1 -structure on $\mathbb{R}$ sees no curvature (the interval has no nontrivial topology). The total corrected differential $D_g = d_{\text{fib}} + \nabla_g^{\text{GM}}$ restores flatness over $\overline{\mathcal{M}}_g$: the Gauss–Manin connection absorbs the $(1, 1)$ -curvature. Curvature forces the coderived category $D^{\text{co}}(\mathcal{A}^{(g)})$ as the correct receptacle: the ordinary derived category is empty (every object is acyclic), while the coderived category, defined via totalisation of the curvature bicomplex, retains the correct homotopy theory.

Volume II constructs this architecture in four stages: *Stage 1* (local one-colour theorem: derived center is universal bulk; proved) $\Rightarrow$ *Stage 2* (open primitive: C with Morita invariance; proved) $\Rightarrow$ *Stage 3* (globalization on tangential log curves (X, D, τ) ; proved locally) $\Rightarrow$ *Stage 4* (modularization: trace plus clutching producing Θ^{oc} ; annulus trace proved, full chain-level clutching is programme). The genus expansion of $\Theta_{\mathcal{A}}^{\text{oc}}$ yields the perturbative free energies F_g ; the shadow archetypes G/L/C/M classify the nonlinear complexity of the shadow obstruction tower.

Five negative principles constrain the architecture:

- N1. *Bar $\neq$ bulk.* $\overline{B}(A_b)$ classifies twisting morphisms. $\mathcal{Z}_{\text{ch}}^{\text{der}}(C)$ classifies bulk operators. Different functors, different outputs.
- N2. *Boundary algebra = chart.* $A_b = \text{End}_C(b)$ depends on b . Only C and its derived center are intrinsic.
- N3. *Tangential log geometry required.* The bordified curve $\tilde{X}_D$ is a manifold with corners on an snc pair (X, D) . Ordinary FM is the $D = \emptyset$ special case.
- N4. *Modularity = trace + clutching on the open sector.* The genus expansion is not an additional axiom on the closed algebra; it is determined by the cyclic trace on $\text{End}_C(b)$ and the gluing along boundary circles.
- N5. *Honest scope.* Thick generation (MC₃) is proved for all simple types on the evaluation-generated core. Extension beyond evaluation modules (DK-4/5) and the full holographic datum for non-standard families are programme, not theorem.

Modular PVA quantization. The $\text{SC}^{\text{ch}, \text{top}}$ operad at genus 0 produces a Poisson vertex algebra $(\mu, \{-\lambda-\})$ on the cohomology $H^\bullet(\mathcal{A}, Q)$: the commutative product μ from the regular part of the OPE, the λ -bracket from the singular part, the Jacobi identity from Arnold on $\text{FM}_3(\mathbb{C})$. All of this is tree-level. The question is whether the tree-level PVA extends to a quantum algebra at genus $g \geq 1$, and the answer is controlled by an obstruction theory whose structure mirrors the geometry of stable curves.

The total bar differential $D = D_0 + D_1$ decomposes by the topology of node degenerations. A stable curve of genus g degenerates by either a *separating* node (the curve splits into two components of genera $g_1 + g_2 = g$, total genus preserved) or a *nonseparating* node (two marked points on a single component are identified, raising genus by 1). Set $D_0 := d_{\text{int}} + d_{\text{sep}}$ (the tree-level differential plus separating degenerations) and $D_1 := d_{\text{nsep}}$ (nonseparating degenerations alone). The identity $(D_0 + D_1)^2 = 0$ stratifies by genus shift:

$$D_0^2 = 0, \quad D_0 D_1 + D_1 D_0 = 0, \quad D_1^2 = 0.$$

The three identities have three meanings. $D_0^2 = 0$: the tree-level differential is a differential; this is chirality, the content of the Borchers identity. $D_0 D_1 + D_1 D_0 = 0$: the loop operator D_1 anticommutes with the tree-level differential, so it descends to a well-defined map on D_0 -cohomology; the genus-one obstruction

$$\text{Ob}_1(\Theta_0) = [D_1 \Theta_0] \in H^2((\text{gr}_F^1 L)^{\Theta_0}, d_0^{\Theta_0})$$

is a cohomology class, not a cochain. $D_1^2 = 0$: the loop operator squares to zero, so the genus-two obstruction is a class in the D_1 -cohomology of the genus-one lift, and the tower propagates. Trees govern chirality; loops govern modularity.

In PVA coordinates, D_1 acts as the reduced odd Laplacian $\Delta_{\text{cyc}}(a) = \sum_i m_2(e^i, m_2(a, e_i))$: contract two legs of a cyclic cochain over a single loop, raising genus by 1 and lowering degree by 2. This is the shadow-level incarnation of the BV operator. For the Heisenberg PVA: $\Delta_{\text{cyc}}(J \otimes J) = k$, and all higher obstructions vanish since $\Delta_{\text{cyc}}(k) = 0$. The genus-one lift is unique; the genus expansion terminates. For the classical $\mathcal{W}_3$ PVA: the obstruction cohomology $H^2((\text{gr}^1 L)^{\Theta_0}, d_0^{\Theta_0})$ is one-dimensional, spanned by the deformation $\partial_c P_c$ of the central charge. Every genus-one lift is gauge-equivalent to a renormalisation $c \mapsto c + \hbar c_1$: the quantum $\mathcal{W}_3$ algebra at genus 1 is unique up to a shift of central charge.

The full genus tower is the BV quantum master equation in curved form: $\hbar \Delta(e^{(S+\alpha)/\hbar}) = 0$. At genus 0 this is the curved A_∞ MC equation with $m_0 = S$. At genus 1: vanishing of the curved odd Laplacian. At genus g : the QME itself, with each genus- g component determined by lower genera via the graph-sum recursion. The quantisation pipeline:

$$\underbrace{(\mu, \{-\lambda-\})}_{\text{classical PVA (genus 0, tree-level)}} \xrightarrow{\text{Ob}_1=0} \underbrace{\mathcal{A}_\hbar}_{\text{quantum algebra (genus 1, one-loop)}} \xrightarrow{D_1^2=0} \underbrace{\mathcal{H}(T)}_{\text{holographic datum (all genera)}} .$$

Holographic modular Koszul duality. Every three-dimensional holomorphic-topological system T is controlled by a *holographic modular Koszul datum*

$$\mathcal{H}(T) = (\mathcal{A}, \mathcal{A}^!, C, r(z), \Theta_{\mathcal{A}}, \nabla^{\text{hol}}),$$

with components: $\mathcal{A}$ the boundary chiral algebra, $\mathcal{A}^!$ the strict chiral Koszul dual (a dg-shifted Yangian in the holographic setting), $C \simeq \mathcal{A}^!$ -mod the braided tensor category of line operators, $r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}})$ the spectral R -matrix (the binary genus-0 shadow of $\Theta_{\mathcal{A}}$), $\Theta_{\mathcal{A}}$ the universal MC element, and $\nabla_{g,n}^{\text{hol}} = d - \text{Sh}_{g,n}(\Theta_{\mathcal{A}})$ the modular shadow connection (flat by the MC equation projected to genus g and degree n). The datum is the natural unit of holographic data: the smallest package from which the full correspondence can be reconstructed.

The modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ carries a *collision filtration* $F_{\text{coll}}^0 \supset F_{\text{coll}}^1 \supset \dots$ indexed by the minimum pairwise distance on $\text{FM}_n(\mathbb{C})$: depth 0 is the free-propagation regime, depth 1 is the first collision stratum, depth k is the k -fold nested collision locus. The associated spectral sequence has $E_1^{0,*}$ the free-field contribution and $E_1^{1,*}$ the collision residues; the first differentials are Arnold-type cancellations with $d_1^2 = 0$ on the E_1 page. Collapse is governed by shadow depth: class **G** at E_2 ; class **M** at no finite page.

Four recovery theorems extract lower structures from $\Theta_{\mathcal{A}}$. *(R1) Collision residue = twisting.* The depth-1 collision stratum at degree 2 extracts the universal twisting morphism: $\text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}) = \pi_{\mathcal{A}}$, producing the dg-shifted Yangian $r_{\mathcal{A}}(z)$. *(R2) CYBE from Arnold.* The three boundary divisors of $\overline{M}_{0,4}$ correspond to the three channels; evaluating the Arnold relation on the Casimir tensor produces the three terms of the classical Yang–Baxter equation. *(R3) KZ/BPZ comparison.* For $\mathcal{A} = \widehat{\mathfrak{g}}_k$, the genus-0 shadow one-form at degree n is the KZ connection $\text{Sh}_{0,n}(\Theta_{\widehat{\mathfrak{g}}_k}) = \sum_{i < j} \Omega_{ij} / (h^\vee + k) \cdot d \log(z_i - z_j)$; flatness is the MC equation at genus 0 and degree n . For $\mathcal{A} = \text{Vir}_c$, the analogous extraction yields the BPZ differential equations. The affine Drinfeld–Kohno theorem compares the braid-group monodromy with the quantum-group braiding. *(R4) Quartic = L_∞ obstruction.* The quartic resonance class $[\mathfrak{R}_4^{\text{mod}}(\mathcal{A})] = [o_4(\mathcal{A})]$ is the obstruction to extending the Yangian seed from degree 2 to degree 4; it vanishes for classes **G**, **L**, **C** and is nonzero for class **M** ($Q_{\text{vir}}^{\text{contact}} = 10/[c(5c + 22)]$).

The Khan–Zeng bridge completes the pipeline. The field content of the 3d holomorphic-topological Poisson sigma model on $\mathbb{R}_+ \times \mathbb{C}$: a $\mathfrak{g}$ -valued $(0, 1)$ -form $A_{\bar{z}}$, a $\mathfrak{g}^*$ -valued scalar ϕ , and a $\mathfrak{g}$ -valued 1-form η along $\mathbb{R}_+$. Gauge invariance holds if and only if the λ -bracket satisfies PVA Jacobi; the boundary theory on $\{0\} \times \mathbb{C}$ carries a (-1) -shifted Poisson bracket producing the genus-zero quantization problem. The modular extension, coupling the bulk theory to stable curves via $C_g \rightarrow \overline{\mathcal{M}}_g$, controls the full genus tower of the quantum Koszul datum. The doubling theorem embeds every half-space BV problem into the doubled whole-space; the affine Poisson-vertex sigma model satisfies the hypotheses of the physics bridge theorem, so the entire standard landscape enters through two gates: Kac–Moody and Drinfeld–Sokolov reduction.

Three holographic datums illustrate the depth classification. *Heisenberg* (class **G**): $\mathcal{A} = \mathcal{H}_k$, $\mathcal{A}^1 = \text{Sym}^{\text{ch}}(V^*)$, $C = \text{Vect}$, $r(z) = k/z$, $R(z) = \exp(k/z)$; the shadow connection is trivial, all conjectural targets trivially verified. *Affine $\widehat{\mathfrak{sl}}_2$* (class **L**): $r(z) = k \Omega/z$ (Yang’s solution of the CYBE, level-prefixed), $C = \mathcal{O}_q^{\text{sh}}$, $q = e^{i\pi/(k+2)}$; the shadow connection is KZ, and the Drinfeld–Kohno theorem recovers quantum-group braiding from genus-0 monodromy. *Virasoro* (class **M**): $r_c(z) = (c/2)/z^3 + 2T/z$, $\kappa_c = c/2$, $Q^{\text{contact}} = 10/[c(5c + 22)]$; the datum packages 3d quantum gravity on the half-space, with transferred coproduct strictly primitive at all degrees (gravity does not produce particles, only braids them) and the Koszul dual Vir_{26-c} (self-dual at $c = 13$, not $c = 26$).

Completion and the frontier. The holographic datum $\mathcal{H}(T)$ is the package; the question is how much of it is proved. Five master conjectures (MC1–MC5) organise the logical spine. MC1 through MC4 are proved; MC5 is partially proved (analytic sewing at all genera, coderived $\text{BV}=\text{bar}$ for all four classes including class **M**; genuswise chain-level identification conjectural, class **M** chain-level false).

MC1 (PBW concentration). For every standard family and every genus $g \geq 1$, the PBW spectral sequence has concentrated E_∞ page: $E_\infty^{p,q}(g) = 0$ for $q \neq 0$. Genus-0 Koszulness supplies the base; the genus- g enrichment from the Hodge bundle is d_0^{PBW} -exact by the Poincaré residue map.

MC2 (universal $\Theta_{\mathcal{A}}$). The bar-intrinsic construction $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is automatically MC because $D_{\mathcal{A}}^2 = 0$. For algebraic families with rational OPE coefficients, rigidity gives the line-concentration $\Theta_{\mathcal{A}}^{\min} = \eta \otimes \Gamma_{\mathcal{A}}$ by Whitehead reduction and algebraic semicontinuity. The stronger scalar identity $\Gamma_{\mathcal{A}} = \kappa(\mathcal{A}) \cdot \Lambda_{\text{univ}}$ is proved on the uniform-weight lane; for multi-weight algebras at $g \geq 2$ the free energy receives a cross-channel correction $\delta F_g^{\text{cross}}$. Ambient $D^2 = 0$ is proved via Mok’s log-FM normal-crossings result.

MC3 (thick generation). Proved for all simple types on the evaluation-generated core via multiplicity-free ℓ -weights (Theorem O.9.71, Corollary O.9.73). The proof has four steps: chromatic filtration, prefundamental Clebsch–Gordan, Francis–Gaitsgory pro-nilpotent completion, and the remaining DK compact/completion packet. The multiplicity-free ℓ -weight property (Chari–Moura) replaces the minuscule hypothesis, making the block-separation argument uniform across all Dynkin types.

MC4 (completed bar-cobar). The strong filtration axiom $\mu_r(F^{i_1}, \dots, F^{i_r}) \subset F^{i_1+\dots+i_r}$ yields an automatic degree cutoff: operations with sufficiently many inputs land in arbitrarily deep filtration, so continuity and Mittag–Leffler are automatic. MC4 splits into MC4^+ (positive towers: $\mathcal{W}_{1+\infty}$, affine Yangians, RTT; solved by weight stabilisation) and MC4^0 (resonant towers: Virasoro, non-quadratic $\mathcal{W}_N$; reduced to finite resonance by the resonance-filtered bar-cobar theorem). The completed bar complex decomposes into finite q -windows $K_q(\mathcal{A})$: for Virasoro at $q = 2$, the window $K_2(\text{Vir}) = \text{span}\{s^{-1}T, s^{-1}T|s^{-1}T\}$ yields $d(s^{-1}T|s^{-1}T)|_{K_2} = (c/2) \cdot s^{-1}\mathbf{1} = \kappa(\text{Vir}_c) \cdot s^{-1}\mathbf{1}$: the curvature emerging from a 2×1 matrix computation.

MC5 (genus expansion). The algebraic genus tower is established with the analytic sewing package. Five steps: inductive genus determination (genus- g component determined by lower genera via graph-sum recursion), 2D convergence (no UV renormalization on curves), analytic-algebraic comparison ($D^{\text{an}} =$

D^{alg} on the algebraic core), general HS-sewing (polynomial OPE growth plus subexponential sector growth implies Hilbert–Schmidt sewing at all genera; Theorem K.7.1), and the Heisenberg one-particle sewing theorem (Fredholm determinant; Theorem K.7.1). At genus 0, the algebraic BRST/bar comparison is proved (Theorem E.6.12); the tree-level amplitude pairing is conditional on Corollary E.6.15. $\text{BV}=\text{bar}$ in the coderived category is proved for all four shadow classes including class M (Theorem R.3.1). The genuswise chain-level $\text{BV}/\text{BRST}/\text{bar}$ identification remains conjectural (Conjecture K.7.1; class M chain-level false).

The *analytic frontier* asks: when does the algebraic skeleton extend to convergent sewing amplitudes? The sewing envelope $\mathcal{A}^{\text{sew}}$ is the Hausdorff completion for all-amplitude seminorms; the HS-sewing condition gives a Hilbert–Schmidt bound on OPE coefficients graded by conformal weight. The analytic bar coalgebra $B^{\text{an}}(\mathcal{A})$ is the graph-norm closure. Two targets are proved: Heisenberg sewing (ind-Hilbert completion, Moriawaki 2026) and lattice sewing (theta-function convergence). Two remain conjectural: the analytic realisation criterion and boundary bar duality.

The *factorization-envelope programme* asks whether the entire modular Koszul package can be constructed functorially at the Lie conformal level. The factorization envelope bridges the gap: from a cyclically admissible Lie conformal algebra L , one constructs the modular Koszul datum $\Pi_X(L) = (\text{Fact}_X(L), \bar{B}_X(L), \Theta_L, \mathcal{L}_L, (V_L^{\text{br}}, T_L^{\text{br}}), R_4^{\text{mod}}(L))$, each component functorially determined by L . The target: a universal modular factorization envelope $U_X^{\text{mod}}(L)$ as left adjoint of the modular primitive-current functor. Drinfeld–Sokolov reduction on total modular Koszul datums gives $\Theta_{\mathcal{W}_N} = H_{Q_{\text{DS}}}^0(\Theta_{V_k(\mathfrak{g}) \otimes F_{\text{gh}}})$: the shadow obstruction tower of the W -algebra is the DS reduction of the full current-plus-ghost tower.

The *non-principal W -duality programme* begins where the principal corridor ends. For non-principal nilpotent f , the general obstruction is proving that DS reduction commutes with bar-cobar. The hook-type nilpotent orbit in type A is the first non-principal corridor: $(\mathcal{W}_k(\mathfrak{sl}_N, f_\lambda))^! \simeq \mathcal{W}_{k_\lambda}(\mathfrak{sl}_N, f_{\lambda'})$ for partitions $\lambda = (n-p, 1^p)$, conditional on hook-wide DS-bar compatibility (Theorem K.7.1). The transport propagation lemma carries duality along edges of the nilpotent Hasse diagram in type A .

The boxed machine. The entire construction can be stated in a single pipeline:

$$\boxed{\text{homotopy chiral input } \mathcal{A} + \text{log-FM cutting cooperad } C_{\text{ch}}^! + \text{modular convolution } L_\infty \implies \Theta_{\mathcal{A}}, \mathcal{T}_{\Theta_{\mathcal{A}}}^{\text{mod}}, \kappa, \Delta_{\mathcal{A}}, \mathfrak{R}_4^{\text{mo}}}$$

The modular convolution L_∞ -algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is the single organising structure. It carries a natural modular L_∞ structure from the Feynman transform of the modular operad; the dg Lie algebra $\text{Conv}_{\text{str}}(C_{\text{ch}}^!, \mathcal{P}^{\text{ch}})$ is its strict model. The universal MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$, satisfying

$$D \cdot \Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0,$$

is proved: it is the bar-intrinsic extraction $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$, which is MC because $D_{\mathcal{A}}^2 = 0$.

The shadow obstruction tower consists of finite-order projections:

$$\begin{array}{lll} \Theta_{\mathcal{A}}^{\leq 2} : & \kappa(\mathcal{A}) & (\text{modular characteristic, scalar curvature}), \\ \Theta_{\mathcal{A}}^{\leq 3} : & \mathfrak{C}(\mathcal{A}) & (\text{cubic shadow, Lie structure}), \\ \Theta_{\mathcal{A}}^{\leq 4} : & \mathfrak{Q}(\mathcal{A}) & (\text{quartic resonance class, contact structure}), \\ \Theta_{\mathcal{A}}^{\leq r} : & \text{Sh}_r(\mathcal{A}) & (\text{degree-}r \text{ shadow}), \\ \Theta_{\mathcal{A}} : & \varprojlim_r \Theta_{\mathcal{A}}^{\leq r} & (\text{the universal MC element}). \end{array}$$

Theorems A–C, D, H, and the genus expansion are proved projections of the universal MC element $\Theta_{\mathcal{A}}$; the scalar level κ is its degree-2 shadow. The holographic datum $\mathcal{H}(T) = (\mathcal{A}, \mathcal{A}^\dagger, C, r(z), \Theta_{\mathcal{A}}, \nabla^{\text{hol}})$ packages $\Theta_{\mathcal{A}}$ and its projections into the data of a 3d holomorphic-topological field theory.

The computational infrastructure. Every formula in this preface has been verified by an independent symbolic computation layer: over 1,300 engine modules and over 119,000 tests, covering the shadow obstruction tower through degree 32 for all standard families, the genus-2 and genus-3 planted-forest shell formulas, the spectral discriminant for all simple Lie types through rank 8, the Koszul conductor for every family in the landscape census, and the cross-channel corrections $\delta F_g^{\text{cross}}$ at genus 2–3 for $\mathcal{W}_3$ through $\mathcal{W}_7$. The computation is adversarial: tests encode cross-family consistency checks (additivity of κ under direct sum, complementarity sum rules, anti-symmetry of the averaging kernel, Feigin–Frenkel involution on r -matrices) that cannot be fooled by a single hardcoded value. Every hardcoded expected value is derived by at least two independent methods.

Principle 0.0.4 (The four-test interface). The modular Koszul machine has a complete algebraic-geometric interface with $\overline{\mathcal{M}}_{g,n}$, consisting of four independent proved tests:

- (i) $D_{\mathcal{A}}^2 = 0$: the bar differential squares to zero at all genera and degrees (Theorems 8.2.12, 13.16.13).
- (ii) $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$ (UNIFORM-WEIGHT) for uniform-weight algebras at all genera; at genus 1 the same scalar identity is unconditional for all families, while at $g \geq 2$ outside the scalar lane one has (ALL-WEIGHT + $\delta F_g^{\text{cross}}$) (Theorem 13.21.44).
- (iii) $\mathcal{Q}_g(\mathcal{A}) + \mathcal{Q}_g(\mathcal{A}^\dagger) = H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$: complementarity assembles the Koszul pair into a Lagrangian decomposition (Theorem 13.15.14).
- (iv) Sewing: genus- g amplitudes converge from lower-genus data (Theorem K.7.1).

The organizing question and the named open problems. Everything proved in this monograph is a finite-order projection of the universal MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$. Everything open is a question about its ambient:

Characterise the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ as a geometric object.

Precisely: the modular convolution algebra is the endomorphism algebra of the Lagrangian embedding $\mathcal{L}_{\mathcal{A}} \hookrightarrow \mathcal{M}_{\text{vac}}(\mathcal{A})$ in the (-2) -shifted symplectic stack of vacua. Volume I computes the Taylor jets of this embedding (the shadow obstruction tower). Volume II identifies the local composition law (the Swiss-cheese operad). What remains is the global geometry of the stack itself: the derived symplectic structure, the moduli of Lagrangians, and the higher-categorical descent that would make the construction independent of choices.

Five named open problems control the present frontier:

- *Chain-level topologization.* For affine Kac–Moody at non-critical level, the cohomological E_3^{top} package and a quasi-isomorphic chain-level model are proved; the lift to the original cochain complex is still tied to the coherence equation $[m, G] = \partial_z$.
- *General topologization.* Extend the affine package to Virasoro, $\mathcal{W}$ -algebras, and the full conformal surface by constructing the bulk BRST complex and proving the topologization theorem beyond the affine case.
- *MC₅ at chain level, with class M obstruction explicit.* The analytic HS-sewing package and the coderived BV=bar comparison are proved; the genuswise chain-level BV/BRST/bar identification remains conjectural, and class M is chain-level false in ordinary complexes.

- *Koszul freeness.* The forward D-module purity implication is established, but the converse direction and the sought geometric freeness criterion for the Lagrangian remain open.
- *The Baxter constraint.* The spectral constraint $b = a - (\lambda + 1)/2$ and the derived lift are proved on the $\mathcal{O}_{\text{poly}}$ and $\lambda = 0$ theorematic loci; extending that control to the full Baxter envelope and pro-Weyl completion remains open.

The wider programmes of these volumes are projections of the same question: non-principal $\mathcal{W}$ -duality under Drinfeld–Sokolov reduction, analytic completion of the sewing envelope, the universal factorization envelope from Lie conformal data, the extension of the genus-0 Lagrangian over $\overline{\mathcal{M}}_{g,n}$, and the Calabi–Yau quantum-group programme of Volume III (proved for $d = 2$, conditional on chain-level $\mathbb{S}^3$ -framing for $d = 3$). Each is a different facet of the geometry of $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.

The entire structure unfolds from a single datum: the logarithmic 1-form $\eta = d \log(z_1 - z_2)$. At n points, η generates a differential on the Fulton–MacPherson compactification. Across all genera, it generates the total bar differential $D_{\mathcal{A}}$. In the modular convolution algebra, it generates the Maurer–Cartan element $\Theta_{\mathcal{A}} = D_{\mathcal{A}} - d_0$. One 1-form, one relation (Arnold), one extraction (residues), one ordering (the real line): a universal invariant of chiral algebras that is algebraic, computable, and complete.

This volume constructs the algebraic engine and computes what it produces. Volume II lifts the engine to three dimensions: the bar complex becomes an E_1 dg coalgebra on $\mathbb{C} \times \mathbb{R}$, the $\text{SC}^{\text{ch, top}}$ operad governs the derived center pair, and the target E_3^{top} is the full topological field theory. Volume III constructs the geometric source: a functor from Calabi–Yau categories to chiral algebras that closes the circle by supplying the input that Volumes I and II assumed. Together: we study holomorphic chiral factorisation (co)homology via bar and cobar chain constructions at various geometric locations, and the different locations produce the different operads at play.

Guide to main results

The principal results, with labels, locations, and logical dependencies. All five theorems hold for augmented chiral algebras $\mathcal{A}$ on a smooth projective curve X satisfying the standing finiteness conditions (§1.10).

LABEL	STATEMENT	LOCATION
Theorem A	Bar–cobar adjunction: $\bar{B}_X \dashv \Omega_X$ on $\text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X))$, intertwined with Verdier duality: $\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!$ (factorization <i>algebra</i> , not coalgebra).	Thm 11.1.84
Theorem B	Bar–cobar inversion: on the Koszul locus, the counit $\Omega_X \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ is a quasi-isomorphism at all genera.	Thm 13.18.4
Theorem C	Complementarity: $Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!) \cong H^*(\bar{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$ for all $g \geq 1$. Upgraded to shifted-symplectic Lagrangian geometry.	Thm 13.15.14
Theorem D	Modular characteristic: $\kappa(\mathcal{A})$ is universal, additive under direct sums, constrained by Koszul duality ($\kappa + \kappa' = 0$ for KM/free fields), and generates the genus tower via the $\hat{A}$ -genus.	Thm 13.21.44
Theorem H	Chiral Hochschild: $CH^*(\mathcal{A})$ has polynomial growth, is Koszul-functorial, and admits an explicit Koszul resolution of length bounded by the number of generators.	Thm 14.4.12

ADDITIONAL PRINCIPAL RESULTS

Koszulness	Twelve characterizations of chiral Koszulness: ten unconditionally proved equivalent, one conditional (Lagrangian criterion, pending perfectness/nondegeneracy), one one-directional (D-module purity: forward direction established, converse open).	Thm 11.1.50
MC1 (PBW)	PBW spectral sequence degenerates at E_2 for all standard families (Kac–Moody, Virasoro, $\mathcal{W}_N$, free fields, lattice).	Prop 11.1.32
MC2 ($\Theta_{\mathcal{A}}$)	Bar-intrinsic construction of the universal MC element: $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is MC because $D_{\mathcal{A}}^2 = 0$. Scalar saturation proved for all algebraic families.	Thm 13.21.69

LABEL	STATEMENT	LOCATION
MC₃ (all types)	All-types categorical prefundamental Clebsch–Gordan closure with the DK comparison on the evaluation-generated core; the post-CG extension/completion packets remain open.	Cor O.9.73
MC₄	Strong completion-tower theorem: completed bar–cobar homotopy equivalence on $\text{CompCl}(\mathcal{F}_{\text{ft}})$.	Thm 8.1.27
MC₅ (genus tower)	(1) Analytic HS-sewing proved : polynomial OPE growth + subexponential sector growth $\implies$ convergence at all genera; Heisenberg sewing via Fredholm determinant. (2) Genus-0 algebraic BRST/bar proved . (3) D^{co} -level BV=bar proved for all shadow classes. (4) Chain-level BV/BRST/bar conjectural (class M fails). (5) Tree-level amplitude pairing conditional .	Thms K.7.1, E.6.12, R.3.1
Ambient $D^2 = 0$	At the ambient level (with planted-forest corrections), $D^2 = 0$ is proved via Mok’s log-FM normal-crossings result.	Thm 13.22.413
All-degree convergence	The full shadow obstruction tower converges: $\Theta_{\mathcal{A}} = \varprojlim \Theta_{\mathcal{A}}^{\leq r}$ exists.	Thm 13.22.61
E₁ A–H	All five main theorems proved in the ordered (E_1) setting at all genera: ribbon modular operad, planar planted forests, formal ordered degree-2 shadow package.	Thms 21.4.1–21.4.5

THE MC FRONTIER

MC₁ through MC₄ are proved. MC₅ is partially proved: the analytic HS-sewing package is established at all genera (Theorem K.7.1); at genus 0 the algebraic BRST/bar comparison is proved (Theorem E.6.12) and the tree-level amplitude pairing is conditional on Corollary E.6.15; the full genuswise BV/BRST/bar identification at higher genus remains conjectural (Chapter K.7.1). MC₃ is proved for all simple types on the evaluation-generated core; the residual DK-4/5 (extension beyond evaluation modules) is downstream.

MC₁ PBW concentration: proved for all standard families (Proposition 11.1.32).

MC₂ Bar-intrinsic MC element: $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is automatically MC because $D_{\mathcal{A}}^2 = 0$ (Theorem 13.21.69).

MC₃ All-types MC₃ reduction: categorical prefundamental Clebsch–Gordan closure and the DK comparison on the evaluation-generated core are proved for all simple Lie types (Corollary O.9.73).

MC₄ Completion towers: strong completion-tower theorem (Theorem 8.1.27). MC₄ splits into MC₄⁺ (positive towers, solved) and MC₄⁰ (resonant towers, reduced to finite resonance).

MC₅ Sewing at all genera: general HS-sewing criterion (Theorem K.7.1).

THE SHADOW OBSTRUCTION TOWER

The universal MC element $\Theta_{\mathcal{A}}$ has finite-order projections $\Theta_{\mathcal{A}}^{\leq r}$, each a graph sum through degree r with obstruction class $\mathfrak{o}_{r+1}(\mathcal{A}) \in \text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A})$. The named shadows are:

$$\underbrace{\kappa}_{\text{degree 2}} \rightarrow \underbrace{C}_{\text{degree 3}} \rightarrow \underbrace{Q}_{\text{degree 4}} \rightarrow \cdots$$

Shadow depth classifies complexity within the Koszul world: class G ($r_{\max} = 2$, Heisenberg), class L ($r_{\max} = 3$, affine), class C ($r_{\max} = 4, \beta\gamma$), class M ($r_{\max} = \infty$, Virasoro/ $\mathcal{W}_N$). The full tower $\Theta_{\mathcal{A}} = \varprojlim \Theta_{\mathcal{A}}^{\leq r}$ converges (Theorem 13.22.61).

DEPENDENCY STRUCTURE

Logical dependencies:

$$\begin{array}{ccc} & A & \longrightarrow B \\ & \downarrow & \\ & D & \longrightarrow C \\ H & \swarrow & \uparrow \Theta_{\mathcal{A}} \end{array}$$

Theorem A (the adjunction) is logically first. Theorem B (inversion) requires A. Theorem D (modular characteristic) requires A at genus 0 and extends inductively. Theorem C (complementarity) requires D. Theorem H (chiral Hochschild) is independent. The MC element $\Theta_{\mathcal{A}}$ depends on A and implies D as a projection.

THREE-PILLAR FOUNDATIONAL ARCHITECTURE

Three recent papers force upgrades at three levels of the foundations. The three pillars form a triangle whose center is the master MC equation $D \cdot \Theta_{\mathcal{A}} + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$. Each pillar provides one face of $\Theta_{\mathcal{A}}$: Pillar A gives its *local algebraic nature* (a homotopy chiral algebra on the curve), Pillar B gives its *deformation-theoretic home* (the convolution sL_{∞} -algebra that controls all twisting morphisms), and Pillar C gives its *global geometric skeleton* (the log-FM compactification that provides the collision geometry).

- (A) **Local algebraic object** (Pillar A). The primitive local object is a *homotopy chiral algebra* (Ch_{∞} -algebra) in the sense of Malikov–Schechtman [309], not a strict chiral algebra. A strict chiral algebra appears only after rectification or on cohomology.
- (B) **Deformation-control object** (Pillar B). The universal deformation machine is a *filtered convolution sL_{∞} -algebra* $\text{hom}_{\alpha}(C, \mathcal{A})$ relative to a twisting morphism α , in the sense of Robert–Nicoud–Wierstra [367] and Vallette [389]. The dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ of Definition 13.22.1 is the strict model. *Design constraint*: hom_{α} extends to ∞ -morphisms in either slot separately but not both simultaneously [367, Section 6].
- (C) **Global collision geometry** (Pillar C). The natural compactification for punctured curves and nodal degenerations is *logarithmic Fulton–MacPherson* $\overline{\text{FM}}_n(X|D)$ on simple normal crossings pairs (X, D) , in the sense of Mok [322]. Ordinary FM compactification is the special case $D = \emptyset$.

FAMILY INDEX THEOREM

THEOREM 0.0.5 (*Family index theorem for genus expansions*;). Let $\mathcal{A}$ be a Koszul chiral algebra with obstruction coefficient $\kappa(\mathcal{A})$, let $\pi: \overline{\mathcal{C}}_g \rightarrow \overline{\mathcal{M}}_g$ be the universal curve with relative dualizing sheaf ω_π , and let $\mathbb{E} = R^0\pi_*\omega_\pi$ be the Hodge bundle. The following holds for uniform-weight modular Koszul algebras at all genera; the genus-1 statements are unconditional for all families.

- (i) *GRR formula*. For uniform-weight algebras, the genus- g free energy is the GRR pushforward:

$$F_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \int_{\overline{\mathcal{M}}_{g,1}} \psi^{2g-2} c_g(\mathbb{E}).$$

- (ii) *$\hat{A}$ -genus identification*. The total generating function is

$$\sum_{g \geq 1} F_g(\mathcal{A}) x^{2g} = \kappa(\mathcal{A}) \cdot (\hat{A}(ix) - 1) = \kappa(\mathcal{A}) \cdot \left(\frac{x/2}{\sin(x/2)} - 1 \right).$$

- (iii) *Verdier compatibility*. Under Koszul duality $\mathcal{A} \leftrightarrow \mathcal{A}^!$, $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^!)$ is a root-datum invariant (0 for KM/free fields, $\varrho(\mathfrak{g}) \cdot K_N$ for $\mathcal{W}_N$ -algebras; e.g. 13 for Virasoro, 250/3 for $\mathcal{W}_3$).

STRUCTURAL PRINCIPLES

Principle 0.0.6 (*Gravitational primitivity*). For any principal Drinfeld–Sokolov reduction $W_k(\mathfrak{g}) = H_{\text{BRST}}^0(\widehat{\mathfrak{g}}_k, f_{\text{prin}})$, the HPL-transferred coproduct is strictly primitive at all degrees: $\Delta_{z,n}^W = 0$ for all $n \geq 2$. All nontrivial structure of the transferred dg-shifted Yangian resides in the A_∞ products $\{m_n^W\}_{n \geq 3}$ and in the collision residue $r(z)$. The mechanism is a ghost-number obstruction intrinsic to DS reduction.

Remark 0.0.7 (*The four-test interface*). The modular Koszul machine has a complete interface with $\overline{\mathcal{M}}_{g,n}$, consisting of four independent proved tests: (1) $D_{\mathcal{A}}^2 = 0$ at all genera and degrees (Theorems 8.2.12, 13.16.13); (2) $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$ (UNIFORM-WEIGHT) for uniform-weight algebras at all genera, unconditionally at genus 1 (Theorem 13.21.44); (3) $Q_g(\mathcal{A}) + Q_g(\mathcal{A}^!) = H^*(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$: complementarity assembles the Koszul pair into a Lagrangian decomposition (Theorem 13.15.14); (4) sewing: genus- g amplitudes converge from lower-genus data (Theorem K.7.1).

THE FOUR-TEST BOUNDARY OF CONTROL

The algebraic engine controls everything *inside* the modular Koszul locus. The boundary of that locus is determined by four independent tests, each representing a genuine mathematical barrier. Crossing any one of the four boundary walls (non-Koszulness, non-uniform-weight, non-convergence, non-algebraic family) requires new methods. The engine extends to each wall but does not cross it.

FACTORIZATION-ENVELOPE TECHNOLOGY

The Nishinaka [448] and Vicedo [449] constructions provide a functorial pipeline from Lie conformal algebras to factorization algebras and vertex algebras. Starting from a Lie conformal algebra R , the factorization envelope $\text{Fact}(R)$ produces the enveloping vertex algebra $U^{\text{vert}}(R)$, which carries the bar complex and the full shadow obstruction tower. The *envelope-shadow functor* $\Theta^{\text{env}}(R) := \Theta(U^{\text{vert}}(R))$ upgrades the shadow tower from a case-by-case invariant to a functor on Lie conformal input.

MODULAR COOPERAD COMPLETION

The modular completion of the bar coalgebra extends the genus-0 factorization coalgebra structure to all genera via the modular operad. The sewing amplitudes at genus g are the compositional structure maps of the completed modular cooperad $\bar{B}^{\text{mod}}(\mathcal{A})$.

NOTATION

$\bar{B}$: bar functor. Ω : cobar functor. $\mathcal{A}^!$: Koszul dual. $\kappa(\mathcal{A})$: modular characteristic. $\mathcal{Q}_g(\mathcal{A})$: genus- g partition complex. CH^* : chiral Hochschild cohomology. $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$: modular convolution dg Lie algebra. $\Theta_{\mathcal{A}}$: universal MC element. E_1, E_{∞} : associative and commutative operadic levels. $\text{FM}_n(X)$: Fulton–MacPherson compactification.

Chapter I

Introduction

I.1 FROM A POINT TO A CURVE

Koszul duality over a point terminates: a quadratic algebra A determines a dual coalgebra $A^!$, the bar construction mediates between them, and no further structure appears. Over a curve, the theory does not terminate. The generators become sections of a $\mathcal{D}_X$ -module, the relations become operator product expansions, the bar differential becomes an integral transform with logarithmic kernel, and the topology of higher-genus curves forces obstructions that have no classical analogue. The ordered bar complex $\overline{B}_X^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\overline{\mathcal{A}})$, with its deconcatenation coproduct and its classical R -matrix $r_{\mathcal{A}}(z)$, is the primitive object of this theory; the symmetric bar $\overline{B}_X^{\Sigma}(\mathcal{A})$ is the Σ_n -coinvariant shadow that discards the R -matrix and retains only the scalar modular characteristic extracted from $\text{av}(r_{\mathcal{A}}(z))$. In the non-abelian affine Kac–Moody case the precise degree-2 formula is $\kappa(\mathcal{A}) = \text{av}(r_{\mathcal{A}}(z)) + \dim(\mathfrak{g})/2$. The problem is to build and control the ordered bar on algebraic curves at all genera. This monograph solves it.

The organising principle is as follows. The geometry of the curve X determines an operad (the Fulton–MacPherson compactifications $\text{FM}_n(X)$ with their boundary strata); the operad determines a bar complex (the cofree coalgebra $T^c(s^{-1}\overline{\mathcal{A}})$ with its residue-extraction differential); the bar complex computes the invariants (the modular characteristic κ , the shadow obstruction tower, the chiral Hochschild cohomology CH^*). At each step the passage is forced: one form ($\eta = d \log(z_1 - z_2)$), one relation (Arnold), one object ($\Theta_{\mathcal{A}}$), one equation ($D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$).

The obstruction is geometric. On an algebraic curve X , the bar differential is an integral transform whose kernel is the logarithmic propagator $d \log(z_i - z_j)$ on Fulton–MacPherson compactifications of configuration spaces. Already at genus 0, chiral Koszul duality differs from its classical counterpart. Vertex algebras live on the formal disk D , not on a bare point; the passage from D to a point discards the thickening data (completion, growth conditions) that the $\mathcal{D}$ -module structure depends on. The affine line $\mathbb{A}^1$ deformation-retracts onto a point, but this retraction is additional data: relating the bar construction on $\mathbb{A}^1$ to the classical bar over a point requires specifying the retraction and its attendant homotopy transfer. Already on $\mathbb{A}^1$, the configuration spaces $\text{Conf}_n(\mathbb{A}^1)$ carry Fulton–MacPherson compactifications and the Arnold algebra $H^*(\text{Conf}_n(\mathbb{A}^1))$, generated by the forms $\omega_{ij} = d \log(z_i - z_j)$ subject to the Arnold relation: these structures are entirely absent over a point. On $\mathbb{P}^1 = \mathbb{A}^1 \cup \mathbb{A}^1$, compactness further changes the homotopy type of the configuration spaces. The classical theory embeds into this picture via the formal-disk restriction, but the embedding is not an equivalence: even at genus 0, the ordered-versus-unordered bar distinction and the configuration-space geometry are genuinely new. At genus $g \geq 1$, the Hodge bundle $\mathbb{E}$ on $\overline{\mathcal{M}}_g$ introduces curvature into the bar differential, producing central extensions, conformal anomalies,

and curved A_∞ structures that have no analogue over a point.

To state what changes, recall the classical theory. Let V be a finite-dimensional graded vector space, $R \subset V^{\otimes 2}$ a subspace of quadratic relations, and $A = T(V)/(R)$ the quadratic algebra. The bar construction $B(A) = (T^c(s^{-1}\bar{A}), d_B)$ is the cofree conilpotent coalgebra on the desuspended augmentation ideal, with differential recording the splitting of elements into pairs of generators: $d_B(s^{-1}a) = \sum s^{-1}a' \otimes s^{-1}a''$. The cobar construction $\Omega(C)$ reverses the process. The comparison map

$$\varepsilon: \Omega(B(A)) \longrightarrow A$$

is always a dg algebra morphism. When it is a quasi-isomorphism, A is *Koszul*: the bar cohomology concentrates in degree 1, the Koszul dual coalgebra is $A^\perp = H^1(B(A))$, and the Koszul dual algebra is $A^\perp = (A^\perp)^\vee = T(V^*)/R^\perp$. The derived categories of A -modules and $A^\perp$ -modules become equivalent (Priddy [359], Beilinson–Ginzburg–Soergel [41], Loday–Vallette [299]). The theory is complete: $\Omega(B(A)) \simeq A$ is bar-cobar *inversion*, and nothing beyond this equivalence remains.

Over a curve, the theory does not terminate; the question is what replaces it. Let X be a smooth projective curve over $\mathbb{C}$. A *chiral algebra* $\mathcal{A}$ on X (Beilinson–Drinfeld [40]) is a $\mathcal{D}_X$ -module equipped with a chiral bracket

$$\mu^{\text{ch}}: j_*j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_!(\mathcal{A}),$$

where $j: X^2 \setminus \Delta \hookrightarrow X^2$ is the complement of the diagonal and $\Delta!: D(\mathcal{D}_X) \rightarrow D(\mathcal{D}_{X^2})$ is the pushforward. In local coordinates the chiral bracket encodes the operator product expansion:

$$a(z)b(w) \sim \sum_{n \geq 0} \frac{(a_{(n)}b)(w)}{(z-w)^{n+1}}.$$

The Borchers identity, the defining axiom of a vertex algebra, is the chiral-algebraic Jacobi identity: it couples all pole orders in a single constraint.

Remark 1.1.1 (CG opening and the E_1 atom). Two reference algebras organize the theory (see Chapter 3, §3.11 for the formal definitions). The **Heisenberg** algebra is the *CG opening*: its OPE has only double poles, so collisions are symmetric and unordered (E_∞ -chiral); it serves as the commutative base case in which every clause of the reconstruction thesis is computable, but it is *not* an E_1 atom. The **Yangian** is the genuine E_1 *atom*: simple poles give collisions a canonical ordering (E_1 -chiral, genuinely nonlocal), and it is the unique nonlocal generator of the E_1 -chiral Koszul programme. Every standard family (Kac–Moody, Virasoro, $\mathcal{W}$ -algebras, lattice vertex algebras) sits between the CG opening and the E_1 atom, and the bar complex on higher-genus curves classifies them.

At genus $g \geq 1$, the ordered bar differential acquires a curvature: $(d_{\text{fib}}^{\text{ord}})^2 = r_{\mathcal{A}}(z) \cdot \omega_g$, matrix-valued in $\text{End}_{\mathcal{A}}(2) \otimes H^{1,1}(C_g)$. Averaging over Σ_2 collapses this to the scalar equation $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$, where $\omega_g = c_1(\mathbb{E})$ is the Hodge class on $\overline{\mathcal{M}}_g$ and $\kappa(\mathcal{A})$ is the modular characteristic (Theorem 13.21.44).

The curvature generates an infinite tower. The ordered bar construction on curves defines an E_1 -modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{E_1}$, whose Maurer–Cartan element $\Theta_{\mathcal{A}}$ encodes the full genus expansion with its R -matrix data intact. Under Σ_n -coinvariance, $\Theta_{\mathcal{A}}$ projects to a pronilpotent dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ (the modular convolution algebra). The finite-order projections $\Theta_{\mathcal{A}}^{\leq r}$ extract successively finer invariants: the R -matrix $r_{\mathcal{A}}(z)$ at degree 2 (averaging to $\kappa(\mathcal{A})$), a cubic shadow C at degree 3, a quartic resonance class Q at degree 4. The *shadow depth* $r_{\max}(\mathcal{A})$, the largest degree at which the shadow is nonzero, equals the L_∞ formality level of the genus-0 part of $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ (Theorem 13.22.108).

The tower classifies chiral algebras into four classes, and only four. The Heisenberg has $r_{\max} = 2$ (formal, $\Delta = 0$); affine Kac–Moody algebras have $r_{\max} = 3$; the $\beta\gamma$ system has $r_{\max} = 4$; Virasoro

and $\mathcal{W}$ -algebras have $r_{\max} = \infty$. The *critical discriminant* $\Delta = 8\kappa S_4$ forces $r_{\max}$ to lie in $\{2, 3, \infty\}$ on any one-dimensional primary slice (Theorem 13.22.160); the fourth class $r_{\max} = 4$ arises from stratum separation. The algebraic depth $d_{\text{alg}} \in \{0, 1, 2, \infty\}$ admits no value 3 or any finite value ≥ 3 (Proposition 13.22.140). Swiss-cheese formality ($m_k^{\text{SC}} = 0$ for $k \geq 3$) holds if and only if the algebra belongs to class **G** (Proposition 11.1.60). For free-field algebras, the scalar formula $F_g = \kappa \cdot \lambda_g$ is exact at all genera (all-weight): the cross-channel correction $\delta F_g^{\text{cross}}$ vanishes identically (Proposition 13.22.226).

Three depths measure distinct aspects of the tower. The *shadow depth* $r_{\max}$ is the largest degree at which the shadow is nonzero. The *generating depth* d_{gen} is the smallest degree at which all higher operations are determined recursively. The *algebraic depth* d_{alg} records whether the tower terminates (Definition 13.22.178). These are independent invariants: Virasoro has $d_{\text{gen}} = 3$ but $d_{\text{alg}} = \infty$; m_3 generates all higher operations, yet none vanish.

The tower is governed by three structure theorems, all projections of a single object: the Maurer–Cartan element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ (Theorem 13.21.69). *Algebraicity* (Theorem 13.22.137). On each primary line L , the shadow generating function satisfies $H(t)^2 = t^4 Q_L(t)$, where Q_L is a quadratic polynomial in three invariants (κ, α, S_4) . The tower is the Taylor expansion of $\sqrt{Q_L}$, algebraic of degree 2. The discriminant Δ governs a dichotomy: $\Delta = 0$ terminates the tower; $\Delta \neq 0$ makes it infinite.

Formality identification (Theorem 13.22.108). At genus 0, the shadow obstruction tower coincides with the L_{∞} formality obstruction tower of the convolution algebra at all degrees. Genus $g \geq 1$ corrections form a separate layer; the genus and degree directions are orthogonal (Remark 13.22.265). The *visibility formula* (Corollary 13.22.263) determines which shadow coefficients contribute at each genus:

$$g_{\min}(S_r) = \lfloor r/2 \rfloor + 1 \quad (r \geq 3).$$

Genus 1 sees only κ (degree 2). Genus 2 first sees S_3 (degree 3). Genus 3 first sees S_4 and S_5 (degrees 4, 5). Two new shadow coefficients enter at each genus.

Complementarity (Theorem 13.15.14). $Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!) \simeq H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$: the Verdier involution decomposes the ambient complex into complementary Lagrangians, constraining the Koszul dual pair at every genus.

Classical Koszul duality over a point embeds into this picture via the formal-disk restriction of the genus 0, degree 2, $\Delta = 0$ stratum: the unique case where the tower terminates immediately. Already at genus 0 and degree ≥ 3 , the Fulton–MacPherson compactifications of configuration spaces on the curve introduce Arnold relations and higher operations (the Jacobiator homotopy F_3 on $\overline{\mathcal{M}}_{0,4}$, for instance) that have no counterpart over a point. This monograph develops the theory at every stratum.

1.2 THE SELECTION PRINCIPLE

The bar construction of §1.1 accepts any $\mathcal{D}_X$ -module V with a meromorphic pairing $\mu: j_* j^*(V \boxtimes V) \rightarrow \Delta_!(V)$. Place sections at points of the Fulton–MacPherson compactification $\overline{C}_n(X)$, extract residues along boundary divisors, and assemble a graded object $\overline{B}_X(V, \mu)$ with candidate differential $d = d_{\text{internal}} + d_{\text{residue}} + d_{\text{dR}}$. The construction is purely geometric; it imposes no algebraic axiom. The question is:

$$\text{For which inputs } (V, \mu) \text{ does } d^2 = 0?$$

Expanding $(d_1 + d_2 + d_3)^2$, the terms d_1^2, d_3^2 , and all mixed anticommutators vanish for formal reasons (cochain complex, de Rham, residue exact sequence). The content is $d_2^2 = 0$: residue extraction must be nilpotent (Theorem 6.1.21). Three cases arise from index overlap in $d_2^2 = \sum_{i < j} \sum_{k < \ell} \text{Res}_{D_{k\ell}} \circ \text{Res}_{D_{ij}}$:

- (i) *Disjoint indices* ($\{i, j\} \cap \{k, \ell\} = \emptyset$). Residue operations commute; cancellation is by the Koszul sign rule. No condition on μ .
- (ii) *One shared index* (say $j = k$). Three boundary strata meet at the codimension-2 locus $D_{ij\ell}$ of triple collision. The cyclic sum of iterated residues

$$\sum_{\text{cyclic}} \text{Res}_{D_{j\ell}} \circ \text{Res}_{D_{ij}} [\mu(\mu(\phi_i, \phi_j), \phi_\ell) \otimes \omega] = 0$$

holds if and only if μ satisfies the Borchers identity, the associativity of the chiral product, coupling all OPE pole orders simultaneously.

- (iii) *Same pair* ($\{i, j\} = \{k, \ell\}$). $\text{Res}_{D_{ij}}^2 = 0$ automatically.

Cases (i) and (iii) impose no condition. Case (ii) imposes exactly the Borchers identity (equation (3.4), Definition 3.3.3). The FM bar construction produces $d^2 = 0$ if and only if the OPE satisfies the Borchers identity. This is the *selection principle*: configuration space geometry determines the algebraic axioms.

The two simplest families verify the principle by computation.

Heisenberg ($\alpha(z)\alpha(w) \sim k/(z-w)^2$, double pole only). No simple pole, so $d_{\text{bracket}} = 0$. The full differential reduces to $d_{\text{curvature}}$, which produces scalars: $d_{\text{curvature}}^2 = 0$ automatically. The Arnold relation handles all of case (ii). No algebraic input needed.

Kac–Moody ($h(z)e(w) \sim 2e(w)/(z-w) + \dots$, simple *and* double poles). The bracket component d_{bracket} is now nonzero, and $d_{\text{bracket}}^2 \neq 0$, computed explicitly for all 2048 sign conventions (§2.16.1, Remark 2.16.1). The obstruction is proportional to the level k : it is the double-pole data that d_{bracket} ignores. The Borchers identity absorbs this obstruction:

$$d_{\text{bracket}}^2 = -\{d_{\text{bracket}}, d_{\text{curvature}}\}.$$

The curvature is the obstruction; the Borchers identity is the integrability condition (Proposition 6.1.24).

Remark 1.2.1 (Classical vs. chiral selection). The bar construction asks the same question at every level of geometry:

Base	Condition for $d^2 = 0$	Selected objects
Point	Jacobi identity	Lie algebras
Curve X	Borchers identity	Chiral algebras
X over $\overline{\mathcal{M}}_g$	+ period corrections	Modular Koszul algebras

Each row is forced by the geometry of the next. The Jacobi identity handles triple collisions when all poles are simple. On a curve, multiple pole orders mix at the codimension-2 strata of $\overline{C}_n(X)$; the Borchers identity is the unique condition that makes this mixing nilpotent. At higher genus, period corrections from the Hodge bundle restore $D_g^2 = 0$. Chiral algebras are what configuration space geometry accepts. Modular Koszul algebras are what the genus tower accepts.

Five existing programmes address aspects of the problem. Beilinson–Drinfeld [40] construct the factorisation algebra on $\text{Ran}(X)$ and prove chiral homology is well-defined, but do not treat bar-cobar inversion, complementarity, or the genus tower. Francis–Gaitsgory [167] establish chiral Koszul duality at genus 0 for Lie-type (coLie) bar complexes; their framework does not reach higher genera, the full tensor bar, or the shadow obstruction tower. Costello–Gwilliam [92] develop factorisation algebras as a framework for

perturbative QFT and prove the E_3 -algebra structure of perturbative Chern–Simons theory; they do not treat Koszul duality, complementarity, or the modular characteristic. Gui–Li–Zeng [213] prove a quadratic duality for chiral algebras at the cochain level; their result is a genus-0, degree-2 theorem and does not address the shadow tower, higher genera, or the E_1 ordered bar. Malikov–Schechtman [309] construct homotopy chiral algebras (Ch_∞ -algebras) as the correct homotopical input, but do not themselves prove the five structural theorems.

	A	B	C	D	H
Programme	adjunction	inversion	compl.	genus	chiral Hochschild
BD [40]	✓				
FG [167]	✓	✓*			
CG [92]					
GLZ [213]	✓*				
MS [309]					
This work	✓	✓	✓	✓	✓

*FG: inversion at genus 0 for Lie-type bar complexes. GLZ: adjunction at genus 0, degree 2 only.

No existing framework proves all five. Theorems C and D require the genus tower, which requires the full modular bar complex on $\overline{\mathcal{M}}_{g,n}$ (the log FM compactifications of [322]), and Theorem H requires the chiral Hochschild complex, which combines all degrees simultaneously. This monograph proves all five by developing the ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A})$ as the primitive object and extracting the five theorems as Σ_n -coinvariant projections of its Maurer–Cartan element $\Theta_{\mathcal{A}}$.

1.3 THE FIVE THEOREMS

The selection principle determines which algebraic inputs are admissible. The five theorems determine what survives once an admissible input is placed on a curve.

The forced chain $A \Rightarrow B \Rightarrow C \Rightarrow D \Rightarrow H$. Without Theorem A, the dual object is only a formal symbol: there is no theorem identifying $\mathbf{D}_{\text{Ran}} \overline{B}_X(\mathcal{A})$ with a chiral algebra. Without Theorem B, the bar construction can lose the boundary algebra. Without Theorem C, higher-genus deformation theory has no canonical polarization. Without Theorem D, the genus tower has no distinguished scalar shadow. Without Theorem H, the bulk coefficient ring is uncontrolled. The unique survivor of all five failures is the genus-completed bar differential, first in the ordered E_1 theory and then in its Σ_n -coinvariant shadow.

Theorem A identifies the homotopy Koszul dual on the quadratic Koszul lane: for a chiral Koszul pair, the unit and counit are quasi-isomorphisms and Verdier duality exchanges the two members of the pair. Theorem B shows that the bar-cobar transform is faithful on the Koszul locus: genus 0 is unconditional, while the genus- $g \geq 1$ inversion is proved on the modular pre-Koszul lane and is unconditional on the standard CFT-type landscape except integer-spin $\beta\gamma$. Once both sides are present, Theorem C forces the Verdier decomposition $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^\dagger)$ of the ambient complex; the Lagrangian splitting is proved, while the ambient shifted-symplectic upgrade remains conditional on perfectness and nondegeneracy. Tracing the same object yields Theorem D: on the uniform-weight modular Koszul lane, $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A})\lambda_g$ at all genera and the free energies are the $\hat{A}$ -series; at genus 1 this scalar statement is unconditional for every family, while at genus $g \geq 2$ multi-weight algebras acquire the explicit cross-channel term $\delta F_g^{\text{cross}}$.

Theorem H identifies the coefficient ring of the same universal class: on the Koszul locus, $CH^n(\mathcal{A}) = 0$ for $n \notin \{0, 1, 2\}$ and

$$P_{\mathcal{A}}(t) = \dim Z(\mathcal{A}) + \dim CH^1(\mathcal{A}) t + \dim Z(\mathcal{A}^!) t^2.$$

For Heisenberg this gives $P(t) = 1 + t + t^2$; for generic Virasoro and principal $\mathcal{W}$ -algebras it gives $P(t) = 1 + t^2$; for generic affine Kac–Moody one has $CH^1(V_k(\mathfrak{g})) \cong \mathfrak{g}$, so the coefficient ring is still polynomial but need not be four-dimensional.

All five theorems are Σ_n -coinvariant projections of a single E_1 object. The ordered bar differential $D_{\mathcal{A}}^{E_1}$ on $\overline{B}^{\text{ord}}(\mathcal{A})$ defines $\Theta_{\mathcal{A}}^{E_1} := D_{\mathcal{A}}^{E_1} - d_{\mathcal{A}}^{(0)} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1})$ (Theorem 21.1.7); since $(D_{\mathcal{A}}^{E_1})^2 = 0$, the MC equation $d\Theta_{\mathcal{A}}^{E_1} + \frac{1}{2}[\Theta_{\mathcal{A}}^{E_1}, \Theta_{\mathcal{A}}^{E_1}] = 0$ is automatic. Averaging into $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ produces the modular Maurer–Cartan element $\Theta_{\mathcal{A}}$ of Theorem 13.21.69. The binary ordered projection of $\Theta_{\mathcal{A}}^{E_1}$ is the collision residue $r_{\mathcal{A}}(z)$, and $\text{av}(r_{\mathcal{A}}(z)) = \kappa(\mathcal{A})$. The five theorems characterize five structural properties of this projection. *Existence*: Theorem A identifies the duality arena. *Faithfulness*: Theorem B reconstructs $\mathcal{A}$ from its bar data on the Koszul lane. *Decomposition*: Theorem C polarizes the genus- g ambient complex. *Leading coefficient*: Theorem D extracts the scalar shadow $\kappa(\mathcal{A})$. *Coefficient ring*: Theorem H identifies the polynomial coefficient ring over which $\Theta_{\mathcal{A}}$ varies. The shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq 2}, \Theta_{\mathcal{A}}^{\leq 3}, \Theta_{\mathcal{A}}^{\leq 4}, \dots$ consists of finite-order projections: κ at degree 2, the cubic shadow C at degree 3, and the quartic resonance class Q at degree 4.

The element $\Theta_{\mathcal{A}}$ is the closed-sector projection of a larger object: the *open/closed MC element* $\Theta_{\mathcal{A}}^{\text{oc}} = \Theta_{\mathcal{A}} + \sum \mu^{M_j}$ (Construction A.17.20, Theorem A.17.21), which packages boundary data (twisting morphisms between $\mathcal{A}$ and $\mathcal{A}^!$) and bulk data (the chiral derived center $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A})$). The five theorems characterize the closed projection $\Theta_{\mathcal{A}} = \pi_{\text{cl}}(\Theta_{\mathcal{A}}^{\text{oc}})$. The bulk projection is controlled by the derived chiral center (Theorem A.17.10); modularity belongs to the trace and clutching operations on the open sector, not to the closed algebra alone.

1.3.1 THE HEISENBERG ALGEBRA

Take $\mathcal{A} = \mathcal{H}_k$ with OPE $J(z)J(w) \sim k/(z-w)^2$. One generator, one double pole, no simple pole.

Theorem A (bar-cobar adjunction). The bar complex is $\overline{B}(\mathcal{H}_k) = T^c(s^{-1}\overline{\mathcal{H}_k}) = T^c(s^{-1}\mathbb{C} \cdot J)$. The instant computation is the binary residue

$$d_{\overline{B}}[s^{-1}J | s^{-1}J] = \text{Res}_{z_1=z_2} \left[\frac{k}{(z_1 - z_2)^2} \cdot d \log(z_1 - z_2) \right] = k.$$

At degree 3: the Arnold relation on $\text{FM}_3(\mathbb{C})$ gives $d_B^2 = 0$. The three collision divisors contribute $k \cdot (\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{13} + \eta_{13} \wedge \eta_{12}) = 0$.

Theorem A says that this bar coalgebra has a Verdier-dual partner: $\mathbb{D}_{\text{Ran}} \overline{B}(\mathcal{H}_k) \simeq (\mathcal{H}_k^!)_{\infty}$.

Theorem B (bar-cobar inversion). The Heisenberg bar cohomology is concentrated in bar degree 1: $H^{-1}(\overline{B}(\mathcal{H}_k)) = \mathbb{C} \cdot s^{-1}J$. Hence the Koszul dual coalgebra is $\mathcal{H}_k^i = \mathbb{C} \cdot s^{-1}J$ and the Koszul dual algebra is the curved symmetric chiral algebra $\mathcal{H}_k^! = (\mathcal{H}_k^i)^{\vee}$ with opposite modular characteristic $\kappa(\mathcal{H}_k^!) = -k$. The cobar of the bar is $\Omega(\overline{B}(\mathcal{H}_k)) = T(s\mathbb{C} \cdot s^{-1}J) = \mathbb{C}[J]$, which is $\mathcal{H}_k$ as a graded algebra. The counit $\varepsilon: \Omega(\overline{B}(\mathcal{H}_k)) \rightarrow \mathcal{H}_k$ is a quasi-isomorphism: the Heisenberg is Koszul.

Theorem C (complementarity). Here the center local system is constant, so the ambient complex already splits in the form asserted by Theorem C:

$$Q_g(\mathcal{H}_k) \oplus Q_g(\mathcal{H}_k^!) \cong H^*(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{H}_k}).$$

For $g \geq 1$ the two summands are Verdier-Lagrangian partners. On the scalar shadow one recovers the Heisenberg identity $\kappa(\mathcal{H}_k) + \kappa(\mathcal{H}_k^!) = k + (-k) = 0$.

Theorem D (modular characteristic). At genus 1: the self-loop graph Γ_{irr} on $\overline{\mathcal{M}}_{1,1}$ contributes $d_{\text{fib}}^2 = k \cdot \omega_1$. The genus-1 obstruction number is $F_1 = k/24$. The generating function:

$$\sum_{g \geq 1} F_g(\mathcal{H}_k) x^{2g} = k \left(\frac{x/2}{\sin(x/2)} - 1 \right) = \frac{k}{24} x^2 + \frac{7k}{5760} x^4 + \frac{31k}{967680} x^6 + \dots$$

The coefficients are $F_g = k \cdot \frac{2^{2g-1}-1}{2^{2g-1}} \cdot \frac{|B_{2g}|}{(2g)!}$, where B_{2g} is the $2g$ -th Bernoulli number. (The chiral partition function $Z_{\text{ch}} = 1/\eta(\tau)$ gives $F_1 = \kappa(\mathcal{H}_k)/24 = k/24$ as the genus-1 free energy on $\overline{\mathcal{M}}_{1,1}$.)

Theorem H (chiral Hochschild). $CH^*(\mathcal{H}_k)$ is the three-term polynomial model $(\mathbb{C}, \mathbb{C}, \mathbb{C})$ concentrated in degrees $\{0, 1, 2\}$: the class in degree 0 is the center (scalars), the class in degree 1 is the outer chiral derivation $D(\alpha) = 1$ (non-inner because $\alpha_{(0)} = 0$ when the OPE has no simple pole), and the class in degree 2 is the level deformation (double-pole OPE datum). The Koszul resolution has length 2, so $CH^n = 0$ for $n \geq 3$; Hilbert series $1 + t + t^2$, the rank-1 case of the polynomial-growth theorem.

The full computation appears in Chapter 2.

I.3.2 THE GENERAL THEOREMS

Here $\text{Fact}(X)$ denotes the symmetric monoidal category of factorization algebras on X (Chapter 3); $\text{Alg}_{\text{aug}}(\text{Fact}(X))$ is the category of *augmented* factorization algebras (equipped with a map $\mathcal{A} \rightarrow \omega_X$ to the vacuum); $\text{CoAlg}_{\text{conil}}(\text{Fact}(X))$ is the category of *conilpotent* factorization coalgebras (the iterated reduced coproduct eventually vanishes).

Each statement below is the av-image of a corresponding E_1 statement on the ordered convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ (see §1.4 for the averaging map $\text{av}: \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ and Chapter 21 for the ordered counterparts $A^{E_1} - H^{E_1}$). The five theorems are the invariants that survive averaging.

- *Theorem A* (Geometric bar-cobar duality, Theorem II.1.8.4). The deficiency is immediate: without Theorem A the symbol $\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A})$ has no proved identification with a chiral algebra. The unique survivor is the chiral Koszul pair itself. For a chiral Koszul pair one has

$$C_i \xrightarrow{\sim} \bar{B}_X(\mathcal{A}_i), \quad \Omega_X(C_i) \xrightarrow{\sim} \mathcal{A}_i, \quad \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1) \simeq \mathcal{A}_2,$$

and similarly with the indices reversed. This is the quadratic proved lane. Instant check: for Heisenberg the binary residue $d_{\bar{B}}[s^{-1}J|s^{-1}J] = k$ already produces the bar coalgebra whose Verdier dual recovers the opposite-level curved dual.

- *Theorem B* (Bar-cobar inversion, Theorem I3.18.4). Without Theorem B, the bar transform can forget the boundary algebra. Theorem B removes that failure on the Koszul locus:

$$\Omega_X \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A},$$

genus by genus, with E_2 -collapse of the bar-cobar spectral sequence. The genus-0 statement is unconditional. The genus- $g \geq 1$ statement is proved on the modular pre-Koszul lane and is unconditional on the standard CFT-type landscape except integer-spin $\beta\gamma$. Off the locus, the curved bar-cobar object persists, but the coderived continuation is kept separate from Theorem B itself. Instant check: for Heisenberg, $\Omega(\bar{B}(\mathcal{H}_k)) \simeq \mathcal{H}_k$.

- *Theorem C* (Deformation-obstruction complementarity, Theorem 13.15.14). The deficiency here is higher-genus ambiguity: without a polarization, one cannot separate deformation from obstruction. Theorem C says that the Verdier involution is the unique survivor. Writing $\mathbf{C}_g(\mathcal{A}) := R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$, one has the homotopy decomposition

$$\mathbf{C}_g(\mathcal{A}) \simeq \mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^\dagger)$$

for every genus, and for $g \geq 1$ the induced pairing is perfect with each summand Lagrangian. At the cohomological shadow level,

$$\mathcal{Q}_g(\mathcal{A}) \oplus \mathcal{Q}_g(\mathcal{A}^\dagger) \cong H^*(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}}).$$

The Verdier-side Lagrangian splitting is proved. The ambient shifted-symplectic upgrade is conditional on perfectness and nondegeneracy. Instant check: for Heisenberg the center local system is constant, so the decomposition is visible at once.

- *Theorem D_{scal}* (Genus universality, Theorem 13.13.16). The deficiency is scalar drift: genus by genus, the bar tower could produce unrelated numbers. Theorem D says that on the proved uniform-weight lane they are forced by one scalar $\kappa(\mathcal{A})$, determined already at genus 1. For algebras whose strong generators have the same conformal weight, $\text{obs}_g = \kappa \cdot \lambda_g \in H^*(\overline{\mathcal{M}}_g)$ and $F_g = \kappa \cdot \hat{A}_g$ at all genera. At genus 1 the scalar formula is unconditional for every family. For multi-weight algebras and $g \geq 2$, the diagonal term remains universal but the full free energy is

$$F_g(\mathcal{A}) = \kappa(\mathcal{A}) \lambda_g^{\text{FP}} + \delta F_g^{\text{cross}}(\mathcal{A}),$$

with $\delta F_g^{\text{cross}}$ the mixed-channel correction of Theorem 13.22.225. For $\mathcal{W}_3$ this correction is nonzero already at genus 2, so the all-weight scalar formula fails there. The scalar κ is universal, additive under tensor product, and duality-constrained ($\kappa + \kappa' = 0$ for affine Kac–Moody and free fields, and a fixed nonzero constant for $\mathcal{W}$ -algebras). On the uniform-weight lane, the generating function is the $\hat{A}$ -genus (Theorem K.7.1):

$$\sum_{g \geq 1} F_g(\mathcal{A}) \cdot \hbar^{2g} = \kappa(\mathcal{A}) \cdot (\hat{A}(i\hbar) - 1).$$

At genus 1 this reduces to $F_1(\mathcal{A}) = \kappa(\mathcal{A})/24$ for every family.

Theorem D_Δ (Spectral characteristic, Theorem 13.21.63): the spectral discriminant $\Delta_{\mathcal{A}}(x)$ is a separately proved non-scalar invariant.

κ is the one-loop coefficient of the effective action; its vanishing removes the scalar genus-1 anomaly, while higher-genus multi-weight corrections are a separate issue. Together, D_{scal} and D_Δ are the characteristic classes of the factorization homology bundle $\int_{\Sigma_g} \mathcal{A}$ (Remark K.7.1); the bundle itself (its fibers, flat connection, and modular functor structure) is the full modular homotopy invariant (Conjecture K.7.1).

- *Theorem H* (Chiral Hochschild cohomology, Theorem 14.4.12). The deficiency is coefficient blow-up: the bulk derived center could a priori live in arbitrarily high degrees. Theorem H says that on the Koszul locus it does not. One has $CH^n(\mathcal{A}) = 0$ for $n < 0$ and $n > 2$, and the Hilbert polynomial is

$$P_{\mathcal{A}}(t) = \dim Z(\mathcal{A}) + \dim CH^1(\mathcal{A}) t + \dim Z(\mathcal{A}^\dagger) t^2.$$

This is the sharp theorem. The specializations are family-sensitive: Heisenberg gives $1 + t + t^2$; generic Virasoro and principal $\mathcal{W}$ -algebras give $1 + t^2$; generic affine Kac–Moody gives $CH^1(V_k(\mathfrak{g})) \cong \mathfrak{g}$, so no uniform four-dimensional bound is available. Critical level is outside the theorem’s regime: there the Beilinson–Drinfeld comparison yields an unbounded oper-type center. The primitive step is the descent lemma (Lemma 14.4.9), reducing Theorem H to Theorem A’s Verdier intertwining.

Warning 1.3.1 (Three Hochschild theories). Three inequivalent notions of “Hochschild cohomology” co-exist in this programme; conflating them is a persistent source of error. *Chiral Hochschild* $CH^*(\mathcal{A}) = H^*(\text{CoDer}(\overline{B}(\mathcal{A})))$ is the cohomology of coderivations of the bar coalgebra; it lives on the curve X and has cohomological amplitude $[0, 2]$ on the Koszul locus (Theorem H). *Topological Hochschild* HH_{top}^* is the factorization homology on the circle S^1 ; it lives in dimension 1 higher and governs the E_1 -chiral bar of Volume II. *Categorical Hochschild* $HH^*(\text{Rep}(\mathcal{A}))$ is the Hochschild cohomology of the module category; it governs the Drinfeld center and the E_2 structure. See Principle 3.11.9 (Chapter 3) for the geometric origin that distinguishes all three.

Principle 1.3.2 (Five facets of $\Theta_{\mathcal{A}}$). Let $\mathcal{A}$ be a modular Koszul chiral algebra on a smooth projective curve X , and let $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_{\mathcal{A}}^{(0)} \in \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ be the bar-intrinsic Maurer–Cartan element (Theorem 13.21.69). The five main theorems characterize five *facets* of $\Theta_{\mathcal{A}}$: existence, faithfulness, decomposition, leading coefficient, and coefficient ring.

- (A) *Arena* (Theorem A). $\Theta_{\mathcal{A}}$ **exists**. The bar–cobar adjunction constructs the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ in which $\Theta_{\mathcal{A}}$ lives; with it, $\Theta_{\mathcal{A}}$ arises automatically as $D_{\mathcal{A}} - d_{\mathcal{A}}^{(0)}$.
- (B) *Faithfulness* (Theorem B). $\Theta_{\mathcal{A}}$ **determines** $\mathcal{A}$. On the Koszul locus, the counit $\Omega_X(\overline{B}_X(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ is a quasi-isomorphism.
- (C) *Decomposition* (Theorem C). $\Theta_{\mathcal{A}}$ **splits**. The genus- g projection decomposes under the Verdier involution into complementary Lagrangians $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!) = H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$.
- (D) *Leading coefficient* (Theorem D). $\Theta_{\mathcal{A}}$ has **universal scalar projection**. On the uniform-weight lane, the degree-2 genus- g component is $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \lambda_g$ at all genera, with $\kappa(\mathcal{A})$ universal and governed by the $\hat{A}$ -genus. At genus 1 this holds unconditionally for all families.
- (E) *Coefficient ring* (Theorem H). $\Theta_{\mathcal{A}}$ has **polynomial coefficients**. $CH^*(\mathcal{A})$ is concentrated in degrees $\{0, 1, 2\}$, controlling the deformation ring over which $\Theta_{\mathcal{A}}$ varies.

Conjecture 1.3.3 (The boundary-bulk reconstruction thesis;). The five theorems A, B, C, D, H admit a single unifying interpretation: the boundary chiral algebra $\mathcal{A}$ determines its bulk via the chiral derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A})$, the modular characteristic $\kappa(\mathcal{A})$ is the holographic central charge, the shadow obstruction tower $\{S_r(\mathcal{A})\}_{r \geq 2}$ is the holographic correction hierarchy, and the Drinfeld double $U_{\mathcal{A}} = \mathcal{A} \bowtie \mathcal{A}^!$ is the universal boundary-bulk algebra that reconstructs the gravitational theory from the VOA. Each theorem corresponds to a single claim of the thesis.

- (A) *Existence of the dual* (Theorem A). The existence of the Verdier dual $\mathcal{A}^!$ is implicit in Definition 11.1.15 of a chiral Koszul pair, which equips the pair $(\mathcal{A}_1, \mathcal{A}_2)$ with Verdier-compatible identifications $\mathbb{D}_{\text{Ran}}(C_1) \simeq C_2$ from the outset; Theorem A part (1), the bar–cobar adjunction, then supplies the unit and counit quasi-isomorphisms $C_i \simeq \overline{B}_X(\mathcal{A}_i)$ on the Koszul locus. Part (2), the Verdier intertwining $\mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}_1) \simeq \mathcal{A}_2$, then unpacks the Verdier clause of the definition by transport across part (1). This supplies the algebraic pair $(\mathcal{A}, \mathcal{A}^!)$ on which the Drinfeld double $U_{\mathcal{A}}$ is defined.

- (B) *Non-degenerate reconstruction* (Theorem B). On the Koszul locus the counit $\Omega_X \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ is a quasi-isomorphism. The genus-0 clause is unconditional. The genus- $g \geq 1$ clause is proved on the modular pre-Koszul lane and is unconditional on the standard CFT-type landscape except integer-spin $\beta\gamma$. No boundary information is lost in the passage boundary $\mapsto$ bar coalgebra $\mapsto$ cobar $\mapsto$ boundary: the holographic transform is injective up to contractible ambiguity.
- (C) *Lagrangian bulk splitting* (Theorem C). Theorem C says first that the ambient genus- g deformation complex splits under Verdier involution into the two eigenspaces $\mathbf{Q}_g(\mathcal{A})$ and $\mathbf{Q}_g(\mathcal{A}^\dagger)$, and second that for $g \geq 1$ these summands are Lagrangian partners for the induced pairing. This Verdier-side polarization is unconditional on the proved lane. The stronger ambient shifted-symplectic upgrade is conditional on perfectness and nondegeneracy. Family-specific scalar sum rules such as $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) = 0$ for affine Kac–Moody or 13 for Virasoro are shadows of this decomposition, not the theorem itself.
- (D) *Brown–Henneaux coefficient* (Theorem D). On the uniform-weight lane, the genus- g obstruction is $\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g$ (UNIFORM-WEIGHT), with λ_g the g -th Mumford class (the gravitational moduli characteristic). The scalar $\kappa(\mathcal{A})$ is the Brown–Henneaux one-loop coefficient of the bulk partition function. At genus 1 the scalar formula holds unconditionally for every standard family; at genus $g \geq 2$ the multi-weight cross-channel correction $\delta F_g^{\text{cross}}$ enters as a separate higher-loop term, and the uniform-weight hypothesis is required for the scalar formula to remain valid in its stated form.
- (E) *Holographic tightness* (Theorem H). On the Koszul locus the bulk algebra $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) = CH^*(\mathcal{A})$ has cohomological amplitude $[0, 2]$ and Hilbert polynomial $P_{\mathcal{A}}(t) = \dim Z(\mathcal{A}) + \dim CH^1(\mathcal{A})t + \dim Z(\mathcal{A}^\dagger)t^2$. For generic Virasoro and principal $\mathcal{W}$ -algebras this specializes to $1 + t^2$; for generic affine Kac–Moody one has $CH^1(V_k(\mathfrak{g})) \cong \mathfrak{g}$, so the bulk need not be four-dimensional. The generic-level hypothesis excludes the critical level $k = -h^\vee$, where the Feigin–Frenkel center enlarges to the oper algebra on the formal disk (Remark 1.3.10; Chapter ??).

The five facets of Principle 1.3.2 are the five algebraic consequences of the MC element; the five claims above are the five boundary-bulk consequences of the same theorems.

PROPOSITION 1.3.4 (*Five facets of the collision residue $r(z)$* ;). The degree-2, genus-0 projection

$$r(z) := \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}^{E_1}) \in \text{End}(V^{\otimes 2}) \otimes \mathcal{O}(*\Delta)$$

of the universal Maurer–Cartan element (Theorem 21.1.7) admits five equivalent characterizations. Each is proved in the indicated chapter; all five describe the same object up to convention.

- (F1) *Classical r -matrix*. $r(z)$ is the classical limit of the quantum R -matrix $R(z; \hbar) = 1 + \hbar r(z) + \mathcal{O}(\hbar^2)$ of the Yangian $Y(\mathcal{A})$; it satisfies the classical Yang–Baxter equation and generates the Drinfeld–Jimbo quantum deformation (Chapter O, Proposition 21.1.13).
- (F2) *Binary component of $\Theta_{\mathcal{A}}^{E_1}$* . $r(z)$ is the degree-2, genus-0 Taylor coefficient of the universal MC element $\Theta_{\mathcal{A}}^{E_1}$ in the ordered convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$; higher-degree components are the KZ associator, the quartic R -matrix identity, and so on (Chapter 21; equation (1.2)). The full tower $(r(z), r_3, r_4, \dots)$ is one object read at ascending degree.

- (F3) *Leading-order modular shadow.* The Σ_2 -coinvariant projection $\text{av}(r(z)) = \kappa(\mathcal{A})$ is the modular characteristic, the first entry of the shadow obstruction tower (equation (1.5); Theorem 1.4.1). The residue contains a matrix-valued refinement; averaging produces the scalar.
- (F4) *Collision kernel of the bar differential.* The bar differential $d_{\bar{B}}$ at degree 2 is the residue of $r(z)$ at the collision divisor: given sections a, b of $\mathcal{A}$, the binary component of $d_{\bar{B}}(a \otimes b)$ extracts $\text{Res}_{z=0} [r(z)(a \otimes b)]$ along the diagonal in $\bar{C}_2(X)$ (Chapter 6; Theorem 6.1.21).
- (F5) *OPE data modulo $d \log$ absorption.* If the OPE $a(z)b(w) \sim \sum_{n \geq 1} (a_{(n-1)}b)(w)/(z-w)^n$ has singular part of pole order p , then $r(z)$ has pole order $p-1$: the bar propagator $d \log(z-w)$ absorbs one pole from the OPE. Thus $r(z)$ is the OPE singular part stripped of its leading pole and normalized by the logarithmic propagator.

The five facets agree as elements of $\text{End}(V^{\otimes 2}) \otimes \mathcal{O}(*\Delta)$; each is the natural presentation in a different framework, and Part .2 (Chapter ??) converts this equivalence into the organizing principle of the seven-face falsification checklist.

Remark 1.3.5 (The five facets as boundary-bulk realizations). The five facets of Proposition 1.3.4 are the five independent realizations of the R -matrix of the Drinfeld double $U_{\mathcal{A}} = \mathcal{A} \bowtie \mathcal{A}^!$ in the boundary-bulk picture. Facet (F1) is the classical r -matrix, the Yangian form of the bulk coupling that propagates boundary scattering data into the three-dimensional interior. Facet (F2) is the binary component of $\Theta_{\mathcal{A}}$, the second-order boundary-bulk interaction: the degree-2 Taylor coefficient of the MC element is exactly the leading boundary-bulk vertex. Facet (F3) is the scalar $\kappa(\mathcal{A})$, the leading holographic central charge: it is the one number that survives coinvariant projection and equals the Brown–Henneaux coefficient of the bulk effective action (see Theorem D). Facet (F4) is the collision kernel of the bar differential, the residue of the bulk propagator along the boundary diagonal: it is the geometric realization of the bulk Feynman rule as a boundary operation. Facet (F5) is the OPE data modulo $d \log$ absorption, the boundary data modulo the gauge redundancy introduced by the logarithmic propagator. The five facets therefore decompose the R -matrix into its five boundary-bulk roles: Yangian coupling, binary vertex, central charge, propagator kernel, and gauge-reduced boundary datum.

Remark 1.3.6 (Five facets versus seven faces). The five facets of Proposition 1.3.4 are intrinsic: they present one object in five languages. The seven faces of Part .2 (Chapter ??) are extrinsic: they are seven independent computational frameworks (classical r -matrix, KZ connection, Yangian presentation, Sklyanin algebra, celestial operator, holographic boundary datum, Drinfeld double) in which the same object is computed by disjoint methods and checked for agreement. The five facets identify what must agree; the seven faces verify that the agreement holds.

Remark 1.3.7 (E_1 -chiral counterparts of the five theorems). Each of Theorems A–H has an E_1 counterpart (Theorems A^{E_1} – H^{E_1} , Chapter 21), in which the symmetric bar $\bar{B}^{\Sigma}(\mathcal{A})$ on unordered configuration spaces is replaced by the *ordered bar* $\bar{B}^{\text{ord}}(\mathcal{A})$ on $\text{Conf}_n^{\text{ord}}(X)$, the chiral Koszul dual $\mathcal{A}^!$ is replaced by the *dg-shifted Yangian* $\mathcal{A}_{\text{line}}^!$, and the commutative modular operad FCom is replaced by the ribbon modular operad FAss . The five facets transfer: $\Theta_{\mathcal{A}}^{E_1}$ exists in the ordered convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}, E_1}$ (Theorem A^{E_1}); the ordered cobar inverts on the ordered Koszul locus (Theorem B^{E_1}); the genus- g projection decomposes into complementary Lagrangians via Verdier duality on ribbon graphs (Theorem C^{E_1}); the leading coefficient is the same scalar $\kappa(\mathcal{A})$ (Theorem D^{E_1}); and the coefficient ring is the ordered chiral Hochschild cohomology (Theorem H^{E_1}). The Σ_n -coinvariant map $\text{FAss} \rightarrow \text{FCom}$ sends $\Theta_{\mathcal{A}}^{E_1} \mapsto \Theta_{\mathcal{A}}$: the symmetric theory is the unordered projection of the ordered theory.

The two Koszul dualities are co-equal but geometrically distinct. The symmetric bar sees unordered collisions and produces the chiral Koszul dual $\mathcal{A}^!$, an E_∞ -chiral algebra on the curve. The ordered bar sees ordered collisions and produces the dg-shifted Yangian $\mathcal{A}_{\text{line}}^!$, an E_1 -chiral algebra whose R -matrix is the Koszul-dual spectral parameter. The symmetric dual lives on X ; the ordered dual lives on a line in the 3d bulk $\mathbb{C}_z \times \mathbb{R}_t$.

THEOREM 1.3.8 (*Central charge complementarity*;). [Regime: curved-central on the Koszul locus (Convention 1.10.2).]

For Koszul dual pairs related by the Feigin–Frenkel involution $k \mapsto k' = -k - 2h^\vee$:

- (a) *Affine Kac–Moody*. $c(\widehat{\mathfrak{g}}_k) + c(\widehat{\mathfrak{g}}_{k'}) = 2 \dim \mathfrak{g}$.
- (b) *Principal $\mathcal{W}$ -algebras*: $c(\mathcal{W}^k(\mathfrak{g})) + c(\mathcal{W}^{k'}(\mathfrak{g})) = 2 \text{rank}(\mathfrak{g}) + 4h^\vee \dim \mathfrak{g}$.

In particular, $\mathfrak{g} = \mathfrak{sl}_2$ in part (b) gives $c + c' = 26$.

Proof. Part (a). The Sugawara central charge is $c(\widehat{\mathfrak{g}}_k) = k \dim \mathfrak{g} / (k + h^\vee)$. Since $k' + h^\vee = -(k + h^\vee)$:

$$c(k) + c(k') = \frac{k \cdot d}{k + h^\vee} + \frac{(k + 2h^\vee) \cdot d}{k + h^\vee} = \frac{2(k + h^\vee) \cdot d}{k + h^\vee} = 2d$$

where $d = \dim \mathfrak{g}$.

Part (b). The Drinfeld–Sokolov central charge is $c(\mathcal{W}^k(\mathfrak{g})) = r - 12|\rho|^2(t - 1)^2/t$ where $r = \text{rank}(\mathfrak{g})$ and $t = k + h^\vee$ (verified for $\mathfrak{sl}_2$ in Theorem H.1.2 and for $\mathfrak{sl}_3$ in Theorem H.5.1). The involution sends $t \mapsto -t$:

$$c(k) + c(k') = 2r + 12|\rho|^2 \cdot \frac{(t + 1)^2 - (t - 1)^2}{t} = 2r + 48|\rho|^2.$$

The Freudenthal–de Vries identity $|\rho|^2 = h^\vee \dim \mathfrak{g} / 12$ (under normalization $(\theta, \theta) = 2$; see [238], Ch. 13) yields $c + c' = 2r + 4h^\vee d$.

Verification. $\mathfrak{sl}_2$: $2(1) + 4(2)(3) = 26$. $\mathfrak{sl}_3$: $2(2) + 4(3)(8) = 100$. $\mathfrak{sl}_N$: $2(N-1) + 4N(N^2-1) = 2(N-1)(2N^2+2N+1)$. $\square$

Remark 1.3.9. The identity $c + c' = 26$ for $\mathfrak{sl}_2$ is the algebraic incarnation of $c_{\text{matter}} + c_{\text{ghost}} = 0$. At the critical point, the relative BRST complex of the bosonic string is quasi-isomorphic to the genus-0 bar complex (Theorem R.3.1). The identification of the ghost system with the cobar of the matter bar complex requires the heuristic BV/bar bridge of Chapter R.3.1; the bosonic string critical dimension follows from Koszul duality at the scalar level without this bridge.

Remark 1.3.10 (*Two critical points: $k = 0$ and $k = -h^\vee$*). The affine Kac–Moody vacuum algebra $V_k(\mathfrak{g})$ has two distinguished values of the level, and the boundary-bulk reconstruction thesis distinguishes them sharply. At $k = 0$ the r -matrix $r_k(z) = k \Omega / z$ vanishes identically, the Drinfeld double degenerates to the tensor product $V_0(\mathfrak{g}) \otimes V_0(\mathfrak{g})^!$, and the bulk theory is classical Chern–Simons on the commutative locus: no scattering, no holographic correction, trivial bulk. Identity (1.6) gives $\kappa(V_0(\mathfrak{g})) = \dim \mathfrak{g} / 2$ from the Sugawara shift alone, with no r -matrix contribution. At $k = -h^\vee$ the Sugawara construction is undefined: the denominator $k + h^\vee$ in κ vanishes, the vacuum stress tensor fails to lie in the appropriate completion, and the bulk theory itself becomes singular. This is the Feigin–Frenkel critical level, where the centre $\mathfrak{z}(\widehat{\mathfrak{g}})$ enlarges to the algebra of opers on the formal disk (Chapter ??). The two critical points play complementary roles: $k = 0$ is the abelian limit on the boundary (the bulk degenerates to a free theory), and $k = -h^\vee$ is the

critical limit on the bulk (the Sugawara stress tensor no longer exists and the Drinfeld double presentation breaks). The Feigin–Frenkel centre at $k = -h^\vee$ is the singular fibre of the boundary-bulk correspondence, while the Drinfeld double describes it on the regular locus $k \notin \{0, -h^\vee\}$.

The five theorems assemble into a single commutative square:

$$\begin{array}{ccc}
 \mathrm{Alg}_{\mathrm{aug}}(\mathrm{Fact}(X)) & \xrightarrow{\bar{B}_X} & \mathrm{CoAlg}_{\mathrm{conil}}(\mathrm{Fact}(X)) \\
 \downarrow (\cdot)^! & & \downarrow \mathbb{D}_{\mathrm{Ran}} \\
 \mathrm{Alg}_{\mathrm{aug}}(\mathrm{Fact}(X)) & \xrightarrow{\bar{B}_X} & \mathrm{CoAlg}_{\mathrm{conil}}(\mathrm{Fact}(X))
 \end{array} \tag{1.1}$$

Commutativity is Theorem A. The cobar functor Ω_X , left adjoint to $\bar{B}_X$, gives the counit of Theorem B. At genus $g \geq 1$, the universal Maurer–Cartan class $\Theta_{\mathcal{A}}$ measures the failure of strict commutativity. Vanishing of the scalar curvature term $\kappa(\mathcal{A})$ removes one obstruction, but the manuscript’s reduction from the intrinsic coderived/contraderived comparison to ordinary derived categories is proved only on the flat finite-type completed-dual loci singled out later in Part I.

Off the Koszul locus, the coderived category (Positselski [350]) is the correct ambient category: the curved bar object can lose ordinary cohomological visibility while remaining nontrivial in the coderived framework. Ordinary derived categories are recovered only on the flat finite-type completed-dual loci.

Beyond the five theorems, the programme produces: (i) the Pixton ideal of the modular curve from the MC tautological relations (Theorem 13.22.277, proved for semisimple shadow CohFTs; obstructed for non-semisimple by Proposition 13.22.279); (ii) a complete resolution of the BV/BRST identification for free fields (Theorem R.3.1); (iii) the multi-weight genus tower through genus 4 with explicit closed forms and a growth theorem (Proposition 13.22.255); (iv) non-principal Koszul duality for the Bershadsky–Polyakov algebra and nilpotent transport through $\mathfrak{sl}_8$ (Computation ??, Proposition .2).

1.4 THE E_1 STORY AS PRIMITIVE: AVERAGING AND THE MODULAR SHADOW

The bar complex $\bar{B}(\mathcal{A})$ presented in §1.1 is the symmetric (commutative) bar: it lives on $(s^{-1}\bar{\mathcal{A}})_{\Sigma_n}^{\otimes n}$ and forgets the order in which collisions occur. This presentation is convenient for formulating the five main theorems and connecting to the modular operad on $\bar{\mathcal{M}}_{g,n}$, but it is not the natural primitive of the theory. The natural primitive is the *ordered* bar

$$\bar{B}^{\mathrm{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}}) = \bigoplus_{n \geq 0} (s^{-1}\bar{\mathcal{A}})^{\otimes n}$$

with deconcatenation coproduct, which by Stasheff’s theorem [382] is the universal cofree conilpotent coalgebra on $s^{-1}\bar{\mathcal{A}}$. Every A_∞ -chiral algebra admits a canonical ordered bar; the symmetric bar arises only after applying Σ_n -coinvariants externally on each tensor factor. The unsymmetrized object retains strictly more information (§1.4).

1.4.0.0.1 The ordered convolution algebra and its MC element. The ordered convolution dg Lie algebra

$$\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1} := \prod_{g,n} \mathrm{Hom}(F\mathrm{Ass}(g,n), \mathrm{End}_{\mathcal{A}}(n)),$$

built on the ribbon (associative) modular operad $F\text{Ass}$ rather than the commutative cooperad Sym^c , houses the bar-intrinsic Maurer–Cartan element

$$\Theta_{\mathcal{A}}^{E_1} := D_{\mathcal{A}}^{E_1} - d_{\mathcal{A}}^{(0)} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}). \quad (1.2)$$

The degree-2 component of $\Theta_{\mathcal{A}}^{E_1}$ at genus 0 is the *classical r -matrix* $r(z) \in \text{End}(V^{\otimes 2}) \otimes \mathcal{O}(*\Delta)$, the meromorphic function whose residue at $z = 0$ controls the spectral scattering of $\mathcal{A}$. The degree-3 component is the *KZ associator* $r_3(z_1, z_2)$, and the degree- ≥ 4 components are the higher Yangian/braided coherences that satisfy the boundary equations of Stasheff associahedra: classical Yang–Baxter for $r(z)$, the pentagon for r_3 , the quartic R -matrix identity for r_4 , and so on (Proposition 21.1.13). The components of $\Theta_{\mathcal{A}}^{E_1}$ are the full data of the line-operator algebra: an R -matrix, a braided category, a Drinfeld–Jimbo Yangian.

1.4.0.0.2 Averaging as the sole information loss. The modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is the Σ_n -coinvariant of $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ via the *averaging map* (Definition 21.1.6, equation (21.1)):

$$\text{av}: \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \twoheadrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}, \quad \text{av}(\phi)(g, n) = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma \cdot (\phi(g, n) \circ \iota_{g, n}^{\text{rib}}). \quad (1.3)$$

The map av is a surjective dg Lie morphism (Theorem 21.1.5) sending the ordered MC element to the symmetric one (Theorem 21.1.7):

$$\text{av}(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}. \quad (1.4)$$

At degree 2, this projection records only one number: the Σ_2 -coinvariant of the residue of $r(z)$ at $z = 0$ is the modular characteristic

$$\kappa(\mathcal{A}) = \text{av}(r(z)) = \frac{1}{2} \text{tr}[\text{Res}_{z=0} r(z)], \quad (1.5)$$

where the trace is the cyclic trace on $\text{End}(V^{\otimes 2})$. For the affine Kac–Moody vacuum algebra $V_k(\mathfrak{g})$ at non-critical level, the averaging formula (1.5) specializes to the Sugawara identity

$$\text{av}(r_k(z)) + \frac{1}{2} \dim \mathfrak{g} = \kappa(V_k(\mathfrak{g})) = \frac{\dim \mathfrak{g} (k + h^\vee)}{2h^\vee}, \quad (1.6)$$

where $r_k(z) = k \Omega/z$ is the level- k classical r -matrix and the shift $\frac{1}{2} \dim \mathfrak{g}$ is the normal-ordering contribution of the bulk Sugawara stress tensor. Identity (1.6) is the boundary-level realization of κ as the holographic central charge: the r -matrix encodes the boundary coupling, the shift encodes the bulk renormalization, and the sum is the one-loop coefficient that enters Theorem D. The shadow obstruction tower $(\kappa, \mathfrak{C}, \mathfrak{Q}, \dots)$ is the degree-by-degree image of $(r(z), r_3, r_4, \dots)$ under av (Proposition 21.1.13). The E_1 side contains the matrix-valued meromorphic function; the E_∞ side contains its Σ_n -symmetrized scalar.

THEOREM 1.4.1 (E_1 primacy;). Let $\mathcal{A}$ be a cyclic chiral algebra on X .

- (i) (Surjectivity.) The averaging map $\text{av}: \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \twoheadrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ ((1.3)) is a surjective dg Lie morphism.
- (ii) (MC projection.) av sends $\Theta_{\mathcal{A}}^{E_1} \mapsto \Theta_{\mathcal{A}}$ ((1.4)). In particular, the shadow obstruction tower $(\kappa, \mathfrak{C}, \mathfrak{Q}, \dots)$ is the degree-by-degree Σ_n -coinvariant image of the R -matrix tower $(r(z), r_3, r_4, \dots)$.
- (iii) (Bracket preservation.) av preserves the dg Lie bracket by Σ_n -equivariance of the operad composition maps.

- (iv) (Non-splitting.) The kernel $\ker(\text{av})$ is non-trivial: at degree 3 it contains the Drinfeld associator $\Phi_{\text{KZ}}(\mathcal{A})$, which is annihilated by av but satisfies the pentagon equation in $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$. In particular, the short exact sequence $0 \rightarrow \ker(\text{av}) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \xrightarrow{\text{av}} \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \rightarrow 0$ does not split as dg Lie algebras. At genus 1, a fourth obstruction to splitting arises from the quasi-modular anomaly of the Eisenstein series E_2 : the genus-1 propagator transforms with a non-holomorphic correction that no Σ_n -equivariant section can absorb (Proposition 21.1.10).

Proof sketch. Parts (i)–(iii) are proved in Chapter 21. The map av is the Reynolds operator $\phi \mapsto \frac{1}{n!} \sum_{\sigma} \sigma \cdot \phi$; surjectivity follows because av restricts to the identity on Σ_n -invariant elements, which span the target $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$. The bracket is preserved because operad composition in $F\text{Ass}$ is Σ_n -equivariant: coinvariant projection converts T^c -convolution to Sym^c -convolution (Theorem 21.1.5). The MC projection $\text{av}(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$ follows from $\text{av}(D_{\mathcal{A}}^{E_1}) = D_{\mathcal{A}}$ (the genus-completed bar differential descends under coinvariants) and $\text{av}(d_0) = d_0$ (Theorem 21.1.7).

For (iv), the Drinfeld associator $\Phi_{\text{KZ}}(\mathcal{A}) \in \ker(\text{av})_{0,3}$ satisfies the pentagon equation in $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ (the genus-0, degree-3 MC equation; Theorem 21.3.2, equation (21.7)). Its Σ_3 -symmetrization vanishes because the pentagon identity is antisymmetric under transposition of the two internal edges. Were av split, there would exist a dg Lie section $s: \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \hookrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ with $\text{av} \circ s = \text{id}$. Such a section would lift the commutative MC element $\Theta_{\mathcal{A}}$ to an ordered element in the image of s ; but the pentagon constraint on $\ker(\text{av})$ forces the degree-3 component of any lift to involve Φ_{KZ} , which does not lie in the image of any linear section. $\square$

Remark 1.4.2 (Categorical E_1 primacy). Theorem 1.4.1 is a dg Lie statement. The categorical analogue (that the braided monoidal category $\mathcal{C}_{\text{line}}$ of line operators is the primitive categorical datum, with modular tensor categories derived via the Drinfeld center $Z(\mathcal{C}_{\text{line}})$) amounts to DK-5 (Conjecture O.13.120). The proved content (MC₃ on the evaluation-generated core for all simple types, Theorem O.9.71) establishes the base case. The full categorical E_1 primacy theorem = DK-5.

Principle 1.4.3 (The E_1 primacy thesis). Theorem 1.4.1 admits a concise restatement. The E_1 /ordered structure is the natural primitive of the theory. The E_{∞} /symmetric/modular structure is its Σ_n -coinvariant shadow under av . The five main theorems A–H are the invariants that survive averaging. Information flows in only one direction: from the rich E_1 side, which contains the R -matrix, the KZ associator, the Drinfeld–Jimbo Yangian, the full braided category of line operators, and the entire spectral scattering data, to the coarser E_{∞} side, which contains only the modular characteristic κ , the shadow obstruction tower, and the genus expansion of the closed sector.

1.4.0.0.3 Five reasons for the inversion. OPERADIC PRIMACY. In the hierarchy of E_n -operads, $E_1 = \text{Ass}$ is the primitive associative operad and $E_{\infty} = \text{Com}$ arises from it as the colimit $\text{Com} = \text{colim}_n E_n$ or, equivalently, by Σ_n -coinvariants on each degree. At the level of cofree coalgebras, Stasheff’s theorem identifies T^c (deconcatenation) as the universal cofree conilpotent coalgebra; the symmetric cooperad Sym^c is recovered from T^c by external Σ_n -coinvariants. The bar functor that respects this universality is $\overline{B}^{\text{ord}} = T^c(s^{-1}\bar{\mathcal{A}})$, not the symmetric bar.

INFORMATION CONTENT. An equivariant $\text{End}(V^{\otimes n})$ -valued meromorphic function strictly contains its scalar trace. The averaging map av is surjective but not injective: the kernel records the non-symmetric components of the line-operator data. For Heisenberg, $r(z) = k/z$ is already scalar, so the symmetrization recovers $\kappa(\mathcal{H}_k) = k$ without losing matrix data. For affine Kac–Moody, $r(z) = k \Omega/z$

contains the full Yangian double; the symmetrization recovers $\kappa(\widehat{\mathfrak{g}}_k) = (k + h^\vee) \dim \mathfrak{g} / (2h^\vee)$ and discards the entire Drinfeld–Jimbo deformation.

PHYSICAL PRIMACY. The natural physical objects are ordered. Three-dimensional holomorphic-topological theories have line operators along the topological direction $\mathbb{R}_t$ (Costello–Gaiotto [433]); these line operators form the ordered convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod} E_1}$ on $\mathbb{C}_z \times \mathbb{R}_t$, and their fusion is the E_1 -multiplication. Open-string field theory and factorization on bordered curves carry intrinsic boundary orderings. Integrable lattice models have R -matrices that satisfy the (ordered) Yang–Baxter equation, not its symmetric projection. In every physical setting where the bar complex appears, the line/boundary direction is ordered before any Σ_n -symmetrization is taken.

CATEGORICAL PRIMACY. The categorical objects of representation theory are ordered. Quantum groups, Yangians, and braided tensor categories are the natural framework for chiral algebras coupled to a spectral parameter; their structure constants are matrix-valued and obey ordered identities (CYBE, pentagon, hexagon, mixed Yang–Baxter). Symmetric monoidal categories are obtained from braided ones by the Σ_n -coinvariant procedure on the braid groupoid; this is exactly the categorical analogue of the averaging map (1.3).

OPERADIC PRIMACY OF SWISS-CHEESE. The Swiss-cheese operad $\text{SC}^{\text{ch}, \text{top}}$ governs the open/closed derived center pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$ (Theorem A.17.10); the bar complex itself is a single-coloured E_1 -chiral coassociative coalgebra over $(\text{ChirAss})^!$. The SC structure emerges on the derived center, not on the bar complex. The closed sector of any Swiss-cheese algebra is recovered from the open sector by passing to Σ_n -coinvariants along the open-to-closed boundary operator. The closed sector is intrinsically a quotient of the open sector, never an enrichment of it.

1.4.0.0.4 Historical context. The manuscript developed from the Beilinson–Drinfeld theory of factorization algebras on the Ran space [40], which is unordered: a factorization algebra assigns sections to finite subsets of points, with no ordering. That framing made the symmetric bar complex the default starting point and treated the ordered bar as a refinement. The reframing recorded here reverses this: the ordered bar is the universal object, and the symmetric bar is its Σ_n -coinvariant. All five-theorem statements and proofs are unchanged; only the reading order of the dependency DAG shifts. Concretely: Chapter 21 presents the ordered theory in full, and the present chapter and Chapter 6 onward present the av-images of the ordered constructions.

Remark 1.4.4 (Scope of the E_1 reframing). The proofs of Theorems A–D and H are unchanged. The conceptual reordering is as follows: the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is now read as $\text{av}(\mathfrak{g}_{\mathcal{A}}^{\text{mod} E_1})$, the universal MC element $\Theta_{\mathcal{A}}$ as $\text{av}(\Theta_{\mathcal{A}}^{E_1})$, and the modular characteristic $\kappa(\mathcal{A})$ as $\text{av}(r(z))$ at degree 2. The ordered theory of Chapter 21 is the upstream object; the symmetric theory is its image.

The E_1 side is strictly richer: at degree 2 alone it distinguishes algebras that the symmetric side identifies. The Heisenberg E_1 -shadow $r_{\mathcal{H}_k}(z) = k/z$ and the $\widehat{\mathfrak{sl}}_2$ -shadow $r_{\widehat{\mathfrak{sl}}_2, k}(z) = k \Omega_{\widehat{\mathfrak{sl}}_2} / z$ already differ before averaging: the former is scalar, while the latter is matrix-valued. The ordered bar separates what the symmetric bar collapses.

Warning 1.4.5 (Five inequivalent notions of “ E_1 -chiral”). The literature uses “ E_1 -chiral” for at least five distinct structures: (i) ordered chiral homology on $C_n^<(X)$ (Definition 21.2.3); (ii) the E_1 -monoidal structure on the category of modules; (iii) the braided-tensor structure from the R -matrix; (iv) the factorization-algebra structure on ordered configuration spaces; (v) the ribbon modular operad $F\text{Ass}$ action on the bar complex. These agree on the Koszul locus at generic level, but differ at critical level, for non-Koszul algebras,

and at the chain level versus the derived level. Throughout this volume, “ E_1 -chiral” refers to (i) unless otherwise stated. See Warning 3.11.8 (Chapter 3) for the full disambiguation.

Remark 1.4.6 (The three-volume dimensional reduction). The three volumes of this work correspond to three levels of a dimensional reduction:

- **Volume I** (2d, the curve X): the modular shadow. The five theorems A–D and H are the invariants that survive the full reduction $4d \rightarrow 3d \rightarrow 2d$. The operadic structure is E_∞ (symmetric, commutative factorisation on $\text{Ran}(X)$).
- **Volume II** ($3d, \mathbb{C}_z \times \mathbb{R}_t$): the E_1 -chiral layer. The bar complex is a dg coalgebra over $(\text{ChirAss})^!$; the SC structure emerges on the derived center. The operadic structure is E_1 with spectral braiding from the $\mathbb{C}_z$ -direction.
- **Volume III** ($4d / \text{CY}$): the geometric source. Calabi–Yau categories produce E_1 -chiral algebras for $d \geq 3$; the Drinfeld center $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}))$ recovers the E_2 -braided structure.

At each level, information is lost: $4d \rightarrow 3d$ forgets one topological direction ($E_2 \rightarrow E_1$); $3d \rightarrow 2d$ forgets the ordering (Σ_n -coinvariance, $r(z) \mapsto \kappa$). The Drinfeld center reconstructs upward; the bar complex determines $r(z)$ on the Koszul locus.

Remark 1.4.7 (The E_n circle). The dimensional reduction of Remark 1.4.6 is not a one-way street; it closes into a circle. Five arrows connect the E_n -levels:

$$E_3 \xrightarrow[\text{topological reduction}]{(1)} E_2 \xrightarrow[\text{boundary restriction}]{(2)} E_1 \xrightarrow[\text{Drinfeld center}]{(3)} E_2 \xrightarrow[\text{topologization}]{(4)} E_3.$$

Arrow (1) forgets the third topological direction (Chern–Simons $\rightarrow$ factorization on $\mathbb{C}$). Arrow (2) restricts to the boundary (holomorphic $\rightarrow$ chiral). Arrow (3) takes the Drinfeld center $\mathcal{Z}(\text{Rep}^{E_1}(\mathcal{A}))$, recovering the braided tensor structure. Arrow (4) is the topologization (Theorem A.12.2 for affine Kac–Moody; Conjecture A.12.7 in general): the conformal vector promotes holomorphic E_2 to topological E_3 . The composite $(4) \circ (3) \circ (2) \circ (1)$ returns to the E_3 level; the conjecture is that it is homotopic to the identity on the Koszul locus at generic level (Chapter A, §A.12).

Definition 1.4.8 (Three-tier R -matrix classification). The collision residue $r(z)$ of a chiral algebra $\mathcal{A}$ falls into exactly one of three tiers, according to how its singular structure is determined by the underlying data.

- Pole-free commutative tier.* $r(z) = \tau$, the Koszul-signed flip on $V \otimes V$, with no meromorphic dependence on z . No collision forces scattering: the R -matrix is the identity up to sign, and the associated Yangian is the symmetric algebra on a finite-dimensional vector space.
- Local OPE tier.* $r(z)$ has poles at $z = 0$, and its entire structure is determined by the local OPE of $\mathcal{A}$ by the residue formula (1.5): the pole orders are one less than the OPE pole orders, and the matrix coefficients are the OPE modes $a_{(n)}b$. The tier is closed under Drinfeld–Sokolov reduction and under free-field realizations.
- Genuinely E_1 tier.* $r(z)$ has poles at $z = 0$, but its structure is not determined by any local OPE of an E_∞ -chiral algebra. The R -matrix is independent input data: there is no underlying vertex algebra whose OPE expands to $r(z)$ via tier (b). The natural algebraic framework is the quantum vertex algebra of Etingof–Kazhdan [490] or the Yangian double, and the associated convolution algebra lives on ordered rather than unordered configurations.

Remark 1.4.9 (Three-tier examples and the three-leaps hierarchy). Tier (a) is the commutative extreme. Finite-dimensional Lie algebras at level 0, commutative vertex algebras, and the trivial chiral algebra ω_X all sit here. $\kappa = 0$, the shadow obstruction tower is empty, and the bar complex collapses to the Koszul resolution of a polynomial ring. Pole-free commutative is the boundary stratum; every richer tier specialises to it when all singular modes vanish.

Tier (b) contains every standard-landscape vertex algebra: the Heisenberg $\mathcal{H}_k$ with $r(z) = k/z$, affine Kac–Moody $\widehat{\mathfrak{g}}_k$ with $r(z) = k\Omega/z$ at level k , Virasoro Vir_c with $r(z) = (c/2)/z^3 + 2T/z$, the $\mathcal{W}_N$ -algebras, the $\beta\gamma$ system, and the lattice vertex algebras V_Λ . In every case the R -matrix is *derived* from the OPE by residue extraction; nothing new enters at the R -matrix level beyond what the local OPE already carries. Tier (b) is still E_∞ -chiral in the three-leaps classification of Volume II: the algebra is commutative up to quasi-isomorphism, and averaging recovers the modular shadow κ without information loss beyond the Σ_n -coinvariant step.

Tier (c) is the genuinely E_1 -primitive extreme. The Yangian $Y(\mathfrak{g})$ and the Etingof–Kazhdan quantum vertex algebras sit here: their R -matrices are solutions to the classical and quantum Yang–Baxter equations that do not arise as residues of any vertex-algebra OPE. The associated convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ is strictly richer than its Σ_n -coinvariant shadow, and the kernel of the averaging map (Theorem 1.4.1(iv)) is non-trivial at degree 3, where the Drinfeld associator Φ_{KZ} records data that no symmetric projection recovers. Tier (c) is where the E_1 primacy thesis becomes nontrivial: the R -matrix is input, not output.

The three tiers organise Part .2 (Seven Faces): tier (a) is the trivial-scattering base case, tier (b) populates the seven-face falsification checklist for every standard family, and tier (c) activates the E_1 -refined checklist of Chapter O. The jump from (b) to (c) is the single irreversible information step in the three-volume dimensional reduction of Remark 1.4.6.

Remark 1.4.10 (Three tiers as boundary-bulk coupling complexity). Read through the boundary-bulk reconstruction thesis, the three tiers of Definition 1.4.8 correspond to increasing complexity of the coupling between the boundary algebra and the bulk it reconstructs. *Tier (a)* is the free-field bulk: the boundary is commutative, the bulk is a free chiral algebra with no scattering, and the Drinfeld double degenerates to the tensor product $\mathcal{A} \otimes \mathcal{A}^!$ with no cross-term. Bulk physics is classical Chern–Simons on the commutative locus. *Tier (b)* is the interacting but E_∞ -chiral bulk: the boundary has OPE poles, the bulk is interacting, but the time ordering of bulk operators is trivial in the sense that all scattering is recovered from the local OPE of the boundary. Every standard vertex algebra (Heisenberg, affine Kac–Moody, Virasoro, $\mathcal{W}_N$, lattice, $\beta\gamma$) sits here; the boundary OPE determines the entire bulk. *Tier (c)* is the genuinely gravitational bulk: the boundary R -matrix is independent input data, and bulk operators have non-trivial time ordering that no boundary OPE recovers. The Yangian double and the Etingof–Kazhdan quantum vertex algebras populate this tier. Here the boundary algebra alone does not determine the bulk; the E_1 structure of the ordered bar is required, and the Drinfeld double $U_{\mathcal{A}}$ must be constructed on ordered configurations rather than unordered ones. The three tiers are therefore the three levels of holographic non-triviality: free bulk, E_∞ -interacting bulk, and time-ordered (gravitational) bulk.

Remark 1.4.11 (Topologization: from $\text{SC}^{\text{ch}, \text{top}}$ to E_3). The E_1 -chiral bar construction, combined with $\text{SC}^{\text{ch}, \text{top}}$, produces an E_2 -algebra via the operadic center. When the chiral algebra admits a conformal vector (equivalently, a Sugawara element at non-critical level), the holomorphic E_2 structure is promoted to topological E_2 : holomorphic translations become Q -exact, hence homotopically trivial. Dunn additivity then gives $E_2^{\text{top}} \otimes E_1^{\text{top}} = E_3^{\text{top}}$. Theorem A.12.2 (§A.12) establishes this for affine Kac–Moody $V_k(\mathfrak{g})$ at non-critical level, where the Sugawara element provides the inner conformal vector explicitly. The conformal vector is the bridge from the chiral ($n = 2$) row of the dimensional ladder to the Chern–Simons ($n = 3$) row. For general chiral algebras with conformal vector (Virasoro, $\mathcal{W}$ -algebras), the same conclusion is expected

but conditional on constructing the bulk BRST complex (Conjecture A.12.7). At critical level $k = -h^\vee$ the Sugawara element is undefined and the promotion fails; the E_2 structure remains holomorphic.

At tier (b), the passage from chiral algebra to quantum group is an equivalence: for affine Kac–Moody $V_k(\mathfrak{g})$ at generic level, the ordered chiral homology $\int_X^{E_1} V_k(\mathfrak{g})$ recovers the quantum group $U_q(\mathfrak{g})$ as a braided tensor category (Theorem 22.29.1; Chapter 22, §21.2). This is the content of the Kazhdan–Lusztig equivalence read through the bar complex.

1.5 ARCHITECTURE

The five theorems and the E_1 primacy thesis rest on five geometric ingredients, which combine into a single functorial correspondence between geometry, algebra, and physics.

Remark 1.5.1 (Five geometric ingredients). Modular Koszul duality rests on five geometric ingredients. The first four belong to the commutative (E_∞) face; the fifth to the associative (E_1) face.

- (i) *Three-point collision.* The Arnold relation ($\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$) is factorization coherence: fusing three insertions does not depend on the order of pairwise collisions. The genus-0 seed.
- (ii) *Verdier duality on $\text{Ran}(X)$.* $\mathbf{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \mathcal{A}_\infty^!$ (Theorem 11.1.84): the Koszul dual algebra as theorem, not definition-by-analogy.
- (iii) *Genus-1 curvature.* $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_1 \cdot \text{id}$ (Theorem 13.13.16). The natural home is Positselski’s coderived category: quantum corrections are a change of ambient category, not extra terms.
- (iv) *Clutching of stable curves.* The genus tower is compatible with boundary clutching via the modular operad (Theorem 15.12.26). The combinatorics is stable graphs, not trees, and $\Theta_{\mathcal{A}}$ (Theorem K.7.1, proved intrinsically by Theorem 13.21.69) is compatible with clutching, trace, and Verdier duality.
- (v) *Associative structure.* The Yangian $Y(\mathfrak{g})$ is E_1 -chiral (Definition 3.11.3): its bar complex uses ordered configuration spaces, and Verdier duality acts by R -matrix inversion $R \mapsto R^{-1}$ (Theorem O.2.2). The sign flip $\hbar \mapsto -\hbar$ replaces the Feigin–Frenkel involution.

In the Heisenberg algebra, only pieces (i)–(iv) are active, and they already force the full commutative/modular package: Arnold ensures $d^2 = 0$; Verdier produces $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$; the genus-1 period integral creates curvature $\kappa = k$; clutching assembles the genus tower.

In the Yangian, piece (v) is required. Ordered configurations, R -matrix inversion on the module category, and the derived Drinfeld–Kohno bridge (Theorem O.13.11) are a genuinely braided determination of the same configuration-space mechanism.

Remark 1.5.2 (The DK square). The coexistence of the commutative and braided determinations is witnessed by the derived Drinfeld–Kohno square (Theorem O.13.5):

$$\begin{array}{ccc}
 \mathcal{O}_k^{\text{int}}(\widehat{\mathfrak{g}}) & \xrightarrow[\sim]{\Phi} & \mathcal{O}_{k'}(\widehat{\mathfrak{g}}) \\
 \Phi_{\text{KL}} \downarrow \sim & & \sim \downarrow \Phi_{\text{KL}} \\
 C(U_q(\mathfrak{g})) & \xrightarrow[\sim]{q \mapsto q^{-1}} & C(U_{q^{-1}}(\mathfrak{g}))
 \end{array}$$

Top: level inversion $k \mapsto k' = -k - 2h^\vee$ (Frame A). Bottom: R -matrix inversion $q \mapsto q^{-1}$ (Frame B). Verticals: Kazhdan–Lusztig equivalences. Commutativity: bar-cobar duality geometrically implements the quantum group involution. The duality constraint on κ ($\kappa + \kappa' = 0$ for KM/free fields; $\kappa + \kappa' = \varrho(\mathfrak{g}) \cdot K(\mathfrak{g})$ for $\mathcal{W}$ -algebras, where $\varrho(\mathfrak{g}) = \sum_i 1/(m_i + 1)$ is the anomaly ratio) is the scalar shadow of the top arrow; $q \mapsto q^{-1}$ is the quantum-group shadow. The four theorems and the DK square are four projections of one geometric structure on $\text{Ran}(X) \times \overline{\mathcal{M}}_g$.

Remark 1.5.3 (Master functorial correspondence). Every row is a theorem.

Geometry	Algebra	Physics
Verdier duality $\mathbb{D}_{\text{Ran}}$	Koszul duality $\mathcal{A} \leftrightarrow \mathcal{A}^!$	CPT
Residue at D_{ij}	Bar differential d_{res}	OPE fusion
FM boundary stratum	Tree contribution to m_k	Feynman diagram
Arnold relation	$d^2 = 0$ (genus 0)	Factorization coherence
Period integral on $\overline{\mathcal{M}}_g$	Obstruction class obs_g	One-loop determinant
Clutching $\partial \overline{\mathcal{M}}_g$	Modular operad	String sewing
DS reduction	Koszul functor = Ham. red. to $J_\infty(S_f)$	Gauge fixing = localization to Slodowy slice
Log form η_{ij}	Propagator	Free-field propagator
Forgetful $\overline{\mathcal{M}}_{g,n+1} \rightarrow \overline{\mathcal{M}}_{g,n}$	Forgetting a marked point	Integrating out a field
Branch locus of $P_{\mathcal{A}^!}(x)$	Discriminant $\Delta_{\mathcal{A}}(x)$	Spectral curve
MC in $\overline{B}(\widehat{\mathfrak{g}}_k)$	L_∞ flatness	CS equations of motion
$\int_{\overline{\mathcal{M}}_{0,n}} \overline{\mathbf{B}}_n^{(0)}$	BRST cohomology pairing	Tree-level string amplitude

The first four rows are proved in Part I (Chapters 6–13); the next three in Part II (Chapters G–O). The physics column is made precise in Chapters R.3.1 and R.3.1.

1.6 BEYOND THE FIVE THEOREMS: THREE CONCENTRIC RINGS

The five geometric ingredients and the master functorial correspondence give the architecture; the standard landscape (Part III, Table K.7.1) tests it. The shared discriminant $\Delta(x) = 1 - 2x - 3x^2$ (Theorem K.7.1) and the universal generating function $\sum_{g \geq 1} F_g x^{2g} = \kappa \cdot (\hat{A}\text{-genus})$ (uniform-weight) (Theorem K.7.1) are consequences of the proved scalar and spectral layers. The results, taken together, form three concentric rings of decreasing logical certainty.

Ring 1: the proved modular Koszul core. Theorems A/B/C/D/H and their E_1 counterparts (Remark 1.3.7), Master Conjectures 1 and 2 (at finite order), and the DK ladder through step 3 on the evaluation-generated core at all simple Lie types. This ring is closed: every claim is proved in the text, and the outlook (Part .2, Chapter K.7.1) records its boundary precisely.

Ring 2: the shadow obstruction tower. The primary mathematical object beyond the linear regime. Between the proved scalar tower $\kappa(\mathcal{A})\lambda_g$ and the full universal class $\Theta_{\mathcal{A}}$ sits a constructive finite-order layer whose visible invariants form a hierarchy:

$$\underbrace{\kappa(\mathcal{A})}_{\text{scalar}} \longrightarrow \underbrace{\Delta_{\mathcal{A}}}_{\text{spectral}} \longrightarrow \underbrace{[\mathfrak{C}_{\mathcal{A}}], \mathfrak{o}_{\mathcal{A}}^{(4)}, [\mathfrak{Q}_{\mathcal{A}}]}_{\text{nonlinear shadows}} \longrightarrow \underbrace{\Theta_{\mathcal{A}}}_{\text{universal class}}.$$

The scalar characteristic $\kappa(\mathcal{A})$ is proved. The spectral discriminant $\Delta_{\mathcal{A}}$ is proved. The cubic and quartic shadow classes $[\mathfrak{C}_{\mathcal{A}}]$ and $[\mathfrak{Q}_{\mathcal{A}}]$ are the first genuinely nonlinear modular invariants, computable on any family where the cyclic deformation package is available through the relevant order (Chapter 18). The branch-line reductions (Appendix 19) extract exact finite-dimensional quotients of this layer, including genus-2 transparency and the universal genus-3 constant 7 on the shared $\widehat{\mathfrak{sl}}_2/\text{Virasoro}/\beta\gamma$ spectral sheet. For class **M** algebras the infinite tower has a computable exponential growth rate $\rho(\mathcal{A})$ governed by the shadow metric Q_L (Proposition 13.22.189); for the Virasoro family this gives $\rho(\text{Vir}_c) = \sqrt{(180c+872)/((5c+22)c^2)}$ (Remark H.16.38), with the equation $\rho = 1$ cutting out the convergence/divergence boundary at $c_{\star} \approx 6.125$. The cubic shadow coefficient α_s on each primary line admits a universal gravitational form determined by the conformal weights of the strong generators alone (Theorem H.16.1).

The unifying principle is the modular L_{∞} convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, whose L_{∞} structure comes from the Feynman transform of the modular operad; Conv_{str} is its strict model. The shadow obstruction tower consists of finite-order projections of $\Theta_{\mathcal{A}}$: κ (degree 2), $\mathfrak{C}$ (degree 3), $\mathfrak{Q}$ (degree 4), each a projection of the next. The weight filtration on $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ controls extension; each truncation $\Theta_{\mathcal{A}}^{\leq r}$ is constructive without requiring the full all-genera modular envelope. The all-degree master equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ is proved by the bar-intrinsic construction (Theorem 13.21.69): $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is automatically Maurer–Cartan because $D_{\mathcal{A}}^2 = 0$.

Ring 3: the physics-facing frontier. Three axes extend the proved core toward mathematical physics.

- (a) *The $\mathcal{W}$ -algebra axis.* Completed Koszulity is ubiquitous: every affine $\mathcal{W}$ -algebra at generic level is completed Koszul. Strict Koszulity is exceptional: the subregular family $\mathcal{W}_n^{(2)}$ has unbounded canonical homotopy degree, and the classical W_3 sector defines the first finite-degree modular higher-spin package. MC4 is proved: the strong completion-tower theorem (Theorem 8.1.27) gives a completion-closed bar-cobar homotopy equivalence on $\text{CompCl}(\text{F}_{\text{ft}})$, with automatic continuity via the degree cutoff (Lemma 8.1.26) and coefficient-stability criterion (Theorem 8.1.48). The DS-HPL transfer theorem (Volume II, Theorem .2) closes the local nonlinear bridge from affine to $\mathcal{W}$ -algebra data: homological perturbation through the BRST SDR transfers the full dg-shifted Yangian triple, with the gravitational coproduct proved strictly primitive at all degrees (Principle o.o.6).
- (b) *The Yangian/RTT axis.* Shifted Yangian duality decomposes into a local quadratic RTT kernel, a weightwise stabilized completed envelope, and a boundary quotient whose dual is an orthogonal coideal. For the Yangian MC3 programme, the all-types proved core is narrower: categorical prefundamental Clebsch–Gordan closure is proved for all simple types (Theorem O.9.71), and the DK comparison on the evaluation-generated core is proved separately (Corollary O.13.20). For type A, shifted-prefundamental generation and pro-Weyl recovery are also proved, while the compact/completed extension packet remains open.
- (c) *The holographic/celestial axis.* The proved modular core supplies a protected transform calculus: dual transform, cotangent reciprocity, Weyl sewing, and a metaplectic determinant-line anomaly. The full bulk/boundary/line Koszul triangle and the celestial boundary transfer programme are developed in Volume II.

1.6.1 KOSZULNESS AND HOLOGRAPHIC RECONSTRUCTION

The bar-cobar adjunction $B \dashv \Omega$ encodes boundary data into a bar coalgebra and recovers it via the co-bar construction. On the Koszul locus, Theorem B guarantees exact recovery. Chapter K.7.1 proves the equivalence: *chiral Koszulness is equivalent to exact holographic reconstruction*.

The twelve characterisations K1–K12 of Koszulness (Theorem 11.1.50) comprise ten unconditional equivalences, one conditional (the Lagrangian criterion, conditional on perfectness; unconditional for the standard landscape), and one one-directional ($\mathcal{D}$ -module purity, with only the forward direction proved). The bifunctor decomposition theorem is a further proved consequence outside the twelve numbered items.

Condition (vii) of Theorem 11.1.50 (factorization homology concentrated in degree 0) is scoped to genus 0 unconditionally and to $g \geq 1$ on the uniform-weight lane; the class-M Virasoro counterexample is documented in Remark 11.1.51. Chiral Koszulness is closed under tensor products, dualization, and base change (Proposition 11.1.55); quotients such as Drinfeld–Sokolov reduction fall outside this closure (Remark 11.1.56).

The Lagrangian isotropy of Theorem C provides a symplectic code structure (Verdier-isotropic summands with non-degenerate cross-pairing), not an orthogonal one. Shadow depth classifies redundancy channels: class G has no channels, class L has one, class M has infinitely many (convergent).

1.6.2 ENTANGLEMENT ENTROPY FROM THE SHADOW OBSTRUCTION TOWER

At the scalar level, the modular characteristic $\kappa(\mathcal{A})$ (equal to $c(\mathcal{A})/2$ for the Virasoro algebra; the ratio κ/c is family-dependent in general) determines the Calabrese–Cardy entropy of a single interval: $S_{EE} = \frac{c}{3} \log(L/\varepsilon)$, recovered as the genus-1 shadow of $\Theta_{\mathcal{A}}$ on the replica orbifold (Theorem K.7.1; Chapter ??).

Complementarity sharpens this for Virasoro: the sum $S_{EE}(\text{Vir}_c) + S_{EE}(\text{Vir}_{26-c}) = \frac{26}{3} \log(L/\varepsilon)$ is a shadow of Theorem C via the central-charge complementarity $c + c' = 26$ (Theorem 1.3.8), saturated at the self-dual point $c = 13$ where $\kappa + \kappa' = 13$.

Beyond the scalar level, the four shadow-depth classes G/L/C/M produce distinct entanglement complexity: class G (Heisenberg) has Gaussian entanglement with no subleading corrections; class L (Kac–Moody) acquires a single logarithmic correction from the cubic shadow; class C ($\beta\gamma$) adds a quartic contact channel; class M (Virasoro, $\mathcal{W}_N$) produces an infinite tower of Rényi corrections controlled by the shadow growth rate $\rho(\mathcal{A})$. The full Knill–Laflamme condition for the holographic code requires the physical inner product and is conjectured at higher genus; at genus 1 it is automatic.

1.7 THE MC FRONTIER

The five Master Conjectures MC1–MC5 organize the structural results. MC1 through MC4 are proved; MC5 is partially proved. The analytic HS-sewing package is proved at all genera (Theorem K.7.1); the genus-0 algebraic BRST/bar comparison is proved (Theorem E.6.12); $BV = \text{bar}$ in the coderived category is proved for all four shadow classes including class M (Theorem R.3.1). The genuswise chain-level $BV/\text{BRST}/\text{bar}$ identification remains conjectural (class M chain-level false), and the tree-level amplitude pairing is conditional on Corollary E.6.15. MC3 holds for all simple types on the evaluation-generated core (Theorem O.9.71, Corollary O.9.73). The residual DK-4/5 problem (extension beyond evaluation modules) is downstream of MC3. Proof status and refinements are in Chapter K.7.1.

MC	Statement	Status	Key input
MC1	PBW concentration	proved	all standard families
MC2	Universal MC class $\Theta_{\mathcal{A}}$	proved	coinvariant bar-intrinsic MC2 (Thm 13.21.69); ordered lift (Thm 21.1.1)
MC3	Thick generation	proved	CG all types + eval-core DK (Cor. O.9.73); DK-4/5 downstream
MC4	$\mathcal{W}_{\infty}$ closure	proved	strong completion towers on weight-completed standard families + w
MC5	Genus tower (analytic sewing)	analytic part proved	HS-sewing (Thm K.7.1); genuswise BV/BRST/bar identification conj

MC1 (PBW concentration): Bar cohomology of every standard-landscape chiral algebra concentrates in PBW degrees, proved for all standard families by explicit computation.

MC2 (Universal MC class): the symmetric, coinvariant statement is $\Theta_{\mathcal{A}} \in \text{MC}(\text{Def}_{\text{cyc}}(\mathcal{A}) \widehat{\otimes} \mathcal{G}^{\text{mod}})$, proved by the bar-intrinsic construction (Theorem 13.21.69): $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ is Maurer–Cartan because $D_{\mathcal{A}}^2 = 0$. The primitive ordered statement is $\Theta_{\mathcal{A}}^{\text{E}_1} := D_{\mathcal{A}}^{\text{E}_1} - d_0 \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod E}_1})$ (Theorem 21.1.7), and averaging recovers $\Theta_{\mathcal{A}}$. The shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ consists of the finite-order projections of this coinvariant class. When $\dim H_{\text{cyc}}^2 = 1$, the MC element collapses to $\Theta_{\mathcal{A}} = \kappa(\mathcal{A}) \cdot \eta \otimes \Lambda$ (Corollary 13.21.120).

MC3 (Thick generation): Proved for all simple types on the evaluation-generated core via multiplicity-free ℓ -weights [450] (Theorem O.9.71), with DK comparison proved separately (Corollary O.13.20, Corollary O.9.73). For type A , shifted-prefundamental generation and pro-Weyl recovery are also proved (Theorem O.9.70). DK-4/5 (extension beyond evaluation modules) is downstream.

The proof decomposes into three layers: MC3a (evaluation core, all types, unconditional), MC3b (categorical thick generation, all types, unconditional), and MC3c (full category $\mathcal{O}$, type A unconditional; other types conditional on Conjecture O.9.53, the rank-independence lift-and-lower conjecture for shifted prefundamental representations; see Remark O.9.54 for the dependency chain).

MC4 ($\mathcal{W}_{\infty}$ closure and completed bar-cobar): The completed bar-cobar problem asks whether finite-stage Koszul duality passes to inverse limits. Two complementary mechanisms cover the proved standard landscape:

Mechanism 1: strong completion towers. If the algebra $\mathcal{A}$ is a strong completion tower, the degree cutoff (Lemma 8.1.26) makes each component of the MC equation finite, and the strong completion-tower theorem (Theorem 8.1.27) produces a quasi-inverse completed bar-cobar equivalence, stable under MC twisting and completed twisting representability (Theorem 8.1.50, Theorem 8.1.49). For the standard graded families of Proposition 8.1.28, this mechanism applies only after passage to the weight-completed tower: the inverse-limit object is the weight completion $\widehat{\mathcal{A}}^{\text{wt}}$ rather than the direct sum $\mathcal{A}$. Accordingly, the MC4 statement for $V_k(\mathfrak{g})$ (non-critical), Vir_c (all c), $\mathcal{W}^k(\mathfrak{g}, f_{\text{prin}})$ (non-critical), and lattice algebras is formulated on their weight-completed towers, not on the uncompleted direct sums.

Mechanism 2: weight cutoff. The algebra $\mathcal{W}_{\infty} = \varprojlim \mathcal{W}_N$ does not satisfy the strong-filtration axiom. Instead, the weight-cutoff criterion (Proposition 8.1.32) and inverse-limit continuity (Proposition 8.1.36) exploit that bar chains of conformal weight w involve only generators of $\text{spin} \leq w$: the inverse system stabilizes levelwise, and the completed duality follows by conformal-weight induction. $\mathcal{W}_N$ rigidity (Theorem 8.1.150) resolves the finite-stage input.

Structural splitting. The coefficient-stability criterion (Theorem 8.1.48) reduces convergence to finite matrix stabilization; the uniform PBW bridge (Theorem 8.1.51) connects MC1 to MC4. The problem splits into MC4^+ (positive towers, solved by weight stabilization; Theorem K.7.1) and MC4^0 (resonant towers, reduced to a finite-dimensional problem by Theorem K.7.1). The remaining example-specific task is coefficient stabilization on finite windows and H-level target identification.

MC5 (Genus tower / BV-BRST comparison): the algebraic genus recursion and the analytic sewing package are **proved**, but the full genuswise BV/BRST/bar identification remains open. The algebraic bar differential at genus g is determined inductively from lower genera (Theorem 13.22.416). Graph amplitudes on Σ_g converge without UV renormalization in dimension 2 (Proposition 13.22.422). The analytic and algebraic differentials agree on the algebraic core (Theorem 13.22.424). HS-sewing holds for the standard landscape (Theorem K.7.1): polynomial OPE growth and subexponential sector growth imply convergent mode sums for all $0 < q < 1$. For the Heisenberg algebra, the genus- g partition function is the Fredholm determinant of the one-particle Bergman sewing operator (Theorem K.7.1). At genus 0, the algebraic BRST/bar comparison is proved, while the top-degree amplitude pairing is only conditional (Theorem E.6.12, Corollary E.6.15).

The proved core has a sharp boundary: the *four-test interface* (Principle o.o.4; Remark K.7.1). $D_{\mathcal{A}}^2 = 0$, the Hodge-class identification $\text{obs}_g = \kappa \cdot \lambda_g$ (uniform-weight lane), complementarity, and sewing are four independent tests forming the complete algebraic-geometric interface with $\overline{\mathcal{M}}_{g,n}$. What lies outside (multi-weight universality at $g \geq 2$, BV/BRST = bar at higher genus, non-perturbative completion) is in Chapter K.7.1.

1.8 THE MASTER INVARIANT TABLE

The standard landscape of Part III is summarized in a single table recording κ , c , $K = c + c'$, Δ , and the shadow archetype for each family.

Family	c	κ	K	Δ	Archetype
Heisenberg $\mathcal{H}_k$	1	k	2	0	Gaussian, @2
Free fermion $\mathcal{F}$	$\frac{1}{2}$	$\frac{1}{4}$	0	0	Gaussian, @2
$\widehat{\mathfrak{sl}}_2$ at level k	$\frac{3k}{k+2}$	$\frac{3(k+2)}{4}$	6	$(1-3x)(1+x)$	Lie/tree, @3
$\beta\gamma$	2	1	0	$(1-3x)(1+x)$	contact, @4
Virasoro c	c	$\frac{c}{2}$	26	$(1-3x)(1+x)$	mixed, ∞
$\mathcal{W}_3$	$c(k)$	DS	100	quartic	mixed, ∞
V_Λ (lattice)	$\text{rk}(\Lambda)$	$\text{rk}(\Lambda)$	2rk	0	braided
$Y(\mathfrak{sl}_2)$	n/a	n/a	n/a	n/a	E_1 , R -matrix

The shared discriminant $\Delta(x) = (1-3x)(1+x)$ across $\widehat{\mathfrak{sl}}_2$, Virasoro, and $\beta\gamma$ reflects Drinfeld–Sokolov reduction as a Koszul functor: quantum Hamiltonian reduction preserves the discriminant. The zeros at $x = 1/3$ and $x = -1$ mark bar-acyclic/bar-active transitions, invariants of the planted-forest tropicalization (Theorem 13.22.402). These three algebras have different shadow depths ($r_{\max} = 3, \infty, 4$) but identical genus-0 spectral geometry: the discriminant depends only on $\Theta_{\mathcal{A}}^{\leq 2}$, a DS invariant (Definition 13.22.343).

1.9 TRAVERSE OF THE VOLUME

Each chapter builds on the previous one; the five theorems emerge as milestones.

Part I: The Bar Complex (*proved core; Thms A–D+H*)

Fourier seed (Ch. K.7.1)	Bar construction as transform; product-formula GF; inversion as Fourier inversion
Algebraic foundations (Ch. 3)	Classical Koszul duality; twisting morphisms; operadic bar-cobar; HTT (A_∞/L_∞ transfer)
Configuration spaces (Ch. 5)	FM compactification $\overline{C}_n(X)$; Arnold relations; residue calculus; cooperadic boundary strata
Geometric bar complex (Ch. 6)	$\overline{B}_X(\mathcal{A})$ via residue extraction; Theorem A (adjunction + Verdier intertwining); $d^2 = 0$
Geometric cobar complex (Ch. 7)	Ω_X as left adjoint; $d_{\text{cobar}}^2 = 0$ via Verdier duality
Bar-cobar adjunction (Ch. 8)	Theorem B (inversion on Koszul locus); curved A_∞ ; coderived continuation
Non-abelian Poincaré duality (Ch. 10)	$\mathcal{A}^1$ as Verdier dual of $\overline{B}(\mathcal{A})$; resolves circularity in defining Koszul dual
Higher genus (Ch. 13)	Genus tower; curvature $d_{\text{fib}}^2 = \kappa\omega_g$; Theorems C+D (complementarity, modular characteristic); Lagrangian upgrade
Koszul pairs + deformation theory (Chs. 11–14)	Chiral Koszul pairs; chiral modules; Theorem H (CH^* polynomial, Koszul-functorial)
Quantum corrections (Ch. 16)	Higher-genus Arnold deformations; filtered-curved hierarchy

Part II: The Characteristic Datum (*shadow obstruction tower; E_1 wing; E_n Koszul duality*)

Nonlinear modular shadows (Ch. 18)	Shadow obstruction tower $\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \dots$; clutching law; archetypes G/L/C/M; branch-line reductions
E_1 modular Koszul duality (Ch. 21)	Ribbon modular operad; $F\text{Ass}$; E_1 convolution; E_1 shadow tower; Thms $A^{E_1} - H^{E_1}$; ordered chiral homology (§21.2); formality bridge (Thm 21.2.10)
Ordered associative chiral KD (Ch. 22)	Diagonal bicomodule; Hochschild-coHochschild dictionary; open trace formalism; chiral–quantum group equivalence (Thm 22.29.1)
E_n Koszul duality (Ch. A)	Higher-dimensional bar complexes; Totaro relations; Ayala–Francis; topologization $\text{SC}^{\text{ch}, \text{top}} + T_{\text{Sug}} \Rightarrow E_3$ (Thm A.12.2, proved for affine KM; Conj A.12.7, general)

Part III: The Standard Landscape (*complete portrait of each family*)

Lattice VOAs (Ch. B)	$\kappa(V_\Lambda) = \text{rank}(\Lambda)$; curvature-braiding orthogonality; screening operators
Free fields (Ch. E)	Heisenberg, free fermion; Eisenstein genus expansion; periodic table of the volume
$\beta\gamma$ system (Ch. F)	First nonabelian computation; $\mu_{\beta\gamma} = 0$ (rank-one rigidity); shadow terminates at degree 4
Kac–Moody (Ch. G)	$\widehat{\mathfrak{g}}_k$ bar complex; Feigin–Frenkel = Koszul duality; PBW at all genera
$\mathcal{W}$ -algebras (Ch. H)	DS reduction as Koszul functor; $\mathcal{W}_3$ composites; curved A_∞ from higher poles
Deformation quantization (Chs. M–N)	Chiral Kontsevich formality; $P_\infty \rightarrow E_\infty$; star products; MC deformations
Yangians (Ch. O)	E_1 -chiral bar on ordered configurations; R -matrix inversion; DK bridge; dg-shifted Yangian

Genus expansions (Ch. K.7.1)	Explicit expansions: modular forms, Eisenstein, Mumford, bosonization (Remark E.5.14: bosonization $\neq$ Koszul duality)
Computations + combinatorial frontier (Chs. K.7.1–K.7.1)	Bar tables through high degree; OEIS; growth rates
Part IV: Physics Bridges (<i>connections to physics and adjacent mathematics</i>)	
Feynman diagrams (Ch. R.3.1)	Perturbative incarnation: Feynman graphs on $\overline{C}_n(X)$; higher operations from nested collapses
BV-BRST (Ch. R.3.1)	Genus-0 bar/BRST quasi-iso; BV/bar dictionary; QME/MC comparison
Open/closed realization (§A.17)	Derived center = universal bulk; open-sector primitive; four-stage architecture
HT boundary conditions (Ch. K.7.1)	3d holomorphic-topological twists; open-sector language (modules, lines, boundaries)
Yang–Mills boundary (Chs. K.7.1–K.7.1)	Boundary BRST; central formality; instanton completion; screening; mass-gap reduction
Derived Langlands (Ch. ??)	Critical-level bar complex; opers; Kazhdan–Lusztig from bar-cobar
Arithmetic shadows (Ch. S)	Shadow L -function; depth decomposition $d = 1 + d_{\text{arith}} + d_{\text{alg}}$; Eisenstein spectral content
Part .2: The Seven Faces of the Collision Residue (<i>archive-only</i>)	
Holographic datum master (Ch. ??)	One object $r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}})$ in seven frameworks; falsification checklist
Genus-1 seven faces (Ch. ??)	Elliptic r -matrix; KZB connection; Belavin; elliptic Gaudin
Part .2: The Frontier (<i>archive-only</i>)	
Concordance (Ch. K.7.1)	Five theorems; three pillars; three rings; Koszulness programme; open frontiers
Volume II	E_1 -chiral bar on $\text{FM}_k(\mathbb{C}) \times \text{Conf}_k(\mathbb{R})$; $\text{SC}^{\text{ch},\text{top}}$ on derived center; curved at $g \geq 1$; recognition; homotopy-Koszulity of $\text{SC}^{\text{ch},\text{top}}$; bulk/boundary/line triangle

1.9.1 NUMBERED TRAVERSE: $\Theta_{\mathcal{A}}$ AS PROTAGONIST

The volume has a single protagonist: the universal Maurer–Cartan element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$, proved bar-intrinsic in Theorem 13.21.69. Every chapter either constructs $\Theta_{\mathcal{A}}$, projects it, tests it, identifies a facet, or sharpens the environment in which it lives. The numbered traverse below is structured around the five theorems (A, B, C, D, H) and the four shadow-depth classes (G, L, C, M), with one entry per chapter and every entry explicitly invoking the bar complex, one of the five theorems, or a depth class.

Part I: The Bar Complex (proved core; Theorems A–D+H).

1. *Fourier seed* (Ch. K.7.1). The bar construction presented as a categorical logarithm: product-formula generating function, inversion as Fourier inversion. First glimpse of $\Theta_{\mathcal{A}}$ as the log of a factorization structure.
2. *Algebraic foundations* (Ch. 3). Classical Koszul duality recalled: twisting morphisms, operadic bar-cobar, HTT. The point-case shadow of Theorems A and B that the chiral theory will later extend to all genera.

3. *Three invariants of a chiral algebra* (Ch. 4). $p_{\max}$ (OPE pole), $k_{\max}$ (collision depth), $r_{\max}$ (shadow depth). Separates the three numerical invariants that govern the bar complex and pre-empts the four shadow-depth classes G/L/C/M.
4. *Configuration spaces* (Ch. 5). Fulton–MacPherson compactification, Arnold relations, residue calculus. The geometric substrate on which the bar differential, hence $\Theta_{\mathcal{A}}$, is built.
5. *Geometric bar complex* (Ch. 6). $\bar{B}_X(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$ via residue extraction on $\bar{C}_n(X)$; the augmentation ideal $\bar{\mathcal{A}}$ enters here. **Theorem A** (bar-cobar adjunction intertwined with Verdier duality on $\text{Ran}(X)$) is proved: $\Theta_{\mathcal{A}}$ has an arena.
6. *Geometric cobar complex* (Ch. 7). Ω_X as left adjoint; $d_{\text{cobar}}^2 = 0$ via Verdier duality. Completes the bar-cobar adjunction pair underlying Theorem A.
7. *Bar-cobar adjunction* (Ch. 8). **Theorem B** (inversion on the Koszul locus): $\Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$, so the cobar inverts the bar and $\Theta_{\mathcal{A}}$ determines $\mathcal{A}$. Curved A_{∞} and coderived continuation enter for the off-Koszul regime.
8. *Non-abelian Poincaré duality* (Ch. 10). $\mathcal{A}^!$ realised as the Verdier dual of $\bar{B}(\mathcal{A})$: one of the four functors is isolated, resolving the circularity in defining the Koszul dual. Prepares the Lagrangian splitting of Theorem C.
9. *Higher genus* (Ch. 13). Genus tower; curvature $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$. **Theorems C and D**: complementarity $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!)$ (C) and the universal scalar projection $\text{obs}_g = \kappa(\mathcal{A}) \lambda_g$ (uniform-weight lane, D). $\Theta_{\mathcal{A}}$ acquires its genus filtration.
10. *Koszul pairs and deformation theory* (Chs. 11–14). Chiral Koszul pairs, chiral modules, and the environment of **Theorem H**: $CH^*(\mathcal{A})$ polynomial of amplitude $[0, 2]$, controlling the deformation ring in which $\Theta_{\mathcal{A}}$ varies.
11. *Quantum corrections* (Ch. 16). Higher-genus Arnold deformations; the filtered-curved hierarchy. Controls the regime boundary between quadratic and curved-central for $\Theta_{\mathcal{A}}$.

Part II: The Characteristic Datum (shadow tower; E_1 wing).

12. *Nonlinear modular shadows* (Ch. 18). The shadow obstruction tower $\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \dots$ as finite-order projections of $\Theta_{\mathcal{A}}$. The four depth classes G, L, C, M appear as the possible termination degrees $r_{\max} \in \{2, 3, 4, \infty\}$.
13. *E_1 modular Koszul duality* (Ch. 21). Ribbon modular operad $F\text{Ass}$; the ordered convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ and its MC element $\Theta_{\mathcal{A}}^{E_1}$. Theorems A^{E_1} through H^{E_1} ; the classical r -matrix emerges as the degree-2 binary component.
14. *Ordered associative chiral Koszul duality* (Ch. 22). Diagonal bicomodule and the Hochschild-coHochschild dictionary. Extends the Theorem H environment to the ordered bar.
15. *E_n Koszul duality* (Ch. A). Higher-dimensional bar complexes, Totaro relations, Ayala–Francis. Places $\Theta_{\mathcal{A}}$ in the tower of E_n -Koszul duals.

Part III: The Standard Landscape (every family, every depth class).

16. *Lattice vertex algebras* (Ch. B). $\kappa(V_\Lambda) = \text{rank}(\Lambda)$; screening operators; curvature-braiding orthogonality. Depth class G (Gaussian) for the heteromorphic sublattice.
17. *Free fields and Heisenberg* (Ch. E). Heisenberg, free fermion, Eisenstein genus expansion. Depth class G: the unique termination at $r_{\max} = 2$ with $\Theta_{\mathcal{A}}$ scalar-saturated.
18. *$\beta\gamma$ system* (Ch. F). First non-abelian bar complex; $\mu_{\beta\gamma} = 0$; shadow terminates at degree 4. Depth class C (contact), the unique termination at $r_{\max} = 4$.
19. *Kac–Moody* (Ch. G). $\widehat{\mathfrak{g}}_k$ bar complex; Feigin–Frenkel as Koszul duality; PBW at all genera. Depth class L (Lie/tree), $r_{\max} = 3$; $\Theta_{\mathcal{A}}$ projects to κ and the cubic shadow $\mathfrak{C}$, no higher.
20. *$\mathcal{W}$ -algebras* (Ch. H). Drinfeld–Sokolov reduction as a Koszul functor; $\mathcal{W}_3$ composite fields; curved A_∞ from higher poles. Depth class M (mixed), $r_{\max} = \infty$; $\Theta_{\mathcal{A}}$ has infinite shadow tower.
21. *Chiral deformation quantization* (Ch. M). Chiral Kontsevich formality; $P_\infty \rightarrow E_\infty$ passage; star products as MC deformations of $\Theta_{\mathcal{A}}$. Bridges the Poisson side to the bar-complex side.
22. *Yangians* (Ch. O). E_1 -chiral bar on ordered configurations; R -matrix inversion as Koszul duality; the DK bridge. The only tier-(c) family of Definition 1.4.8, with $\Theta_{\mathcal{A}}^{E_1}$ independent of any E_∞ shadow.
23. *Genus expansions* (Ch. K.7.1). Explicit expansions: modular forms, Eisenstein, Mumford, bosonization. Verifies Theorem D scalar saturation family-by-family.
24. *Detailed computations + combinatorial frontier* (Ch. K.7.1). Bar cohomology tables through high degree; OEIS; growth rates. Empirical calibration of $\Theta_{\mathcal{A}}^{\leq r}$ across the standard landscape.

Part IV: Physics Bridges.

25. *Feynman diagrams* (Ch. R.3.1). Perturbative incarnation of the bar complex: Feynman graphs on $\overline{C}_n(X)$; higher operations from nested collapses. $\Theta_{\mathcal{A}}$ as generating function for tree-plus-loop amplitudes.
26. *BV-BRST* (Ch. R.3.1). Genus-0 bar/BRST quasi-isomorphism; BV/bar dictionary; the quantum master equation compared to the MC equation for $\Theta_{\mathcal{A}}$.
27. *Derived Langlands* (Ch. ??). Critical-level bar complex; opers; Kazhdan–Lusztig obtained by bar-cobar. Depth class L (Kac–Moody) at the critical level $k = -h^\vee$.
28. *Arithmetic shadows* (Ch. S). Shadow L -function; depth decomposition $d = 1 + d_{\text{arith}} + d_{\text{alg}}$; Eisenstein spectral content. Projects $\Theta_{\mathcal{A}}$ to its arithmetic residue.

Part .2: The Seven Faces of the Collision Residue.

29. *Holographic datum master* (Ch. ??). One object $r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}^{E_1})$ computed in seven frameworks and verified to agree. The five-facets formulation of Proposition 1.3.4 becomes the falsification checklist.
30. *Genus-1 seven faces* (Ch. ??). Elliptic r -matrix, KZB connection, Belavin, elliptic Gaudin. Seven-face verification transported to genus 1, where Theorem D is unconditional.

Part .2: The Frontier.

31. *Concordance* (Ch. K.7.1). Five theorems reconciled with the three pillars, three rings, and the Koszulness programme; open frontiers recorded with precise boundaries. Final audit of $\Theta_{\mathcal{A}}$ and its facets.
32. *Outlook and Volume II bridge*. E_1 -chiral bar on $\mathrm{FM}_k(\mathbf{C}) \times \mathrm{Conf}_k(\mathbf{R})$; $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ on the derived center pair; curved at $g \geq 1$; homotopy-Koszulity of $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$; the bulk/boundary/line triangle that propagates $\Theta_{\mathcal{A}}$ to Volume II and Volume III.

Thirty-two chapters, one protagonist. The five theorems A/B/C/D/H and the four depth classes G/L/C/M mark its landmarks; the remainder test, project, and extend it.

The formal definitions of E_∞ -chiral, E_1 -chiral, and P_∞ -chiral algebras, the four Koszul duality mechanisms, the anomaly ratio, the Koszul conductor, and the Koszul spectrum appear in Chapter 3.

1.10 CONVENTIONS

Convention 1.10.1 (Semantic levels: homotopy, model, shadow). **H-level (homotopy/native).** The statement in the stable ∞ -category of factorization (co)algebras on $\mathrm{Ran}(X)$, or in the associated formal moduli / shifted-symplectic language. Defined up to contractible ambiguity.

M-level (model). An explicit dg / L_∞ / filtered complex. The geometric bar complex $\bar{B}_X(\mathcal{A}) = (T^c(s^{-1}\bar{\mathcal{A}}), d)$ built from configuration space integrals on $\bar{C}_n(X)$ is the canonical model.

S-level (shadow). The cohomological, Ext, numerical, or generating-function consequence: bar cohomology dimensions, Hilbert series, $\kappa(\mathcal{A})$, free energies $F_g(\mathcal{A})$.

Notation.

- $\simeq$: equivalence in the homotopy/ ∞ -categorical sense (H-level).
- $\cong$: strict isomorphism of chosen dg models (M-level).
- $=$: definition or literal equality only.

The proved results are proved at M-level and stated at H-level.

Model independence. Any two admissible dg presentations are connected by a contractible space of quasi-isomorphisms (Proposition 6.1.45).

Convention 1.10.2 (Regime tags). Four regimes, in order of increasing generality. The three bar differentials are: d_0 (the genus-0 bar differential), d_{fib} (the fibered bar differential, genus- g but uncorrected for period monodromy), and D_g (the full genus- g corrected bar differential, incorporating period corrections via the Hodge bundle).

1. **Quadratic.** $d_0^2 = 0$; Theorems A–D hold without qualification. Heisenberg, free fermions, lattice VOAs.
2. **Curved-central.** $d_{\mathrm{fib}}^2 = \kappa \cdot \omega_g$; $D_g^2 = 0$. $\widehat{\mathfrak{g}}_k$ at non-critical level, Virasoro with $c \neq 0$.
3. **Filtered-complete.** Complete filtration with $\mathrm{gr}^F \mathcal{A}$ quadratic Koszul. $\mathcal{W}$ -algebras via DS reduction, deformation quantizations.
4. **Programmatic.** Stratum II (Remark 1.1.1); stated as conjectures. Derived DK, $\mathbb{E}_n$ for $n \geq 2$.

The four regimes correspond to increasing monodromy of the categorical logarithm: single-valued, scalar curvature, filtered convergence, full structure.

Convention 1.10.3 (Standing assumptions). (SA1) Ground field $\mathbb{C}$. All vector spaces, algebras, and categories are over $\mathbb{C}$.

(SA2) Cohomological grading: $|d| = +1$. See Appendix G, §G.7.

(SA3) Formal power series in completed tensor products. Configuration space integrals converge absolutely on FM compactifications (Theorem 5.7.16).

(SA4) Smooth projective geometrically connected curves over $\mathbb{C}$.

(SA5) Completed chiral algebras at genus $g \geq 1$ (Appendix K.7.1).

1.10.1 AMBIENT CATEGORY

All $\mathcal{D}$ -modules are holonomic. The cobar construction is the Verdier dual of the bar complex (Definition 7.0.10), so $d_{\text{cobar}}^2 = 0$ follows from $d_{\text{bar}}^2 = 0$ (Corollary 7.0.15). Grading is cohomological ($|d| = +1$); see Appendix G. All chiral algebras are augmented ($\varepsilon: \mathcal{A} \rightarrow \omega_X$, $\bar{\mathcal{A}} = \ker(\varepsilon)$); the bar complex is always reduced. Forms $\eta_{ij} \in \Omega^1(\log D)$ and residue maps are intrinsic to the FM compactification.

Bar complex notation. Several variants of the bar complex appear; here is the dictionary:

- $\bar{B}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$: the *algebraic* bar complex (underlying coalgebra, no curve dependence);
- $\bar{B}_X(\mathcal{A})$: the *geometric* bar complex on X (incorporating configuration-space forms on $\bar{C}_n(X)$);
- $\bar{B}_X^{(g)}(\mathcal{A})$: the *genus- g bar complex* (the component of $\bar{B}_X(\mathcal{A})$ over $\bar{\mathcal{M}}_g$);
- $\Omega_X(C)$: the *cobar* of a factorization coalgebra C (the right adjoint of $\bar{B}_X$).

1.10.2 CRITICAL PITFALLS

The following distinctions are the most common sources of error:

Four objects. $\mathcal{A}$ is the algebra. $\bar{B}(\mathcal{A})$ is the bar coalgebra. $\mathcal{A}^\vee = H^*(\bar{B}(\mathcal{A}))$ is the Koszul dual coalgebra. $\mathcal{A}^\dagger = (\mathcal{A}^\vee)^\vee$ is the Koszul dual algebra. The cobar $\Omega(\bar{B}(\mathcal{A}))$ recovers $\mathcal{A}$ (bar-cobar *inversion*, not duality); $\mathcal{A}^\dagger$ is obtained by Verdier/linear duality, not cobar.

Grading. Cohomological ($|d| = +1$) throughout. The bar complex uses desuspension: s^{-1} lowers degree by 1.

Classical vs. chiral Koszul duality. $\text{Com}^1 = \text{Lie}$ (not coLie): the Koszul dual *operad* of Com involves an operadic suspension $\mathfrak{S}$ that shifts degrees and twists by the sign representation ($\mathfrak{S}\mathcal{P}(n) = \text{sgn}_n \otimes \mathcal{P}(n)[n-1]$); omitting the suspension yields coLie instead of Lie , which changes the sign of the bracket in all convolution computations (Appendix G, Pitfall 9). The Heisenberg algebra is *not* self-dual. Chiral Koszulness is not the same as classical Koszulness.

Curved A_∞ . $m_1^2(a) = [m_0, a]$ (commutator, with a minus sign). The bar differential satisfies $d^2 = 0$ always; curvature shows as $m_1^2 \neq 0$ in the A_∞ algebra, not in the bar complex.

Sugawara. The Sugawara construction is *undefined* at critical level $k = -h^\vee$; the Sugawara vector does not lie in the appropriate completion. This is not “ c diverges”; the construction does not exist.

Virasoro self-duality. The Virasoro algebra is chiral Koszul self-dual at $c = 13$ ($\mathrm{Vir}_c^\dagger = \mathrm{Vir}_{26-c}$), not $c = 26$. Quadratic self-duality (uncurved bar, $\kappa = 0$) holds at $c = 0$.

FM compactification. The Fulton–MacPherson compactification is the blowup along diagonals, not the complement of diagonals.

Prime form. The prime form $E(z_1, z_2)$ is a section of $K^{-1/2} \boxtimes K^{-1/2}$, not $K^{+1/2}$.

QME. The quantum master equation is $\hbar\Delta S + \frac{1}{2}\{S, S\} = 0$ (factor $\frac{1}{2}$, not 1).

$d_{\mathrm{bracket}}^2 \neq 0$. The bracket component of the bar differential does not square to zero on its own: this is proved for all 2048 sign conventions for $\mathfrak{sl}_2$. The full Borchers differential gives $d^2 = 0$.

Overture

Chapter 2

The Gaussian Archetype

One generator. One relation.

$$J(z)J(w) \sim \frac{k}{(z-w)^2}.$$

If bar-cobar duality fails for this OPE, it fails everywhere. The Heisenberg vertex algebra $\mathcal{H}_k$ is the simplest chiral algebra: a single current J of conformal weight 1, a level $k \in \mathbb{C}$, a double pole, nothing else. It is the abelian Kac–Moody algebra at level k ; equivalently, the boundary algebra of abelian Chern–Simons theory on $\Sigma \times \mathbb{R}_+$. Every construction in this monograph is already present, in closed form, in the residues of this single OPE. The programme must be tested here first.

Extract the double-pole coefficient at a collision $z_i \rightarrow z_j$ inside the Fulton–MacPherson compactification $\overline{C}_n(X)$: the result is k times the logarithmic form $\eta_{ij} = d \log(z_i - z_j)$. Three points suffice. The Arnold relation $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ among triple collisions forces $d^2 = 0$: one OPE coefficient, applied twice, annihilates itself through the geometry of configuration spaces. The bar complex $\overline{B}(\mathcal{H}_k) = T^c(s^{-1}\overline{\mathcal{H}}_k)$ exists, with deconcatenation coproduct and differential encoding every iterated residue, because Arnold is the *only* relation the double pole requires.

From $d^2 = 0$ the rest is forced. Verdier duality on the FM compactification produces the Koszul dual $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$ (the chiral symmetric algebra on the dual; *not* $\mathcal{H}_{-k}$) with curvature $m_0 = -k\omega$. Bar-cobar inversion recovers $\mathcal{H}_k$ from $\overline{B}(\mathcal{H}_k)$. The Maurer–Cartan element $\Theta_{\mathcal{H}_k}$ that governs the modular deformation collapses to a single scalar: $\kappa(\mathcal{H}_k) = k$. The cubic shadow S_3 vanishes. The quartic contact invariant S_4 vanishes. The discriminant $\Delta = 8\kappa S_4 = 0$. The entire obstruction tower terminates at degree 2: $\mathcal{H}_k$ is class G, the unique shadow class where this happens. The genus expansion $\sum_{g \geq 1} F_g x^{2g} = k \left(\frac{x/2}{\sinh(x/2)} - 1 \right)$ is the $\hat{A}$ -genus with one input: the level. Complementarity reduces to the identity $\kappa(\mathcal{H}_k) + \kappa(\mathcal{H}_k^!) = 0$ (Heisenberg complementarity conductor $K_{\text{Heis}} = 0$; contrast $K_{\text{Vir}} = \kappa + \kappa' = 13$ for Virasoro): the algebra and its Koszul dual have equal and opposite curvatures, and their quantum corrections cancel exactly.

This is the Gaussian archetype. The Maurer–Cartan equation $d\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ linearizes: $[\Theta, \Theta] = 0$ because the algebra is abelian, so Θ is closed, and the modular tangent complex has rank one at every genus. No nonlinear obstructions, no resonances, no wall-crossing. The simplicity is not a weakness; it is the diagnostic. Every theorem of Part I is instantiated here in closed form before it is stated in generality. A reader who computes the Arnold relation at three points and checks that Bernoulli numbers appear in the genus expansion will have seen the entire machine operate on the simplest input that is not trivial.

The MC element is scalar:

$$\Theta_{\mathcal{H}_k} = k \cdot \eta \otimes \Lambda,$$

where η is the shadow class and Λ is the universal Hodge class. This is the protagonist of the entire monograph, written in coordinates for the simplest algebra. Every projection of the theory (bar complex, Koszul dual, genus tower, complementarity) reduces to $\kappa = k$ times a universal form. In the log-FM convolution algebra (Construction 13.22.24), the five-component differential collapses: $d_{\text{Ch}_\infty} = 0$ (the OPE is abelian), $d_{\text{coll}} = 0$ (no nonlinear collision residues), $d_{\text{pf}} = 0$ (no planted-forest corrections). Only $d_{\tilde{\mathcal{C}}} + d_{\text{loop}}$ survive. The genus-two shell decomposition (Construction 13.22.39) reduces to a single term: $\Theta_{\text{loop}^2}^{(2)}$, the iterated BV operator applied twice. Neither the separating/loop shell nor the planted-forest shell contributes. The modular tangent complex $T_{\Theta_{\mathcal{H}_k}}^{\text{mod}}$ has rank one at every genus, and all characteristic invariants are determined by the single scalar $\kappa = k$.

The classical r -matrix $r^{\text{Heis}}(z) = k/z$ is nontrivial but scalar. At $k = 0$ the r -matrix vanishes: the abelian limit is uncurved. The R -matrix $R(z) = e^{kh/z}$ carries spectral data, yet the braiding is commutative and the ordered bar complex adds no structural information beyond the symmetric one. The Yangian supplies the first example where the E_1 ordering is genuine: the R -matrix is matrix-valued, the braiding non-commutative, and the averaging map av irreversibly destroys categorical data.

The escalation begins here. Heisenberg is class G: shadow depth 2, tower terminates, SC-formal. The bar construction is the *categorical logarithm*: its kernel is the logarithmic form $\eta_{ij} = d \log(z_i - z_j)$, mapping the multiplicative OPE structure to the nilpotent bar differential with $d^2 = 0$. At genus 0 on $\mathbb{P}^1$, this logarithm is single-valued and the Arnold relation holds without correction; the bar differential satisfies $d^2 = 0$ from the FM compactification of configuration spaces alone. This is *not* classical operadic Koszul duality: the Arnold relation on $\overline{\mathcal{C}}_n(\mathbb{P}^1)$, the FM boundary stratification, and the full Borchers extraction rule are genuinely chiral structures absent over a point. Classical Koszul duality is recovered only on the contractible affine line $X = \mathbb{A}^1$, where the FM cooperad is quasi-isomorphic to the associative cooperad and all configuration-space topology collapses (the comparison requires a choice of homotopy retraction data from $\mathbb{A}^1$ to a point; the retraction is not canonical, and the formal disk carries completion data that the point does not see). Already at genus 0 the chiral bar complex is richer than its classical shadow. At genus $g \geq 1$, the logarithm acquires monodromy from the period structure of the curve, the propagator acquires corrections from the Hodge bundle over $\overline{\mathcal{M}}_g$, the bar differential develops curvature $d_{\text{fb}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ whose coefficient $\kappa(\mathcal{A})$ is the infinitesimal generator of this monodromy, and the genus tower organizes into a modular deformation whose generating function is the $\hat{A}$ -genus. *Nilpotence is the logarithm of periodicity*: the nilpotent data ($d^2 = 0$, κ , the bar differential) determine the periodic data (modular transformations, periodicity of bar cohomology, the monodromy representation) via exponentiation (Remark 6.1.9).

Each subsequent family in this chapter adds exactly one source of complexity that the previous family lacked. The escalation is monotone: from the abelian double pole to the full modular obstruction tower.

- The **Heisenberg algebra** $\mathcal{H}_k$ (§2.1–§2.12): class G, shadow depth 2, $\kappa = k$, $S_4 = 0$, $\Delta = 0$. One double pole. The bar complex, the Koszul dual, bar-cobar inversion, genus-1 curvature, the $\hat{A}$ -genus, and complementarity are all instantiated in closed form. Every theorem of Part I is verified here first.
- **Free fermions and the $\beta\gamma$ system** (§2.15): class G, depth 2. The new ingredient is the *simple pole*. The fermion, governed by $\psi(z)\psi(w) \sim 1/(z - w)$, is Koszul dual to the $\beta\gamma$ system: the chiral incarnation of $\text{Lie}^! = \text{Com}$. This clarifies the distinction between Koszul duality, bosonization, and level-shifting.
- **Affine Kac–Moody algebras** (§2.16): class L, shadow depth 3. The new ingredient is *non-abelianity*. Both simple and double poles coexist. The bar differential acquires a bracket component from the simple pole and a curvature component from the double pole; neither is individually a differential.

The Borchers identity, coupling both pole orders, replaces the Jacobi identity. The PBW spectral sequence emerges as the correct computational tool, and the Feigin–Frenkel involution $k \leftrightarrow -k - 2h^\vee$ is Koszul duality.

- **$\mathcal{W}$ -algebras** (§2.18): class M, shadow depth infinite. The new ingredient is *composite fields*. Generators such as $\Lambda =: TT = -\frac{3}{10}\partial^2 T$ introduce quartic OPE poles; the PBW spectral sequence does not automatically degenerate. The obstruction tower never terminates: $S_4 \neq 0$, $\Delta \neq 0$. Koszul duality commutes with Drinfeld–Sokolov reduction, extending the Feigin–Frenkel involution to the full $\mathcal{W}$ -algebra tower.
- **Lattice vertex algebras** (§2.19): the new ingredient is E_1 -*monoidal structure* from the braiding. Cocycle deformations produce quantum lattice algebras, and the E_1 bar-cobar adjunction inverts the quantum parameter: $\varepsilon \mapsto \varepsilon^{-1}$.
- **Yangians** (§2.19): the R -matrix is matrix-valued, the braiding non-commutative, the averaging map av irreversibly lossy. The $R \leftrightarrow R^{-1}$ duality in factorization form recovers, through factorization homology, the Drinfeld–Kohno equivalence between KZ monodromy and quantum group representations.

Remark 2.0.1 (The six theorems for Heisenberg). The five main theorems and the center theorem for $\mathcal{H}_k$: **A** (§2.5): $\mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*), m_0 = -k\omega)$. **B** (§2.6): $\Omega\bar{B}(\mathcal{H}_k) \xrightarrow{\sim} \mathcal{H}_k$. **C** (§2.12): $Q_g(\mathcal{H}_k) \oplus Q_g(\mathcal{H}_k^!) = H^*(\bar{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{H}_k})$. **D** (§2.11): $\kappa(\mathcal{H}_k) = k$; $\sum_{g \geq 1} F_g x^{2g} = k(\frac{x/2}{\sin(x/2)} - 1)$. **H** (Theorem 14.4.12): $\text{ChirHoch}^*(\mathcal{H}_k) = (\mathbb{C}, \mathbb{C}, \mathbb{C})$ concentrated in degrees $\{0, 1, 2\}$; Hilbert polynomial $P(t) = 1 + t + t^2$. **Center** (Theorem A.10.7): $C_{\text{ch}}^\bullet(\mathcal{H}_k, \mathcal{H}_k)$ is the operadic center; the bar coproduct (deconcatenation) provides the coassociative E_1 -coalgebra structure, and the outer derivation $D(\alpha) = 1$ is the nontrivial class in ChirHoch^1 .

The Heisenberg algebra is the smallest E_∞ -chiral algebra in which every load-bearing phenomenon on the commutative/modular face of this monograph is already forced. The computation begins now.

Let X be a smooth algebraic curve. The Heisenberg chiral algebra $\mathcal{H}_k$ at level $k \in \mathbb{C}^\times$ has a single current $\alpha(z)$ of conformal weight 1, with operator product expansion

$$\alpha(z)\alpha(w) = \frac{k}{(z-w)^2} + \text{regular}. \quad (2.1)$$

The double pole is the entire structure. In mode expansion, $\alpha(z) = \sum_{n \in \mathbb{Z}} \alpha_n z^{-n-1}$, and the commutation relations are

$$[\alpha_m, \alpha_n] = k \cdot m \cdot \delta_{m+n,0}.$$

The vacuum representation (Fock space) is $\mathcal{F}_k = \mathbb{C}[\alpha_{-1}, \alpha_{-2}, \dots] |0\rangle$ with $\alpha_n |0\rangle = 0$ for $n > 0$. The Sugawara construction gives the stress tensor $T = \frac{1}{2k} : \alpha(z)\alpha(z) :$ with central charge $c = 1$.

No simple pole appears in the self-OPE. This is the defining feature. Free fermions have a simple pole $\psi(z)\psi(w) \sim 1/(z-w)$; affine Kac–Moody algebras $\hat{\mathfrak{g}}_k$ have both simple and double poles. The double pole alone isolates the curvature sector, free from the bracket sector. The bar differential has a single component; at Kac–Moody, it will acquire two.

Remark 2.0.2 (Fourier identification). The bar complex $\bar{B}(\mathcal{H}_k)$ is the abelian one-dimensional Fourier transform of the Heisenberg algebra (Chapter K.7.1). The $\hat{A}$ -genus appearing in Theorem D (Theorem 13.21.44) is its characteristic function, the analogue of $e^{-t|\xi|^2}$ for the classical heat kernel.

2.1 THE BAR COMPLEX AT DEGREE 1

The geometric bar complex of $\mathcal{H}_k$ on X has underlying graded space

$$\bar{B}_n^{\text{ch}}(\mathcal{H}_k) = \Gamma\left(\bar{C}_{n+1}(X), \alpha^{\boxtimes(n+1)} \otimes \Omega_{\log}^n\right)$$

where $\bar{C}_{n+1}(X)$ is the Fulton–MacPherson compactification of the configuration space of $n + 1$ distinct points on X , and $\Omega_{\log}^n$ denotes logarithmic n -forms along the boundary divisors $D_{ij} = \{z_i = z_j\}$.

A typical element of $\bar{B}_1^{\text{ch}}$ is

$$\alpha(z_1) \otimes \alpha(z_2) \otimes \eta_{12}$$

where

$$\eta_{ij} = d \log(z_i - z_j) = \frac{dz_i - dz_j}{z_i - z_j}$$

is the logarithmic 1-form associated to the diagonal $D_{ij} \subset X \times X$.

The bar differential d_{res} extracts OPE data at boundary divisors via the Borchers identity.

Grading and desuspension accounting

The bar complex uses cohomological grading and desuspension (Appendix G, §G.3). The current $\alpha(z)$ has conformal weight $|\alpha| = 1$. Desuspension lowers cohomological degree by 1 (Definition G.3.1: $|s^{-1}v| = |v| - 1$):

$$\deg(s^{-1}\alpha) = |\alpha| - 1 = 0.$$

A bar-degree- n element (involving $(n + 1)$ desuspended currents and an n -form in the log-FM sense) carries bar degree n in the bar complex grading. The logarithmic forms η_{ij} carry form-degree 1 but cohomological degree 0; the bar degree itself (tensor length minus one) records the degree. The bar differential has $|d_{\text{res}}| = +1$ in cohomological degree, reducing bar degree by 1 (see Appendix G).

For a degree-1 element, the data is:

$$\begin{aligned} \text{two desuspended currents: } & s^{-1}\alpha(z_1) \otimes s^{-1}\alpha(z_2), \\ \text{one logarithmic 1-form: } & \eta_{12} = \frac{dz_1 - dz_2}{z_1 - z_2}. \end{aligned}$$

Action of d_{res} at degree 1

The bar differential acts by restriction to the boundary stratum $D_{12} = \{z_1 = z_2\} \subset \bar{C}_2(X)$. The mechanism is the Borchers identity: for fields $a(z), b(w)$ with OPE $a(z)b(w) = \sum_{n \geq 1} c_n(w)/(z - w)^n + \text{regular}$, the bar differential extracts the OPE coefficients via the $\mathcal{D}$ -module chiral product:

$$d_{\text{res}}(s^{-1}a(z_1) \otimes s^{-1}b(z_2) \otimes \eta_{12}) = \sum_{n \geq 0} a_{(n)}b = \sum_{n \geq 1} c_n(z_2) \Big|_{z_1=z_2} \quad (2.2)$$

where $a_{(n)}b$ denotes the n -th mode product and c_n the coefficient of $(z - w)^{-n}$ in the OPE. This sums *all* OPE polar coefficients: simple pole, double pole, and higher.

For the Heisenberg OPE (2.1), $c_1 = 0$ (no simple pole) and $c_2 = k$ (double pole), so:

$$d_{\text{res}}(\alpha(z_1) \otimes \alpha(z_2) \otimes \eta_{12}) = c_1 + c_2 = 0 + k = k \cdot 1 \quad (2.3)$$

extracting the second-order pole coefficient into the degree-0 component $\bar{B}_0^{\text{ch}} = \mathbb{C}$.

Mechanism

The extraction (2.2) uses the full chiral product μ (Convention 6.0.5), which sums *all* OPE modes $a_{(n)}b$ for $n \geq 0$. The Heisenberg OPE has no simple pole ($\alpha_{(0)}\alpha = 0$), so the entire contribution comes from the double pole: $d_{\text{res}} = \alpha_{(1)}\alpha = k$.

One must *not* form the combined meromorphic integral $\text{Res}_{\epsilon=0}[k\epsilon^{-2} \cdot d\epsilon/\epsilon]$: that triple pole has zero Poincaré residue. The chiral product μ acts by the Borchers extraction rule, not by multiplicatively composing the OPE pole with the logarithmic form. The form η_{12} serves as a test form for the boundary pairing on D_{12} , marking which stratum to restrict to; the mode sum $\sum a_{(n)}b$ is the $\mathcal{D}$ -module !-pushforward along D_{12} (cf. Beilinson–Drinfeld [40, §3.7.4]).

Remark 2.1.1 (Where the OPE data goes). The map $d_{\text{res}}: \bar{B}_1^{\text{ch}} \rightarrow \bar{B}_0^{\text{ch}} = \mathbb{C}$ sends the Heisenberg pair to the constant k . On $\mathbb{P}^1$, where $H^1(X) = 0$, the kernel of d_{res} on B_1 is trivial: every element maps to a nonzero multiple of the vacuum. At higher genus, zero modes of $\alpha(z)$ along cycles of Σ_g contribute nontrivially to $\ker(d_{\text{res}})$, producing $H^1 \cong H^1(\Sigma_g, \mathbb{C})$ (Theorem E.2.25).

2.2 THE BAR COMPLEX AT DEGREE 2: ARNOLD ENTERS

The degree-2 bar complex $\bar{B}_2^{\text{ch}}$ involves three currents and two logarithmic forms:

$$\alpha(z_1) \otimes \alpha(z_2) \otimes \alpha(z_3) \otimes \eta_{12} \wedge \eta_{23}. \quad (2.4)$$

Sign conventions for the bar differential at degree 2

Before computing, we fix signs. The bar differential is a sum over boundary strata:

$$d_{\text{res}} = \sum_{1 \leq i < j \leq n+1} (-1)^{\sigma(i,j)} \partial_{D_{ij}}$$

where $\partial_{D_{ij}}$ restricts to the divisor $D_{ij} = \{z_i = z_j\}$ and extracts the OPE coefficient, and $\sigma(i, j)$ is the Koszul sign arising from permuting the desuspended elements past each other.

For degree-2 elements with three desuspended currents $s^{-1}\alpha(z_1) \otimes s^{-1}\alpha(z_2) \otimes s^{-1}\alpha(z_3)$, the Koszul sign rule gives the following. Desuspension lowers cohomological degree by 1 (Appendix G; $|s^{-1}v| = |v| - 1$), so the desuspended current $s^{-1}\alpha$ has degree $|\alpha| - 1 = 0$, hence is *even* in the graded sense. Moving even-degree elements past each other produces sign $(-1)^{0 \cdot 0} = +1$. Consequently, for the Heisenberg algebra (single even-degree generator), *all Koszul signs from the coalgebra coproduct are +1*. The signs in the bar differential come entirely from the orientation of the logarithmic forms on the boundary strata.

Term-by-term computation of d_{res}

The element (2.4) lives on $\bar{C}_3(X)$, whose boundary divisors are D_{12} , D_{23} , and D_{13} . The bar differential restricts to each:

Boundary stratum D_{12} : collision $z_1 = z_2$. The OPE $\alpha(z_1)\alpha(z_2) = k/(z_1 - z_2)^2 + \text{reg.}$ collapses the pair to the scalar k . The form $\eta_{12} \wedge \eta_{23}$ restricts to D_{12} by the rule: η_{12} is “consumed” by the boundary pairing on D_{12} (it is the test form for this stratum), and the residual form is $\eta_{23}|_{z_1=z_2}$. Since $z_1 = z_2$ on D_{12} , the residual form is simply η_{23} (which does not involve z_1 , so it is unaffected by the collision). The sign from the wedge product is +1 because η_{12} is the *left* factor:

$$\partial_{D_{12}}(\alpha \otimes \alpha \otimes \alpha \otimes \eta_{12} \wedge \eta_{23}) = +k \cdot \alpha(z_3) \otimes \eta_{23}. \quad (2.5)$$

Here $\alpha(z_3) \otimes \eta_{23}$ is a degree-1 element: a single surviving current with a single logarithmic form, living on $\overline{C}_2(X)$ with coordinates (z_{12}, z_3) where z_{12} is the collision point.

Boundary stratum D_{23} : collision $z_2 = z_3$. The OPE $\alpha(z_2)\alpha(z_3) = k/(z_2 - z_3)^2 + \text{reg.}$ collapses the pair to k . The form $\eta_{12} \wedge \eta_{23}$ restricts to D_{23} by consuming η_{23} (the test form for this stratum). To consume η_{23} , we must move it to the left of η_{12} , producing a sign from the wedge:

$$\eta_{12} \wedge \eta_{23} = -\eta_{23} \wedge \eta_{12}.$$

The residual form after consuming η_{23} is $\eta_{12}|_{z_2=z_3}$. On D_{23} , $z_2 = z_3$, so $\eta_{12}|_{z_2=z_3} = \eta_{13}$ (the form $d \log(z_1 - z_2)$ becomes $d \log(z_1 - z_3)$ when $z_2 = z_3$). The surviving current is $\alpha(z_1)$. Including the sign from the wedge permutation:

$$\partial_{D_{23}}(\alpha \otimes \alpha \otimes \alpha \otimes \eta_{12} \wedge \eta_{23}) = -k \cdot \alpha(z_1) \otimes \eta_{13}.$$

Boundary stratum D_{13} : collision $z_1 = z_3$. The OPE $\alpha(z_1)\alpha(z_3) = k/(z_1 - z_3)^2 + \text{reg.}$ collapses the pair to k . However, the 2-form $\eta_{12} \wedge \eta_{23}$ does *not* contain the factor η_{13} as a wedge component. The restriction of $\eta_{12} \wedge \eta_{23}$ to D_{13} involves:

$$\eta_{12}|_{z_1=z_3} = \eta_{32} = -\eta_{23}, \quad \eta_{23}|_{z_1=z_3} = \eta_{23}.$$

So $(\eta_{12} \wedge \eta_{23})|_{D_{13}} = (-\eta_{23}) \wedge \eta_{23} = 0$. The boundary stratum D_{13} contributes *zero*:

$$\partial_{D_{13}}(\alpha \otimes \alpha \otimes \alpha \otimes \eta_{12} \wedge \eta_{23}) = 0. \quad (2.6)$$

This vanishing is specific to the chosen basis element $\eta_{12} \wedge \eta_{23}$; for a general 2-form, D_{13} can contribute.

Assembling the differential. Summing the three contributions (2.5)–(2.6):

$$d_{\text{res}}(\alpha(z_1) \otimes \alpha(z_2) \otimes \alpha(z_3) \otimes \eta_{12} \wedge \eta_{23}) = k \cdot \alpha(z_3) \otimes \eta_{23} - k \cdot \alpha(z_1) \otimes \eta_{13}. \quad (2.7)$$

Verification: $d_{\text{res}}^2 = 0$ at degree 2

Now apply d_{res} a second time. Each term in the right-hand side of (2.7) is a degree-1 element, and d_{res} on degree 1 extracts k by (2.3):

$$d_{\text{res}}^2 = k \cdot d_{\text{res}}(\alpha(z_3) \otimes \eta_{23}) - k \cdot d_{\text{res}}(\alpha(z_1) \otimes \eta_{13}) = k^2 - k^2 = 0. \quad (2.8)$$

The first term: $d_{\text{res}}(\alpha(z_3) \otimes \eta_{23})$ extracts the OPE of α with itself at the collision $z_2 = z_3$, giving k . The second term: $d_{\text{res}}(\alpha(z_1) \otimes \eta_{13})$ extracts the OPE at $z_1 = z_3$, also giving k . These are equal, and the relative sign -1 forces exact cancellation.

Alternative basis and the role of D_{13}

To see that the vanishing of D_{13} above was a feature of the basis choice, consider the alternative degree-2 element $\alpha^{\otimes 3} \otimes \eta_{23} \wedge \eta_{31}$. The Arnold relation (2.9) below gives

$$\eta_{23} \wedge \eta_{31} = -\eta_{12} \wedge \eta_{23} - \eta_{31} \wedge \eta_{12} = -\eta_{12} \wedge \eta_{23} + \eta_{12} \wedge \eta_{31}.$$

Computing d_{res} on this element, the stratum D_{13} *does* contribute (with coefficient $+k$), but the stratum D_{12} picks up an additional sign. The computation of $d_{\text{res}}^2 = 0$ on *any* basis element requires the *full* Arnold relation, not just pairwise cancellation. The Arnold relation is the universal identity guaranteeing $d^2 = 0$.

PROPOSITION 2.2.1 (*Arnold relation*;). For any three distinct points $z_1, z_2, z_3 \in X$, the logarithmic forms satisfy:

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0 \quad (2.9)$$

in $\Omega_{\log}^2(\overline{C}_3(X))$.

Proof. The identity $\frac{1}{z_1 - z_2} \cdot \frac{1}{z_2 - z_3} + \frac{1}{z_2 - z_3} \cdot \frac{1}{z_3 - z_1} + \frac{1}{z_3 - z_1} \cdot \frac{1}{z_1 - z_2} = 0$ follows from partial fractions: the three terms have total numerator $(z_3 - z_1) + (z_1 - z_2) + (z_2 - z_3) = 0$. Taking d log of each factor and wedging produces (2.9). $\square$

The Arnold relation forces $d^2 = 0$ on the bar complex. At degree 2, the two paths from $\bar{B}_2$ to $\bar{B}_0$ through $\bar{B}_1$ correspond to the two codimension-2 strata $D_{12} \cap D_{23}$ and $D_{13} \cap D_{23}$ in $\overline{C}_3(X)$. Arnold ensures these contribute with opposite signs. More precisely, the differential d sums residue maps along all collision divisors; applying d twice, each pair of successive collisions defines a codimension-2 stratum of $\overline{C}_{n+1}(X)$. By Stokes' theorem on manifolds with corners, $d^2 = 0$ if and only if the boundary of the boundary vanishes: the Arnold relation on the logarithmic forms.

Remark 2.2.2 (The Arnold relation as factorization coherence). The identity (2.9) is the fundamental coherence relation of factorization algebras: the bar complex is well-defined because Arnold holds, Verdier duality sends the bar coalgebra to the homotopy Koszul dual algebra $(\mathbb{D}_{\text{Ran}} \overline{B}(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!)$ because Arnold is self-dual, and the genus tower extends over $\overline{M}_g$ because Arnold lifts to boundary strata of the FM operad. In the operadic language at genus 0, (2.9) defines the gravity operad Grav , which is Koszul dual to the hypercommutative operad HyCom in the sense of Getzler–Kapranov [203]; the identification $\text{Grav} = \text{HyCom}^!$ is a genus-0 operadic Koszul duality, and it does not automatically extend to the modular operad (the higher-genus analogue requires the Feynman transform, which twists the operadic Koszul picture by the self-gluing maps of $\overline{M}_{g,n}$). The genus-0 bar-cobar adjunction is the operadic Koszul duality at that level.

2.3 THE BAR COMPLEX AT ALL DEGREES: $d^2 = 0$

At degree n , the bar complex element is

$$\alpha(z_1) \otimes \cdots \otimes \alpha(z_{n+1}) \otimes \eta_{i_1 j_1} \wedge \cdots \wedge \eta_{i_n j_n}$$

and the bar differential extracts OPE data at each collision divisor. The Heisenberg OPE has no simple pole, so d_{bracket} vanishes identically; only $d_{\text{curvature}}$ (the double-pole extraction) survives.

The degree-3 computation below is the first where the cancellation mechanism for $d^2 = 0$ involves *pairs* of Arnold relations, revealing the pattern that persists at all higher degrees.

2.3.1 EXPLICIT DEGREE-3 COMPUTATION ($n = 3$, FOUR POINTS)

A degree-3 bar element lives on $\overline{C}_4(X)$ with four points z_1, z_2, z_3, z_4 and involves a 3-form in the logarithmic algebra. A natural basis element is:

$$\xi_3 = \alpha(z_1) \otimes \alpha(z_2) \otimes \alpha(z_3) \otimes \alpha(z_4) \otimes \eta_{12} \wedge \eta_{23} \wedge \eta_{34} \in \overline{B}_3^{\text{ch}}.$$

This is the “chain” basis element, where the logarithmic forms link consecutive pairs 1–2, 2–3, 3–4.

Boundary strata of $\overline{C}_4(X)$

The boundary divisors of $\overline{C}_4(X)$ are D_{ij} for $1 \leq i < j \leq 4$; there are $\binom{4}{2} = 6$ of them. For each divisor D_{ij} , the bar differential extracts the OPE $\alpha(z_i)\alpha(z_j) = k/(z_i - z_j)^2 + \text{reg.}$, collapses two of the four currents to the scalar k , and restricts the 3-form to a 2-form on $\overline{C}_3(X)$.

We compute the contribution of each stratum.

Stratum D_{12} : collision $z_1 = z_2$. The form η_{12} is consumed (it is the leftmost factor and is the test form for D_{12}). The OPE gives k . The residual 2-form is $(\eta_{23} \wedge \eta_{34})|_{z_1=z_2}$. Since η_{23} and η_{34} do not involve z_1 in a way that changes under $z_1 = z_2$, the residual form is $\eta_{23} \wedge \eta_{34}$ (with z_1 replaced by the collision point z_{12} , but the forms only involve z_2, z_3, z_4). The surviving currents are $\alpha(z_3)$ and $\alpha(z_4)$ (plus the collision point, which carries the scalar k). The sign is $+1$ (leftmost form consumed):

$$\partial_{D_{12}}(\xi_3) = +k \cdot \alpha(z_3) \otimes \alpha(z_4) \otimes \eta_{23} \wedge \eta_{34}. \quad (2.10)$$

(Here and below, we relabel the collision point: z_{12} is identified with z_2 on the residual configuration space.)

Stratum D_{23} : collision $z_2 = z_3$. The form η_{23} must be consumed. It sits in the middle of the wedge product $\eta_{12} \wedge \eta_{23} \wedge \eta_{34}$. Moving η_{23} to the left past η_{12} costs one transposition sign:

$$\eta_{12} \wedge \eta_{23} \wedge \eta_{34} = -\eta_{23} \wedge \eta_{12} \wedge \eta_{34}.$$

After consuming η_{23} , the residual 2-form is $\eta_{12}|_{z_2=z_3} \wedge \eta_{34}|_{z_2=z_3} = \eta_{13} \wedge \eta_{34}$ (since $z_2 = z_3$ sends $\eta_{12} \mapsto \eta_{13}$ and leaves η_{34} unchanged). The surviving currents are $\alpha(z_1)$ and $\alpha(z_4)$:

$$\partial_{D_{23}}(\xi_3) = -k \cdot \alpha(z_1) \otimes \alpha(z_4) \otimes \eta_{13} \wedge \eta_{34}.$$

Stratum D_{34} : collision $z_3 = z_4$. The form η_{34} is consumed. It is the rightmost factor, so moving it to the front costs two transpositions:

$$\eta_{12} \wedge \eta_{23} \wedge \eta_{34} = +\eta_{34} \wedge \eta_{12} \wedge \eta_{23}$$

(two transpositions: $(-1)^2 = +1$; alternatively, a cyclic permutation of three 1-forms has sign $(-1)^{3-1} = +1$). After consuming η_{34} , the residual 2-form is $\eta_{12} \wedge \eta_{23}|_{z_3=z_4} = \eta_{12} \wedge \eta_{23}$ (since $z_3 = z_4$ does not affect η_{12} or η_{23} , and we relabel the collision point as z_3). The surviving currents are $\alpha(z_1)$ and $\alpha(z_2)$:

$$\partial_{D_{34}}(\xi_3) = +k \cdot \alpha(z_1) \otimes \alpha(z_2) \otimes \eta_{12} \wedge \eta_{23}. \quad (2.11)$$

Stratum D_{13} : collision $z_1 = z_3$. The form η_{13} does not appear explicitly in the wedge $\eta_{12} \wedge \eta_{23} \wedge \eta_{34}$. We must restrict each factor to D_{13} :

$$\begin{aligned} \eta_{12}|_{z_1=z_3} &= \eta_{32} = -\eta_{23}, \\ \eta_{23}|_{z_1=z_3} &= \eta_{23}, \\ \eta_{34}|_{z_1=z_3} &= \eta_{34}. \end{aligned}$$

The restricted 3-form is $(-\eta_{23}) \wedge \eta_{23} \wedge \eta_{34} = 0$ since $\eta_{23} \wedge \eta_{23} = 0$. Therefore:

$$\partial_{D_{13}}(\xi_3) = 0.$$

Stratum D_{24} : collision $z_2 = z_4$. Restrict each factor to D_{24} :

$$\begin{aligned}\eta_{12}|_{z_2=z_4} &= \eta_{14}, \\ \eta_{23}|_{z_2=z_4} &= \eta_{43} = -\eta_{34}, \\ \eta_{34}|_{z_2=z_4} &= \eta_{34}.\end{aligned}$$

The restricted 3-form is $\eta_{14} \wedge (-\eta_{34}) \wedge \eta_{34} = -\eta_{14} \wedge \eta_{34} \wedge \eta_{34} = 0$ since $\eta_{34} \wedge \eta_{34} = 0$. Therefore:

$$\partial_{D_{24}}(\xi_3) = 0.$$

Stratum D_{14} : collision $z_1 = z_4$. Restrict each factor to D_{14} :

$$\begin{aligned}\eta_{12}|_{z_1=z_4} &= \eta_{42} = -\eta_{24}, \\ \eta_{23}|_{z_1=z_4} &= \eta_{23}, \\ \eta_{34}|_{z_1=z_4} &= \eta_{34}.\end{aligned}$$

After the collision $z_1 = z_4$, the restricted form $(-\eta_{24}) \wedge \eta_{23} \wedge \eta_{34}$ is a 3-fold wedge of logarithmic 1-forms on $\overline{C}_3(X)$ with coordinates (z_2, z_3, z_4) . By Arnold's theorem, the space of log-1-forms on three points is 2-dimensional (spanned by any two of $\eta_{23}, \eta_{34}, \eta_{24}$, with the third determined by the Arnold relation), so every 3-fold wedge vanishes. The boundary pairing therefore gives zero.

$$\partial_{D_{14}}(\xi_3) = 0.$$

Assembling d_{res} at degree 3

Only the three “adjacent” strata D_{12}, D_{23}, D_{34} contribute. The three “non-adjacent” strata D_{13}, D_{24}, D_{14} all vanish by form-degree reasons. Summing (2.10)–(2.11):

$$\begin{aligned}d_{\text{res}}(\xi_3) &= k \cdot \alpha(z_3) \otimes \alpha(z_4) \otimes \eta_{23} \wedge \eta_{34} \\ &\quad - k \cdot \alpha(z_1) \otimes \alpha(z_4) \otimes \eta_{13} \wedge \eta_{34} \\ &\quad + k \cdot \alpha(z_1) \otimes \alpha(z_2) \otimes \eta_{12} \wedge \eta_{23}.\end{aligned}\tag{2.12}$$

Observe the alternating signs $+, -, +$ from the position of the consumed form in the wedge product: leftmost $(+1)$, middle (-1) , rightmost $(+1)$.

Verification: $d_{\text{res}}^2 = 0$ at degree 3

We now apply d_{res} again to each of the three terms in (2.12). Each term is a degree-2 element, and from (2.7) we know how d_{res} acts at degree 2.

First term: $d_{\text{res}}(k \cdot \alpha(z_3) \otimes \alpha(z_4) \otimes \eta_{23} \wedge \eta_{34})$.

The element $k \cdot \alpha(z_3) \otimes \alpha(z_4) \otimes \eta_{23} \wedge \eta_{34}$ is a degree-2 element on $\overline{C}_3$ with coordinates (z_2, z_3, z_4) , carrying the scalar coefficient k from the previous contraction. The two surviving currents sit at z_3 and z_4 .

The next residue can therefore come only from the OPE of $\alpha(z_3)$ with $\alpha(z_4)$, hence from the boundary stratum D_{34} . Extracting that residue consumes η_{34} , and moving that factor past η_{23} contributes the sign -1 :

$$d_{\text{res}}(k \cdot \alpha(z_3) \otimes \alpha(z_4) \otimes \eta_{23} \wedge \eta_{34}) = k \cdot (-1) \cdot k \cdot \eta_{23}|_{z_3=z_4} = -k^2 \cdot \eta_{24}.$$

After the collapse $z_3 = z_4$, no currents remain. The output $-k^2 \cdot \eta_{24}$ is a scalar 1-form on $\overline{C}_2$, equivalently an element of $\overline{B}_1^{\text{ch}}$ with scalar coefficient. For the cancellation argument, only the coefficient and sign matter.

Verification of $d^2 = 0$ via Arnold pairs

Rather than applying d_{res} term-by-term to all three summands and tracking relabeling, we verify $d^2 = 0$ structurally. The bar differential $d = d_{\text{res}}$ satisfies $d^2 = 0$ if and only if every codimension-2 boundary stratum of $\overline{C}_4(X)$ contributes zero. The codimension-2 strata are of two types:

Type I: nested collisions $D_{ij} \cap D_{jk}$ (three points z_i, z_j, z_k collide in sequence). These contribute via the composition $\partial_{D_{jk}} \circ \partial_{D_{ij}}$: first z_i collides with z_j , then the collision point collides with z_k . The reverse order $\partial_{D_{ij}} \circ \partial_{D_{jk}}$ gives the same codimension-2 stratum with opposite orientation. By the Arnold relation on the triple (z_i, z_j, z_k) , these two contributions cancel.

For the four-point configuration, the nested triples are: $(1, 2, 3)$, $(2, 3, 4)$, $(1, 2, 4)$, $(1, 3, 4)$. Each produces one Arnold-relation cancellation.

Type II: disjoint collisions $D_{ij} \cap D_{kl}$ where $\{i, j\} \cap \{k, l\} = \emptyset$. For four points, the only such stratum is $D_{12} \cap D_{34}$ (simultaneous collision $z_1 = z_2$ and $z_3 = z_4$). The two orderings $\partial_{D_{34}} \circ \partial_{D_{12}}$ and $\partial_{D_{12}} \circ \partial_{D_{34}}$ commute (they act on disjoint pairs), and the sign from the form restriction ensures they cancel. Explicitly, for the form $\eta_{12} \wedge \eta_{23} \wedge \eta_{34}$:

- $\partial_{D_{12}}$ then $\partial_{D_{34}}$: consume η_{12} (sign +1), leaving $\eta_{23} \wedge \eta_{34}$; then consume η_{34} (sign -1 from moving past η_{23}). Net: (-1) .
- $\partial_{D_{34}}$ then $\partial_{D_{12}}$: consume η_{34} (sign +1 by cyclic permutation), leaving $\eta_{12} \wedge \eta_{23}$; then consume η_{12} (sign +1). Net: $(+1)$.

The two orderings produce opposite signs:

$$\partial_{D_{34}} \circ \partial_{D_{12}}(\xi_3) + \partial_{D_{12}} \circ \partial_{D_{34}}(\xi_3) = k^2 \cdot (-1 + 1) = 0.$$

Since every codimension-2 stratum contributes zero (Type I by Arnold, Type II by sign cancellation), we conclude:

$$d_{\text{res}}^2(\xi_3) = 0.$$

(The same conclusion can be reached by explicit term-by-term computation of d_{res} applied to each summand in (2.12), using Arnold relations to expose the residue factors; the boundary-stratum argument above is cleaner and generalizes immediately to arbitrary degree.)

The adjacency pattern

The degree-3 computation reveals a structural feature. For the chain basis element $\alpha^{\otimes 4} \otimes \eta_{12} \wedge \eta_{23} \wedge \eta_{34}$, only “adjacent” strata (those D_{ij} where η_{ij} appears as a factor in the wedge) give nonzero contributions to d . The non-adjacent strata D_{13}, D_{24}, D_{14} all vanish by form-squaring ($\eta \wedge \eta = 0$). This adjacency pattern persists at all degrees for the chain basis: the differential on $\alpha^{\otimes(n+1)} \otimes \eta_{12} \wedge \eta_{23} \wedge \cdots \wedge \eta_{n,n+1}$ receives contributions only from $D_{12}, D_{23}, \dots, D_{n,n+1}$, producing an alternating sum of n terms with signs $+1, -1, +1, -1, \dots$.

For a general basis element (not the chain basis), all strata can contribute, and $d^2 = 0$ requires the full Arnold relation. The chain basis is special precisely because it diagonalizes the “adjacency” of the logarithmic forms.

2.3.2 THE GENERAL THEOREM

THEOREM 2.3.1 (*Heisenberg bar complex at genus 0*;). For $\mathcal{H}_k$ on $\mathbb{P}^1$:

$$H^n(\bar{B}_{\text{geom}}^{\text{ch}}(\mathcal{H}_k)) = \begin{cases} \mathbb{C} & n = 0, \\ 0 & n = 1, \\ \mathbb{C} \cdot c_k & n = 2, \\ 0 & n > 2. \end{cases}$$

The class $c_k \in H^2$ arises from the triple-collision residue and is the homological manifestation of the central extension. The differential satisfies $d^2 = 0$ at all degrees by the Arnold relation.

Proof. Degree 0. $\bar{B}^0 = \mathbb{C} \cdot 1$ (vacuum), $d = 0$.

Degree 1. The differential $d_{\text{res}}: \bar{B}^1 \rightarrow \bar{B}^0$ sends $\alpha(z_1) \otimes \alpha(z_2) \otimes \eta_{12} \mapsto k \cdot 1$ (equation (2.3)). On $\mathbb{P}^1$, where $H^1(X) = 0$, this map is surjective and has trivial kernel, so $H^1 = 0$.

Degree 2. The three-current collision produces the central charge class. When $\alpha(z_1), \alpha(z_2), \alpha(z_3)$ approach a common point, the iterated OPE produces:

$$\text{Res}_{D_{123}} [\alpha(z_1)\alpha(z_2)\alpha(z_3) \otimes \eta_{12} \wedge \eta_{23}] = k \cdot [\text{central class}]$$

The commutator $[\alpha(z), \alpha(w)] = k \cdot \partial_w \delta(z - w)$ contributes a central term at the triple collision. This produces a nontrivial class $c_k \in H^2$.

Degrees ≥ 3 . The vanishing is genuinely chiral, not a restatement of Chevalley–Eilenberg. The mechanism is the following. Heisenberg has a single quadratic OPE datum (the double pole $J_{(1)}J = k$) and no higher collisions; the Arnold relation (Proposition 2.2.1) forces the chiral bar differential to receive contributions only from binary collisions. At degree $n \geq 3$, iterated binary collisions on $\bar{C}_{n+1}(\mathbb{P}^1)$ produce cocycles whose residues are built from n -fold products of k ; by the Arnold relation these products telescope to zero against the alternating sum on adjacent strata. A detailed degree-by-degree verification is carried out in the free-field chapter (the Heisenberg bar is the boundary case of the $\beta\gamma$ analysis); here we record the conclusion.

$d^2 = 0$. At each degree, $d^2 = 0$ by the Arnold relation (Proposition 2.2.1) applied to the logarithmic forms on $\bar{C}_{n+1}(X)$. The degree-2 verification is (2.8); the general case follows by the same argument on all codimension-2 strata of $\bar{C}_{n+1}(X)$. $\square$

At degree 3, the cancellation mechanism for $d^2 = 0$ involves both nested Arnold relations (Type I) and disjoint-collision sign cancellations (Type II), as detailed in §2.3.1.

2.4 THE TWISTING MORPHISM: THE PROPAGATOR AS ALGEBRAIC MAP

Beyond its coalgebra structure, $\bar{B}(\mathcal{H}_k)$ carries a canonical map back to $\mathcal{H}_k$, the *universal twisting morphism*

$$\tau: \bar{B}(\mathcal{H}_k) \longrightarrow \mathcal{H}_k,$$

defined by projecting a bar element to its single-insertion (cogenerator) component. Concretely, for a bar element $\phi_1 \otimes \cdots \otimes \phi_n \otimes \omega \in \bar{B}^n(\mathcal{H}_k)$:

$$\tau(\phi_1 \otimes \cdots \otimes \phi_n \otimes \omega) = \begin{cases} \phi_1 & n = 1, \omega = 1, \\ 0 & n \geq 2. \end{cases}$$

The twisting morphism has degree +1 (bar desuspension shifts degree by -1).

PROPOSITION 2.4.1 (*Maurer–Cartan equation for Heisenberg*;). The twisting morphism τ satisfies

$$d\tau + \tau \star \tau = 0$$

in the convolution dg Lie algebra $\text{Hom}(\bar{B}(\mathcal{H}_k), \mathcal{H}_k)$, where $(\tau \star \tau)(x) = \mu \circ (\tau \otimes \tau) \circ \Delta(x)$.

The Maurer–Cartan equation is the *Arnold relation in algebraic disguise*. The convolution $\tau \star \tau$ computes the propagator residue at $D_{12} \subset \bar{C}_2(\mathbb{P}^1)$; the bar differential d computes the boundary of this residue. The equation $d\tau + \tau \star \tau = 0$ says that the boundary of a single collision cancels the propagator residue: Stokes’ theorem on $\bar{C}_2(\mathbb{P}^1)$. At three points, this becomes the Arnold relation; at n points, $d_{\text{bar}}^2 = 0$.

Proof. Degree 1. For $x = \alpha^* \in \bar{B}^1$: $\Delta(\alpha^*) = \alpha^* \otimes 1 + 1 \otimes \alpha^*$ (primitive), so $(\tau \star \tau)(\alpha^*) = 0$ (since $\tau(1) = 0$). Also $d\tau(\alpha^*) = d(\alpha) = 0$.

Degree 2. For $x = \alpha^*(z_1) \otimes \alpha^*(z_2) \otimes \eta_{12} \in \bar{B}^2$: the coproduct splits the pair, giving $(\tau \star \tau)(x) = \text{Res}_{z_1=z_2} [\alpha(z_1) \alpha(z_2) \eta_{12}] = k$ (the OPE residue). The bar differential gives $d\tau(x) = \tau(d_{\text{bar}} x) = -k$ by equation (2.3). Hence $d\tau + \tau \star \tau = -k + k = 0$. $\square$

Definition 2.4.2 (*Koszul complex for Heisenberg*). The Koszul complex (twisted tensor product) of τ is

$$K(\tau) := \mathcal{H}_k \otimes_{\tau} \bar{B}(\mathcal{H}_k) = (\mathcal{H}_k \otimes \bar{B}(\mathcal{H}_k), d_{\mathcal{H}} + d_{\bar{B}} + d_{\tau}),$$

where $d_{\tau}(\phi \otimes x) = \mu(\phi \otimes \tau(x_{(1)})) \otimes x_{(2)}$ inserts τ of the first coproduct factor into the algebra.

By the fundamental theorem of twisting morphisms (Theorem II.1.9): $\mathcal{H}_k$ is Koszul if and only if $K(\tau)$ is acyclic. The bar cohomology of Theorem 2.3.1 (concentrated in degrees 0 and 2) is exactly the obstruction to acyclicity of $K(\tau)$; the unique class in degree 2 is the central extension, and it is the twisting morphism that detects it.

The twisting morphism τ determines bar differential, Koszul complex, bar cohomology, and Koszul dual (Corollary II.1.10). The three bijections for τ become the distinction between the Koszul dual *coalgebra*, the Koszul dual *algebra*, and the bar-cobar *resolution*.

Remark 2.4.3 (*The twisting morphism at higher genus*). At genus 0, the MC equation $d\tau + \tau \star \tau = 0$ holds exactly: the propagator $\eta_{12} = d \log(z_1 - z_2)$ on $\mathbb{P}^1$ is single-valued and the Arnold relation is exact. At genus $g \geq 1$, the propagator acquires monodromy and the Arnold relation develops a defect (Theorem 13.5.9):

$$d\tau_g + \tau_g \star \tau_g = \kappa(\mathcal{H}_k) \cdot \omega_g.$$

The twisting morphism becomes *curved*: the curvature $\kappa \cdot \omega_g$ is the Arakelov form weighted by the level. The corrected differential D_g restores flatness by passing to the holomorphic propagator (Theorem 13.16.13; Remark 13.16.14).

2.5 READING OFF THE KOSZUL DUAL

The bar coalgebra $\bar{B}(\mathcal{H}_k)$ carries a coproduct determined by the OPE. On the single cogenerator $\alpha^* \in \bar{B}^1$, there is nothing to decompose:

$$\Delta(\alpha^*) = \alpha^* \otimes 1 + 1 \otimes \alpha^*.$$

This is the definition of a *primitive* element. Every element of $\bar{B}^1$ is primitive, and the double-pole residue is symmetric under $z_i \leftrightarrow z_j$, so the coproduct is cocommutative at all degrees. The bar coalgebra is also conilpotent (Theorem 6.1.21): every element is eventually annihilated by iterated reduced coproducts. By the Milnor–Moore theorem (characteristic zero, conilpotent, cocommutative), such a coalgebra is the universal enveloping coalgebra of its primitives.

Let us spell out what this says. Write $V = \text{Span}\{\alpha\}$ for the one-dimensional space of generators of $\mathcal{H}_k$ (the current α), and $V^* = \text{Span}\{\alpha^*\}$ for its linear dual. The *cofree conilpotent chiral Lie coalgebra cogenerated by V^** , denoted $\text{coLie}^{\text{ch}}(V^*)$, is the chiral Lie coalgebra whose underlying graded vector space is $\bigoplus_{n \geq 1} \text{Lie}^{\text{ch}}(n)^* \otimes_{\mathfrak{S}_n} (V^*)^{\otimes n}$, where $\text{Lie}^{\text{ch}}(n)$ denotes the n -th component of the chiral Lie operad. The coproduct (cobracket) is the graded dual of the Lie bracket.

For $\dim V^* = 1$ a decisive simplification occurs: the free Lie algebra on a single generator is abelian. $\text{Lie}(1) = \mathbb{C}$ and $\text{Lie}(n) = 0$ for all $n \geq 2$; there are no nontrivial brackets among copies of a single element. (Here $\text{Lie}(n)$ denotes the n -th graded piece of the free Lie algebra on a single generator, the image of the operad component $\text{Lie}(n)$ under the one-dimensional representation, not the operad component itself, which has dimension $(n-1)!$.) Dually, the cofree Lie coalgebra on one cogenerator is concentrated in degree 1:

$$\text{coLie}^{\text{ch}}(V^*) \cong V^* \quad \text{as a graded vector space.}$$

The bar coalgebra of $\mathcal{H}_k$ therefore has a single cogenerator $\alpha^* \in \bar{B}^1$ and nothing in higher bar degrees:

$$\bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*) \cong V^*, \quad V^* = \text{Span}\{\alpha^*\}.$$

This is the coalgebraic expression of the fact that $\mathcal{H}_k$ is a *free* commutative chiral algebra on one generator: its bar complex sees only the generator and no relations. For algebras with nontrivial brackets (affine Kac–Moody, $\mathcal{W}_N, \dots$), coLie^{ch} on a higher-dimensional cogenerator space produces a genuinely infinite-dimensional coalgebra, with bar degrees counted by the Witt necklace formula (Computation E.3.17).

Two constructions, two targets. From the coalgebra $\bar{B}(\mathcal{H}_k)$, two different operations produce two different algebras:

1. *Dualize* (graded linear dual): $\text{coLie}^{\text{ch}}(V^*)^\vee \cong \text{Sym}^{\text{ch}}(V^*)$, the free commutative algebra in one generator, the *Koszul dual algebra* $\mathcal{H}_k^!$.
2. *Cobar* (free algebra on the desuspended coalgebra): $\Omega(\bar{B}(\mathcal{H}_k)) \xrightarrow{\sim} \mathcal{H}_k$, a quasi-isomorphism recovering the *original* algebra (Theorem 8.6.1).

In display:

$$\bar{B}^{\text{ch}}(\mathcal{H}_k)^\vee \cong \text{Sym}^{\text{ch}}(V^*) = \mathcal{H}_k^!$$

versus

$$\Omega(\bar{B}^{\text{ch}}(\mathcal{H}_k)) = \Omega(\text{coLie}^{\text{ch}}(V^*)) \xrightarrow{\sim} \mathcal{H}_k.$$

Both operations start from the bar coalgebra $\bar{B}(\mathcal{H}_k)$ and land in the algebra category, but by different routes: dualizing applies linear duality (coalgebra $\rightarrow$ algebra, $\text{coLie} \rightarrow \text{Sym}$) and produces the Koszul dual $\mathcal{H}_k^!$; cobar applies the functor Ω (coalgebra $\rightarrow$ algebra) and recovers the original $\mathcal{H}_k$ as a resolution. They point in opposite algebraic directions, and this is the $\text{Com}^! = \text{Lie}$ duality made concrete.

The level k determines a curvature element $m_0 = -k \cdot \omega \in \text{Sym}^2(V^*)$, encoding the central extension.

THEOREM 2.5.1 (*Heisenberg Koszul dual*;). The Koszul dual of $\mathcal{H}_k$ is the curved commutative chiral algebra

$$\mathcal{H}_k^! \simeq (\mathrm{Sym}^{\mathrm{ch}}(V^*), d = 0, m_0 = -k \cdot \omega).$$

This is *not* $\mathcal{H}_{-k}$: the Heisenberg algebra is not self-dual.

The two algebras differ in every structural property:

Heisenberg $\mathcal{H}_k$	Koszul dual $\mathrm{Sym}^{\mathrm{ch}}(V^*)$
Centrally extended	Free commutative
$\{J_\lambda J\} = k\lambda \neq 0$	$\{J_\lambda^* J^*\} = 0$
Double-pole OPE	Regular OPE
Uncurved ($m_0 = 0$); genus tower $\kappa = k$	Curved ($m_0 = -k\omega$)
Lie-type (LCA envelope)	Com-type ($\mathrm{Sym}^{\mathrm{ch}}$)

For a general augmented chiral algebra $\mathcal{A}$, the same two-arrow pattern holds: the bar $\bar{B}(\mathcal{A})$ is a coalgebra (the Koszul dual *coalgebra*), its linear dual $\bar{B}(\mathcal{A})^\vee = \mathcal{A}^!$ is the Koszul dual *algebra* (realized via Verdier duality on $\mathrm{Ran}(X)$; Theorem 7.0.36), and the cobar recovers the original: $\Omega(\bar{B}(\mathcal{A})) \simeq \mathcal{A}$ on the Koszul locus (Theorem 8.6.1). The general bar-cobar adjunction is developed in Chapter 6.

Remark 2.5.2 (The canonical twisting morphism for Heisenberg). The Koszul duality above is witnessed by the twisting morphism $\tau_{\mathcal{H}}: \mathrm{coLie}^{\mathrm{ch}}(V^*) \rightarrow \mathcal{H}_k, v^* \mapsto J_v$. It solves $\partial\tau + \tau \star \tau = 0$ because the only OPE pole is the double pole: $\tau \star \tau$ extracts the level $k\omega(v, w)$, which lies in the center and is killed by the augmentation. The counit ε_τ is bar-cobar inversion (§2.6); the unit η_τ is bar concentration (Theorem 2.3.1).

Remark 2.5.3 (Three different “dualities”). Three distinct operations must not be confused: (1) Koszul duality $\mathcal{H}_k \leftrightarrow \mathrm{Sym}^{\mathrm{ch}}(V^*)$, where the bar coalgebra $\bar{B}(\mathcal{H}_k)$ is the Koszul dual coalgebra and its linear dual is the Koszul dual algebra $\mathcal{H}_k^!$ (this chapter); (2) level-shifting $\mathrm{Rep}(\mathcal{H}_k) \simeq \mathrm{Rep}(\mathcal{H}_{-k})$; (3) boson-fermion correspondence $\mathrm{Rep}(\mathcal{H}_k) \simeq \mathrm{Rep}(\mathcal{F}^{\otimes 2})$. Only (1) is the subject of this monograph.

2.6 BAR-COBAR INVERSION: THEOREM B IN ACTION

The bar and cobar constructions form an adjoint pair $\Omega \dashv \bar{B}$ between augmented chiral algebras and conilpotent chiral coalgebras (Chapter 6). The counit

$$\varepsilon: \Omega^{\mathrm{ch}}(\bar{B}^{\mathrm{ch}}(\mathcal{H}_k)) \xrightarrow{\sim} \mathcal{H}_k$$

is a quasi-isomorphism: the bar-cobar round trip recovers the original algebra.

2.6.1 THE DATA FLOW

The double-pole coefficient k passes through the bar-cobar cycle without loss:

Stage	Data	Form
$\mathcal{H}_k$	$\alpha(z)\alpha(w) \sim k/(z-w)^2$	OPE
$\bar{B}$	$d_{\mathrm{res}}(\alpha \otimes \alpha \otimes \eta_{12}) = k$	Residue
$H^*(\bar{B})$	$c_k \in H^2(\bar{B}(\mathcal{H}_k))$	Central class
Ω	$m_0 = -k\omega$ in $\Omega\bar{B}(\mathcal{H}_k)$	Curvature
ε	$s\alpha^* \mapsto \alpha$	OPE recovered

The bar differential extracts k as a residue (§2.1); the bar cohomology stores it in the central class c_k (Theorem 2.3.1); the cobar functor reads the coalgebra structure of $\bar{B}(\mathcal{H}_k)$ and installs it as the differential of a free chiral algebra on the cogenerator $s\alpha^*$; the counit projects to $\mathcal{H}_k$. Bar is a lossless encoding.

2.6.2 THE KOSZUL PROPERTY

$\mathcal{H}_k$ is Koszul: the bar cohomology

$$H^n(\bar{B}(\mathcal{H}_k)) = \begin{cases} \mathbb{C} & n = 0, \\ \mathbb{C} \cdot c_k & n = 2, \\ 0 & \text{otherwise} \end{cases}$$

is concentrated in the minimal degrees consistent with the central extension, so the bar complex is formal (quasi-isomorphic to its cohomology as a coalgebra). Formality forces the counit ε to be a quasi-isomorphism: the resolution carries no higher obstructions.

The chain of identifications underlying the duality:

$$\bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*) \xrightarrow{\Omega} \text{Sym}^{\text{ch}}(V^*) = \mathcal{H}_k^!, \quad \bar{B}^{\text{ch}}(\mathcal{H}_k^!) \simeq \text{coLie}^{\text{ch}}(V) \xrightarrow{\Omega} \mathcal{H}_k.$$

The last step uses that the free Lie algebra on a single generator is abelian ($\text{Lie}(V) \cong V$ for $\dim V = 1$). The bar-cobar adjunction restricts to an equivalence on the Koszul locus (Theorem 11.1.84): $\mathcal{H}_k$ and $\mathcal{H}_k^!$ mutually determine each other.

This is Theorem B (Theorem 13.18.4) for the simplest non-trivial case. The general theorem (with the $A_0/A_1/A_2$ decomposition of Remark 11.1.12) establishes bar-cobar duality for all augmented chiral algebras, with the quasi-isomorphism $\Omega\bar{B}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ holding on the Koszul locus. The PBW spectral sequence (Chapter 6) controls convergence: affine Kac–Moody algebras and $\mathcal{W}$ -algebras with collapsing PBW sequence are all Koszul.

2.7 THE PASSAGE TO GENUS 1: CURVATURE APPEARS

Replace $X = \mathbb{P}^1$ by an elliptic curve $E_\tau = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ with modular parameter $\tau \in \mathbb{H}$.

On $\mathbb{P}^1$, the logarithmic form $\eta_{12} = d \log(z_1 - z_2)$ has a simple pole at $z_1 = z_2$ and is single-valued. On E_τ , no meromorphic function with a single simple pole can be doubly periodic (Liouville). The correct replacement is the *elliptic propagator*:

$$G_\tau(z) = \zeta_\tau(z) - \frac{\pi^2 E_2(\tau)}{3} z \tag{2.13}$$

where $\zeta_\tau(z)$ is the Weierstrass zeta function

$$\zeta_\tau(z) = \frac{1}{z} + \sum_{(m,n) \neq (0,0)} \left[\frac{1}{z - m - n\tau} + \frac{1}{m + n\tau} + \frac{z}{(m + n\tau)^2} \right]$$

and $E_2(\tau)$ is the weight-2 Eisenstein series

$$E_2(\tau) = 1 - 24 \sum_{n=1}^{\infty} \sigma_1(n) q^n, \quad q = e^{2\pi i \tau}.$$

The Weierstrass ζ -function is quasi-periodic: $\zeta_\tau(z+1) = \zeta_\tau(z) + 2\eta_1$ and $\zeta_\tau(z+\tau) = \zeta_\tau(z) + 2\eta_2$, where $\eta_1 = \pi^2 E_2(\tau)/6$. The E_2 -correction in (2.13) is the price of modular covariance: without it, the propagator fails to transform correctly under $\mathrm{SL}_2(\mathbb{Z})$.

The Laurent expansion near $z = 0$ is:

$$G_\tau(z) = \frac{1}{z} - \frac{\pi^2 E_2(\tau)}{3} z + O(z^3).$$

At genus 0, only the pole $1/z$ survives. The E_2 -term is the first appearance of modular forms in the bar complex.

2.7.1 THE GENUS-1 TWO-POINT FUNCTION

The Heisenberg two-point function on E_τ is

$$\langle \alpha(z_1) \alpha(z_2) \rangle_{E_\tau} = k \cdot G_\tau(z_1 - z_2).$$

The genus-1 partition function is computed by the following theorem.

THEOREM 2.7.1 (*Genus-1 Heisenberg partition function*;). The genus-1 partition function of the Heisenberg algebra $\mathcal{H}_k$ on the elliptic curve E_τ is

$$Z_{E_\tau}^{\mathcal{H}} = \mathrm{Tr}_{\mathcal{F}_k} q^{L_0 - c/24} = \frac{1}{\eta(\tau)} = q^{-1/24} \prod_{n=1}^{\infty} \frac{1}{1 - q^n}$$

where $\eta(\tau)$ is the Dedekind eta function. The coefficients are the partition numbers $p(n)$: the number of partitions of n counts the number of states at excitation level n in the Fock space.

2.7.2 CURVATURE: $d_{\mathrm{fib}}^2 \neq 0$ AT GENUS 1

Compute the bar differential on E_τ using the elliptic propagator (2.13). The B-cycle monodromy of G_τ produces a defect: transporting the propagator around the B-cycle of E_τ shifts it by the constant $-2\pi i$. This shift is the genus-1 curvature.

THEOREM 2.7.2 (*Genus-1 curvature*;). For $\mathcal{H}_k$ on E_τ , the fiberwise differential satisfies

$$d_{\mathrm{fib}}^2 = k \cdot \omega_1 \cdot \mathrm{id}$$

where $\omega_1 = c_1(\mathbb{E}) \in H^2(\overline{\mathcal{M}}_1)$ is the first Chern class of the Hodge bundle on the moduli space of elliptic curves.

The proof is the direct computation: the B-cycle monodromy of the elliptic propagator contributes a phase $e^{2\pi i k}$ to the parallel transport of bar complex elements. Squaring the differential, the two B-cycle transports contribute a factor $(-2\pi i)^2$ that, after integration over $\overline{\mathcal{M}}_1$, produces the Hodge class $\omega_1 = c_1(\mathbb{E})$ with coefficient k . The detailed computation appears in Theorem 13.13.3.

At genus 0, $d_0^2 = 0$ and bar cohomology is well-defined. At genus 1, the bar complex is *curved*: $d_{\mathrm{fib}}^2 = k \cdot \omega_1$, proportional to the level. The curvature vanishes only at $k = 0$, where the Heisenberg algebra degenerates.

Remark 2.7.3 (Physical meaning of curvature). The curvature $d_{\mathrm{fib}}^2 = k \cdot \omega_1$ is the conformal anomaly: k controls the central extension strength, ω_1 is the gravitational coupling, and $k \cdot \omega_1 = c_1(\det(R\pi_* \mathcal{F}_k))$ on $\overline{\mathcal{M}}_1$ measures the obstruction to consistent definition on all elliptic curves.

2.8 THE HOLOMORPHIC ANOMALY AND E_2

The appearance of E_2 introduces a *holomorphic anomaly*. Under modular transformations $\tau \mapsto (a\tau + b)/(c\tau + d)$, the weight-4 and weight-6 Eisenstein series transform as modular forms:

$$E_4(\gamma \cdot \tau) = (c\tau + d)^4 E_4(\tau), \quad E_6(\gamma \cdot \tau) = (c\tau + d)^6 E_6(\tau).$$

The weight-2 Eisenstein series does not:

$$E_2\left(\frac{a\tau + b}{c\tau + d}\right) = (c\tau + d)^2 E_2(\tau) + \frac{6c(c\tau + d)}{\pi i}.$$

The extra term $6c(c\tau + d)/(\pi i)$ is the holomorphic anomaly.

For the Heisenberg two-point function on E_τ , this anomaly produces:

$$\langle \alpha(z_1) \alpha(z_2) \rangle_{\gamma \cdot \tau} = (c\tau + d)^2 \langle \alpha((c\tau + d)^{-1} z_1) \alpha((c\tau + d)^{-1} z_2) \rangle_\tau - \frac{6ck}{\pi i} z_{12}.$$

The anomaly term is proportional to k (the level) and to c (the lower-left entry of the modular matrix).

This is the genus-1 obstruction class (Theorem 2.7.2), seen from the modular side. The bar complex curvature $d_{\text{fib}}^2 = k \cdot \omega_1$ and the holomorphic anomaly in E_2 are two manifestations of the same phenomenon: the failure of the Heisenberg algebra to extend coherently over the moduli space $\overline{\mathcal{M}}_1$.

2.9 WHY THE ORDINARY DERIVED CATEGORY FAILS

The curvature $d_{\text{fib}}^2 = k \cdot \omega_1$ means the genus-1 bar complex is not a chain complex in the ordinary sense: it lives not in $D(\text{Vect})$ but in the *coderived category* $D^{\text{co}}(\text{Vect})$ of Positselski [350]. In the ordinary derived category, a complex with $d_{\text{fib}}^2 \neq 0$ is undefined. In Positselski's framework, a curved dg (co)algebra with $d_{\text{fib}}^2 = m_0 \neq 0$ has a well-defined coderived category in which:

1. The bar-cobar adjunction still holds (as an adjunction of curved (co)algebras).
2. The notion of “acyclic” is refined: a curved complex can be *coacyclic* (contractible in the coderived sense) without being acyclic in the ordinary sense.
3. The bar-cobar quasi-isomorphism $\Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$ holds in the coderived category when it fails in the ordinary derived category.

At $k = 0$, $d_{\text{fib}}^2 = 0$ and the ordinary derived category suffices; at $k \neq 0$, only the coderived category gives correct homological algebra. The genus-1 bar complex of $\mathcal{H}_k$ with $k \neq 0$ is *not coacyclic* in Positselski's sense: it carries genuine invariants (the Hodge class ω_1 , the partition function $1/\eta(\tau)$) invisible to ordinary homological algebra but visible in the coderived category. The general theory appears in Chapter 6 (Theorem II.1.84).

2.10 GENUS 2: SIEGEL MODULAR FORMS

At genus 2, the Riemann surface Σ_2 has period matrix $\Omega = \begin{pmatrix} \tau_1 & z \\ z & \tau_2 \end{pmatrix} \in \mathcal{H}_2$ (the Siegel upper half-space). The genus-2 propagator is

$$K^{(2)}(w_1, w_2 | \Omega) = \partial_{w_1} \log E(w_1, w_2; \Omega)$$

where $E(w_1, w_2; \Omega)$ is the prime form on Σ_2 .

Near $w_1 = w_2$, the prime form has the expansion

$$E(w_1, w_2; \Omega) = (w_1 - w_2)(1 + c_2(\Omega)(w_1 - w_2)^2 + c_4(\Omega)(w_1 - w_2)^4 + \dots)$$

where the coefficients $c_{2j}(\Omega)$ are Siegel modular forms for $\mathrm{Sp}(4, \mathbb{Z})$.

Three features invisible at genus 1 emerge:

1. *Multi-dimensional Hodge bundle.* At genus 1, the Hodge bundle $\mathbb{E}$ is a line bundle and $\lambda_1 = c_1(\mathbb{E})$. At genus 2, $\mathbb{E}$ has rank 2, and $\lambda_2 = c_2(\mathbb{E})$ is a determinantal class involving the interaction of both B-cycle monodromies.
2. *Off-diagonal periods.* The entry $z = \Omega_{12}$ encodes the interaction between the two handles of Σ_2 .
3. *Function-valued monodromies.* The genus-1 B-cycle monodromy of the propagator is the constant $-2\pi i$. At genus 2, the monodromies $-2\pi i \cdot \omega_j(w)$ are sections of ω_{Σ_2} . Each B-cycle defect contributes a 2-form on moduli space, and the two defects combine multiplicatively: hence λ_2 lives in H^4 (not H^2).

THEOREM 2.10.1 (*Genus-2 curvature*;). The genus-2 bar complex of $\mathcal{H}_k$ has curvature:

$$(d^{(2)})^2 = k \cdot \lambda_2$$

where $\lambda_2 = c_2(\mathbb{E}) \in H^4(\overline{\mathcal{M}}_2)$.

The free energy at genus 2 is

$$F_2(\mathcal{H}_k) = k \cdot \int_{\overline{\mathcal{M}}_{2,1}} \psi_1^2 \lambda_2 = k \cdot \frac{7}{8} \cdot \frac{|B_4|}{4!} = \frac{7k}{5760}$$

where $B_4 = -1/30$ is the fourth Bernoulli number.

2.11 THE GENUS TOWER: RECOGNIZING THE $\hat{A}$ -GENUS

The pattern from genus 1 and genus 2 extends. At genus g , the bar complex curvature is

$$d_{\mathrm{fib}}^2 = k \cdot \lambda_g$$

where $\lambda_g = c_g(\mathbb{E}) \in H^{2g}(\overline{\mathcal{M}}_g)$ is the top Chern class of the Hodge bundle (Theorem 13.13.3). This genus tower is the simplest instance of the explicit universal MC class (Theorem 13.21.80): $\Theta_{\mathcal{H}_k}^{\min} = k \cdot \eta \otimes \Lambda$, where $\Lambda = \sum_{g \geq 1} \lambda_g$. For Heisenberg, $\kappa = k$ and the spectral discriminant is trivial ($\Delta = 1$), so the full modular package reduces to this single formula. The $\hat{A}$ -genus emerges because $\mathrm{tr}(\Theta) = k \cdot (\hat{A}(ix) - 1)$: the Todd class of the universal curve, pushed forward by GRR, is the genus tower.

The genus- g free energy is

$$F_g(\mathcal{H}_k) = k \cdot \frac{2^{2g-1} - 1}{2^{2g-1}} \cdot \frac{|B_{2g}|}{(2g)!}$$

for all $g \geq 1$. The first values are:

$$\begin{aligned} F_1 &= k \cdot \frac{1}{24}, \\ F_2 &= k \cdot \frac{7}{5760}, \\ F_3 &= k \cdot \frac{31}{967680}, \\ F_4 &= k \cdot \frac{127}{154828800}. \end{aligned}$$

The generating function assembles these into a closed form:

$$\sum_{g=1}^{\infty} F_g(\mathcal{H}_k) x^{2g} = k \left(\frac{x/2}{\sin(x/2)} - 1 \right). \quad (2.14)$$

Including the leading term ($g = 0$, where $F_0 = 1$ by convention):

$$1 + \sum_{g=1}^{\infty} F_g x^{2g} = \frac{x/2}{\sin(x/2)}. \quad (2.15)$$

The function $x/2/\sin(x/2)$ is the $\hat{A}$ -genus evaluated at imaginary argument. The $\hat{A}$ -genus of a complex manifold M is the multiplicative genus associated to the power series

$$\hat{A}(x) = \frac{x/2}{\sinh(x/2)} = 1 - \frac{x^2}{24} + \frac{7x^4}{5760} - \dots$$

and the Wick rotation $x \mapsto ix$ sends $\sinh(x/2)$ to $i \sin(x/2)$, producing precisely the generating function (2.15).

This follows from the Faber–Pandharipande λ_g formula and the Grothendieck–Riemann–Roch theorem. We derive both connections here.

The Faber–Pandharipande formula

The genus- g obstruction class is $\text{obs}_g(\mathcal{H}_k) = k \cdot \lambda_g$ where $\lambda_g = c_g(\mathbb{E}) \in H^{2g}(\overline{\mathcal{M}}_g)$ is the top Chern class of the Hodge bundle $\mathbb{E} = \pi_* \omega_{C/\overline{\mathcal{M}}_g}$. The uniform-weight tag is conservative here: since $\mathcal{H}_k$ is a free field (the OPE $J(z)J(w) \sim k/(z-w)^2$ is purely quadratic, so $m_k = 0$ for $k \geq 3$), the cross-channel correction vanishes at every genus, $\delta F_g^{\text{cross}}(\mathcal{H}_k) = 0$ (Proposition 13.22.226). The scalar formula is therefore exact at all-weight; the same holds for all free-field families (bc , $\beta\gamma$, lattice algebras). The free energy extracts this as a number via integration against powers of the cotangent line class $\psi_1 = c_1(\mathbb{L}_1)$ on $\overline{\mathcal{M}}_{g,1}$:

$$F_g(\mathcal{H}_k) = k \cdot \int_{\overline{\mathcal{M}}_{g,1}} \psi_1^{2g-2} \lambda_g.$$

The Faber–Pandharipande formula [153] evaluates this integral:

$$\int_{\overline{\mathcal{M}}_{g,1}} \psi_1^{2g-2} \lambda_g = \frac{2^{2g-1} - 1}{2^{2g-1}} \cdot \frac{|B_{2g}|}{(2g)!} \quad (2.16)$$

where B_{2g} is the $2g$ -th Bernoulli number.

The connection to the $\hat{A}$ -genus is visible at the level of generating functions. The Bernoulli numbers are defined by

$$\frac{x}{e^x - 1} = \sum_{n=0}^{\infty} \frac{B_n}{n!} x^n = 1 - \frac{x}{2} + \frac{x^2}{12} - \frac{x^4}{720} + \cdots$$

which is the Todd genus generating function. The factor $(2^{2g-1} - 1)/2^{2g-1}$ in (2.16) arises from the relationship between the Todd class and the $\hat{A}$ -class:

$$\text{Td}(x) = \frac{x}{1 - e^{-x}} = e^{x/2} \cdot \hat{A}(x), \quad \hat{A}(x) = \frac{x/2}{\sinh(x/2)}.$$

Expanding $\hat{A}(x) = \sum_{g=0}^{\infty} a_g x^{2g}$ (the $\hat{A}$ -class is even), the coefficients are

$$a_g = \frac{(-1)^g (2^{2g-1} - 1)}{2^{2g-1}} \cdot \frac{B_{2g}}{(2g)!}$$

which matches (2.16) up to the sign $(-1)^g$ absorbed by the Wick rotation $x \mapsto ix$, verifying (2.15).

The GRR derivation

Remark 2.11.1 (The family index theorem). The $\hat{A}$ -genus arises from Grothendieck–Riemann–Roch. For $\mathcal{H}_k$, the modular deformation complex is $k \cdot \mathbb{E}$; the GRR formula

$$\text{ch}(\pi_! \omega_C) = \pi_*(\text{ch}(\omega_C) \cdot \text{Td}(T_\pi))$$

applied to $\pi: \overline{\mathcal{M}}_{g,1} \rightarrow \overline{\mathcal{M}}_g$ recovers the Mumford formula $\text{ch}_g(\mathbb{E}) = B_{2g} \cdot \kappa_{2g-1}/(2g)!$, which combined with $\text{obs}_g = k \cdot \lambda_g$ (UNIFORM-WEIGHT) yields (2.14). The genus expansion of every Koszul chiral algebra is an index: the $\hat{A}$ -class pushforward of the Hodge bundle scaled by bar-complex curvature.

Table 2.1: Free energy values F_g for $\mathcal{H}_k$ ($k = 1$), genera $1 \leq g \leq 6$

g	F_g (exact)	F_g (decimal)	Bernoulli $ B_{2g} $
1	1/24	4.17×10^{-2}	1/6
2	7/5760	1.22×10^{-3}	1/30
3	31/967680	3.20×10^{-5}	1/42
4	127/154828800	8.20×10^{-7}	1/30
5	73/3503554560	2.08×10^{-8}	5/66
6	1414477/2678117105664000	5.28×10^{-10}	691/2730

The generating function (2.14) has radius of convergence $|x| < 2\pi$ (the first zero of $\sin(x/2)$). The free energies F_g decrease geometrically: $F_g \sim 2k/(2\pi)^{2g}$ by the Bernoulli asymptotics $|B_{2g}| \sim 2(2g)!/(2\pi)^{2g}$, so the genus expansion converges absolutely for $|x| < 2\pi$. The Weil–Petersson volumes $V_{g,n}$, by contrast, grow as $(2g)!$ (Mirzakhani): the Heisenberg genus tower is convergent where the volume series is asymptotic.

2.12 COMPLEMENTARITY: THEOREM C IN ACTION

At genus 1, the Heisenberg algebra sees one deformation (the level k) and the Koszul dual $\mathrm{Sym}^{\mathrm{ch}}(V^*)$ sees one obstruction (the curvature $m_0 = -k \cdot \omega$). Neither algebra alone accounts for the full modular picture: $H^*(\overline{\mathcal{M}}_1, \mathcal{Z}(\mathcal{H}_k)) \cong \mathbb{C}^2$ is two-dimensional, while each algebra contributes a one-dimensional subspace. The two subspaces are complementary.

THEOREM 2.12.1 (*Quantum complementarity for Heisenberg*). For the Koszul pair $(\mathcal{H}_k, \mathrm{Sym}^{\mathrm{ch}}(V^*))$ at genus g :

$$Q_g(\mathcal{H}_k) + Q_g(\mathcal{H}_k^\dagger) = H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{H}_k))$$

where Q_g denotes the genus- g quantum correction (the obstruction to extending the genus-0 bar-cobar quasi-isomorphism to genus g), and $\mathcal{Z}(\mathcal{H}_k)$ is the center local system on $\overline{\mathcal{M}}_g$.

Verdier duality on $\overline{\mathcal{M}}_g$ controls the decomposition: deformations are classified by the bar complex, obstructions by the cobar complex, and Verdier duality exchanges them. What $\mathcal{H}_k$ sees as a deformation (varying the level k), its Koszul dual sees as an obstruction (the curvature m_0), and vice versa.

This is Theorem C (Theorem 13.15.14) for the Heisenberg case. The general theorem establishes complementarity for all Koszul chiral algebra pairs, with the ambient space $H^*(\overline{\mathcal{M}}_g, \mathcal{Z})$ carrying a shifted-symplectic pairing from Verdier duality on the center local system.

2.13 THE CHARACTERISTIC HIERARCHY IN THE HEISENBERG FRAME

The bar complex, Koszul dual, curvature, free energy tower, and complementarity assemble into a characteristic hierarchy with three proved layers: a scalar package, an ambient/spectral shadow, and a full homotopy completion (Theorem 13.21.69).

Definition 2.13.1 (*Characteristic hierarchy for Heisenberg*). The Heisenberg frame exhibits the following characteristic data:

1. The *proved scalar characteristic data* $\kappa(\mathcal{H}_k) = k$ (Theorem 13.21.44), which determines the entire *scalar* modular package: $\mathrm{obs}_g = k \cdot \lambda_g$ (UNIFORM-WEIGHT) for all $g \geq 1$
2. The *proved ambient complementarity complex*

$$H_{\mathcal{H}_k} := R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{H}_k})$$

Verdier duality then provides the shifted-symplectic structure needed for complementarity (Theorem 13.15.14).

3. The *proved spectral shadow* $\Delta_{\mathcal{H}_k}(x) = 1$ (trivial for rank 1; for affine Kac–Moody algebras, the discriminant acquires the form $\Delta(x) = (1 - 3x)(1 + x)$; Theorem 13.21.63).
4. The *proved full homotopy completion*

$$\Theta_{\mathcal{H}_k} \in \mathrm{MC}(\mathrm{Def}_{\mathrm{cyc}}(\mathcal{H}_k) \widehat{\otimes} R\Gamma(\overline{\mathcal{M}}_{g,\bullet}, \mathbb{Q}))$$

whose scalar trace recovers items (1)–(3). The universal class $\Theta_{\mathcal{H}_k}$ is constructed by Theorem 13.21.69; for Heisenberg the non-scalar content is trivial ($\Delta = 1$), so the full modular package reduces to the scalar hierarchy (Theorem 13.21.66).

For the Heisenberg algebra, the scalar genus tower is fully determined by the single number $\kappa = k$, and the spectral shadow is trivial: $\Delta_{\mathcal{H}_k}(x) = 1$. This collapse is an artifact of the abelian (rank-1) structure. In Chapters G and H, the hierarchy acquires non-trivial spectral discriminant and richer ambient deformation data.

Remark 2.13.2 (Hierarchy and status). Definition 2.13.1 is a hierarchy: items (1)–(3) are proved (Theorems 13.21.44, 13.15.14, 13.21.63); item (4), the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ (Definition 13.22.46), is proved at finite order through degree 4, with one-channel line concentration of the minimal class on the simple-Lie-symmetry locus (Corollary 13.21.120) and scalar saturation only on the proved scalar lane (Definition 13.21.41); the all-degree limit exists by the bar-intrinsic construction (Theorem 13.21.69). The genus-1 coefficient $\kappa(\mathcal{A})$ ($= k$ for Heisenberg, $c/2$ for Virasoro, $(k + h^\vee) \dim(\mathfrak{g})/(2h^\vee)$ for KM) is the scalar level $\Theta_{\mathcal{A}}^{\leq 2}$ of the tower, not the fundamental object.

Remark 2.13.3 (The shadow metric for Heisenberg). The shadow metric (Definition 13.22.136) makes the Gaussian collapse quantitative. For $\mathcal{H}_k$: $\kappa = k$, $\alpha = S_3 = 0$ (the OPE $J(z)J(w) \sim k/(z-w)^2$ has no cubic coupling), $S_4 = 0$, critical discriminant $\Delta = 8\kappa S_4 = 0$. The shadow metric (13.87) evaluates to

$$Q_{\mathcal{H}}(t) = (2k)^2 = 4k^2,$$

a *constant*: no t -dependence survives. The weighted shadow generating function $H(t) = t^2 \sqrt{Q_{\mathcal{H}}} = 2k t^2$ is purely quadratic; only $S_2 = k$ contributes. The spectral curve $\Sigma_{\mathcal{H}}$ degenerates to a point, the shadow connection (Theorem 13.22.167) is trivial ($\omega = d \log Q = 0$), and parallel transport has no monodromy.

Contrast with the Virasoro algebra (Example 13.22.186), where $Q_{\text{Vir}}(t) = c^2 + 12ct + \alpha(c) t^2$ is a genuine quadratic, the spectral curve is a genus-0 double cover, and the shadow connection carries monodromy -1 (Theorem 13.22.137). The passage from constant to non-constant shadow metric, governed by a single invariant, the critical discriminant Δ , is the passage from free to interacting, from Gaussian to non-Gaussian.

2.14 VERIFYING THE THESIS AT THE ATOM

The monograph advances a unifying thesis about chiral algebras and their holographic duals. We state it once, in coordinates, and check it against the computations already performed on $\mathcal{H}_k$.

Thesis. A chiral algebra $\mathcal{A}$ determines a bulk theory through its derived chiral center $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$. The level $\kappa(\mathcal{A})$ is the holographic central charge of the induced bulk. The shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ is the hierarchy of holographic corrections to the leading scalar datum. The Drinfeld double $U_{\mathcal{A}} = \mathcal{A} \bowtie \mathcal{A}^!$, with braiding governed by the classical r -matrix, is the universal boundary-to-bulk reconstructor: it assembles the boundary algebra and its Koszul dual into a single braided object that the bulk theory realises as its category of line operators.

The Heisenberg algebra is the minimal instance where every term of this thesis admits an elementary verification. If the thesis fails on $\mathcal{H}_k$, the programme has no atomic foundation; if it holds, every subsequent chapter refines a structure that is already present at degree 2 with a single double-pole coefficient.

2.14.1 THE SEVEN ITEMS, IN COORDINATES

We list each datum of the thesis, the explicit value it takes for $\mathcal{H}_k$, and the earlier section that verified it. The list is exhaustive: if an item is missing, the thesis is incomplete for the atom, and the programme must be revised before proceeding to Kac–Moody and beyond.

1. **Boundary VOA.** The boundary object is $\mathcal{A} = \mathcal{H}_k$ with the double-pole self-OPE

$$\alpha(z) \alpha(w) \sim \frac{k}{(z-w)^2},$$

fixed in equation (2.1). This is the defining datum from which the bar complex is built.

2. **Koszul dual.** The Koszul dual algebra is

$$\mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*), d = 0, m_0 = -k \cdot \omega),$$

obtained from Verdier duality on the factorization coalgebra $\overline{B}(\mathcal{H}_k)$ on $\text{Ran}(X)$ (Theorem 2.5.1). This is *not* the level-flipped algebra $\mathcal{H}_{-k}$, which is a representation-theoretic duality distinct from Koszul duality (Remark 2.5.3). The bar coalgebra itself, $\overline{B}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*)$, is the Koszul dual *coalgebra*; linear dualisation exchanges coLie and Sym .

3. **Drinfeld double.** The universal reconstructor is

$$U_{\mathcal{H}_k} = \mathcal{H}_k \bowtie \mathcal{H}_k^!,$$

with braiding generated by the classical r -matrix at degree 2. For the abelian case this r -matrix is $r(z) = k/z$ (after d log absorption of the double pole, with the level surviving), and the quantum R -matrix is the scalar exponential $R(z) = \exp(k\hbar/z)$ (Theorem 2.17.24 for the odd current variant; the Heisenberg version is derived in §2.14.2 below). Higher degrees of the braiding vanish because the OPE has only a single pole order: there is one generator, one relation, one scalar, and no place for a genuine degree-3 braiding structure to hide.

4. **Derived chiral center and bulk.** The derived chiral center of $\mathcal{H}_k$ is the chiral Hochschild complex

$$Z_{\text{ch}}^{\text{der}}(\mathcal{H}_k) = CH^*(\mathcal{H}_k, \mathcal{H}_k).$$

By Theorem H (Theorem 14.4.12) this complex is concentrated in degrees $\{0, 1, 2\}$ with Hilbert polynomial $P(t) = 1 + t + t^2$, hence total dimension 3. The explicit computation in §2.21 (Computation 2.21.1) gives

$$CH^0(\mathcal{H}_k) = \mathbb{C}, \quad CH^1(\mathcal{H}_k) = \mathbb{C} \cdot D, \quad CH^2(\mathcal{H}_k) = \mathbb{C} \cdot \delta_k,$$

total dimension 3. The degree-0 class is the vacuum; the degree-1 class is the outer derivation $D(\alpha) = 1$; the degree-2 class is the level deformation $\delta_k : \alpha \otimes \alpha \mapsto 1$. The bulk theory physically realised by this derived center is abelian Chern–Simons at level k : the three classes correspond respectively to the partition function of the bulk, the topological shift deforming the bulk Lagrangian by a $B \wedge F$ term, and the level-varying deformation of the bulk coupling. The amplitude of this complex is $[0, 2]$ (cohomological amplitude, *not* virtual dimension).

5. **κ as holographic central charge.** The scalar level is

$$\kappa(\mathcal{H}_k) = k$$

(Theorem 13.21.44 and Remark 2.17.14), with no factor of two. In the 4d–3d–2d cascade of Heuristic 2.17.23 this number is the Chern–Simons level of the 3d bulk, and is therefore the $U(1)$ holographic central charge: it controls the large- k entanglement entropy $S_{\text{EE}} \sim k^{-1} \cdot (\text{area})$ through

the $U(1)$ analogue of the Brown–Henneaux formula. The Heisenberg has no stress tensor of its own (there is no Virasoro subalgebra built from α without invoking the Sugawara construction), so the Brown–Henneaux central charge does not arise here in the Virasoro sense. The level $\kappa = k$ plays the role directly: it is the holographic coupling that couples the boundary current to the bulk gauge field.

6. **Shadow tower termination.** Heisenberg is of class G (Gaussian): the shadow obstruction tower $\Theta_{\mathcal{H}_k}^{\leq r}$ terminates at $r = 2$ with $S_2 = \kappa = k$ and $S_{\geq 3} = 0$. The explicit calculation in Remark 2.13.3 gives $\mathcal{Q}_{\mathcal{H}}(t) = 4k^2$ (constant in t), critical discriminant $\Delta_{\mathcal{H}} = 8\kappa S_4 = 0$, and trivial spectral curve. No holographic correction beyond the leading scalar is present: at the Gaussian atom the thesis reduces to its base case, and the shadow tower is literally a single scalar.
7. **4d–3d–2d cascade.** The boundary-to-bulk reconstruction of the thesis is physically realised by the cascade

$$4d \mathcal{N} = 2 \text{ abelian gauge theory} \longrightarrow 3d \text{ abelian Chern–Simons at level } k \longrightarrow 2d \text{ Heisenberg } \mathcal{H}_k,$$

each arrow being a half-line reduction with chiral Dirichlet boundary conditions (§2.17.6.4, Heuristic 2.17.23). The 4d theory is abelian; the 3d bulk is abelian Chern–Simons; the 2d boundary is the Heisenberg algebra. The entire cascade is flat at the Gaussian atom, and Koszul duality $\mathcal{H}_k \leftrightarrow \mathcal{H}_k^!$ is the boundary duality $\mathcal{D} \leftrightarrow \mathcal{N}$ of the 3d slab.

Each of the seven items is a specific, checkable claim on the Heisenberg algebra. Every one of them reduces to a single scalar, the level k , or to a construction determined by that scalar. The Gaussian archetype is the statement that the thesis *collapses* to a single scalar at the atom: the bulk reconstruction, the holographic central charge, and the shadow tower are all captured by $\kappa(\mathcal{H}_k) = k$, and no additional data survives.

2.14.2 THE DRINFELD DOUBLE OF THE HEISENBERG ALGEBRA

The Drinfeld double $U_{\mathcal{H}_k}$ is the universal braided reconstructor paired to $(\mathcal{H}_k, \mathcal{H}_k^!)$. For Heisenberg the construction is elementary and the classical limit recovers $r(z) = k/z$ exactly. We record both the construction and the verification.

Definition 2.14.1 (Drinfeld double of $\mathcal{H}_k$). Let $\mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*), m_0 = -k\omega)$ be the Koszul dual of $\mathcal{H}_k$ (Theorem 2.5.1). The *Drinfeld double* of $\mathcal{H}_k$ is the chiral algebra

$$U_{\mathcal{H}_k} = \mathcal{H}_k \otimes \mathcal{H}_k^!$$

with Hopf pairing determined by the evaluation $\langle \alpha^*, \alpha \rangle = 1$, and with braiding given at degree 2 by the classical r -matrix

$$r(z) = \frac{k}{z} = k \partial_z \eta(z), \quad \eta(z) = d \log z, \quad (2.17)$$

the collision residue of the double pole in the Heisenberg self-OPE, with the level surviving $d \log$ absorption. The quantum R -matrix is the scalar exponential

$$R(z) = \exp(k\hbar/z) = 1 + \frac{k\hbar}{z} + \frac{1}{2} \left(\frac{k\hbar}{z} \right)^2 + \cdots,$$

a formal power series in z^{-1} .

PROPOSITION 2.14.2 (*Classical limit and vanishing check ;*). The classical r -matrix of $U_{\mathcal{H}_k}$ obtained from $R(z) = \exp(k\hbar/z)$ by expanding to first order in $\hbar$ is

$$r(z) = \lim_{\hbar \rightarrow 0} \frac{R(z) - 1}{\hbar} = \frac{k}{z},$$

with k surviving as a multiplicative prefactor. At $k = 0$ the r -matrix vanishes identically: the consistency check is satisfied. The Drinfeld double $U_{\mathcal{H}_k}$ has no higher-degree braiding: $R(z_1, z_2, z_3) = R_{12}(z_{12}) R_{13}(z_{13}) R_{23}(z_{23})$, a product of degree-2 factors with no genuinely trilinear component.

Proof. Expanding $R(z) = 1 + k\hbar/z + O(\hbar^2)$ and extracting the coefficient of $\hbar^1$ gives $r(z) = k/z$. At $k = 0$ this vanishes. The absence of higher-degree braiding follows from the rank-one structure of $\mathcal{H}_k$: the Casimir tensor $\Omega \in \mathfrak{g} \otimes \mathfrak{g}$ is one-dimensional (no nontrivial $\mathfrak{g} \otimes \mathfrak{g} \otimes \mathfrak{g}$ component), so the Yang–Baxter equation for three-point braiding reduces to the scalar identity $\exp(k\hbar/u) \exp(k\hbar/(u+v)) \exp(k\hbar/v) = \exp(k\hbar/v) \exp(k\hbar/(u+v)) \exp(k\hbar/u)$, which holds by commutativity of scalar multiplication (Theorem 2.17.24, part (ii), applied with the replacement $c \leftrightarrow \alpha$ and the simple/double pole distinction tracked through the Laplace transform). $\square$

The Drinfeld double of $\mathcal{H}_k$ is the universal boundary-to-bulk reconstructor in the sense of the thesis: it assembles $\mathcal{H}_k$ (Dirichlet boundary) and $\mathcal{H}_k^!$ (Neumann boundary) into a single braided object whose braiding data is exactly the scalar r -matrix (2.17) read off the Heisenberg collision residue. The bulk Chern–Simons theory recovers this braiding as the framing anomaly of its line operators: a Wilson line of charge q in the 3d bulk acquires a topological phase $\exp(2\pi i q^2/k)$ under a 2π self-twist, which is the boundary-value of the exponentiated R -matrix after specialising to the charge- q insertion. At the atom the entire construction is scalar, and no categorical data is hidden in higher degrees.

2.14.3 SHADOW TOWER TERMINATION: THE BASE CASE

The shadow obstruction tower (Definition 13.22.46) is the Postnikov tower of the MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$, with graded pieces $S_2, S_3, S_4, \dots$, each encoding an obstruction at a fixed symmetric degree on the symmetric bar. The thesis identifies this tower with the hierarchy of holographic corrections to the leading scalar κ : for a generic chiral algebra, successive pieces S_r refine the Gaussian approximation provided by S_2 . For the Heisenberg, the tower terminates immediately.

PROPOSITION 2.14.3 (*Shadow tower termination for Heisenberg ;*). The shadow obstruction tower for $\mathcal{H}_k$ satisfies

$$S_2(\mathcal{H}_k) = \kappa(\mathcal{H}_k) = k, \quad S_r(\mathcal{H}_k) = 0 \quad \text{for all } r \geq 3.$$

Equivalently, $\mathcal{H}_k$ is of class G (Gaussian), and the full MC element $\Theta_{\mathcal{H}_k}$ is determined by its degree-2 projection.

Proof. The scalar $S_2 = \kappa = k$ is computed directly from the collision residue in Theorem 13.21.44; this is the double-pole coefficient of the Heisenberg OPE. The vanishing of S_r for $r \geq 3$ follows from three independent paths.

(i) *Direct OPE count.* The Heisenberg OPE has only a double pole; there is no cubic or higher OPE coupling, so the degree-3 collision residue $\alpha_{(2)}(\alpha_{(1)}\alpha)$ and its higher analogues are identically zero. In particular the cubic shadow $\alpha = S_3 = 0$ and the quartic contact invariant $S_4 = 0$ (Remark 2.13.3).

(ii) *Critical discriminant.* The critical discriminant of the shadow metric is $\Delta_{\mathcal{H}} = 8\kappa \cdot S_4 = 0$, so the spectral curve degenerates to a point and the Postnikov tower has no nontrivial fibre beyond degree 2.

(iii) *Rank-one uniqueness.* For a rank-one chiral algebra with a single generator and a single OPE pole, the symmetric bar complex $\overline{B}^\Sigma(\mathcal{H}_k)$ has cohomological dimension ≤ 2 (Theorem 2.3.1); the degree- r piece of the obstruction tower is a Σ_r -coinvariant of a tensor power of the bar cohomology, and for $r \geq 3$ this coinvariant vanishes because the underlying tensor has no symmetric invariants beyond the vacuum. $\square$

This is the *base case* of the shadow-as-holographic-correction hierarchy. At the atom, the hierarchy is trivial: there is exactly one layer, and it is the scalar $\kappa = k$. The passage to Virasoro (class M, tower infinite) and Kac–Moody (class L, tower of finite length 3) is the statement that nontrivial boundary VOAs produce nontrivial holographic correction hierarchies; the Heisenberg supplies the empty ladder against which every subsequent ladder is measured.

2.14.4 THESIS VERIFIED AT THE GAUSSIAN ATOM

The seven items of Subsection 2.14.1 are checked against the Heisenberg computations of §2.1–§2.13 and the chiral center computation of §2.21. No item requires a structure absent from the bar complex or the Koszul dual; every item reduces to a direct calculation with the double-pole coefficient k . The Drinfeld double construction of Definition 2.14.1 assembles the $(\mathcal{H}_k, \mathcal{H}_k^\dagger)$ pair into a braided object whose classical r -matrix is $r(z) = k/z$, and the shadow tower terminates at $r = 2$ by Proposition 2.14.3.

The thesis holds at the atom. Every subsequent chapter of the monograph constitutes a verification of the same seven items at a *more complicated* algebra: free fermions and $\beta\gamma$ (statistics-driven refinements), $\widehat{\mathfrak{sl}}_2$ (non-abelian bulk with curvature on the Koszul dual), Virasoro and $\mathcal{W}$ -algebras (infinite shadow tower, class M), lattice algebras and Yangians (braided double with nonscalar R -matrix). In every case the structural form of the thesis is unchanged; only the complexity of the data grows. The reader who has followed the Heisenberg computation has, in miniature, followed the entire programme.

2.15 FREE FIELDS AND THE LIE–COM DUALITY

The Heisenberg algebra has a single bosonic current with a *double* pole. The free fermion has a single *fermionic* current with a *simple* pole:

$$\psi(z)\psi(w) = \frac{1}{z-w} + \text{regular}.$$

Two differences from Heisenberg: the pole order drops from 2 to 1, and the statistics change from bosonic to fermionic. Each has an independent algebraic consequence.

The first difference concerns pole order: the simple pole means that the bar differential $d = d_{\text{bracket}}$ has no curvature component and is entirely bracket-type. At degree 1, it extracts the simple-pole residue $\text{Res}_{z=w} \psi(z)\psi(w) = 1$, a scalar.

The second, and more consequential, difference concerns statistics. The Koszul sign rule acts on the bar complex: since ψ is fermionic ($|\psi| = 1$), two desuspended cogenerators in $\overline{B}^2$ satisfy $\psi^* \otimes \psi^* = -\psi^* \otimes \psi^*$ under transposition, forcing antisymmetry. The coproduct on $\overline{B}(\mathcal{F})$ is therefore co-antisymmetric, so the bar coalgebra is a coLie coalgebra and the Koszul dual algebra is the commutative algebra Com. This is the classical duality $\text{Lie}^! = \text{Com}$, already visible in the OPE: the self-pairing $\psi(z)\psi(w) \sim 1/(z-w)$ is antisymmetric under $z \leftrightarrow w$ (fermionic), encoding Lie structure.

By contrast, the Heisenberg current α is bosonic ($|\alpha| = 0$), so the desuspended cogenerators commute, the bar coalgebra is cocommutative (coLie $\rightarrow$ Sym), and the Koszul dual is $\text{Sym}^{\text{ch}}(V^*)$. In both cases, it is the *statistics of the generators*, not the pole order, that determines the operadic type.

THEOREM 2.15.1 (*Free fermion bar complex; see Theorem E.2.1;*). The bar complex $\overline{B}(\mathcal{F})$ of the free fermion is acyclic: $H^n(\overline{B}(\mathcal{F})) = 0$ for $n \geq 1$, with $H^0 = \mathbb{C}$. In particular, $\mathcal{F}$ is chiral Koszul.

Acyclicity is the strongest form of the Koszul property: no cohomological obstruction at any degree. For Heisenberg, $H^2(\overline{B}(\mathcal{H}_k)) = \mathbb{C} \cdot c_k \neq 0$ (Theorem 2.3.1); the double-pole curvature creates a class that obstructs acyclicity. The free fermion, having only a simple pole, has no such obstruction.

The Koszul dual: the $\beta\gamma$ system. The Koszul dual of the free fermion is the $\beta\gamma$ system, a chiral algebra with two bosonic generators $\beta(z)$ of weight 1 and $\gamma(z)$ of weight 0. Compute the OPE directly:

$$\beta(z) \gamma(w) = \frac{1}{z-w} + \text{regular}, \quad \gamma(z) \beta(w) = \frac{-1}{z-w} + \text{regular}.$$

The pole order is 1, the same as the fermion. But the generators β, γ are bosonic: the sign flip in the second OPE comes from the *symplectic pairing* $\langle \beta, \gamma \rangle = -\langle \gamma, \beta \rangle$, not from fermionic statistics. The bar coalgebra of the $\beta\gamma$ system is cocommutative (bosonic generators), and its coproduct encodes the commutative (symmetric) product structure. Dualizing gives $(\beta\gamma)^\dagger = \mathcal{F}$: Koszul duality exchanges $\text{Com} \leftrightarrow \text{Lie}$ by exchanging statistics.

The following table records the data governing the bar complex and the Koszul dual for all three free-field systems. The operadic type is determined by the row “Statistics,” not by “OPE poles”:

	Heisenberg $\mathcal{H}_k$	Free fermion $\mathcal{F}$	$\beta\gamma$ system
Generators	1 (bosonic)	1 (fermionic)	2 (bosonic)
Statistics	bosonic	fermionic	bosonic
OPE poles	double $(1/(z-w)^2)$	simple $(1/(z-w))$	simple $(1/(z-w))$
Bar coalgebra	cocommutative	co-antisymmetric	cocommutative
Operadic type	Com^{ch}	Lie^{ch}	Com^{ch}
Bar differential	d_{residue} only	d_{bracket} only	d_{bracket} (mixed pairs)
Koszul dual	$\text{Sym}^{\text{ch}}(V^*)$	$\beta\gamma$	$\mathcal{F}$

The free-field examples expose the two independent axes of the bar complex. The bar differential of any augmented chiral algebra decomposes as $d = d_{\text{bracket}} + d_{\text{residue}}$: the bracket component from simple poles, the curvature component from double poles. Heisenberg has $d_{\text{bracket}} = 0$; the free fermion has $d_{\text{residue}} = 0$. The general case, affine Kac–Moody algebras, has both, and neither is individually a differential.

2.16 THE NON-ABELIAN WORLD: AFFINE $\widehat{\mathfrak{sl}}_2$

The Heisenberg algebra has a single current with a double-pole self-OPE and no simple pole. The simplest non-abelian chiral algebra, $\widehat{\mathfrak{sl}}_2$ at level k , has three currents $e(z), f(z), h(z)$ with OPE:

$$e(z) f(w) \sim \frac{h(w)}{z-w} + \frac{k}{(z-w)^2}, \quad (2.18)$$

$$h(z) e(w) \sim \frac{2e(w)}{z-w}, \quad h(z) f(w) \sim \frac{-2f(w)}{z-w}, \quad (2.19)$$

$$h(z) h(w) \sim \frac{2k}{(z-w)^2}.$$

The simple poles in (2.18)–(2.19) are the new feature. They contribute a *bracket component* d_{bracket} to the bar differential, which was identically zero for Heisenberg.

2.16.1 THE BAR DIFFERENTIAL AT DEGREES 0–2

We repeat the Heisenberg computation of §2.1–§2.2 for $\widehat{\mathfrak{sl}}_2$, emphasizing what changes.

Degree 0

The degree-0 bar space is $\bar{B}_0^{\text{ch}} = \mathbb{C}$, as before: the augmentation ideal modulo products.

Degree 1: two types of pole

A degree-1 element now involves two currents from $\{e, f, h\}$ and a single logarithmic form η_{12} . The bar differential $d = d_{\text{bracket}} + d_{\text{residue}}$ has two components, one for each pole order.

Simple-pole component d_{bracket} . The OPE $h(z) e(w) \sim 2e(w)/(z-w)$ has a simple pole with residue $c_1(w) = 2e(w)$. The bar differential extracts this as

$$d_{\text{bracket}}(s^{-1}h(z_1) \otimes s^{-1}e(z_2) \otimes \eta_{12}) = c_1(z_2) = 2e(z_2). \quad (2.20)$$

This is the Lie bracket $[h, e] = 2e$ encoded in OPE language. Contrast with Heisenberg, where $c_1 = 0$ and d_{bracket} vanishes identically. For the full $\mathfrak{sl}_2$ system, d_{bracket} on degree-1 elements recovers the Chevalley–Eilenberg differential of $\mathfrak{sl}_2$:

$$\begin{aligned} d_{\text{bracket}}(h \otimes e \otimes \eta) &= 2e, & d_{\text{bracket}}(h \otimes f \otimes \eta) &= -2f, \\ d_{\text{bracket}}(e \otimes f \otimes \eta) &= h, & d_{\text{bracket}}(h \otimes h \otimes \eta) &= 0. \end{aligned}$$

Double-pole component d_{residue} . The double poles $h(z) h(w) \sim 2k/(z-w)^2$ and $e(z) f(w) \sim k/(z-w)^2 + \dots$ contribute a curvature component:

$$\begin{aligned} d_{\text{residue}}(h \otimes h \otimes \eta) &= 2k, \\ d_{\text{residue}}(e \otimes f \otimes \eta) &= k, \\ d_{\text{residue}}(h \otimes e \otimes \eta) &= 0. \end{aligned} \quad (2.21)$$

This is the Killing form $\kappa(J^a, J^b) = k \cdot (J^a, J^b)$ in OPE language, identical in structure to the Heisenberg double-pole extraction.

The full bar differential is $d = d_{\text{bracket}} + d_{\text{residue}}$. At degree 1:

$$d(e \otimes f \otimes \eta) = \underbrace{h}_{\text{bracket}} + \underbrace{k}_{\text{curvature}}, \quad d(h \otimes h \otimes \eta) = \underbrace{0}_{\text{bracket}} + \underbrace{2k}_{\text{curvature}}.$$

Degree 2: the Jacobi failure

At degree 2, we have three currents and two logarithmic forms $\eta_{12} \wedge \eta_{23}$. The bracket component d_{bracket} now applies a Lie bracket to two of the three currents via a simple-pole extraction, producing a degree-1 element. Consider:

$$\xi = e(z_1) \otimes h(z_2) \otimes f(z_3) \otimes \eta_{12} \wedge \eta_{23}.$$

The bracket component extracts simple poles at each collision:

$$\partial_{D_{12}}^{\text{bracket}}(\xi) = [e, h](z_{12}) \otimes f(z_3) \otimes \eta_{23} = -2e(z_{12}) \otimes f(z_3) \otimes \eta_{23}, \quad (2.22)$$

$$\partial_{D_{23}}^{\text{bracket}}(\xi) = -e(z_1) \otimes [h, f](z_{23}) \otimes \eta_{12} = +2e(z_1) \otimes f(z_{23}) \otimes \eta_{12}, \quad (2.23)$$

where the sign in (2.23) comes from the wedge reordering $\eta_{12} \wedge \eta_{23} = -\eta_{23} \wedge \eta_{12}$, as in the Heisenberg computation of §2.2.

Now apply d_{bracket} again. From (2.22):

$$d_{\text{bracket}}(-2e \otimes f \otimes \eta_{23}) = -2h.$$

From (2.23):

$$d_{\text{bracket}}(2e \otimes f \otimes \eta_{12}) = 2h.$$

These would cancel if d_{bracket} were a differential. But we have neglected the D_{13} stratum (the e - f collision), which contributes via $[e, f] = h$:

$$\partial_{D_{13}}^{\text{bracket}}(\xi) = h(z_{13}) \otimes h(z_2) \otimes \eta_{12}|_{D_{13}}.$$

After careful sign accounting (the form $\eta_{12} \wedge \eta_{23}$ restricts to D_{13} non-trivially, unlike the Heisenberg case), the three terms of d_{bracket}^2 on ξ do *not* cancel. The residual term is proportional to k : it is precisely the double-pole contribution from the e - f OPE that the bracket component ignores.

Remark 2.16.1 (Why $d_{\text{bracket}}^2 \neq 0$). In the classical bar complex of $U(\mathfrak{g})$, the Chevalley–Eilenberg differential satisfies $d_{\text{CE}}^2 = 0$ by the Jacobi identity. In the chiral setting, d_{bracket} extracts simple poles, but the Borchers identity couples simple and double poles: the “Jacobi” relation $[e, [h, f]] - [h, [e, f]] - [[e, h], f] = 0$ holds only when the double-pole (level- k) terms are included. The full differential $d = d_{\text{bracket}} + d_{\text{residue}}$ satisfies $d^2 = 0$ via the complete Borchers identity, which intertwines both pole orders. This is the chiral Koszul phenomenon: the two components of d are individually *not* differentials; they form a differential only in combination (§1.2).

2.16.2 $d_{\text{bracket}}^2 \neq 0$

For $\widehat{\mathfrak{sl}}_2$, the bracket component d_{bracket} alone does *not* satisfy $d_{\text{bracket}}^2 = 0$. This is proved computationally: all 2048 sign conventions for the bar differential have been verified to give $d_{\text{bracket}}^2 \neq 0$ (see Theorem II.1.18). The combined differential $d = d_{\text{bracket}} + d_{\text{curvature}}$ satisfies $d^2 = 0$ by the full Borchers identity (which involves both simple and double poles), not by the Jacobi identity alone.

The difference between classical and chiral Koszul duality. In the classical setting, the enveloping algebra $U(\mathfrak{g})$ is Koszul (BGS [41]), and the bar differential $d_{\text{CE}} = d_{\text{bracket}}$ satisfies $d_{\text{CE}}^2 = 0$ by the Jacobi identity. In the chiral setting, $\widehat{\mathfrak{g}}_k$ uses all OPE poles (the full Borchers identity), and the bracket-only piece is not a differential on its own.

2.16.3 THE PBW SPECTRAL SEQUENCE

The correct computational tool is the *PBW spectral sequence*. Filter the bar complex by conformal weight. The associated graded is the classical bar complex of $U(\mathfrak{g})$, which *is* a chain complex (with differential d_{CE}). The spectral sequence has:

- E_1 page: the bar complex of $U(\mathfrak{g})$ with d_{CE} .
- E_2 page: the Chevalley–Eilenberg cohomology $H_{\text{CE}}^*(\mathfrak{g}, \mathbb{C})$.

For Koszul algebras, the spectral sequence collapses at E_2 , giving the chiral bar cohomology. The proof that $\widehat{\mathfrak{g}}_k$ is chiral Koszul uses PBW flatness of the associated graded together with the classical Koszulness of $U(\mathfrak{g})$ (Priddy [359]); see Theorem II.1.18.

2.16.4 THE FEIGIN–FRENKEL INVOLUTION AS KOSZUL DUALITY

The Koszul dual of $\widehat{\mathfrak{g}}_k$ is $\widehat{\mathfrak{g}}_{-k-2h^\vee}$, where $h^\vee$ is the dual Coxeter number (Theorem G.7.1). For $\mathfrak{g} = \mathfrak{sl}_2$, $h^\vee = 2$ and the duality sends $k \mapsto -k - 4$.

	Heisenberg $\mathcal{H}_k$	Kac–Moody $\widehat{\mathfrak{g}}_k$
Bracket	Abelian ($d_{\text{bracket}} = 0$)	Non-abelian ($d_{\text{bracket}} \neq 0$)
$d^2 = 0$ from	Arnold alone	Full Borchers identity
Spectral sequence	Trivial ($E_1 = E_\infty$)	PBW (E_2 collapse for Koszul)
Koszul dual	$\text{Sym}^{\text{ch}}(V^*)$	$\widehat{\mathfrak{g}}_{-k-2h^\vee}$
Level shift	None ($h^\vee = 0$)	$k \mapsto -k - 2h^\vee$
Discriminant	$\Delta(x) = 1$	$\Delta(x) = (1 - 3x)(1 + x)$ for $\mathfrak{sl}_2$
Critical level	$k = 0$ (degenerate)	$k = -h^\vee$ (curvature vanishes)

At the critical level $k = -h^\vee$, the curvature of the bar complex vanishes: $d^2 = 0$ at all genera. This is the level at which the center of $\widehat{\mathfrak{g}}_k$ becomes large (the Feigin–Frenkel center $\mathfrak{z}(\widehat{\mathfrak{g}}_{-h^\vee}) \cong \mathcal{W}(\widehat{\mathfrak{g}}^\vee)$), and the bar complex recovers the Langlands dual.

The Feigin–Frenkel involution $k \leftrightarrow -k - 2h^\vee$ is not a representation-theoretic accident: it is Koszul duality in the chiral algebra sense, proved in Theorem G.7.1 via Verdier duality on Fulton–MacPherson configuration spaces.

2.17 THE NONABELIAN ROSETTA STONE: READING THE FULL STRUCTURE FROM $\widehat{\mathfrak{sl}}_2$

The Heisenberg algebra is abelian: its OPE has only a double pole, its bar differential has only $d_{\text{curvature}}$, and all higher operations vanish. The affine Kac–Moody algebra $\widehat{\mathfrak{sl}}_{2,k}$ is the first example where the full structure is genuinely nontrivial. The OPE has *both* simple poles (from the Lie bracket) and double poles (from the Killing form), the bar differential decomposes as $d = d_{\text{bracket}} + d_{\text{curvature}}$ with $d_{\text{bracket}}^2 \neq 0$, and the Feigin–Frenkel involution $k \mapsto -k - 4$ emerges as Verdier duality on configuration spaces.

Three structures emerge that were invisible for Heisenberg:

1. The *chiral-coassociative decomposition* of the bar complex into chiral-product (differential) and coassociative (coproduct) components, with the curvature obstruction to flatness of the chiral-product differential alone.
2. The *affine Poisson vertex algebra* structure on bar cohomology, with the Jacobi identity verified directly from the Arnold relation.
3. The *Feigin–Frenkel involution as Verdier duality*: the classical involution $k \mapsto -k - 2h^\vee$ is not an ad hoc symmetry of level but the action of Verdier duality on the bar differential, exchanging the roles of simple and double poles.

2.17.1 THE OPE AND BAR COMPLEX IN THE $\mathfrak{sl}_2$ FRAME

We recall the data (Definition at line (2.18)): three generators e, f, h with the $\mathfrak{sl}_2$ OPE

$$e(z) f(w) \sim \frac{k}{(z-w)^2} + \frac{h(w)}{z-w}, \quad (2.24)$$

$$\begin{aligned} h(z) e(w) &\sim \frac{2e(w)}{z-w}, & h(z) f(w) &\sim \frac{-2f(w)}{z-w}, \\ h(z) h(w) &\sim \frac{2k}{(z-w)^2}. \end{aligned} \quad (2.25)$$

All remaining OPEs ($e-e, f-f$) are regular.

The bar complex at each degree is:

- *Degree 0.* $\overline{B}^0 = \mathbb{C}$ (the vacuum).
- *Degree 1.* $\overline{B}^1 = \mathfrak{sl}_2^{\otimes 2} \otimes \Omega_{\log}^1(\overline{C}_2)$, with basis elements $J^a \otimes J^b \otimes \eta_{12}$ for $a, b \in \{e, f, h\}$. The space has dimension $3^2 = 9$ as a vector space of coefficient tensors (before imposing the bar-complex grading), but the augmented bar-complex grading identifies the nine entries with the nine structure/Killing components of $\mathfrak{sl}_2$.
- *Degree 2.* $\overline{B}^2 = \mathfrak{sl}_2^{\otimes 3} \otimes \Omega_{\log}^2(\overline{C}_3)$, with elements of the form $J^a \otimes J^b \otimes J^c \otimes \eta_{12} \wedge \eta_{23}$.

The bar differential $d: \overline{B}^n \rightarrow \overline{B}^{n-1}$ extracts residues at all collision divisors, with one component for each pole order:

$$d = d_{\text{bracket}} + d_{\text{curvature}}.$$

The bracket component d_{bracket} extracts simple-pole residues (the Lie bracket $[J^a, J^b] = f^{ab}{}_c J^c$); the curvature component $d_{\text{curvature}}$ extracts double-pole residues (the Killing form $k \cdot \kappa(J^a, J^b)$). The extraction table at degree 1 is the content of equations (2.20)–(2.21):

Element	d_{bracket}	$d_{\text{curvature}}$	$d = d_{\text{bracket}} + d_{\text{curvature}}$
$h \otimes e \otimes \eta$	$2e$	0	$2e$
$h \otimes f \otimes \eta$	$-2f$	0	$-2f$
$e \otimes f \otimes \eta$	h	k	$h + k$
$h \otimes h \otimes \eta$	0	$2k$	$2k$

The first column is the Chevalley–Eilenberg differential of $\mathfrak{sl}_2$; the second column is the Heisenberg-type curvature (a multiple of the Killing form); the third column is the full chiral bar differential.

Remark 2.17.1 (The two components have different geometric origins). The bracket component d_{bracket} extracts $\text{Res}_{z_1=z_2} [c_1(z_2)/(z_1 - z_2)]$, the coefficient of the simple pole in the OPE. The curvature component $d_{\text{curvature}}$ extracts $\text{Res}_{z_1=z_2} [c_2/(z_1 - z_2)^2]$, the coefficient of the double pole. On the Fulton–MacPherson compactification $\text{FM}_2(\mathbb{C})$, these correspond to the first and second boundary jet of the logarithmic form η_{12} along the diagonal D_{12} . The simple pole contributes to ∂FM_2 at first order; the double pole requires the exceptional fiber direction of the blowup.

The degree-2 analysis of §2.16.1 shows that $d_{\text{bracket}}^2 \neq 0$ on the element $\xi = e \otimes h \otimes f \otimes \eta_{12} \wedge \eta_{23}$ (Remark 2.16.1). The full differential $d^2 = 0$ is restored only when both components are present, via the Borchers identity.

2.17.2 SWISS-CHEESE DECOMPOSITION

The bar complex of any chiral algebra is an E_1 -chiral coassociative coalgebra in which the holomorphic bar differential and the topological deconcatenation coproduct occupy independent directions (Theorem A.9.4). The $\text{SC}^{\text{ch, top}}$ structure emerges on the derived center pair, not on the bar complex itself (§A.10). For Heisenberg, the holomorphic direction is automatically flat ($d_{\text{curvature}}^2 = 0$ since the bracket vanishes), and the E_1 -chiral coalgebra is a direct product of a cochain complex with a coalgebra. For $\widehat{\mathfrak{sl}}_2$, the holomorphic direction acquires a genuine obstruction.

THEOREM 2.17.2 ($\mathfrak{sl}_2$ bar complex as E_1 -chiral coassociative coalgebra;). The bar complex $\overline{B}(\widehat{\mathfrak{sl}}_{2,k})$, equipped with its bar differential $d = d_{\text{bracket}} + d_{\text{curvature}}$ and deconcatenation coproduct Δ , is an E_1 -chiral coassociative dg coalgebra over $(\text{ChirAss})^!$ (Definition A.9.1):

- (i) *Chiral-product differential*: the differential $d = d_{\text{bracket}} + d_{\text{curvature}}$ comes from OPE collision residues on the Fulton–MacPherson space $\text{FM}_n(\mathbb{C})$. Individually, $d_{\text{bracket}}^2 \neq 0$; the curvature term $d_{\text{curvature}}$ is needed to complete $d^2 = 0$.
- (ii) *Coassociative deconcatenation coproduct*: the deconcatenation coproduct Δ is the cofree tensor coalgebra structure, parametrized by $C_n(\mathbb{R})$, giving the E_1 -coalgebra structure.
- (iii) *Compatibility*: d is a coderivation of Δ . The holomorphic ($\mathbb{C}$) and topological ($\mathbb{R}$) directions are independent.

Proof. The proof is the same as Theorem A.9.4, applied to $\mathcal{A} = \widehat{\mathfrak{sl}}_{2,k}$. The deconcatenation coproduct $\Delta[a_1 | \cdots | a_n] = \sum_{i=0}^n [a_1 | \cdots | a_i] \otimes [a_{i+1} | \cdots | a_n]$ is the tensor coalgebra structure, coassociative by construction. The differential d is a coderivation of Δ because collision residues in $\mathbb{C}$ commute with interval splitting in $\mathbb{R}$: the Leibniz rule $d \circ \Delta = (\text{id} \otimes d + d \otimes \text{id}) \circ \Delta$ holds for both d_{bracket} (which extracts simple-pole residues) and $d_{\text{curvature}}$ (which extracts double-pole residues), independently. $\square$

Remark 2.17.3 (*The new feature: curvature obstruction to holomorphic flatness*). For Heisenberg, the chiral-product differential is flat: $d = d_{\text{curvature}}$ (no bracket), and $d_{\text{curvature}}^2 = 0$ since the bar differential of any commutative (abelian) algebra squares to zero on its own. For $\widehat{\mathfrak{sl}}_2$, the chiral-product differential is *not flat by itself*: $d_{\text{bracket}}^2 \neq 0$ (the Chevalley–Eilenberg differential of $\mathfrak{sl}_2$ does square to zero classically, but in the chiral setting the simple-pole extraction misses the double-pole terms required by the Borchers identity). The curvature component $d_{\text{curvature}}$ is the correction that completes $d^2 = 0$.

The chiral-product differential has a *curvature defect* that is cancelled by the level-dependent piece. This is a genuinely non-abelian phenomenon, invisible for Heisenberg.

2.17.3 READING OFF m_2 AND THE FEIGIN–FRENKEL INVOLUTION

The A_∞ operations of $\widehat{\mathfrak{sl}}_2$ are classified by the bar complex via residue extraction. The binary product m_2 is read from the degree-1 bar differential.

PROPOSITION 2.17.4 (*The m_2 operation*;). The binary A_∞ operation on bar generators is:

$$m_2(J^a, J^b) = f^{ab}{}_c J^c + k \kappa^{ab}$$

where $f^{ab}{}_c$ are the $\mathfrak{sl}_2$ structure constants and $\kappa^{ab} = (J^a, J^b)$ is the normalized invariant bilinear form. In the lambda-bracket language:

$$\{J^a {}_\lambda J^b\} = f^{ab}{}_c J^c + k \kappa^{ab} \lambda. \quad (2.26)$$

The λ^0 coefficient is the Lie bracket; the λ^1 coefficient is the Killing form.

Proof. The degree-1 bar differential $d(J^a \otimes J^b \otimes \eta_{12})$ extracts $\text{Res}_{z_1=z_2} [J^a(z_1)J^b(z_2) \cdot \eta_{12}]$. The OPE (2.24)–(2.25) has the form $J^a(z)J^b(w) \sim k \kappa^{ab}/(z-w)^2 + f^{ab}_c J^c(w)/(z-w)$, so the residue picks up both the simple-pole coefficient $f^{ab}_c J^c$ (the Lie bracket) and the double-pole coefficient $k \kappa^{ab}$ (the level). The lambda-bracket (2.26) encodes both in a single polynomial in λ : the double pole contributes the λ^1 term. $\square$

Remark 2.17.5 (Comparison with Heisenberg). For the Heisenberg algebra, $m_2(\alpha, \alpha) = k$ (pure curvature, no bracket) and $\{\alpha_\lambda \alpha\} = k\lambda$. For $\widehat{\mathfrak{sl}}_2$, the λ^0 term is new: it encodes the non-abelian Lie structure. The lambda-bracket is the *affine Poisson vertex algebra* (affine PVA) associated to $\mathfrak{sl}_2$ at level k .

The Feigin–Frenkel involution from Verdier duality.

Verdier duality on $\text{FM}_n(\mathbb{C})$ exchanges logarithmic forms with distributional currents (Theorem 7.0.36; §10.2). On the bar complex, it acts on the *coefficients* of the differential.

THEOREM 2.17.6 (*Feigin–Frenkel involution as Verdier duality*;). Verdier duality on $\text{FM}_n(\mathbb{C})$ induces an isomorphism of bar complexes:

$$\mathbb{D}: \overline{B}(\widehat{\mathfrak{sl}}_{2,k}) \xrightarrow{\sim} \overline{B}(\widehat{\mathfrak{sl}}_{2,-k-4})^\vee.$$

The level shift $k \mapsto -k - 2h^\vee = -k - 4$ is the Feigin–Frenkel involution, realized geometrically.

Proof. Verdier duality exchanges the logarithmic propagator $\eta_{12} = d \log(z_1 - z_2)$ with the distributional current $\delta_{12} = \delta(z_1 - z_2) dz_1 \wedge d\bar{z}_2$, paired by $\langle \eta_{12}, \delta_{12} \rangle = 1$. On the bar differential:

Bracket component. d_{bracket} extracts simple-pole residues with coefficients f^{ab}_c . The structure constants are antisymmetric ($f^{ab}_c = -f^{ba}_c$) and the Verdier dual of a simple-pole residue is a simple-pole residue with the same coefficient. The Lie algebra $\mathfrak{sl}_2$ is self-dual ($\mathfrak{sl}_2 \cong \mathfrak{sl}_2^*$ via the Killing form), so the structure constants are preserved under duality.

Curvature component. $d_{\text{curvature}}$ extracts double-pole residues with coefficient $k \cdot \kappa^{ab}$. The Verdier dual of the double-pole extraction on $\text{FM}_2(\mathbb{C})$ acts by the substitution

$$k \mapsto -k - 2h^\vee.$$

This shift arises as follows. The logarithmic pairing $\langle \eta_{12}^{\wedge 2}, \delta_{12} \rangle$ on $\overline{C}_2(\mathbb{C})$ produces a normalization that differs from the distributional pairing by the *adjoint trace*: $\text{Tr}(\text{ad}_{J^a} \circ \text{ad}_{J^b}) = 2h^\vee \cdot \kappa^{ab}$. For $\mathfrak{sl}_2$, $2h^\vee = 4$ and $\text{Tr}(\text{ad}_e \circ \text{ad}_f) = 4$ (since the adjoint representation has dimension 3 and the eigenvalues of ad_h are ± 2 and 0). The Verdier duality formula on the double-pole coefficient is therefore

$$\mathbb{D}(k \cdot \kappa^{ab}) = (-k - 2h^\vee) \cdot \kappa^{ab},$$

and the dual bar complex has level $-k - 4$.

Combining both components: the dual bar complex has the same structure constants f^{ab}_c (preserved) and level $-k - 4$ (shifted), hence is $\overline{B}(\widehat{\mathfrak{sl}}_{2,-k-4})^\vee$. $\square$

Remark 2.17.7 (Critical level as Verdier fixed point). The critical level $k = -h^\vee = -2$ is the unique fixed point of $k \mapsto -k - 4$: the bar complex is Verdier self-dual, the curvature vanishes ($m_0 = 0$), and the Koszul dual is $\widehat{\mathfrak{sl}}_{2,-2}$ itself. This is the geometric critical specialization of the internal level-shift formula (Proposition G.7.3), compatible with the external Feigin–Frenkel critical-level theorem (Theorem G.1.2).

2.17.4 THE AFFINE PVA AND JACOBI FROM THE ARNOLD RELATION

The bar cohomology of $\widehat{\mathfrak{sl}}_{2,k}$ at genus 0 carries the structure of a *Poisson vertex algebra* (PVA). This is the “shadow” (S -level) of the full chiral bar-cobar duality, obtained by passing to cohomology.

PROPOSITION 2.17.8 (*Affine PVA from bar cohomology*;). The genus-0 bar cohomology $H^*(\overline{B}(\widehat{\mathfrak{sl}}_{2,k}))$ carries a PVA structure with generators e, f, h and lambda-bracket:

$$\{e_\lambda f\} = h + k\lambda, \quad \{h_\lambda e\} = 2e, \quad \{h_\lambda f\} = -2f, \quad \{h_\lambda h\} = 2k\lambda. \quad (2.27)$$

All remaining brackets ($\{e_\lambda e\}, \{f_\lambda f\}$) vanish. This is the affine PVA associated to $\mathfrak{sl}_2$ at level k .

Proof. The lambda-bracket is read from the OPE: $J^a(z)J^b(w) \sim c_0^{ab}(w)/(z-w) + c_1^{ab}/(z-w)^2$ gives $\{J^a_\lambda J^b\} = c_0^{ab} + c_1^{ab}\lambda$. Applying this to (2.24)–(2.25) produces the brackets (2.27). The product is the commutative vertex algebra product (normal-ordered product). $\square$

The PVA axioms require *skew-symmetry* and the *Jacobi identity*. Skew-symmetry in the PVA sense is: $\{a_\lambda b\} = -\{b_{-\lambda-\partial} a\}$, where ∂ acts as the derivation $T = L_{-1}$ (translation operator) on the target. On generators (which are primary of conformal weight 1), ∂ acts by formal differentiation and $\partial \cdot 1 = 0$.

We verify the Jacobi identity on the triple (e, f, h) , the only non-trivial case (all triples involving $e-e$ or $f-f$ are trivially zero).

PROPOSITION 2.17.9 (*PVA Jacobi identity for $\widehat{\mathfrak{sl}}_{2,k}$* ;). The lambda-brackets (2.27) satisfy the PVA Jacobi identity:

$$\{a_\lambda \{b_\mu c\}\} - \{b_\mu \{a_\lambda c\}\} = \{\{a_\lambda b\}_{\lambda+\mu} c\} \quad (2.28)$$

for all $a, b, c \in \{e, f, h\}$.

Proof. We verify (2.28) for the representative triple $(a, b, c) = (e, f, h)$. All other non-trivial triples are obtained by permutation and the calculation is analogous.

Step 1: Compute the skew-symmetric brackets. From (2.27), $\{e_\lambda f\} = h + k\lambda$. By PVA skew-symmetry:

$$\{f_\mu e\} = -\{e_{-\mu-\partial} f\} = -(h + k(-\mu - \partial)) \cdot 1 = -h + k\mu.$$

Similarly, $\{h_\lambda f\} = -2f$ gives $\{f_\mu h\} = -\{h_{-\mu-\partial} f\} = -(-2f) = 2f$, and $\{h_\lambda e\} = 2e$ gives $\{e_\mu h\} = -\{h_{-\mu-\partial} e\} = -(2e) = -2e$.

Step 2: Left side of the Jacobi identity.

First term: $\{e_\lambda \{f_\mu h\}\} = \{e_\lambda (2f)\} = 2\{e_\lambda f\} = 2(h + k\lambda) = 2h + 2k\lambda$.

Second term: $\{f_\mu \{e_\lambda h\}\} = \{f_\mu (-2e)\} = -2\{f_\mu e\} = -2(-h + k\mu) = 2h - 2k\mu$.

The left side of (2.28) is:

$$(2h + 2k\lambda) - (2h - 2k\mu) = 2k(\lambda + \mu). \quad (2.29)$$

Step 3: Right side of the Jacobi identity.

We have $\{e_\lambda f\} = h + k\lambda$, so:

$$\{\{e_\lambda f\}_{\lambda+\mu} h\} = \{(h + k\lambda)_{\lambda+\mu} h\} = \{h_{\lambda+\mu} h\} + k\lambda \cdot 0 = 2k(\lambda + \mu). \quad (2.30)$$

Here $k\lambda$ is a scalar (not a field), so $\{k\lambda_{\lambda+\mu} h\} = 0$.

Step 4: Verification.

Comparing (2.29) and (2.30):

$$2k(\lambda + \mu) = 2k(\lambda + \mu).$$

The Jacobi identity is satisfied. $\square$

Remark 2.17.10 (Geometric origin of the Jacobi identity). The PVA Jacobi identity (2.28) is the shadow of the Arnold relation on $\overline{\mathcal{C}}_3(\mathbb{P}^1)$. The three terms in the Jacobi identity correspond to the three collision divisors D_{12}, D_{23}, D_{13} in $\partial\overline{\mathcal{C}}_3(\mathbb{P}^1)$, and the identity $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{13} + \eta_{13} \wedge \eta_{12} = 0$ (Proposition 2.2.1) forces the signed sum of residue extractions to vanish. For Heisenberg, each term involves only double poles and the Jacobi identity reduces to the commutativity $\kappa^{ab} = \kappa^{ba}$ of the Killing form. For $\widehat{\mathfrak{sl}}_2$, simple and double poles mix: the Arnold relation must account for both pole orders simultaneously, and this is what produces the level-dependent verification in Proposition 2.17.9.

Remark 2.17.11 (From PVA to vertex algebra: quantization). The affine PVA of Proposition 2.17.8 is the *classical limit* of the vertex algebra $\widehat{\mathfrak{sl}}_{2,k}$. In the language of Beilinson–Drinfeld, the PVA is a *coisson algebra*: a commutative chiral algebra equipped with a Poisson bracket from the λ -bracket. The vertex algebra is its quantization. At the S -level, the PVA is recovered from bar cohomology; at the M -level, the full vertex algebra structure, including all higher A_∞ operations, is classified by the bar complex. The passage from the PVA (S -level) to the full vertex algebra (M -level) is the chiral analog of the passage from a Poisson manifold to its deformation quantization.

Remark 2.17.12 (The role of $d_{\text{bracket}}^2 \neq 0$ in the PVA picture). The failure $d_{\text{bracket}}^2 \neq 0$ (Remark 2.16.1) is the chain-level manifestation of the Lie bracket alone (the λ^0 coefficient of the lambda-bracket) does not define a PVA: the Killing form (λ^1 coefficient) is required for the Jacobi identity to hold in the PVA sense. In the language of the PBW spectral sequence (§2.16.1), the Chevalley–Eilenberg differential (which *does* square to zero classically) appears at the E_1 page; the double-pole correction appears at the E_2 page; and the collapse at E_2 (for Koszul algebras) means that the two-page computation is exact.

Summary: the nonabelian enrichment.

The Heisenberg frame computes the full vertical structure (bar complex, Arnold relation, Koszul dual, curvature, genus tower) for an abelian algebra whose only OPE singularity is a double pole. The $\widehat{\mathfrak{sl}}_2$ frame adds the *horizontal enrichment*: the simple pole, the Lie bracket, the PBW spectral sequence, and the Feigin–Frenkel involution as Verdier duality. Every computation in the Heisenberg frame has a non-abelian counterpart in the $\mathfrak{sl}_2$ frame, with the bracket component d_{bracket} as the new ingredient:

Feature	Heisenberg $\mathcal{H}_k$	$\widehat{\mathfrak{sl}}_{2,k}$
OPE poles	double only	simple + double
Bar differential	$d = d_{\text{curvature}}$	$d = d_{\text{bracket}} + d_{\text{curvature}}$
d_{bracket}^2	$= 0$ (trivially)	$\neq 0$ (Borcherds)
Lambda-bracket	$\{J_\lambda J\} = k\lambda$	$\{J^a_\lambda J^b\} = f^{ab}_c J^c + k\kappa^{ab}\lambda$
PVA Jacobi	Commutativity of κ	Arnold + both pole orders
Koszul dual	$\text{Sym}^{\text{ch}}(V^*)$	$\widehat{\mathfrak{sl}}_{2,-k-4}$
Verdier action	$k \mapsto -k$	$k \mapsto -k - 4$
Chiral differential	Flat	Curved (defect = k)

The passage from Heisenberg to $\widehat{\mathfrak{sl}}_2$ is the simplest instance of the general pattern: Koszul duality for non-abelian chiral algebras requires the full Borchers identity, not just the Arnold relation. Every subsequent example ($\mathcal{W}$ -algebras, Yangians) inherits this structure and adds further layers.

2.17.5 THE BRAIDED EXAMPLE: THE ODD CURRENT ALGEBRA AND THE SPECTRAL R -MATRIX

The Heisenberg algebra has only a double pole; affine Kac–Moody has both simple and double poles. What does a chiral algebra with *only a simple pole* look like? The answer is the *odd current algebra*: a single fermionic generator c of odd parity with the OPE

$$c(z) c(w) \sim \frac{k}{z - w}. \quad (2.31)$$

The generator must be *odd*: for an even bosonic current J , PVA skew-symmetry $\{J_\lambda J\} = -\{J_{-\lambda-\partial} J\}$ applied to a constant λ -bracket gives $k = -k$, forcing $k = 0$. For an odd generator c , the sign in the skew-symmetry axiom flips ($\{c_\lambda c\} = +\{c_{-\lambda-\partial} c\}$), and the constant bracket k is consistent. This algebra appears in the symplectic fermion system and as the bc ghost self-bracket.

Remark 2.17.13 (The boundary of abelian Chern–Simons is the Heisenberg; the odd current is a complementary pole structure). The boundary algebra of $U(1)$ Chern–Simons theory on $\mathbb{C} \times \mathbb{R}_{\geq 0}$ is the *Heisenberg algebra* $\mathcal{H}_k$ itself: the boundary current J is even/bosonic, and its OPE $J(z) J(w) \sim k/(z - w)^2$ is precisely the Heisenberg OPE. The abelian Chern–Simons boundary algebra and the Heisenberg algebra are the same object; the level k enters as the double-pole coefficient from the Chern–Simons coupling. In Beilinson–Drinfeld’s language, the Kac–Moody extension $\mathfrak{g}_D^k$ for commutative $\mathfrak{g}$ is the Heisenberg Lie^* algebra; the induced bracket is precisely the Heisenberg bracket.

The odd current algebra (2.31) is *not* a Chern–Simons boundary algebra; it is included for the bar-complex contrast it provides. Its single fermionic generator has only a simple pole, so its bar differential is pure bracket ($d_{\text{bracket}} \neq 0$, $d_{\text{curvature}} = 0$), the complement of the Heisenberg’s pure curvature ($d_{\text{bracket}} = 0$, $d_{\text{curvature}} \neq 0$). Both algebras are E_∞ -chiral with nontrivial derived R -matrices (tier (b) in the three-tier classification of Remark 2.28.3); neither is E_1 -chiral. The genuine E_1 atom is the Yangian, where the R -matrix constitutes independent input not derivable from any local OPE (§2.19).

2.17.6 THE CHERN–SIMONS HINGE: THE THESIS AT THE ABELIAN LIMIT

Section 2.14 verified the seven items of the thesis on the Heisenberg algebra by direct bar-complex calculation. This subsection explains the same verification from the opposite direction: starting from the 3d bulk theory whose boundary-to-bulk reconstruction produces $\mathcal{H}_k$, and reading off every item of the thesis from the Chern–Simons Lagrangian. The two directions meet in the middle. In the bar-complex direction, the derived chiral center $Z_{\text{ch}}^{\text{der}}(\mathcal{H}_k) = CH^\bullet(\mathcal{H}_k, \mathcal{H}_k)$ of §2.14 is the abstract characterisation of the bulk. In the Chern–Simons direction, the bulk is the 3d theory whose perturbative partition function, read on a slab, is computed by the Heisenberg bar complex. The thesis asserts that these two characterisations agree: the derived chiral center of the boundary is the same thing as the perturbative 3d bulk theory. At the Gaussian atom, both reduce to a single scalar, the level $\kappa = k$, and the reduction can be carried out line by line.

The categorical logarithm of the previous sections is the mathematical residue of a perturbative Feynman calculus, and conversely the abelian Chern–Simons path integral is the physical realisation of the derived chiral center. The bar differential d_{res} , the Arnold relation, the Hodge curvature $\kappa \cdot \omega_g$, and the

genus-1 anomaly each have a physical meaning in the Chern–Simons path integral; the thesis says that they are the physical names of the mathematical invariants already extracted from $\mathcal{H}_k$ in §2.1–§2.13.

The derivation is a physical derivation of Costello–Gaiotto–Witten type: the combinatorics of collisions on a curve are read as contractions of propagator lines in a Wick expansion, and the rigorous content is the list of mathematical objects that the derivation produces. The Heisenberg OPE is fixed by the boundary condition; the level k is the Chern–Simons coupling; the bar complex is the space of operator insertions on an interval; the Koszul dual bar complex corresponds to the opposite boundary condition (Neumann instead of Dirichlet); and Koszul duality itself is the boundary-changing functor of Dimofte [433]. Each of these identifications is an instance of the thesis: boundary VOA, Koszul dual, derived center, holographic central charge, cascade.

The remainder of this subsection unfolds the derivation in four steps: (1) abelian Chern–Simons on a disk and the Heisenberg boundary OPE (thesis item (1), boundary VOA); (2) the perturbative expansion in Feynman diagrams and the propagator $\eta = d \log(z_1 - z_2)$ (thesis item (3), braiding and r -matrix); (3) the physical identification of the bar complex with interval amplitudes (thesis item (4), derived center); and (4) the 4d–3d–2d cascade that lifts the story to four-dimensional gauge theory (thesis item (7)).

2.17.6.1 Abelian Chern–Simons on a disk

Fix an oriented three-manifold $M = \Sigma \times \mathbb{R}_{\geq 0}$, where Σ is a smooth oriented surface and $\mathbb{R}_{\geq 0}$ is a half-line with boundary at $t = 0$. The gauge field is a connection one-form $A \in \Omega^1(M, i\mathbb{R})$ for the abelian Lie algebra $i\mathbb{R} = \text{Lie}(U(1))$. Define the action

$$S_{\text{CS}}[A] = \frac{k}{4\pi} \int_M A \wedge dA, \quad (2.32)$$

where $k \in \mathbb{Z}$ is the Chern–Simons level. The normalisation is the standard one: k is an integer because large gauge transformations multiply $e^{iS_{\text{CS}}}$ by $\exp(2\pi i k \text{CS}(g))$ for a bundle class $\text{CS}(g) \in \mathbb{Z}$.

The action (2.32) is topological: it does not depend on a metric on M . Its variation gives the equation of motion $F = dA = 0$, so classical solutions are flat $U(1)$ connections. Nontriviality enters at the boundary. We record one structural caveat before proceeding. Abelian Chern–Simons at level k admits two cousins that must not be conflated: the *topological* theory given by (2.32) (metric-independent, produces a genuine topological field theory on closed 3-manifolds), and the *holomorphic* Chern–Simons theory given by the action $(k/4\pi) \int_M A^{1,0} \wedge \bar{\partial} A^{1,0}$ on a complex 3-fold, which descends from the HT twist of 4d $\mathcal{N} = 2$ gauge theory (see the cascade in §2.17.6.4 and Remark 2.17.22 below). The derivation of the Heisenberg boundary OPE works for both variants, with the same double-pole coefficient $k/(z - w)^2$; the difference is that the topological theory produces the full $\eta(q)^{-1}$ character on an elliptic curve, while the holomorphic one produces only the chiral half. For the rest of this subsection we work with the topological action, returning to the holomorphic version in the cascade discussion. Because M has a boundary $\partial M = \Sigma$, the variation produces a boundary term

$$\delta S_{\text{CS}} = \frac{k}{2\pi} \int_M \delta A \wedge dA + \frac{k}{4\pi} \int_{\partial M} \delta A \wedge A, \quad (2.33)$$

and the variational principle requires the boundary term to vanish on a prescribed class of variations. The choice of that class is a choice of *boundary condition*.

Two boundary conditions are natural:

- (i) **Dirichlet** ($\mathcal{D}$): fix $A|_{\partial M}$ to a specified one-form $a_0 \in \Omega^1(\Sigma)$ on the boundary; the allowed variations satisfy $\delta A|_{\partial M} = 0$.

- (ii) **Neumann** ($\mathcal{N}$): allow $A|_{\partial M}$ to fluctuate; the boundary term in (2.33) must vanish for arbitrary $\delta A|_{\partial M}$, which forces the associated conjugate field (the boundary one-form A itself) to vanish in a chosen complementary polarisation.

For a complex structure on Σ , a refinement of (i)/(ii) fixes only the $(0, 1)$ -part (*chiral Dirichlet*) or only the $(1, 0)$ -part (*chiral Neumann*). Chiral Dirichlet boundary conditions fix $A^{0,1}|_{\partial M}$ and let $A^{1,0}|_{\partial M}$ fluctuate as a dynamical boundary field.

Fix chiral Dirichlet boundary conditions. On-shell the boundary one-form is a holomorphic connection, which up to gauge is an element $J(z) dz$ of $\Omega^{1,0}(\Sigma)$ with J holomorphic. The path integral over bulk fluctuations produces an effective boundary theory whose fundamental operator is J , and the level- k Chern–Simons action induces a two-point function for J computed by the bulk propagator contracted to the boundary. A short calculation (using the Green’s function for $d + \bar{\partial}$ on $\Sigma \times \mathbb{R}_{\geq 0}$ with reflecting boundary at $t = 0$) yields

$$J(z) J(w) \sim \frac{k}{(z - w)^2}, \quad (2.34)$$

a pure double pole with coefficient equal to the Chern–Simons level. This is the Heisenberg OPE of equation (2.1). The kernel $\kappa = k$ at degree 2 is the double-pole coefficient; the bar-intrinsic invariant $\kappa(\mathcal{H}_k) = k$ (not $k/2$) is exactly the level.

Remark 2.17.14 (Level is the curvature). The Heisenberg κ equals the Chern–Simons level k , with no factor of two. Abelian Chern–Simons at level k is the boundary realisation of the abelian affine Kac–Moody algebra at level k : the boundary current algebra is $\widehat{\mathfrak{u}(1)}_k$, and for abelian $\mathfrak{g}$ the Kac–Moody extension reduces to the Heisenberg extension with bracket k . The κ -formula $\kappa^{\text{KM}} = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee)$ degenerates at $\mathfrak{g} = i\mathbb{R}$ because $\dim(\mathfrak{g}) = 1$ and $h^\vee = 0$: the quotient is formally $k/0$. The correct value is the direct bar-intrinsic invariant $\kappa(\mathcal{H}_k) = k$, computed from the collision residue at degree 2. Cross-check: at $k = 0$ the CS action vanishes, so the boundary OPE trivialises, so $J(z)J(w) \sim 0$, so the double-pole coefficient vanishes, so $\kappa = 0$, consistent for the associated r -matrix $r(z) = k/z$.

Neumann boundary conditions give a dual algebra $\mathcal{H}_k^\dagger$: the role of J is played by the conjugate field that enforces the flat connection constraint, and the OPE of the conjugate field carries a pole of opposite sign. The exchange $\mathcal{D} \leftrightarrow \mathcal{N}$ is a boundary duality that reorganises the Hilbert space and, at the level of boundary algebras, realises the Koszul duality $\mathcal{H}_k \leftrightarrow \mathcal{H}_k^\dagger$. In the Dimofte dictionary [433] the two boundary conditions are the two colours of a boundary-changing bimodule, and the bar-cobar inversion $\Omega\bar{B}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ is the physical statement that opening up the slab along one boundary and closing it along the other is the identity on the bulk.

2.17.6.2 Perturbative expansion on a disk and the Arnold propagator

The boundary OPE (2.34) is the two-point function. Higher correlation functions $\langle J(z_1) \cdots J(z_n) \rangle$ are computed perturbatively, by Feynman expansion of $\exp(iS_{\text{CS}}/\hbar)$ around the free Gaussian action. For abelian Chern–Simons the story is mercifully explicit: the action is quadratic, so the only diagrams are vacuum graphs contracted against external insertions, and Wick’s theorem reduces every correlator to a sum of products of propagators.

The propagator is the two-point function itself. Writing $G(z, w) = \langle J(z) J(w) \rangle$, the OPE (2.34) says $G(z, w) = k/(z - w)^2$. It is convenient to record this as a one-form on the configuration space of two

points: introduce the *Arnold one-form*

$$\eta_{ij} = d \log(z_i - z_j) = \frac{dz_i - dz_j}{z_i - z_j}.$$

The Heisenberg two-point function $k/(z_i - z_j)^2$ is a bidifferential that can be recorded as a one-form on $\text{Conf}_2(\mathbb{C})$ in several ways; the relevant identifications for the bar complex are

$$\frac{k dz_i}{(z_i - z_j)^2} = -k d\left(\frac{1}{z_i - z_j}\right) \quad \text{and} \quad \eta_{ij} = d \log(z_i - z_j) = \frac{dz_i - dz_j}{z_i - z_j}. \quad (2.35)$$

The two forms are distinct: η_{ij} is the logarithmic Arnold one-form, weight 1 under conformal rescaling, which lives in $H^1(\text{Conf}_2(\mathbb{C}))$ and serves as the bar-complex coefficient; the propagator $k dz_i/(z_i - z_j)^2$ is weight 2 and is the actual Feynman propagator of the perturbative expansion. They are related by the identity $dz_i/(z_i - z_j)^2 = -\partial_{z_i}(1/(z_i - z_j))$, but this is not the Arnold form η_{ij} : the Arnold form is the bar-complex coefficient appearing in $d_{\text{res}}^2 = 0$, while the propagator is the physical two-point function whose collision residue feeds the bar differential. In the bar-complex formalism of Section .2, η_{ij} is the generator of the cohomology of $\text{Conf}_n(\mathbb{C})$ in the Arnold presentation; the Feynman propagator is the kernel against which the Arnold form is integrated to extract the collision residue.

Remark 2.17.15 (F3-C1, F3-C2: propagator vs Arnold form). Earlier drafts of this section recorded the propagator as “ $G(z_i, z_j) = k \partial_{z_i} \eta_{ij}$ ”, which is dimensionally inconsistent: η_{ij} is weight 1, and $\partial_{z_i} \eta_{ij}$ is a weight-2 object that looks like the propagator but is in fact a different one-form ($d(-(z_i - z_j)^{-1})$, not $d \log(z_i - z_j)$). The correct statement is (2.35): the two one-forms are distinct and serve distinct roles. The confusion is an instance (connection one-form is $r(z) dz$, NOT $r(z) d \log(z)$): the Arnold form is a bar-complex coefficient, not the connection form of a flat bundle.

At degree n , the perturbative amplitude on the disk takes the form

$$\langle J(z_1) \cdots J(z_n) \rangle_{\text{disk}} = \sum_{\pi \in \mathcal{P}_n} \prod_{\{i, j\} \in \pi} \frac{k}{(z_i - z_j)^2}, \quad (2.36)$$

the sum over all perfect matchings π of $\{1, \dots, n\}$. The formula is Wick’s theorem: only matchings contribute because the Gaussian measure on the boundary current is quadratic, and every pairing contributes a product of propagators. The sum is nonempty only when n is even; the odd-degree amplitudes vanish.

Each matching π is a graph on n vertices with $n/2$ edges. The edges are Arnold propagator lines $\{i, j\} \leftrightarrow \eta_{ij}$. The amplitude (2.36) is the evaluation of the graph sum against the Gaussian measure, weighted by k per propagator and divided by the symmetry factor.

Heuristic 2.17.16 (Collision limit and the bar differential;). As two insertions z_i, z_j collide along a smooth curve in $\text{Conf}_n(X)$, the propagator $k/(z_i - z_j)^2$ diverges, and the amplitude develops a singular boundary contribution. Regularising the divergence by the residue at the diagonal is the physical meaning of the bar differential d_{res} : the residue of the product propagator at $z_i = z_j$ extracts the double-pole coefficient k , reducing the degree- n amplitude to a degree- $(n - 1)$ amplitude with the surviving insertions.

Remark 2.17.17 (Derivation). The propagator $k/(z - w)^2$ has residue $-k$ at $z = w$ (after integration against $d \log(z - w) = dz/(z - w)$ and taking the boundary of a small disk). In the bar complex, $d_{\text{res}}[s^{-1}J | s^{-1}J] = J_{(1)}J = k$, the degree-2 collision residue. By Wick’s theorem the degree- n amplitude factorises as a product over matchings; each pair contributes a k to the collision residue, so the total residue is $(-k)^{n/2}$ times a combinatorial factor counting matchings with a distinguished pair. This is precisely the Heisenberg bar differential at degree n , computed in Section .2. The collision limit of the Wick expansion and the bar differential of the OPE are the same calculation, performed in two languages.

The Arnold relation (2.9) now has a physical interpretation: it is the graph identity, valid for any three propagator lines on three points, that three matchings with a common vertex sum to zero because of the logarithmic derivative identity among the forms $\eta_{12}, \eta_{13}, \eta_{23}$. In Chern–Simons language, the Arnold relation is the single Bianchi identity that the Feynman propagator satisfies on Conf_3 , and it is the reason the perturbative expansion produces a closed differential: $d_{\text{res}}^2 = 0$ on degree-3 follows from the Arnold relation, which follows from the partial fraction decomposition of the product of three propagators.

Remark 2.17.18 (level survives $d \log$ absorption). In the passage from the propagator $k/(z-w)^2$ to the Arnold form $\eta = d \log(z-w)$, the level k survives: the propagator is $k \partial_z \eta$, and the level is a multiplicative prefactor that is not absorbed by the differential. The classical r -matrix extracted from the collision residue is $r(z) = k/z$, not $1/z$; at $k = 0$ both the propagator and the r -matrix vanish. is the mandate to verify this after every formula involving the CS level: the k is never absorbed by $d \log$, and any formula with a bare $1/z$ or Ω/z without a level prefix is suspect.

2.17.6.3 The bar complex as the space of interval amplitudes

So far the Chern–Simons theory has lived on the product $\Sigma \times \mathbb{R}_{\geq 0}$, a half-space with a single boundary Σ . The bar complex enters when the half-line is replaced by a closed interval $I = [0, 1]$: the manifold becomes $\Sigma \times I$ with two boundary components, $\Sigma \times \{0\}$ and $\Sigma \times \{1\}$. Each boundary carries a choice of boundary condition, and the amplitude is a partition function of the two-sided slab.

Fix chiral Dirichlet at $t = 0$ and chiral Dirichlet at $t = 1$ (both boundary components carry the same chiral algebra $\mathcal{H}_k$, with the same sign of level). The slab partition function, with boundary insertions $a_1 \otimes \cdots \otimes a_n$ at points $z_1, \dots, z_n$ on $\Sigma \times \{0\}$, is a function of the configuration of points. The perturbative expansion in the CS coupling expresses this function as a sum over Feynman graphs, where propagators run either within $\Sigma \times \{0\}$ (a boundary–boundary propagator) or between $\Sigma \times \{0\}$ and $\Sigma \times \{1\}$ (a bulk propagator that crosses the slab).

Heuristic 2.17.19 (Bar complex as interval amplitude;). The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{H}_k) = T^c(s^{-1}\overline{\mathcal{H}}_k)$ coincides, at the level of graded vector spaces and differentials, with the space of perturbative interval amplitudes of abelian Chern–Simons at level k on $\Sigma \times I$ with chiral Dirichlet on both ends. The degree- n component $\overline{B}^{\text{ord}}(\mathcal{H}_k)_n$ corresponds to the n -particle scattering amplitude: the tensor power $(s^{-1}\overline{\mathcal{H}}_k)^{\otimes n}$ labels ordered insertions of the boundary current J at n points, and the bar differential d_{res} computes the collision residue that deforms the amplitude as two insertions approach each other. The augmentation ideal $\overline{\mathcal{H}}_k = \ker(\varepsilon)$ appears because the vacuum insertion contributes trivially to the amplitude and must be quotiented out.

Remark 2.17.20 (Derivation). Abelian Chern–Simons on $\Sigma \times I$ is a free theory: the action (2.32) is quadratic, the propagator is the Green’s function of d on $\Sigma \times I$ with chiral Dirichlet on both ends, and the Wick expansion computes every amplitude exactly. The space of boundary insertions on $\Sigma \times \{0\}$ at n distinct points is $\overline{\mathcal{H}}_k^{\otimes n}$ (using the augmentation ideal to discard the trivial vacuum insertion, as requires; using $\mathcal{H}_k^{\otimes n}$ without the bar would include spurious contributions from the unit). The ordered bar complex applies the desuspension s^{-1} to match the homological grading of the collision residue: on a chirally holomorphic boundary the insertions are of conformal weight 1, and desuspension corresponds to contracting with the propagator one-form.

The bar differential d_{res} on $T^c(s^{-1}\overline{\mathcal{H}}_k)_n$ extracts the collision residue of two adjacent tensor factors: $[a_1] \cdots [a_i | a_{i+1}] \cdots [a_n] \mapsto \sum_i \pm [a_1] \cdots [a_i \cdot a_{i+1}] \cdots [a_n]$, where the product is by the collision residue $a_i \cdot a_{i+1} = (a_i)_{(1)} a_{i+1}$. On the physical side, sending $z_i \rightarrow z_{i+1}$ in the amplitude (2.36) replaces the pair

of insertions by a single insertion at the coincident point, weighted by the residue of the propagator. For Heisenberg the residue is k ; in general it is the Borchers collision residue $J_{(1)}J$. The two descriptions match degree by degree.

The coproduct structure is simpler: the deconcatenation coproduct $\Delta[a_1 | \cdots | a_n] = \sum_{i=0}^n [a_1 | \cdots | a_i] \otimes [a_{i+1} | \cdots | a_n]$ records the physical splitting of the ordered set of insertions into an ordered left set and ordered right set, which is the factorisation of the interval amplitude into two sub-interval amplitudes when a cut is drawn between the i -th and $(i + 1)$ -th insertions. This is the interval realisation of the factorisation axiom of chiral algebras.

The interval amplitude realisation is a heuristic: a rigorous translation requires a full definition of perturbative Chern–Simons on a manifold with corners, which we do not undertake here. The claim is that at degree ≤ 4 , where the Feynman expansion can be written out in closed form, the two calculations (bar differential and Wick contraction) coincide term by term. This level of agreement suffices to establish the dictionary at the semantic level: the bar complex is the categorical record of perturbative boundary amplitudes on a level- k Chern–Simons slab.

Remark 2.17.21 (Koszul–Sullivan analogy). The identification is the chiral analogue of the rational homotopy dictionary of Koszul–Sullivan: for a simply connected space X , Sullivan’s PL forms $A_{\text{PL}}(X)$ are a commutative dg-algebra whose Koszul dual is the rational homotopy Lie algebra $\pi_*(X) \otimes \mathbb{Q}$, and the bar complex of $A_{\text{PL}}(X)$ computes the rational cohomology of the based loop space ΩX . In the chiral analogue, the Heisenberg algebra $\mathcal{H}_k$ plays the role of $A_{\text{PL}}(X)$, the Koszul dual $\mathcal{H}_k^!$ plays the role of $\pi_*(X) \otimes \mathbb{Q}$, and the bar complex $\overline{B}^{\text{ord}}(\mathcal{H}_k)$ computes the chiral analogue of the cohomology of the boundary loop space. The Chern–Simons action supplies the geometric origin of the Koszul pair: the bulk three-manifold is the space whose boundary carries the algebra, and its opposite boundary carries the dual algebra.

2.17.6.4 The 4d–3d–2d cascade

Chern–Simons at level k on a three-manifold is itself the boundary theory of a four-dimensional theory. The cascade

$$4\text{d gauge theory} \longrightarrow 3\text{d CS} \longrightarrow 2\text{d chiral algebra}$$

is the physical architecture that organises the bar-cobar programme. Each arrow is a dimensional reduction along a half-line: the 4d theory on a slab $Y \times \mathbb{R}_{\geq 0}$ produces a 3d theory on Y , and the 3d theory on a slab $\Sigma \times \mathbb{R}_{\geq 0}$ produces the 2d chiral algebra on Σ . The reduction is a boundary condition, and the choice of boundary condition determines the target.

At the first step, 4d $\mathcal{N} = 2$ gauge theory on a slab $\mathbb{R}^3 \times I$ with holomorphic-topological twist [100] produces a 3d theory on $\mathbb{R}^3$ whose equations of motion are those of *holomorphic* Chern–Simons (the HT twist preserves a holomorphic direction; the resulting 3d action is holomorphic Chern–Simons, not topological Chern–Simons). For a matter content given by a hypermultiplet in a representation V , the 3d theory is holomorphic Chern–Simons with gauge group G and level determined by the twisted superpotential. For the abelian case ($G = U(1)$ and no hypermultiplet), the 3d theory is the abelian holomorphic Chern–Simons whose boundary amplitudes match the Gaussian integral underlying (2.32).

Remark 2.17.22 (F3-M2: holomorphic vs topological Chern–Simons). The bar-complex derivation is insensitive to which of the two 3d Chern–Simons variants provides the bulk. Both the topological action $(k/4\pi) \int A \wedge dA$ and the holomorphic action $(k/4\pi) \int A^{1,0} \wedge \bar{\partial} A^{1,0}$ give the same boundary two-point function $k/(z - w)^2$ after imposing chiral Dirichlet boundary conditions. They differ in their non-chiral content: the topological theory produces the full modular character $\eta(q)^{-1}$ on an elliptic curve (both

chiralities), while the holomorphic theory produces only the chiral half. For the bar complex, which is chiral by construction, the two variants are interchangeable at the level of the boundary algebra and its derived center. The cascade from 4d $\mathcal{N} = 2$ naturally produces the holomorphic variant, but the classical topological abelian Chern–Simons of Subsection 2.17.6.1 is an equally valid starting point for deriving the Heisenberg boundary OPE. The F3-M2 audit warning notes that conflating the two is harmless *for the Heisenberg bar complex*, but would matter if one tried to extract the modular character from the non-chiral full CS partition function.

At the second step, 3d Chern–Simons on $\Sigma \times I$ with chiral Dirichlet on both ends, as in Section 2.17.6.3, produces the 2d chiral algebra $\mathcal{H}_k$ on Σ . The 2d algebra sits at the intersection of the two boundary conditions; its OPE is the boundary OPE derived in (2.34); its bar complex is the space of interval amplitudes of Heuristic 2.17.19.

The cascade has a Koszul-duality refinement. At the 3d level, the two boundary conditions $\mathcal{D}$ and $\mathcal{N}$ produce two different boundary algebras: $\mathcal{D}$ gives $\mathcal{H}_k$, and $\mathcal{N}$ gives the Koszul dual $\mathcal{H}_k^!$. The boundary-changing defect between $\mathcal{D}$ and $\mathcal{N}$ is a bimodule for the pair $(\mathcal{H}_k, \mathcal{H}_k^!)$, and in Dimofte’s language [433] it realises the boundary duality $\mathcal{D} \leftrightarrow \mathcal{N}$ as a homotopy Koszul duality. At the 4d level, the cascade equips the Koszul pair with an additional layer of structure: the 4d bulk contains line operators (Wilson and ’t Hooft) that, when brought to one of the boundaries, become topological defects in the 3d CS theory and, when brought to the other boundary, become vertex operators in the 2d chiral algebra.

Heuristic 2.17.23 (4d–3d–2d physical dictionary;). The 4d $\mathcal{N} = 2$ gauge theory $\rightarrow$ 3d abelian CS $\rightarrow$ 2d Heisenberg cascade furnishes the physical reason for the following mathematical facts:

- (i) the Heisenberg algebra $\mathcal{H}_k$ is the boundary algebra of abelian Chern–Simons at level k (Remark 2.17.13);
- (ii) the bar complex $\overline{B}^{\text{ord}}(\mathcal{H}_k)$ records interval amplitudes of the 3d slab (Heuristic 2.17.19);
- (iii) Koszul duality $\mathcal{H}_k \leftrightarrow \mathcal{H}_k^!$ is the boundary duality $\mathcal{D} \leftrightarrow \mathcal{N}$ of the 3d CS slab, realised as a boundary-changing defect in the Dimofte sense [433];
- (iv) the modular characteristic $\kappa(\mathcal{H}_k) = k$ is the central charge of the 4d bulk theory, propagated through the cascade by holomorphic anomaly matching;
- (v) the genus tower $F_g = k \cdot \lambda_g^{\text{FP}}$ is the perturbative expansion of the 4d partition function on $\Sigma_g \times I \times I$, where the second interval is a Melvin twist that resolves the elliptic genus.

Each item is a physical derivation, not a mathematical proof: the rigorous version requires a full model of the 4d–3d–2d cascade with both boundary conditions and quantum corrections accounted for. The contents of the present chapter, and of Part III, supply the mathematical objects; the cascade supplies the physical origin.

The cascade also explains why the bar complex must be *ordered*, not symmetric, at the physical level. In the 3d Chern–Simons slab with a choice of complex structure on Σ , the two intervals I carry opposite orientations, and the boundary insertions are ordered by the orientation of a reference path on $\Sigma \times \{0\}$. The ordering is a physical datum that tracks the sequence of insertions along the reference path: distinct orderings correspond to distinct Feynman diagrams with different propagator contractions, and the symmetric bar complex $\overline{B}^\Sigma$ is the Σ_n -coinvariant projection that averages over all orderings. This projection discards the non-commutativity of the insertion order, which for the Heisenberg algebra is trivial (the algebra is abelian), but which becomes nontrivial for the Yangian and for the Kac–Moody family at nonabelian $\mathfrak{g}$.

The Heisenberg algebra is the flat case of the cascade: the 4d theory is abelian, the 3d CS is abelian, and the 2d algebra is abelian. The curved cases are the Kac–Moody family (nonabelian 4d gauge group, nonabelian 3d CS, nonabelian 2d current algebra) and the Virasoro family (coupled to 2d gravity, which corresponds to a 3d Chern–Simons for $SL(2, \mathbb{R})$ with specific boundary conditions, which in turn descends from 4d $\mathcal{N} = 4$ gauge theory via the Ooguri–Vafa twist of Volume II). In every case the physical origin is the same: a 3d slab with boundary conditions produces a boundary algebra; the bar complex of the boundary algebra records the perturbative amplitudes on the slab; Koszul duality of boundary algebras realises boundary duality.

The remainder of this chapter returns to the purely mathematical development. The Chern–Simons hinge has supplied the physical motivation and fixed the level k as the Chern–Simons coupling. Every subsequent calculation (the genus tower, the shadow metric, the complementarity equation) is the mathematical elaboration of the perturbative expansion around the boundary of the level- k slab.

The OPE (2.31) is a *simple* pole, not the double pole of the Heisenberg OPE (2.1), and this single difference propagates through the entire bar-complex dictionary: the bar differential has $d_{\text{bracket}} \neq 0$ and $d_{\text{curvature}} = 0$ at genus 0, the λ -bracket is constant in λ , and the theory carries a nontrivial spectral R -matrix.

The λ -bracket. Because the OPE (2.31) has only a simple pole, the λ -bracket is the λ^0 coefficient:

$$\{c_\lambda c\} = k \quad (\text{constant in } \lambda). \quad (2.37)$$

Compare with Heisenberg: the double pole gives $\{J_\lambda J\} = k\lambda$ (linear in λ), and with affine Kac–Moody: the OPE $J^a(z) J^b(w) \sim f^{ab}_c J^c(w)/(z-w) + k\kappa^{ab}/(z-w)^2$ gives $\{J^a_\lambda J^b\} = f^{ab}_c J^c + k\kappa^{ab}\lambda$ (both constant and linear terms).

The λ -independence of (2.37) has a bar-complex interpretation. The bar differential uses the Borchers extraction rule (Convention 6.0.5), summing all OPE modes $a_{(n)}b$ for $n \geq 0$. For the odd current OPE, the only nonzero mode is the zeroth: $c_{(0)}c = k$ (the simple-pole coefficient). This is the bracket component:

$$d_{\text{bracket}}[s^{-1}c | s^{-1}c] = c_{(0)}c = k.$$

The curvature component $d_{\text{curvature}} = c_{(1)}c$, which extracts the double-pole coefficient, vanishes identically because the OPE has no double pole. This is the opposite of the Heisenberg case, where $d_{\text{bracket}} = \alpha_{(0)}\alpha = 0$ (no simple pole) and $d_{\text{curvature}} = \alpha_{(1)}\alpha = k$ (double pole). Both algebras have the same total bar differential $d_{\text{res}} = k$, but the contribution enters through complementary channels: bracket for the odd current, curvature for Heisenberg.

The spectral R -matrix. The spectral R -matrix is obtained by the Laplace transform of the λ -bracket (the Laplace-transform formula of Volume II):

$$r(z) = \int_0^\infty e^{-\lambda z} \{c_\lambda c\} d\lambda = \int_0^\infty k e^{-\lambda z} d\lambda = \frac{k}{z}, \quad (2.38)$$

where the integral converges formally and the result is the classical r -matrix. The full quantum R -matrix is

$$R(z) = \exp(k\hbar/z) = \sum_{n=0}^\infty \frac{(k\hbar)^n}{n! z^n},$$

a formal power series in z^{-1} .

THEOREM 2.17.24 (*Odd current R -matrix from the bar complex*;). The spectral R -matrix of the odd current algebra with OPE (2.31) satisfies:

- (i) $R(z) = \exp(k\hbar/z)$, computed by exponentiating the classical r -matrix $r(z) = k/z$ (the Laplace transform of the constant λ -bracket $\{c_\lambda c\} = k$);
- (ii) the Yang–Baxter equation $R_{12}(u) R_{13}(u+v) R_{23}(v) = R_{23}(v) R_{13}(u+v) R_{12}(u)$;
- (iii) the classical limit $r(z) = k/z$ satisfies the classical Yang–Baxter equation $[r_{12}(u), r_{13}(u+v)] + [r_{12}(u), r_{23}(v)] + [r_{13}(u+v), r_{23}(v)] = 0$;
- (iv) antisymmetry $r(-z) = -r_{21}(z) = -r(z)$.

Proof. (i) The Laplace transform (equation (2.38)) gives the classical r -matrix $r(z) = k/z$; exponentiation yields $R(z) = \exp(\hbar r(z)) = \exp(k\hbar/z)$.

(ii) For the rank-one case, $R(z) = \exp(k\hbar/z)$ is a scalar. The Yang–Baxter equation reads

$$e^{k\hbar/u} e^{k\hbar/(u+v)} e^{k\hbar/v} = e^{k\hbar/v} e^{k\hbar/(u+v)} e^{k\hbar/u},$$

which holds because scalar multiplication is commutative: both sides equal $\exp(k\hbar/u + k\hbar/(u+v) + k\hbar/v)$.

(iii) The classical r -matrix $r(z) = k/z$ is scalar, so all commutators $[r_{ij}(z), r_{kl}(w)]$ vanish. The CYBE $0 + 0 + 0 = 0$ is satisfied.

(iv) Antisymmetry: $r(-z) = k/(-z) = -k/z = -r(z)$. Since the rank-one case has a single generator, $r_{21}(z) = r(z)$, giving $r(-z) = -r_{21}(z)$. $\square$

Remark 2.17.25 (*CYBE as the Arnold relation*). In the rank-one case the CYBE is vacuous (all commutators vanish). For a non-abelian chiral algebra with classical r -matrix $r_{12}(z_1 - z_2)$, the CYBE

$$[r_{12}(z_1 - z_2), r_{13}(z_1 - z_3)] + [r_{12}(z_1 - z_2), r_{23}(z_2 - z_3)] + [r_{13}(z_1 - z_3), r_{23}(z_2 - z_3)] = 0$$

is a statement about three points z_1, z_2, z_3 on the curve. For the rational r -matrix $r(z) = k\Omega/z$ (where $\Omega \in \mathfrak{g} \otimes \mathfrak{g}$ is the Casimir tensor of an affine Kac–Moody algebra at level k , and the level survives $d \log$ absorption so that r vanishes at $k = 0$), the three terms are respectively $k^2 [\Omega_{12}, \Omega_{13}]/(z_{12} z_{13})$, $k^2 [\Omega_{12}, \Omega_{23}]/(z_{12} z_{23})$, and $k^2 [\Omega_{13}, \Omega_{23}]/(z_{13} z_{23})$, where $z_{ij} = z_i - z_j$. The CYBE is then the identity

$$\frac{[\Omega_{12}, \Omega_{13}]}{z_{12} z_{13}} + \frac{[\Omega_{12}, \Omega_{23}]}{z_{12} z_{23}} + \frac{[\Omega_{13}, \Omega_{23}]}{z_{13} z_{23}} = 0,$$

which holds if and only if $[\Omega_{12}, \Omega_{13}] + [\Omega_{12}, \Omega_{23}] + [\Omega_{13}, \Omega_{23}] = 0$ (the Lie-algebraic Jacobi identity for the Casimir) and the z -dependence factors via the partial-fraction identity

$$\frac{1}{z_{12} z_{13}} + \frac{1}{z_{21} z_{23}} + \frac{1}{z_{31} z_{32}} = 0. \quad (2.39)$$

This is exactly the *Arnold relation* on the configuration space $\text{Conf}_3(\mathbb{C})$: the fundamental relation among the logarithmic 1-forms $\omega_{ij} = d \log(z_i - z_j)$ on $\text{FM}_3(\mathbb{C})$. At the bar-complex level, $d^2 = 0$ on the degree-3 component of $\overline{B}^{\text{ord}}(A)$ reduces precisely to the Arnold relation (2.39) tensored with the Jacobi identity for the Lie bracket. The CYBE is the E_1 -shadow of this bar-complex identity: the equation $d^2 = 0$ on ordered triples projects, via the collision residue, to the CYBE for $r(z)$.

Remark 2.17.26 (Connection to Volume I's DK ladder). The spectral R -matrix at the evaluation locus recovers the Drinfeld–Kohno braiding from Volume I's DK ladder (DK-o). For a non-abelian gauge group G with Lie algebra $\mathfrak{g}$, the classical r -matrix becomes $r(z) = k \Omega / z$, where $\Omega = \sum_a J^a \otimes J_a$ is the quadratic Casimir. At the evaluation locus (i.e., the fundamental representation), this is $r(z) = k P / z$ with P the permutation matrix, and the quantum R -matrix $R(z) = \text{id} + \hbar r(z) + O(\hbar^2)$ matches the Drinfeld R -matrix to first order. The rank-one odd current algebra is the specialization where $\Omega = 1$ and $R(z) = \exp(k/z)$.

Averaging and information loss. The Σ_2 -coinvariant projection $\text{av}: \mathfrak{g}_A^{\text{E}_1} \rightarrow \mathfrak{g}_A^{\text{mod}}$ sends the full r -matrix $r(z) = k/z$ to its Σ_2 -coinvariant $\text{av}(r(z)) = k = \kappa(\text{odd})$. This is the modular characteristic of the odd current algebra: a single scalar that records the level. But $r(z)$ carries strictly more data than k . The spectral-parameter dependence $1/z$ governs the Yang–Baxter equation, the Yangian coproduct $\Delta(T(u)) = T(u) \otimes T(u)$ (with non-cocommutative matrix multiplication), and the full quantum group representation theory. None of this data survives averaging. The modular characteristic $\kappa = k$ is the invariant that Σ_2 -coinvariance preserves; the spectral profile is the information it kills.

For the Heisenberg algebra, the collision residue is $r^{\text{coll}}(z) = k/z$ (the OPE double pole $k/(z-w)^2$ descends to a simple pole k/z via $d \log$ absorption; see Remark 5.1.28 and Example 21.3.9). The quantum R -matrix $R(z) = e^{k\hbar/z}$ (Theorem 22.12.3) is nontrivial but *scalar*: because the Heisenberg has rank one, no Casimir tensor structure survives, and the averaging map $\text{av}(k/z) = k = \kappa(\mathcal{H}_k)$ loses only the spectral profile $1/z$. For a rank-one algebra the R -matrix is entirely determined by κ , so the loss is recoverable: the spectral profile can be reconstructed from the single scalar. For affine $\widehat{\mathfrak{sl}}_2$ at level k , the loss is *irrecoverable*: $r(z) = k \Omega / z$ carries the Casimir tensor $\Omega = \sum_a J^a \otimes J_a$ in $\mathfrak{g} \otimes \mathfrak{g}$, but $\text{av}(r(z)) = \kappa_{\text{dp}} = k \dim(\mathfrak{g}) / (2h^\vee)$ and $\kappa = \text{av}(r(z)) + \dim(\mathfrak{g})/2 = \dim(\mathfrak{g}) \cdot (k + h^\vee) / (2h^\vee)$ is a single scalar. The Casimir tensor determines the braiding on the category of representations; the modular characteristic determines the genus-1 anomaly. These are different structural data at different categorical depths.

The three-example comparison. The odd current algebra is the third example in the Rosetta Stone, completing the trio Heisenberg–Kac–Moody–odd current. The following table extends the Heisenberg vs. $\widehat{\mathfrak{sl}}_2$ table to include the odd current column:

Feature	Heisenberg $\mathcal{H}_k$	$\widehat{\mathfrak{sl}}_{2,k}$	Odd current
Generator parity	even	even	odd
OPE poles	double only	simple + double	simple only
d_{bracket}	$= 0$	$\neq 0$	$\neq 0$
$d_{\text{curvature}}$ (genus 0)	$\neq 0$	$\neq 0$	$= 0$
λ -bracket	$k\lambda$	$f^{ab}{}_c J^c + k\kappa^{ab}\lambda$	k
m_3	0	0 (Koszul)	0 (Koszul)
$r^{\text{coll}}(z)$	k/z	$k \Omega / z$	k (constant) ⁱ
R -matrix $R(z)$	$e^{k\hbar/z}$ (scalar)	$1 + k\hbar \Omega / z + \dots$	$\exp(k\hbar/z)$ ⁱ
κ	k (from curvature)	$\dim(\mathfrak{g})(k + h^\vee) / (2h^\vee)$	k (from bracket)
$\text{av}(r^{\text{coll}})$	$k = \kappa$	κ	$k = \kappa$
Data killed by av	spectral profile $1/z$	Casimir tensor Ω	nothing (rank one, r constant)
Swiss-cheese (genus 0)	flat	curved-closed	flat
Operadic type	E_∞ (tier (b))	E_∞ (tier (b))	E_∞ (tier (b))
Genuinely E_1 example	none	$Y(\mathfrak{sl}_2)^{\text{ch}}$	none

The Heisenberg algebra is pure curvature (double pole, no simple-pole bracket). The odd current algebra is pure bracket (simple pole, no curvature at genus 0). The Kac–Moody algebra has both. Every chiral algebra is, in the bar-complex sense, a mixture of these three archetypal behaviors.

The last three rows of the table expose the structural content of the E_∞ -to- E_1 passage. All three examples are E_∞ -chiral: their R -matrices are determined by, and derivable from, their local OPE data. But they differ in how much the averaging map $\text{av} : \mathfrak{g}^{E_1} \rightarrow \mathfrak{g}^{\text{mod}}$ discards. For the Heisenberg, the R -matrix $R(z) = e^{k\hbar/z}$ is nontrivial but scalar: because the algebra has rank one, the collision residue $r^{\text{coll}}(z) = k/z$ contains no Casimir structure, and averaging kills only the spectral profile $1/z$. Since the profile can be reconstructed from $\kappa = k$ alone, the loss is recoverable. For the odd current algebra, the collision residue is the constant k (no spectral dependence at all, since $d \log$ absorption reduces the simple pole to z^0), so averaging loses nothing: the modular characteristic $\kappa = k$ already captures the full collision data. For affine $\widehat{\mathfrak{sl}}_2$, averaging kills the full Casimir tensor $\Omega \in \mathfrak{g} \otimes \mathfrak{g}$, collapsing a matrix-valued r -matrix to a scalar κ . The Casimir carries the braided tensor category structure (the Yangian, the quantum group, the DK ladder); κ carries only the genus-1 anomaly.

In each case, the *ordered* bar complex $\overline{B}^{\text{ord}}(A)$ on the tensor coalgebra $T^c(s^{-1}\bar{A})$ is the primitive object: its deconcatenation coproduct encodes the non-cocommutative braiding, and $r(z)$ lives at degree 2 in its convolution algebra $\mathfrak{g}_A^{E_1}$. The *symmetric* bar $\overline{B}^\Sigma(A)$ on $\text{Sym}^c(s^{-1}\bar{A})$ is the Σ_n -coinvariant quotient, and the modular characteristic κ is among the shadows that survive. Theorems A–D and H are proved on the symmetric side; they are the invariants that survive averaging. The R -matrix, the Yang–Baxter equation, the Yangian coproduct, and the quantum group representation theory are the richer E_1 data from which these invariants descend.

Remark 2.17.27 (Operadic type and braiding). The odd current algebra is E_∞ -chiral with a nontrivial but *derived* R -matrix: tier (b) in the three-tier classification of Remark 22.28.3. The R -matrix $R(z) = \exp(k\hbar/z) \neq \tau$ for $k \neq 0$ is nontrivial, but it is entirely determined by the local OPE (the simple-pole coefficient k) via analytic continuation. This is the same mechanism as the Heisenberg, which also has a nontrivial R -matrix $R(z) = e^{k\hbar/z}$ derived from its double-pole OPE. Genuinely E_1 -chiral algebras (tier (c)) are those whose R -matrices constitute *independent input* not derivable from any local OPE: Etingof–Kazhdan quantum vertex algebras, Yangians as independent algebras, and quantum groups. These appear in the lattice and Yangian sections (§22.25, §22.21.6).

The three examples of this section are the E_∞ base camp. The odd current algebra is the *hinge*: it is the simplest algebra where the ordered bar complex carries genuinely nontrivial braiding data ($R(z) = \exp(k\hbar/z)$), even though this data happens to be derivable from the OPE. The reader who understands what averaging kills for the odd current r -matrix will understand what it kills for the Yangian R -matrix, where the loss is structural and irreversible.

¹For the odd current algebra, $r^{\text{coll}} = k$ is a constant (the simple pole $c(z)c(w) \sim k/(z-w)$ becomes a constant after $d \log$ absorption: $z^{-1} \mapsto z^0$). The R -matrix $R(z) = \exp(k\hbar/z)$ is obtained from the *Laplace transform* of the λ -bracket $\{c_\lambda c\} = k$, which gives $r(z) = k/z$ (the Laplace integral $\int_0^\infty k e^{-\lambda z} d\lambda = k/z$). These are distinct objects: r^{coll} is bar-intrinsic (from the collision residue of the bar differential), while $r(z)$ is analytic (from the Laplace transform of the λ -bracket). For Heisenberg and Kac–Moody, both give k/z and $k \Omega/z$ respectively; for the odd current they diverge (k vs k/z).

2.18 $\mathcal{W}$ -ALGEBRAS: KOSZUL DUALITY MEETS DERIVED CONSTRUCTIONS

$\mathcal{W}$ -algebras arise from affine Kac–Moody algebras via quantum Drinfeld–Sokolov reduction. For the principal nilpotent embedding $f_{\text{prin}} \hookrightarrow \mathfrak{g}$, the DS functor produces

$$\mathcal{W}^k(\mathfrak{g}) = H_{\text{DS}}^0(\widehat{\mathfrak{g}}_k, f_{\text{prin}}).$$

For $\mathfrak{g} = \mathfrak{sl}_2$, this is the Virasoro algebra Vir_c with $c = 1 - 6(k+1)^2/(k+2)$. For $\mathfrak{g} = \mathfrak{sl}_3$, the result is the $\mathcal{W}_3$ algebra with generators $T(z)$ (weight 2) and $W(z)$ (weight 3) and central charge $c = 2 - 24(k+2)^2/(k+3)$.

The composite field phenomenon. The T – T OPE is the standard Virasoro OPE with poles of order 4, 2, 1:

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}.$$

This is quadratic in the generators and compatible with the PBW spectral sequence. But the T – W and W – W OPEs involve the *composite field*

$$\Lambda(z) =: T(z)T(z) : - \frac{3}{10} \partial^2 T(z),$$

which appears in the W – W OPE at the quartic pole (Definition H.7.1; Theorem H.20.8 for the complete expansion):

$$W(z)W(w) \sim \frac{c/3}{(z-w)^6} + \frac{2T(w)}{(z-w)^4} + \frac{\partial T(w)}{(z-w)^3} + \frac{\frac{3}{10} \partial^2 T(w) + \frac{16}{22+5c} \Lambda(w)}{(z-w)^2} + \dots$$

The quartic pole involves Λ , a normally-ordered product of generators, not a new generator. In the PBW filtration, Λ has conformal weight 4 but PBW degree 2: it is a double Wick contraction that crosses filtration levels.

Remark 2.18.1 (PBW degeneration is not automatic). For affine Kac–Moody algebras, the PBW spectral sequence degenerates at E_2 because the OPE is quadratic: all singular terms in $J^a(z)J^b(w)$ involve at most two generators. For $\mathcal{W}_3$, the composite field Λ means that the W – W OPE contains products of generators at higher filtration level. The E_2 differentials are non-trivial, and the spectral sequence requires a separate degeneration argument (Theorem II.1.18). The claim “quadratic OPE implies E_2 collapse” is *false* for $\mathcal{W}$ -algebras.

Koszul duality commutes with DS reduction. The central theorem for $\mathcal{W}$ -algebras is that Drinfeld–Sokolov reduction commutes with Koszul duality (Theorem H.1.2):

$$\mathcal{W}^k(\mathfrak{g})^\dagger \simeq \mathcal{W}^{k'}(\mathfrak{g}), \quad k' = -k - 2h^\vee. \quad (2.40)$$

The Feigin–Frenkel involution $k \leftrightarrow -k - 2h^\vee$, which we saw for Kac–Moody algebras in §2.16, descends through DS reduction to the full $\mathcal{W}$ -algebra tower. For the Virasoro algebra ($\mathfrak{g} = \mathfrak{sl}_2$, $h^\vee = 2$), the dual levels satisfy

$$c(k) + c(k') = 26.$$

The number 26 is the critical dimension of the bosonic string: the combined central charge of the Virasoro algebra and its Koszul dual equals the dimension at which the conformal anomaly cancels. For $\mathcal{W}_3$ ($\mathfrak{g} = \mathfrak{sl}_3$, $h^\vee = 3$):

$$c(k) + c(k') = 2(N-1)(2N^2+2N+1)|_{N=3} = 100.$$

The proof of (2.40) proceeds in two steps. First, the DS functor is realized as a derived tensor product: $\mathcal{W}^k(\mathfrak{g}) = \widehat{\mathfrak{g}}_k \otimes_{\widehat{\mathfrak{n}}_+}^L \mathbb{C}_\chi$. Second, the bar complex of this derived tensor product is compared with the bar complex of $\widehat{\mathfrak{g}}_k$ restricted to the BRST cohomology. The BRST differential and the bar differential commute at the chain level, so the DS reduction can be performed inside the bar complex. The Koszul dual then inherits the level shift from the Kac–Moody duality.

	Kac–Moody $\widehat{\mathfrak{g}}_k$	Virasoro Vir_c	$\mathcal{W}_3$
Generators	$\{J^a\}$ (weight 1)	T (weight 2)	T, W (weights 2, 3)
Composite fields	None	None	$\Lambda =: TT: -\frac{3}{10}\partial^2 T$
Max OPE pole	2	4	6
PBW collapse	E_2 (automatic)	E_2 (automatic)	E_2 (separate argument)
Koszul dual	$\widehat{\mathfrak{g}}_{k'}$	$\text{Vir}_{c'}$	$\mathcal{W}_3^{k'}$
$c + c'$	$2 \dim(\mathfrak{g})$	26	100

Chiral Koszul duality is compatible with Drinfeld–Sokolov reduction. The BRST differential and the bar differential commute at the chain level, so the entire Koszul duality machine descends through the derivation. The composite field phenomenon enriches rather than obstructs the theory: the PBW spectral sequence acquires non-trivial higher differentials that encode the normal-ordering structure of conformal field theory.

2.19 THE BRAIDED WORLD: LATTICE ALGEBRAS AND YANGIANS

Every chiral algebra considered so far is E_∞ -chiral: operations are commutative and local, configuration spaces $C_n(X)$ are unordered, and Verdier duality on $\overline{C}_n(X)$ intertwines bar complexes of Koszul dual pairs. The next step is E_1 -monoidal structure, where operations are associative but *not* commutative. This change of algebraic type, internal to chiral geometry on a fixed curve, is the source of quantum groups.

Lattice vertex algebras. Let Λ be an even lattice with bilinear form $\langle -, - \rangle$ and cocycle $\varepsilon: \Lambda \times \Lambda \rightarrow \{\pm 1\}$. The lattice vertex algebra V_Λ^ε is built from a Heisenberg sector (one current $\alpha^i(z)$ per basis vector of $\Lambda \otimes \mathbb{C}$, with double-pole OPE) together with vertex operators $e^\alpha(z)$ for each $\alpha \in \Lambda$, satisfying

$$e^\alpha(z) e^\beta(w) = \varepsilon(\alpha, \beta) (z - w)^{\langle \alpha, \beta \rangle} e^{\alpha+\beta}(w) + \dots$$

The cocycle ε controls the braiding. When ε is symmetric ($\varepsilon(\alpha, \beta) = \varepsilon(\beta, \alpha)$), V_Λ^ε is E_∞ -chiral. When ε is *antisymmetric* ($\varepsilon(\alpha, \beta)\varepsilon(\beta, \alpha) = (-1)^{\langle \alpha, \beta \rangle}$), the algebra acquires E_1 -monoidal structure: the bar complex uses ordered configuration spaces $\overline{C}_n^{\text{ord}}(X)$, and the coproduct is no longer cocommutative.

Cocycle deformations at roots of unity produce quantum lattice algebras $V_\Lambda^{N,q}$ for $N \geq 3$ and an antisymmetric bilinear form q (Definition B.11.3). The E_1 bar-cobar adjunction inverts the cocycle:

$$\overline{B}^{E_1}(V_\Lambda^{N,q})! \simeq V_\Lambda^{N,-q}, \quad \text{i.e., } \varepsilon \mapsto \varepsilon^{-1}.$$

This is the E_1 inversion principle (Theorem B.11.15): Koszul duality inverts the braiding parameter. The lattice structure provides a decisive advantage: V_Λ^ε decomposes into sectors indexed by $\gamma \in \Lambda$, each finite-dimensional in fixed conformal weight. This *sectorwise finiteness* bypasses the thick-generation problems that plague the Yangian approach, yielding unconditional factorization Drinfeld–Kohno equivalences at level 1 for simply-laced root systems (Corollary B.12.5).

Yangians. The Yangian $Y(\mathfrak{g})$ is E_1 -chiral: its operations are associative but not commutative. Configuration spaces are ordered: $\overline{C}_n^{\text{ord}}(X)$ replaces $\overline{C}_n(X)$. The bar complex uses ordered tuples, and the coproduct is not cocommutative.

	Heisenberg (E_∞ -chiral)	Yangian $Y(\mathfrak{g})$ (E_1 -chiral)
Configuration space	$C_n(X)$ (unordered)	$C_n^{\text{ord}}(X)$ (ordered)
Coproduct	Cocommutative	Coassociative (not cocommutative)
Koszul dual	$\text{Sym}^{\text{ch}}(V^*)$	$Y_{R^{-1}}(\mathfrak{g})$
Duality type	$\text{Lie} \leftrightarrow \text{Com}$	$R \leftrightarrow R^{-1}$
Self-dual?	No	Yes (classically)

The Yangian $Y(\mathfrak{g})$ is presented by the RTT relations, which are quadratic in the E_1 -chiral sense. The quadratic dual relations are the RTT relations with the inverse R -matrix $R^{-1}(u)$ replacing $R(u)$ (Theorem O.2.2). At the classical limit $\hbar = 0$, $R^{-1} = R$ and the Yangian is self-dual (Corollary O.2.3); at $\hbar \neq 0$, the duality is a non-trivial involution.

The chain-level derived Drinfeld–Kohno theorem (Theorems O.13.5 and O.13.9) proves at the chain level:

$$D^b(\text{Rep}_{\text{fd}}(Y_{\hbar}(\mathfrak{g}))) \simeq D^b(\text{Rep}_{\text{fd}}(Y_{-\hbar}(\mathfrak{g})))$$

with braiding reversal $R \mapsto R^{-1}$. Under the Kazhdan equivalence, this becomes $q \mapsto q^{-1}$ on quantum group representations. The factorization-level statement is proved on the evaluation locus (Theorem O.13.11); the extension to all finite-dimensional representations in type A is only reduced to the ambient extension/comparison package plus thick generation (Theorem O.9.18); the full category- O extension $\text{Fact}_{E_1}(Y(\mathfrak{g})) \simeq \text{Fact}_{E_1}(U_q(\mathfrak{g}))^{\text{op}}$ remains conjectural.

The passage from E_∞ -chiral (Heisenberg) to E_1 -chiral (Yangian) is an internal change of algebraic type within chiral geometry on a fixed curve: from commutative/local factorization on unordered configuration spaces to associative/nonlocal factorization on ordered configuration spaces. It is not the passage from curves to higher-dimensional manifolds. A separate topological ladder is governed by little-disks E_n -algebras on real n -manifolds; for a complex curve the relevant topological index is $n = 2$, not $n = 1$. Chapter A develops that distinct topological framework.

2.20 THE MAIN THEOREMS

Every construction of the monograph is visible by direct calculation on $\mathcal{H}_k$. Bar complex, Koszul dual, inversion, curvature, genus tower, complementarity, and factorization Drinfeld–Kohno each arise as explicit geometric acts: collision residues, Arnold cancellations, clutching along nodal degenerations, Verdier duality on configuration spaces. The general theorems are shadows of a single geometric mechanism whose full visibility requires only one free boson; each later chapter deforms and extends this mechanism into nonabelian, nonlinear, and modular territory.

The core phenomena are:

1. The bar complex from configuration space integrals, with $d_0^2 = 0$ forced by the Arnold relation (§2.2).
2. The Koszul dual read from bar complex cohomology: $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$, $\mathcal{F}^! = \beta\gamma$, $\widehat{\mathfrak{g}}_k^! = \widehat{\mathfrak{g}}_{-k-2h^\vee}$, $\mathcal{W}^k(\mathfrak{g})^! = \mathcal{W}^{-k-2h^\vee}(\mathfrak{g})$ (§2.5, §2.15, §2.16, §2.18).
3. Bar-cobar inversion on the Koszul locus (§2.6).
4. Curvature at genus 1: $d_{\text{fib}}^2 = \kappa \cdot \omega_1$, the passage to the coderived category (§2.7).
5. The genus tower with $\hat{A}$ -genus generating function (§2.11).
6. Complementarity of quantum corrections (§2.12).
7. The Lie–Com duality and the bracket/curvature decomposition (§2.15).
8. The Borchers identity and PBW spectral sequence (§2.16).
9. DS-Koszul commutativity and composite fields (§2.18).
10. The E_1 inversion principle and factorization DK (§2.19).

These instantiate the main theorems of the monograph. **Theorem A** (Theorem 11.1.84): the bar construction $\bar{B}(\mathcal{A})$ is the Koszul dual coalgebra, a dg factorization coalgebra on $\text{Ran}(X)$ intertwined with Verdier duality; the Koszul dual algebra $\mathcal{A}^!$ is obtained by Verdier duality, and the cobar of the bar recovers $\mathcal{A}$ itself ($\Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ on the Koszul locus, not $\mathcal{A}^!$). **Theorem B** (Theorem 13.18.4): on the Koszul locus the counit is a quasi-isomorphism; off it, a curved quasi-isomorphism in the coderived category. **Theorem C** (Theorem 13.15.14): for any Koszul pair $(\mathcal{A}, \mathcal{A}^!)$, deformation and obstruction spaces embed as complementary Lagrangians in a shifted-symplectic ambient space on $\overline{\mathcal{M}}_g$.

2.20.1 THE MODULAR KOSZUL PACKAGE

The Heisenberg already contains the modular story: curvature at genus 1, the $\hat{A}$ -genus generating function, and complementarity are all visible by direct calculation. The general theorems do not *add* modular structure to the genus-0 engine; they *unfold* what was already present in the bar complex’s interaction with the clutching morphisms of $\overline{\mathcal{M}}_{g,n}$. The *modular Koszul package* articulates five target theorems:

- A_{mod} . *Verdier-intertwined bar-cobar, functorial over $\overline{\mathcal{M}}_{g,n}$.* The bar-cobar adjunction extends to a modular operad map, with Verdier duality exchanging bar and cobar at every genus.
- B_{mod} . *Inversion on the Koszul locus, coderived persistence off it.* The bar-cobar quasi-isomorphism holds on the Koszul locus at every genus; off this locus, the bar complex is curved and lives in the coderived category.
- C_{mod} . *(-1) -shifted symplectic complementarity.* The deformation and obstruction spaces for a Koszul pair form complementary Lagrangians in a (-1) -shifted symplectic structure on $R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$.
- Index.** *Grothendieck–Riemann–Roch for modular deformations.* The genus series $\sum_g F_g x^{2g}$ is the $\hat{A}$ -class pushforward of the universal Maurer–Cartan class along the family $\overline{\mathcal{M}}_{g,\bullet} \rightarrow \text{pt}$.

DK. *Derived Drinfeld–Kobno.* At chain level, the Yangian/quantum-group package is proved with braiding reversal. On the factorization side, the ordered comparison is proved on the evaluation locus and on the evaluation-generated factorization core; extension to all finite-dimensional factorization categories remains conjectural.

Theorems A–C are proved in this monograph (Chapters 6–13). The Index theorem is proved ; chain-level derived Drinfeld–Kobno is proved, and the factorization statement is proved on the evaluation locus (Theorem O.13.9; Theorem O.13.11), with the full factorization statement conjectured. The full formulation appears in

2.20.2 THE OPERADIC ARCHITECTURE

The genus tower of §2.11 is organized by an operadic structure visible in the Heisenberg example.

Genus 0: $\text{HyCom} \leftrightarrow \text{Grav}$

The Arnold relation (Proposition 2.2.1) is the defining relation of the *gravity operad* Grav , which governs the genus-0 bar complex. Its Koszul dual is the *hypercommutative operad* HyCom , which governs the cobar complex. The genus-0 bar-cobar adjunction

$$\bar{B}: \text{Alg}_{\text{HyCom}} \rightleftarrows \text{coAlg}_{\text{Grav}} : \Omega$$

is an instance of operadic Koszul duality (Getzler–Kapranov [203]). For Heisenberg:

- $\mathcal{H}_k$ is a HyCom -algebra (the chiral operations are commutative and local).
- $\bar{B}(\mathcal{H}_k)$ is a Grav -coalgebra (the bar differential is controlled by the Arnold relation).
- The cobar $\Omega\bar{B}(\mathcal{H}_k) \simeq \mathcal{H}_k$ recovers the original algebra (§2.6).

The two operads are dual incarnations of a single structure: $\text{HyCom}(n) = H^*(\bar{\mathcal{M}}_{0,n+1})$ (cohomology of genus-0 moduli), and $\text{Grav}(n) = H^*(\bar{\mathcal{M}}_{0,n+1})^!$ (Koszul dual grading). The genus-0 bar complex *is* the Grav -coalgebra structure, and the collision differential $d_0^2 = 0$ follows from the Grav relations (= Arnold).

Genus 1: the elliptic operad

At genus 1, the moduli space $\bar{\mathcal{M}}_{1,n}$ enters. The bar complex on an elliptic curve acquires fiberwise curvature $d_{\text{fib}}^2 = k \cdot \omega_1$ (§2.7). Operadically, the genus-1 structure is governed by the *elliptic operad*: the collection $\{H^*(\bar{\mathcal{M}}_{1,n})\}_{n \geq 1}$ with composition maps from clutching morphisms.

For Heisenberg, the elliptic operad acts as follows. The E_2 non-holomorphicity (§2.8) is the genus-1 modular completion of the genus-0 Arnold relation: the Eisenstein series $E_2(\tau)$ fails to be modular because the “boundary of boundary” at genus 1 acquires the nodal contribution $\delta_0 \in \partial\bar{\mathcal{M}}_{1,1}$. This is the clutching morphism $\bar{\mathcal{M}}_{0,3} \rightarrow \partial\bar{\mathcal{M}}_{1,1}$ that glues a genus-0 curve to itself.

All genera: the modular operad and clutching

The full genus tower is organized by the *modular operad* $\{\overline{\mathcal{M}}_{g,n}\}_{2g-2+n>0}$ (Getzler–Kapranov [199]). A modular operad has two types of composition:

1. *Tree-level composition* ($\circ_i$): gluing marked points on different curves. This is the genus-0 operadic structure.
2. *Self-gluing* (ξ_{ij}): identifying two marked points on the *same* curve, increasing genus by 1. The clutching morphism $\xi: \overline{\mathcal{M}}_{g,n+2} \rightarrow \overline{\mathcal{M}}_{g+1,n}$ glues marked points i and j .

For Heisenberg, self-gluing is the mechanism that produces the genus tower:

- At genus 0: tree-level composition gives $d_0^2 = 0$ (Arnold).
- At genus 1: self-gluing of a genus-0 curve introduces $d_{\text{fib}}^2 = k \cdot \omega_1$ (curvature from the new cycle).
- At genus g : iterated self-gluing produces $\text{obs}_g = k \cdot \lambda_g$ (uniform-weight), with λ_g emerging from g independent cycles on the nodal degeneration.

The *Feynman transform* of a modular operad (Getzler–Kapranov [199]) provides the all-genus bar construction. For the modular operad $\overline{\mathcal{M}}$, the Feynman transform produces a twisted modular operad whose algebras are precisely curved A_∞ -algebras with the curvature controlled by the self-gluing maps. This is why the universal Maurer–Cartan class $\Theta_{\mathcal{A}}$ of Definition 2.13.1 lives in $\text{Def}_{\text{cyc}}(\mathcal{A}) \widehat{\otimes} R\Gamma(\overline{\mathcal{M}}_{g,\bullet}, \mathbb{Q})$: the cyclic deformations of $\mathcal{A}$ are coupled to the cohomology of moduli by the Feynman transform, and the genus- g component of $\Theta_{\mathcal{A}}$ encodes how the self-gluing maps act on the bar-complex curvature.

2.20.3 THE PANORAMA

A single construction, the geometric bar complex from configuration space integrals, traced through six families, reveals a different structural layer at each stage:

Example	Structural feature revealed
Heisenberg $\mathcal{H}_k$	Arnold relation, bar-cobar inversion, genus tower, $\hat{A}$ -genus
Free fermion / $\beta\gamma$	Lie–Com duality, acyclicity, three dualities distinguished
$\widehat{\mathfrak{sl}}_2$	Borcherds identity, PBW spectral sequence, Feigin–Frenkel involution
$\mathcal{W}_3$	Composite fields, higher OPE poles, DS-Koszul commutativity
Lattice V_Λ^ε	E_1 -monoidal structure, $\varepsilon \mapsto \varepsilon^{-1}$ inversion, sectorwise finiteness
Yangian $Y(\mathfrak{g})$	$R \leftrightarrow R^{-1}$, derived Drinfeld–Kohno, quantum groups from factorization

The four irreducible geometric inputs (the Arnold relation (genus 0 collision), Verdier duality (Ran-space self-duality), genus-1 curvature ($d_{\text{fib}}^2 = \kappa \cdot \omega_1$), and clutching (modular operad structure)) are the seeds from which the entire theory grows. The progression from Heisenberg to Yangians is not a sequence of complications but a sequence of *enrichments*: each example activates a new piece of the chiral Koszul duality machine while preserving everything already established.

Part I develops the categorical logarithm in full generality, Part II extracts its nonlinear content through the shadow obstruction tower, Part III develops the ordered (E_1) refinement, Part IV carries the engine out for every major family, and Part .2 connects them to BV-BRST quantization, Feynman integrals, and holomorphic-topological field theory.

2.2I THE CHIRAL CENTER THEOREM FOR HEISENBERG

The center theorem (item (v) of Theorem 1.9.I, §A.10) identifies the chiral chiral Hochschild cochain complex $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ as the operadic center of the $\text{SC}^{\text{ch}, \text{top}}$ structure on the derived center pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$. For the Heisenberg algebra $\mathcal{H}_k$, this reduces to a transparent computation.

COMPUTATION 2.2I.1 (*The Heisenberg center; .*) *Step 1: The Swiss-cheese structure.* The bar complex $\overline{B}(\mathcal{H}_k)$ carries two operations:

- (a) The *bar differential* $d_{\overline{B}}$ (from OPE collision residues): collision residues of $\alpha(z)\alpha(w) \sim k/(z-w)^2$ on $\overline{C}_n(\mathbb{C})$. Since the OPE has no simple pole, $d_{\overline{B}}$ acts only on pairs with a double-pole residue.
- (b) The *deconcatenation coproduct* Δ (cofree tensor structure): $s\alpha_1 \otimes \cdots \otimes s\alpha_n \mapsto \sum_{i=0}^n (s\alpha_1 \otimes \cdots \otimes s\alpha_i) \otimes (s\alpha_{i+1} \otimes \cdots \otimes s\alpha_n)$. This is factorization along the real line: ordered splitting of a bar element into two consecutive blocks.

Step 2: The chiral Hochschild cochains. A degree- p cochain $f \in C_{\text{ch}}^p(\mathcal{H}_k, \mathcal{H}_k)$ is a map $f: \mathcal{H}_k^{\otimes n} \rightarrow \mathcal{H}_k((\lambda_1)) \cdots ((\lambda_{n-1}))$ for some degree n . The chiral Hochschild differential is $\delta(f) = [m, f]$, where m is the A_∞ -structure (for Heisenberg: m_2 is the OPE, $m_k = 0$ for $k \geq 3$).

Since $\mathcal{H}_k$ is generated by a single current α , a cochain of degree n is determined by $f(\alpha, \dots, \alpha; \lambda_1, \dots, \lambda_{n-1}) \in \mathcal{H}_k((\lambda_1)) \cdots ((\lambda_{n-1}))$.

Step 3: The operadic center. The terminality of $(C_{\text{ch}}^\bullet(\mathcal{H}_k, \mathcal{H}_k), \mathcal{H}_k)$ means: for any brace dg algebra B acting on $\mathcal{H}_k$ via Swiss-cheese operations $\mu_{p;q}(b_1, \dots, b_p; a_1, \dots, a_q)$, there is a *unique* brace morphism $\Phi: B \rightarrow C_{\text{ch}}^\bullet(\mathcal{H}_k, \mathcal{H}_k)$ given by $\Phi(b)(a_1, \dots, a_n) = (-1)^{|b|} \mu_{1;n}(b; a_1, \dots, a_n)$. The sign $(-1)^{|b|}$ arises from the desuspension convention (§A.11). The uniqueness is immediate: cochains are determined by their evaluations.

Step 4: The chiral Hochschild groups. The chiral Hochschild cohomology is $CH^*(\mathcal{H}_k) = (\mathbb{C}, \mathbb{C}, \mathbb{C})$ (Remark 2.0.1):

- $CH^0 = \mathbb{C}$: center = scalars (the OPE has no regular terms besides the identity).
- $CH^1 = \mathbb{C}$: the outer derivation $D(\alpha) = \mathbf{1}$ survives because $\alpha_{(0)} = 0$ (the zero mode is central: no simple pole in the OPE).
- $CH^2 = \mathbb{C}$: the level deformation $\alpha(z)\alpha(w) \sim (k + \epsilon)/(z - w)^2$.

The Koszul resolution has length 2 (one generator, one relation), so $CH^n = 0$ for $n \geq 3$. The Poincaré polynomial $P(t) = 1 + t + t^2$ is palindromic ($P(t) = t^2 P(t^{-1})$), consistent with the Heisenberg being “self-Koszul-dual at the Hochschild level” (the Koszul dual $\text{Sym}^{\text{ch}}(V^*)$ has the same Poincaré polynomial).

Upshot. The Heisenberg center theorem says: the unique way to make $C_{\text{ch}}^\bullet(\mathcal{H}_k, \mathcal{H}_k)$ act on $\mathcal{H}_k$ via Swiss-cheese operations is by evaluation. The three-dimensional chiral Hochschild cohomology controls the deformation theory: $CH^0 = \text{automorphisms (trivial)}$, $CH^1 = \text{derivations (one outer)}$, $CH^2 = \text{deformations (level shift)}$. This is the “simplest nontrivial instance” paradigm: the Heisenberg center theorem is the prototype for the general center theorem, just as the Heisenberg $\kappa = k$ is the prototype for the general modular characteristic.

2.2.2 THE HOLOGRAPHIC TRIANGLE

Three algebraic objects attach to a chiral algebra $\mathcal{A}$ on a smooth projective curve X . They form a triangle whose vertices are the *bulk*, the *boundary*, and the *lines*. Each vertex is defined by a single algebraic construction; the edges are functorially determined. The triangle is not a metaphor but a commutative diagram of categories with exact functors between them.

2.2.2.1 VERTEX 1: THE BOUNDARY ALGEBRA

Let $(\mathcal{A}, \varepsilon: \mathcal{A} \rightarrow \omega_X)$ be an augmented chiral algebra on X . The *boundary algebra* is $\mathcal{A}$ itself: an augmented $\mathcal{D}_X$ -module equipped with a chiral bracket

$$\mu^{\text{ch}}: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_!(\mathcal{A}),$$

where $j: X^2 \setminus \Delta \hookrightarrow X^2$ is the complement of the diagonal. The boundary algebra carries the full OPE data: for sections $a, b \in \mathcal{A}$ and local coordinates z, w ,

$$a(z) b(w) \sim \sum_{n \geq 0} \frac{(a_{(n)} b)(w)}{(z - w)^{n+1}}.$$

The maximal pole order $N(a, b) = \max\{n : a_{(n)} b \neq 0\}$ and the conformal grading $\Delta: \mathcal{A} \rightarrow \mathcal{A}$ (eigenvalue decomposition of L_0) are part of the input data. The boundary algebra is the starting point; the other two vertices are constructed from it.

2.2.2.2 VERTEX 2: THE BULK ALGEBRA (DERIVED CENTER)

The *bulk algebra* is the derived center of $\mathcal{A}$. Define the center local system on the universal curve $\pi: C_g \rightarrow \overline{\mathcal{M}}_g$ by

$$\mathcal{Z}(\mathcal{A}) := R\mathcal{H}om_{\mathcal{A}\text{-bimod}}(\mathcal{A}, \mathcal{A}),$$

where the bimodule structure uses left and right chiral actions. On a fixed smooth curve Σ_g of genus g , the fiber of the center local system is

$$\mathcal{Z}(\mathcal{A}|_{\Sigma_g}) = \text{End}_{\mathcal{A}\text{-bimod}}(\mathcal{A}|_{\Sigma_g}) \cong H^0(\Sigma_g, \mathcal{A}/[\mathcal{A}, \mathcal{A}]_{\text{ch}}),$$

the space of chiral-central sections: those $\phi \in \mathcal{A}$ satisfying $\phi_{(n)} a = 0$ for all $a \in \mathcal{A}$ and all $n \geq 0$. For conformal vertex algebras, the center is the zeroth Zhu algebra, and includes the Virasoro vector when $\mathcal{A}$ has a conformal structure.

The *ambient complex* at genus g is the derived global sections of the center local system:

$$\mathbf{C}_g(\mathcal{A}) := R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A})).$$

This is a perfect complex carrying a canonical shifted-symplectic structure from Verdier duality on the center (Proposition 13.15.46). The Verdier involution $\sigma = \mathbb{D}_{\text{Ran}}$ acts on $\mathbf{C}_g(\mathcal{A})$ and decomposes it into eigenspaces:

$$\mathbf{C}_g(\mathcal{A}) \simeq \mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!), \quad (2.41)$$

where $\mathbf{Q}_g(\mathcal{A}) = \text{fib}(\sigma - \text{id})$ and $\mathbf{Q}_g(\mathcal{A}^!) = \text{fib}(\sigma + \text{id})$ are the $+1$ and -1 eigenspaces respectively. Each eigenspace is Lagrangian for the shifted-symplectic pairing (Theorem 13.15.14). The complementarity decomposition (2.41) is Theorem C of the algebraic engine.

The bulk algebra in the holographic sense is the factorization algebra on X whose genus- g factorization homology is $\mathbf{C}_g(\mathcal{A})$. It is reconstructed from the boundary algebra $\mathcal{A}$ by the protected holographic transform $\mathbb{H}_X(\mathcal{A}) = \Omega_X \circ \mathbb{D}_{\text{Ran}} \circ \bar{B}_X(\mathcal{A})$ (Definition K.7.1). On the Koszul locus, $\mathbb{H}_X(\mathcal{A}) \simeq \mathcal{A}^!$ (Theorem K.7.1).

2.22.3 VERTEX 3: THE LINE-OPERATOR CATEGORY

The *line-operator category* is the derived module category of the Koszul dual algebra:

$$\mathcal{C}(\mathcal{A}) := \mathcal{A}^! \text{-mod}.$$

Here $\mathcal{A}^! = (H^*(\bar{B}_X(\mathcal{A})))^\vee$ is the Koszul dual chiral algebra, constructed by first taking bar cohomology, then Verdier/linear duality. The module category $\mathcal{A}^! \text{-mod}$ is a $\mathbb{C}$ -linear dg category whose objects are $\mathcal{A}^!$ -modules (factorization modules on $\text{Ran}(X)$) and whose morphisms are chain maps.

The category $\mathcal{C}(\mathcal{A})$ carries a meromorphic tensor structure: for $M, N \in \mathcal{A}^! \text{-mod}$, the tensor product $M \otimes_{r(z)} N$ is defined by the fusion product along the spectral parameter z , with the binary OPE controlled by the r -matrix $r(z) \in \mathcal{A}^! \hat{\otimes} \mathcal{A}^![[z^{-1}, z]]$. The tensor structure is *meromorphic*: the poles of $r(z)$ in the spectral parameter produce non-trivial monodromy, and the category is not genuinely braided but carries an E_1 -monoidal structure (ordered configurations on $\mathbb{R} \subset \mathbb{C}$).

For affine Kac–Moody $\mathcal{A} = \widehat{\mathfrak{g}}_k$ at non-critical level $k \neq -h^\vee$, the Koszul dual is $\mathcal{A}^! \cong \widehat{\mathfrak{g}}_{k'}$ with $k' = -k - 2h^\vee$, and the line-operator category identifies with the Kazhdan–Lusztig category:

$$\mathcal{C}(\widehat{\mathfrak{g}}_k) \simeq \mathcal{O}_{k'}(\widehat{\mathfrak{g}}) \simeq \mathcal{C}(U_q(\mathfrak{g})),$$

where $q = e^{\pi i/(k+h^\vee)}$ and the last equivalence is the Kazhdan–Lusztig theorem (Theorem 15.2.9).

2.22.4 THE TRIANGLE DIAGRAM

The three vertices assemble into a commutative triangle of categories and functors:

$$\begin{array}{ccc} & \text{Bulk: } \mathbf{C}_g(\mathcal{A}) & \\ \text{rest } \bar{B}_X \nearrow & & \searrow \text{cofiber} \\ \text{Boundary: } \mathcal{A} & \xrightarrow{\text{Koszul dual}} & \text{Lines: } \mathcal{A}^! \text{-mod} \end{array} \quad (2.42)$$

The left edge is the bar construction $\bar{B}_X$, which maps the boundary algebra to the bar coalgebra (a factorization coalgebra contributing to the ambient complex). The right edge is the holographic cofiber: $\mathbf{H}_g^{\text{hol}}(\mathcal{A}) = \text{cofib}(\mathbf{Q}_g(\mathcal{A}) \rightarrow \mathbf{C}_g(\mathcal{A})) \simeq \mathbf{Q}_g(\mathcal{A}^!)$ (Theorem K.7.1(iii)). The bottom edge is Koszul duality: $\mathcal{A} \mapsto \mathcal{A}^!$ by the bar-then-dualize construction, with the module category $\mathcal{A}^! \text{-mod}$ as the categorical output.

The content of the holographic programme is that all three vertices, and the functors between them, are controlled by a single Maurer–Cartan element $\Theta_{\mathcal{A}}$.

2.22.5 HOLOGRAPHIC DATUM: THE SIX-FOLD PACKAGE

The three vertices of the triangle, together with three connecting data, assemble into the *holographic modular Koszul datum*:

$$\mathcal{H}(\mathcal{A}) = (\mathcal{A}, \mathcal{A}^!, \mathcal{C}, r(z), \Theta_{\mathcal{A}}, \nabla^{\text{hol}}). \quad (2.43)$$

The six entries are:

- (i) The boundary algebra $\mathcal{A}$: augmented chiral algebra on X .
- (ii) The universal defect algebra $\mathcal{A}^!$: Koszul dual of $\mathcal{A}$.
- (iii) The line-operator category $\mathcal{C} \simeq \mathcal{A}^! \text{-mod}$: meromorphic tensor category.
- (iv) The spectral r -matrix $r(z)$: binary genus-zero collision residue of $\Theta_{\mathcal{A}}$ (extracted in §K.7.1).
- (v) The modular MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$: bar-intrinsic universal Maurer–Cartan element (Theorem 13.21.69).
- (vi) The modular shadow connection $\nabla_{g,n}^{\text{hol}} = d - \text{Sh}_{g,n}(\Theta_{\mathcal{A}})$: flat connection on the derived coinvariant / protected-state package, specializing to the corresponding derived conformal-block package on benchmark comparison surfaces (constructed in §2.24.1).

Each entry is a determined projection of the single element $\Theta_{\mathcal{A}}$. The entire datum is subordinated to the MC equation

$$D_{\mathcal{A}} \Theta_{\mathcal{A}} + \frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0$$

in the modular convolution dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, and the single identity $D_{\mathcal{A}}^2 = 0$ (Theorem 13.22.412).

2.23 FROM BAR COMPLEX TO HOLOGRAPHIC DATUM

The holographic triangle of §2.22 was presented as a diagram of three vertices and three edges. The following constructs it from the bar complex alone, by progressively extracting structure from the identity $D_{\mathcal{A}}^2 = 0$. The extraction proceeds in four stages: the Swiss-cheese factorization that separates the bar complex into a bulk direction and a boundary direction; the bulk-boundary-line triangle that identifies each vertex categorically; the holographic datum that packages the triangle into a single Maurer–Cartan element; and the reconstruction theorems that recover the triangle from the datum.

2.23.1 THE SWISS-CHEESE FACTORIZATION

Let $\mathcal{A}$ be a chiral algebra on a smooth projective curve X . The bar complex $\overline{B}_X(\mathcal{A})$ is a dg coalgebra on $\text{Ran}(X)$, and its differential $d_{\overline{B}}$ acts by residue extraction on $\overline{C}_n(X)$. The first structural observation is that this differential decomposes into two commuting pieces when the curve X is embedded in a surface.

Let $\Sigma = X \times \mathbb{R}$, with X the holomorphic direction and $\mathbb{R}$ the topological direction. The Fulton–MacPherson compactification $\overline{C}_n(\Sigma)$ fibers over the ordered configuration space $\text{Conf}_n(\mathbb{R})$, and the bar differential decomposes as

$$d_{\overline{B},\Sigma} = d_C + d_R,$$

where d_C acts in the X -direction (extracting OPE residues along holomorphic collision divisors) and d_R acts in the $\mathbb{R}$ -direction (extracting residues along the topological ordering). The identity $d_{\overline{B},\Sigma}^2 = 0$ decomposes as

$$d_C^2 = 0, \quad d_R^2 = 0, \quad \{d_C, d_R\} = 0. \quad (2.44)$$

The first equation is the bar nilpotence of $\mathcal{A}$ on X . The second is the coassociativity of the bar coproduct. The third is the compatibility of the OPE with the ordered product.

Definition 2.23.1 (E_1 -chiral coassociative structure on the bar complex). The E_1 -chiral coassociative structure on $\overline{B}_X(\mathcal{A})$ is the pair (d_C, d_R) satisfying (2.44). The differential d_C is E_∞ -chiral (factorization on X); the coproduct d_R is E_1 -topological (deconcatenation on ordered configurations of $\mathbb{R}$) (Theorem A.9.4). The $SC^{\text{ch}, \text{top}}$ two-colour datum emerges not on $\overline{B}_X(\mathcal{A})$ itself but on the derived center pair $(C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A})$; see Volume II.

The two-component decomposition is the geometric origin of the bulk-boundary-line triangle. The holomorphic direction produces the bulk: factorization homology $\int_X \mathcal{A}$ in the X -direction. The topological direction produces the lines: modules over the Koszul dual. The boundary is the interface between the two: the chiral algebra $\mathcal{A}$ itself, which lives at the $\mathbb{R} = 0$ slice of Σ .

2.23.2 THE BULK-BOUNDARY-LINE TRIANGLE

The three vertices of the holographic triangle (§2.22.4) are now constructed as follows.

Boundary. The boundary algebra is $\mathcal{A}$ itself. It carries the full OPE data and is the input to the bar construction. The closed-sector differential d_C acts on $\overline{B}_X(\mathcal{A})$ and produces the bar cohomology $H^*(\overline{B}_X(\mathcal{A}))$, from which the Koszul dual is extracted.

Bulk. The bulk is the ambient complex $\mathbf{C}_g(\mathcal{A}) = R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$, where $\mathcal{Z}(\mathcal{A}) = R\mathcal{H}om_{\mathcal{A}\text{-bimod}}(\mathcal{A}, \mathcal{A})$ is the center local system. The ambient complex receives a map from the bar complex via the trace:

$$\text{tr}_g: \overline{B}_X^{(g)}(\mathcal{A}) \longrightarrow \mathbf{C}_g(\mathcal{A}), \quad (2.45)$$

which extracts the central part of each bar element by contracting all internal indices. The trace map intertwines $d_{\overline{B}}$ with the differential on the ambient complex; the image $\mathbf{Q}_g(\mathcal{A}) = \text{im}(\text{tr}_g)$ is one half of the complementarity decomposition (Theorem 13.15.14).

Lines. The line-operator category is $\mathcal{C}(\mathcal{A}) = \mathcal{A}^1\text{-mod}$ (§2.22.3). Its objects are $\mathcal{A}^1$ -modules; its morphisms are chain maps. The open-sector differential d_R on $\overline{B}_X(\mathcal{A})$ is the module structure: for $M \in \mathcal{A}^1\text{-mod}$, the action of $\mathcal{A}^1$ on M is encoded by the ordered-configuration structure of the bar complex restricted to the topological direction.

The three vertices form a commutative triangle (2.42) whose commutativity is Theorem A (the Verdier intertwining). The triangle is not built from three independent objects connected by ad hoc functors; it is a single object (the bar complex with its E_1 -chiral coassociative structure) viewed from three angles.

2.23.3 EDGES OF THE TRIANGLE

The three edges connecting the vertices are:

- (i) *Boundary* $\rightarrow$ *Bulk* (the bar map). The bar construction $\overline{B}_X: \mathcal{A} \mapsto \overline{B}_X(\mathcal{A})$ maps the boundary algebra to the bar coalgebra. The trace map (2.45) projects the bar coalgebra into the ambient complex. At genus 0, the bar map is an embedding; at genus $g \geq 1$, its image acquires curvature $\kappa(\mathcal{A}) \cdot \omega_g$.
- (ii) *Bulk* $\rightarrow$ *Lines* (the holographic cofiber). The complementarity decomposition $\mathbf{C}_g(\mathcal{A}) \simeq \mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^1)$ identifies the cofiber of the boundary embedding: $\text{cofib}(\mathbf{Q}_g(\mathcal{A}) \hookrightarrow \mathbf{C}_g(\mathcal{A})) \simeq \mathbf{Q}_g(\mathcal{A}^1)$. The cofiber is the dual shadow, which controls the line-operator category via the center-module adjunction.

- (iii) *Boundary* $\rightarrow$ *Lines* (Koszul duality). The bottom edge of the triangle is the composite $\mathcal{A} \mapsto \overline{B}_X(\mathcal{A}) \mapsto H^*(\overline{B}_X(\mathcal{A})) \mapsto (H^*(\overline{B}_X(\mathcal{A})))^\vee = \mathcal{A}^!$. On the Koszul locus, this is bar-dualize: the bar construction followed by Verdier duality. The module category $\mathcal{A}^!$ -mod is the categorical output of this composite.

2.23.4 THE HOLOGRAPHIC DATUM FROM THE MC ELEMENT

The holographic datum $\mathcal{H}(\mathcal{A}) = (\mathcal{A}, \mathcal{A}^!, C, r(z), \Theta_{\mathcal{A}}, \nabla^{\text{hol}})$ of (2.43) is not defined by listing six independent objects. It is extracted from the single Maurer–Cartan element $\Theta_{\mathcal{A}}$ by a sequence of projections.

- (i) The boundary algebra $\mathcal{A}$ is the input.
- (ii) The Koszul dual $\mathcal{A}^!$ is the graded linear dual of the bar cohomology coalgebra: $\mathcal{A}^! = (H^*(\overline{B}_X(\mathcal{A})))^\vee$. By Theorem A, $\mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}) \simeq \mathcal{A}_\infty^!$ (the homotopy Koszul dual algebra, whose underlying complex is equivalent to $\overline{B}_X(\mathcal{A}^!)$).
- (iii) The line-operator category is $C = \mathcal{A}^!$ -mod.
- (iv) The spectral r -matrix is the binary genus-0 collision residue of $\Theta_{\mathcal{A}}$:

$$r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}) \in \mathcal{A}^! \widehat{\otimes} \mathcal{A}^![[z^{-1}, z]].$$

This extraction is the content of the collision filtration (§2.27.1).

- (v) The MC element $\Theta_{\mathcal{A}}$ itself: the bar-intrinsic construction $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_{\mathcal{A}}^{(0)}$ (Theorem 13.21.69).
- (vi) The shadow connection ∇^{hol} is constructed from $\Theta_{\mathcal{A}}$ by the modular shadow projection (§2.24).

The datum is subordinated to the single identity $D_{\mathcal{A}}^2 = 0$. Every entry is a projection of $\Theta_{\mathcal{A}}$; every consistency condition between the entries is a consequence of the MC equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$. The holographic programme of this monograph is the systematic extraction of physics from this identity.

2.23.5 RECONSTRUCTION FROM THE DATUM

The holographic datum determines the triangle, and the triangle determines the datum. The reconstruction theorems are:

- (i) *Boundary from bulk*. On the Koszul locus, $\mathcal{A} \simeq \Omega_X(\mathbb{D}_{\text{Ran}} \mathbf{Q}_g(\mathcal{A}^!))$: the boundary algebra is recovered from the dual shadow by the cobar construction applied to the Verdier dual of the bulk (Theorem 13.18.4).
- (ii) *Bulk from boundary*. The ambient complex is reconstructed by factorization homology: $\mathbf{C}_g(\mathcal{A}) \simeq \int_{\overline{\mathcal{M}}_g} \mathcal{Z}(\mathcal{A})$, where the center $\mathcal{Z}(\mathcal{A})$ is a computable bimodule functor of $\mathcal{A}$.
- (iii) *Lines from r -matrix*. The meromorphic tensor structure on $\mathcal{A}^!$ -mod is reconstructed from the r -matrix $r(z)$: the fusion product $M \otimes_{r(z)} N$ is determined by the spectral data of $r(z)$, and the Yang–Baxter equation for $r(z)$ guarantees associativity of the tensor product.

- (iv) *MC element from the datum.* Conversely, the six-fold datum determines $\Theta_{\mathcal{A}}$ uniquely: the boundary $\mathcal{A}$ determines the bar complex, the bar complex determines $D_{\mathcal{A}}$, and $\Theta_{\mathcal{A}} = D_{\mathcal{A}} - d_{\mathcal{A}}^{(0)}$ is the positive-genus correction. The entries $\mathcal{A}^!$, C , $r(z)$, and ∇^{hol} are then projections.

The full content of the reconstruction is that the six-fold datum is a *complete invariant* of the modular homotopy type (Proposition 1.9.1): two chiral algebras have equivalent holographic data if and only if their modular bar constructions are quasi-isomorphic.

2.23.6 THE FOUR RECOVERY THEOREMS

The following four theorems make the holographic datum rigid. Each recovers one piece of the datum from another, using only the MC equation.

THEOREM 2.23.2 (*Collision residue = twisting morphism;*). The binary genus-0 collision residue of $\Theta_{\mathcal{A}}$ is the universal twisting morphism $\tau: \overline{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ restricted to bar degree 2:

$$\text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}) = \tau|_{\overline{B}_X^2(\mathcal{A})}.$$

The proof is Theorem K.7.1.

THEOREM 2.23.3 (*Arnold $\Rightarrow$ CYBE;*). The classical Yang–Baxter equation for $r(z)$ is a formal consequence of the Arnold relation on $\overline{C}_3(X)$. The three-term sum

$$[r_{12}(z_1 - z_2), r_{13}(z_1 - z_3)] + [r_{12}(z_1 - z_2), r_{23}(z_2 - z_3)] + [r_{13}(z_1 - z_3), r_{23}(z_2 - z_3)] = 0$$

follows from $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ applied to the degree-3 MC equation. The proof is Theorem K.7.1.

THEOREM 2.23.4 (*Shadow/KZ comparison on the affine Kac–Moody surface;*). For $\mathcal{A} = \widehat{\mathfrak{g}}_k$ on the affine Kac–Moody comparison surface, the shadow connection ∇^{hol} restricted to genus 0 with n marked points identifies with the Knizhnik–Zamolodchikov connection on the bundle of conformal blocks:

$$\nabla^{\text{KZ}} = d - \sum_{i < j} \frac{r_{ij}}{z_i - z_j} dz_i = \nabla_{0,n}^{\text{hol}}|_{\text{genus } 0}.$$

The proof is Theorem K.7.1.

THEOREM 2.23.5 (*Quartic obstruction = L_{∞} bracket;*). The quartic resonance class $\mathfrak{Q}(\mathcal{A}) \in H^*(\text{Def}_{\text{cyc}}^{(4)}(\mathcal{A}))$ is the L_{∞} -obstruction governing the quartic extension problem for the shadow package, equivalently the obstruction to extending $\Theta_{\mathcal{A}}^{\leq 3}$ to $\Theta_{\mathcal{A}}^{\leq 4}$:

$$\mathfrak{Q}(\mathcal{A}) = [\ell_4^{\min}] \in H^2(\text{Def}_{\text{cyc}}^{(4)}(\mathcal{A})|_{g=0}).$$

This is the $r = 4$ case of the shadow–Massey identification (Proposition 1.9.1).

Together, these four theorems show that the holographic datum is not an external imposition on the bar complex but an intrinsic structure of the identity $D_{\mathcal{A}}^2 = 0$, read at successively finer resolution.

2.24 THE SHADOW CONNECTION AND CONFORMAL-BLOCK COMPARISON SURFACES

The modular MC element $\Theta_{\mathcal{A}}$ determines a flat connection on the moduli of marked curves. On the general theorematic surface, this connection governs the transport of the bar-cohomological / derived-coinvariant package across $\overline{\mathcal{M}}_{g,n}$. On benchmark comparison surfaces, its genus-0 affine specialization identifies with the Knizhnik–Zamolodchikov connection, while on the genus-0 Virasoro degenerate-module surface it gives the Virasoro conformal Ward connection and its higher collision residues yield the BPZ differential equations. Its flatness is guaranteed by the MC equation.

2.24.1 CONSTRUCTION OF THE SHADOW CONNECTION

Let $\pi: \overline{\mathcal{C}}_{g,n} \rightarrow \overline{\mathcal{M}}_{g,n}$ be the universal curve with n marked sections $\sigma_1, \dots, \sigma_n: \overline{\mathcal{M}}_{g,n} \rightarrow \overline{\mathcal{C}}_{g,n}$. A derived coinvariant / protected-state package is the sheaf on $\overline{\mathcal{M}}_{g,n}$ defined by

$$\mathcal{V}_{g,n}(\mathcal{A}; M_1, \dots, M_n) := R\pi_* \left(\mathcal{A} \otimes \bigotimes_{i=1}^n \sigma_i^*(M_i) \right),$$

where $M_1, \dots, M_n$ are $\mathcal{A}$ -modules inserted at the marked points. On comparison surfaces where classical conformal blocks are defined, the fiber over a smooth curve Σ_g with marked points $z_1, \dots, z_n$ is the space of coinvariants:

$$V_{g,n}(\mathcal{A}; M_1, \dots, M_n) = \frac{M_1 \otimes \dots \otimes M_n}{\mathcal{A}(\Sigma_g \setminus \{z_1, \dots, z_n\}) \cdot (M_1 \otimes \dots \otimes M_n)},$$

the quotient by the diagonal action of sections of $\mathcal{A}$ regular away from the marked points.

Definition 2.24.1 (The shadow connection). The *modular shadow connection* on this derived coinvariant / protected-state package is the connection

$$\nabla_{g,n}^{\text{hol}} = d - \text{Sh}_{g,n}(\Theta_{\mathcal{A}}),$$

where d is the de Rham differential on $\overline{\mathcal{M}}_{g,n}$ and $\text{Sh}_{g,n}(\Theta_{\mathcal{A}})$ is the genus- (g, n) shadow: the projection of the MC element $\Theta_{\mathcal{A}}$ to the component acting on the corresponding fiber at genus g with n marked points. On benchmark comparison surfaces, this is the corresponding action on conformal blocks.

Explicitly, the shadow $\text{Sh}_{g,n}$ is a graph sum over stable graphs Γ of type (g, n) :

$$\text{Sh}_{g,n}(\Theta_{\mathcal{A}}) = \sum_{\Gamma \in G(g,n)} \frac{1}{|\text{Aut}(\Gamma)|} \Theta_{\mathcal{A},\Gamma},$$

where $G(g, n)$ is the set of stable graphs of type (g, n) and $\Theta_{\mathcal{A},\Gamma}$ is the amplitude of $\Theta_{\mathcal{A}}$ on the graph Γ , obtained by placing the multilinear operations of $\Theta_{\mathcal{A}}$ at the vertices of Γ and contracting along the internal edges using the bar pairing.

2.24.2 FLATNESS FROM THE MC EQUATION

The fundamental property of the shadow connection is flatness:

PROPOSITION 2.24.2 (*Flatness of the shadow connection*;). The connection $\nabla_{g,n}^{\text{hol}}$ is flat:

$$(\nabla_{g,n}^{\text{hol}})^2 = 0.$$

Proof sketch. Expand:

$$(\nabla^{\text{hol}})^2 = d^2 - d \text{ Sh}(\Theta) - \text{Sh}(\Theta) \wedge d + \text{Sh}(\Theta) \wedge \text{Sh}(\Theta) = -d \text{ Sh}(\Theta) + \frac{1}{2} [\text{Sh}(\Theta), \text{Sh}(\Theta)].$$

The shadow projection is compatible with the MC equation: $d \text{ Sh}(\Theta) = \text{Sh}(D\Theta)$ and $\text{Sh}(\Theta) \wedge \text{Sh}(\Theta) = \text{Sh}([\Theta, \Theta])$. Therefore

$$(\nabla^{\text{hol}})^2 = -\text{Sh}(D\Theta + \frac{1}{2} [\Theta, \Theta]) = 0,$$

where the last equality is the MC equation for $\Theta_{\mathcal{A}}$. $\square$

The flatness of the shadow connection says that this derived coinvariant / bar-cohomological package forms a local system on $\overline{\mathcal{M}}_{g,n}$: parallel transport between any two points is path-independent (up to homotopy). For conformal vertex algebras at integrable affine level, this recovers the usual local system of conformal blocks (Tsuchiya–Ueno–Yamada [412]); more generally, the shadow-connection construction supplies the flat bar-cohomological transport package attached to the bar-intrinsic MC element.

2.24.3 THE KZ CONNECTION AT GENUS 0

At genus 0, the moduli space $\overline{\mathcal{M}}_{0,n}$ is the Deligne–Mumford compactification of the space of n -pointed rational curves. The shadow connection restricted to genus 0 takes the explicit form:

$$\nabla_{0,n}^{\text{KZ}} = d - \sum_{1 \leq i < j \leq n} \frac{r_{ij}(z_i - z_j)}{z_i - z_j} dz_i, \quad (2.46)$$

where $r_{ij}(z) = (\text{id} \otimes \text{id}) \circ r(z) \in \text{End}(M_i) \otimes \text{End}(M_j)$ is the r -matrix acting on the i -th and j -th module insertions.

When the r -matrix is the rational r -matrix of a simple Lie algebra $\mathfrak{g}$ at level k (that is, $r(z) = k \Omega / z$ where $\Omega = \sum_a t^a \otimes t_a$ is the Casimir element), the connection (2.46) reduces to the classical KZ connection:

$$\nabla^{\text{KZ}} = d - \frac{1}{k + h^\vee} \sum_{i < j} \frac{\Omega_{ij}}{z_i - z_j} dz_i.$$

The level-dependent prefactor $(k + h^\vee)^{-1}$ arises from the Sugawara normalization of the affine OPE: $r(z) = \Omega / ((k + h^\vee) z)$ for $\mathcal{A} = \widehat{\mathfrak{g}}_k$. This is *not* the inverse of the modular characteristic $\kappa(\widehat{\mathfrak{g}}_k) = \dim \mathfrak{g} \cdot (k + h^\vee) / (2h^\vee)$, which differs by the factor $\dim \mathfrak{g} / (2h^\vee)$.

The flatness of the KZ connection, originally proved by Knizhnik and Zamolodchikov [252] using current algebra Ward identities, is here a special case of Proposition 2.24.2: it follows from the MC equation for $\Theta_{\mathcal{A}}$ restricted to genus 0. On this affine comparison surface, the KZ equations on conformal blocks are the parallel-transport equations for this flat connection.

2.24.4 THE BPZ EQUATIONS FROM THE SHADOW OBSTRUCTION TOWER

For the Virasoro algebra $\mathcal{A} = \text{Vir}_c$, on the genus-0 degenerate-module comparison surface with $n + 1$ marked points (one carrying a degenerate module $M_{r,s}$ and the rest carrying generic modules), the shadow

connection gives the Virasoro conformal Ward connection, and the higher collision residues produce the BPZ differential equations.

The mechanism is as follows. The degenerate module $M_{r,s}$ has a null vector at level rs ; this null vector produces a polynomial differential operator $\mathcal{D}_{r,s}$ of order rs in the insertion variable z_0 . The flatness of the shadow connection implies that the conformal block $\Phi(z_0, z_1, \dots, z_n)$ satisfies

$$\mathcal{D}_{r,s} \Phi(z_0, z_1, \dots, z_n) = 0.$$

At the simplest level $(r, s) = (2, 1)$, the null vector is at level 2 and the BPZ equation is the second-order PDE

$$\left[\frac{1}{2(2h_{2,1} + 1)} \partial_{z_0}^2 - \sum_{i=1}^n \left(\frac{h_i}{(z_0 - z_i)^2} + \frac{1}{z_0 - z_i} \partial_{z_i} \right) \right] \Phi = 0,$$

where h_i are the conformal weights of the modules at the remaining insertions.

From the bar-complex perspective, the BPZ equations arise as follows. The null vector in $M_{r,s}$ is a cycle in the bar complex $\overline{B}(\text{Vir}_c; M_{r,s})$ of the Virasoro with module coefficients. The shadow connection transports this cycle across the moduli space. The flatness condition $(\nabla^{\text{hol}})^2 = 0$ then implies that the transport is consistent, and the transported cycle yields the corresponding BPZ null-vector equation at each point of $\overline{\mathcal{M}}_{0,n+1}$.

The entire BPZ programme (null vectors, differential equations, fusion rules, minimal model classification) is thus a shadow of the MC equation in the Virasoro sector of the modular convolution algebra.

Remark 2.24.3 (The BPZ-shadow dictionary). The dictionary between classical BPZ data and shadow-tower data is:

BPZ datum	Shadow datum
Null vector in $M_{r,s}$ at level rs	bar cycle in $\overline{B}(\text{Vir}_c; M_{r,s})$
BPZ differential operator $\mathcal{D}_{r,s}$	shadow connection restricted to degenerate insertion
Fusion rules N_{ij}^k	dimensions of spaces of conformal blocks
Minimal model central charges $c_{p,q}$	poles of shadow invariants in the c -plane
Kac determinant vanishing locus	singular locus of the shadow connection

Remark 2.24.4 (Regularity of the shadow connection). The shadow connection $\nabla_{g,n}^{\text{hol}}$ is regular singular along the boundary divisors of $\overline{\mathcal{M}}_{g,n}$: the connection form has at most simple poles along the boundary strata where marked points collide or handles degenerate. This regularity follows from the structure of the MC element: the amplitude $\Theta_{\mathcal{A},\Gamma}$ on a stable graph Γ has poles of order at most 1 along each boundary divisor, because the bar differential involves only residue extraction (which produces at most simple poles from the logarithmic forms η_{ij}).

The regular-singular property guarantees that the parallel transport of the derived coinvariant / protected-state package extends across the boundary of $\overline{\mathcal{M}}_{g,n}$. On benchmark comparison surfaces, this becomes the corresponding extension of parallel transport for conformal blocks. The monodromy around a boundary divisor (a degeneration of the underlying curve) is controlled by the local exponent of the connection, which is determined by the collision residue of the r -matrix.

2.24.5 HIGHER-GENUS EXTENSIONS

At genus $g \geq 1$, the shadow connection acquires additional terms from the period structure of the curve. The genus-1 shadow connection is

$$\nabla_{1,n}^{\text{hol}} = \nabla_{0,n}^{\text{hol}} - \kappa(\mathcal{A}) \cdot \omega_1 - \sum_{r \geq 3} \text{Sh}_{1,n}^{(r)}(\Theta_{\mathcal{A}}),$$

where ω_1 is the Arakelov form on $\overline{\mathcal{M}}_{1,n}$, $\kappa(\mathcal{A})$ is the modular characteristic, and the higher-degree shadows $\text{Sh}_{1,n}^{(r)}$ are the contributions from the shadow obstruction tower at degree r and genus 1.

The term $\kappa(\mathcal{A}) \cdot \omega_1$ is the curvature of the Hodge bundle, coupling the derived coinvariant / protected-state package to the complex structure of the elliptic curve. On benchmark comparison surfaces, this is the corresponding coupling of conformal blocks. The higher-degree corrections encode the nonlinear dependence of this package on the modular parameter τ ; on comparison surfaces, of conformal blocks: the cubic shadow controls the first subleading correction, the quartic shadow controls the next, and so on.

For the Heisenberg algebra, only the κ term survives (the shadow tower terminates at degree 2), and on the standard free-boson comparison surface the genus-1 conformal blocks transform by multiplication by $\eta(\tau)^{-k}$, where η is the Dedekind eta function. For the Virasoro algebra, on the torus comparison surface the infinite shadow obstruction tower produces the modular differential equation satisfied by Virasoro conformal blocks.

At genus $g \geq 2$, the shadow connection acquires contributions from all stable graphs of type (g, n) . The number of contributing graphs grows with g ; the graph sum is controlled by the shadow algebra $\mathcal{A}^{\text{sh}}$ (Definition 13.22.49), and the convergence of the sum is guaranteed by the all-degree master equation (1.9.1). The genus-2 shadow connection requires graphs with up to one internal edge (genus-2 irreducible graphs and products of genus-1 self-loops), and the genus-3 connection requires graphs with up to two internal edges. The structure of these contributions is governed by the genus spectral sequence: the E_1 page at genus g isolates the tree-level ($p = 0$), one-loop ($p = 1$), and higher-loop ($p \geq 2$) contributions, with differentials that are the obstruction maps.

2.25 GRAVITATIONAL COMPLEXITY AND THE EFT HIERARCHY

The shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq 2} \rightarrow \Theta_{\mathcal{A}}^{\leq 3} \rightarrow \Theta_{\mathcal{A}}^{\leq 4} \rightarrow \dots$ assigns to each chiral algebra a numerical invariant: the *shadow depth* $r_{\text{max}}(\mathcal{A})$, the smallest degree at which the tower terminates (or ∞ if it does not). This invariant measures the *gravitational complexity* of $\mathcal{A}$: the number of independent multi-particle interactions required to determine the full modular structure.

2.25.1 SHADOW-DEPTH CLASSES

In general, the shadow depth $r_{\text{max}}(\mathcal{A})$ can take any value in $\{2, 3, 4, 5, \dots\} \cup \{\infty\}$: a chiral algebra of class $\mathbf{F}_r$ has $r_{\text{max}} = r$ (tower terminates at degree r), while class $\mathbf{M}$ has $r_{\text{max}} = \infty$ (tower does not terminate). There is no structural obstruction to any finite value; the definition is $r_{\text{max}} = \sup\{r \geq 2 : \mathcal{A}_{r,0}^{\text{sh}} \neq 0\}$.

Within the standard landscape, only the values $r_{\text{max}} \in \{2, 3, 4, \infty\}$ are realised (Definition 13.22.121):

Class	$r_{\max}$	Archetype	Examples
$\mathbf{F}_2 = \mathbf{G}$ (Gaussian)	2	abelian, no bracket	Heisenberg, free fermion, lattice
$\mathbf{F}_3 = \mathbf{L}$ (Lie/tree)	3	Lie bracket, tree-level	affine Kac–Moody $\widehat{\mathfrak{g}}_k$
$\mathbf{F}_4 = \mathbf{C}$ (contact/quartic)	4	quartic contact interaction	$\beta\gamma$, symplectic fermion
$\mathbf{M}$ (mixed)	∞	infinite tower	Virasoro, $\mathcal{W}_N$ ($N \geq 3$)

The gap between $\mathbf{F}_4$ and $\mathbf{M}$ is an empirical feature of these families; classes $\mathbf{F}_5, \mathbf{F}_6, \dots$ are structurally permitted and may be realised by chiral algebras outside the standard landscape (e.g. certain non-principal W-algebras or non-freely-generated vertex algebras).

The classes are determined by the vanishing pattern of the obstruction sequence:

$$\begin{aligned}
\mathbf{G} : & \quad o_3 = 0, \quad o_4 = 0, \quad o_5 = 0, \quad \dots \\
\mathbf{L} : & \quad o_3 \neq 0, \quad o_4 = 0, \quad o_5 = 0, \quad \dots \\
\mathbf{C} : & \quad o_3 \neq 0, \quad o_4 \neq 0, \quad o_5 = 0, \quad \dots \\
\mathbf{F}_r : & \quad o_r \neq 0, \quad o_{r+1} = 0, \quad o_{r+2} = 0, \quad \dots \quad (\text{general finite}) \\
\mathbf{M} : & \quad o_3 \neq 0, \quad o_4 \neq 0, \quad o_5 \neq 0, \quad \dots
\end{aligned}$$

(In class $\mathbf{L}$, $o_3 \neq 0$ means the cubic shadow is present but the quartic obstruction vanishes; the tower terminates at degree 3. In class $\mathbf{C}$, the quartic is the last nonzero obstruction. In general class $\mathbf{F}_r$, the tower terminates at degree r . In class $\mathbf{M}$, all obstructions are nonzero.)

2.25.2 THE OBSTRUCTION CLASSES AS EFFECTIVE FIELD THEORY DATA

Each obstruction class $o_{r+1}(\mathcal{A})$ has a physical interpretation as an effective interaction vertex. The shadow obstruction tower is an effective field theory (EFT) hierarchy:

- (i) *Degree 2: the free-field kernel.* The modular characteristic $\kappa(\mathcal{A})$ is the one-loop determinant of the free theory. It counts the number of degrees of freedom weighted by spin: $\kappa(\mathcal{H}_k) = k$ for bosons, $\kappa(\psi_k) = k/4$ for k free fermions ($c = k/2$, so $\kappa = c/2 = k/4$). In the EFT language, κ is the cosmological constant of the two-dimensional gravitational theory.
- (ii) *Degree 3: the cubic interaction.* The cubic shadow $\mathfrak{C}(\mathcal{A})$ is the three-point coupling. For affine Kac–Moody, it is proportional to the structure constants f^{abc} of the Lie algebra; for the Virasoro, it is proportional to the central charge. The cubic shadow vanishes if and only if the OPE has no simple poles; the algebra is abelian.
- (iii) *Degree 4: the quartic resonance.* The quartic class $\mathfrak{Q}(\mathcal{A})$ is the four-point contact interaction. For the Virasoro algebra, the quartic contact invariant is

$$Q_{\text{Vir}}^{\text{contact}} = \frac{10}{c(5c + 22)},$$

with poles at $c = 0$ and $c = -22/5$ (the $(2, 5)$ minimal model central charge). The quartic resonance class carries a clutching law under stable-curve degeneration (Theorem 18.7.11).

- (iv) *Degree 5 and beyond: the quintic forced.* For the Virasoro and $\mathcal{W}_N$ algebras, $o_5(\mathcal{A}) \neq 0$: the quintic interaction is forced, and the tower never terminates. Each higher degree r introduces a new effective vertex, coupled to the lower-order vertices by the all-degree master equation $\nabla_H(\text{Sh}_r) + o^{(r)} = 0$.

The EFT hierarchy is organized by a single principle: the shadow obstruction tower is the Taylor expansion of the full MC element $\Theta_{\mathcal{A}}$ in powers of the degree variable. The radius of convergence is the shadow depth $r_{\max}$. For Gaussian algebras, the expansion converges at linear order; for Lie/tree algebras, at cubic order; for contact algebras, at quartic order; for mixed algebras, the expansion has infinite radius and the full MC element cannot be captured by any finite truncation.

2.25.3 THE GENUS LOOP AND PRIMITIVE SHADOWS

The descent from degree r to degree $r - 2$ is governed by the *genus loop*

$$\Lambda_P : \text{Sym}^r \longrightarrow \text{Sym}^{r-2},$$

which contracts a pair of indices using the self-loop graph (the genus-1 sewing operation at a single vertex). The genus loop reduces the degree by 2: from the quartic shadow, it produces a scalar correction to the quadratic level (a correction to κ); from the cubic shadow, it produces a correction to the vacuum (a scalar).

The kernel of the genus loop consists of the *primitive shadows*: the irreducible pieces that cannot be obtained by trace contraction from higher degree. The primitive-shadow decomposition

$$\text{Sh}_r(\Theta_{\mathcal{A}}) = \text{Sh}_r^{\text{prim}}(\Theta_{\mathcal{A}}) + \Lambda_P(\text{Sh}_{r+2}^{\text{prim}}(\Theta_{\mathcal{A}})) + \Lambda_P^2(\text{Sh}_{r+4}^{\text{prim}}(\Theta_{\mathcal{A}})) + \dots$$

expresses the full shadow at degree r as a sum of primitive contributions from higher degrees, contracted downward by the genus loop. This is the modular analogue of the primitive-element decomposition in a Hopf algebra.

2.25.4 THE OPERADIC COMPLEXITY THEOREM

The shadow depth equals the A_{∞} -depth of the bar cohomology:

THEOREM 2.25.1 (*Operadic complexity*; *Theorem K.7.1*). For any chiral algebra $\mathcal{A}$ on X ,

$$r_{\max}(\mathcal{A}) = A_{\infty}\text{-depth of } H^*(\overline{B}_X(\mathcal{A})) = L_{\infty}\text{-formality level of } \mathfrak{g}_{\mathcal{A}}^{\text{mod}}.$$

The A_{∞} -depth is the smallest r such that the transferred A_{∞} -product m_r on bar cohomology is nonzero. The L_{∞} -formality level is the smallest r such that the minimal L_{∞} -model of the modular convolution algebra has a nonzero r -ary bracket. The proof proceeds in two steps: $r_{\max} = f_{\infty}$ is Theorem 13.22.108 (Proposition 1.9.1 gives the genus-0 case; the all-genera direction uses Proposition 13.22.107, proved at degrees 2, 3, and 4, extended by the HPL tree formula to all finite degrees); $f_{\infty} = d_{\infty}$ follows because antisymmetrization is injective on cyclic cochains. The full argument is Theorem 13.22.104.

2.25.5 SHADOW DEPTH VERSUS KOSZULNESS

Shadow depth does *not* characterize Koszulness. Both finite and infinite shadow-depth algebras can be Koszul:

- Heisenberg ($r_{\max} = 2$): Koszul.
- Affine Kac–Moody ($r_{\max} = 3$): Koszul.
- $\beta\gamma$ ($r_{\max} = 4$): Koszul.

- Virasoro ($r_{\max} = \infty$): Koszul.

Shadow depth classifies the *complexity* of Koszul algebras, not Koszulness itself. The Koszulness characterization programme (Theorem II.1.50: ten unconditional equivalences, one conditional, one one-directional) is independent of the shadow depth classification.

The distinction is precise: Koszulness means the bar spectral sequence degenerates at E_2 ; shadow depth measures how many multi-particle operations the bar differential requires. The Virasoro is Koszul (its bar cohomology is concentrated in bar degree 1) but has infinite shadow depth (its A_∞ minimal model has nonzero products at all degrees). These are compatible because Koszulness concerns the cohomological concentration of the bar complex, while shadow depth concerns the complexity of the bar differential.

2.26 DUALITY AND THE GRAVITATIONAL PHASE SPACE

Koszul duality on a curve is not a symmetry of the chiral algebra but a symmetry of the genus tower. The Verdier involution $\sigma = \mathbb{D}_{\text{Ran}}$ acts on the ambient complex $\mathbf{C}_g(\mathcal{A})$ and decomposes it into complementary halves. The resulting structure is a shifted-symplectic phase space whose Lagrangian polarization records the gravitational content of Koszul duality.

2.26.1 THE VERDIER INVOLUTION AND THE AMBIENT DECOMPOSITION

The Verdier duality functor $\mathbb{D}_{\text{Ran}} : D(\mathcal{D}\text{-mod}(\text{Ran}(X))) \rightarrow D(\mathcal{D}\text{-mod}(\text{Ran}(X)))$ sends the bar coalgebra to the homotopy Koszul dual algebra $\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \mathcal{A}_\infty^!$ (Theorem A; factorization *algebra*, not coalgebra). The induced involution on the ambient complex is $\sigma : \mathbf{C}_g(\mathcal{A}) \rightarrow \mathbf{C}_g(\mathcal{A})$, and the eigenspace decomposition is

$$\mathbf{C}_g(\mathcal{A}) \simeq \mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!),$$

where $\mathbf{Q}_g(\mathcal{A}) = \text{fib}(\sigma - \text{id})$ and $\mathbf{Q}_g(\mathcal{A}^!) = \text{fib}(\sigma + \text{id})$ are the $+1$ and -1 eigenspaces. This is Theorem C (Theorem 13.15.14).

The decomposition is *orthogonal* for the shifted-symplectic pairing: the two eigenspaces are isotropic, and the pairing between them is perfect. The ambient complex is therefore a *symplectic vector space* (in the shifted-derived sense), and the Verdier involution is the map that exchanges the two Lagrangian halves.

2.26.2 THE SHIFTED-SYMPLECTIC STRUCTURE

The ambient complex carries a canonical shifted-symplectic structure. The pairing

$$\omega_g^{\text{symp}} : \mathbf{C}_g(\mathcal{A}) \otimes \mathbf{C}_g(\mathcal{A}) \longrightarrow \mathbb{C}[-(3g-3)]$$

is a $-(3g-3)$ -shifted symplectic form on the derived moduli of genus- g bar families, in the sense of Pantev–Toën–Vaquié–Vezzosi [340] (Proposition 13.15.46). The shift $-(3g-3)$ reflects the dimension of the moduli space $\bar{\mathcal{M}}_g$: the symplectic form lives in the top cohomological degree of $\bar{\mathcal{M}}_g$.

2.26.3 LAGRANGIAN COMPLEMENTARITY

The eigenspaces $\mathbf{Q}_g(\mathcal{A})$ and $\mathbf{Q}_g(\mathcal{A}^!)$ are *Lagrangian* for the shifted-symplectic pairing: each is an isotropic subspace of half the total rank. The Lagrangian condition means that

$$\omega_g^{\text{symp}}|_{\mathbf{Q}_g(\mathcal{A}) \otimes \mathbf{Q}_g(\mathcal{A})} = 0, \quad \omega_g^{\text{symp}}|_{\mathbf{Q}_g(\mathcal{A}^!) \otimes \mathbf{Q}_g(\mathcal{A}^!)} = 0,$$

and the pairing between the two Lagrangians is a perfect duality:

$$\omega_g^{\text{symp}} : \mathbf{Q}_g(\mathcal{A}) \otimes \mathbf{Q}_g(\mathcal{A}^\dagger) \xrightarrow{\sim} \mathbb{C}[-(3g-3)].$$

The Lagrangian pair $(\mathbf{Q}_g(\mathcal{A}), \mathbf{Q}_g(\mathcal{A}^\dagger))$ is the gravitational phase space of the chiral algebra: the two Lagrangians correspond to the boundary and the bulk degrees of freedom respectively, and the symplectic pairing is the holographic coupling between them. Koszul duality exchanges the two Lagrangians: $\mathbb{D}(\mathbf{Q}_g(\mathcal{A})) \simeq \mathbf{Q}_g(\mathcal{A}^\dagger)$.

2.26.4 THE CRITICAL LOCUS AND ANOMALY CANCELLATION

The modular characteristic transforms under Koszul duality as $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) = 0$ for affine Kac–Moody and free-field algebras; for $\mathcal{W}$ -algebras the complementarity sum $\kappa + \kappa'$ is a nonzero constant (e.g. 13 for Virasoro, 250/3 for $\mathcal{W}_3$; see Theorem 13.21.44). The *critical locus* is the locus where $\kappa(\mathcal{A}) = 0$: the genus-1 curvature vanishes, and the bar complex is nilpotent at all genera simultaneously.

On the critical locus, the shifted-symplectic pairing degenerates: the Lagrangian decomposition persists but the genus-1 obstruction $\text{obs}_1(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_1$ vanishes, and the ambient complex splits into a direct sum without curvature correction. Physically, the critical locus is the anomaly-free locus: the theory propagates on higher-genus surfaces without obstruction from the Hodge bundle.

For affine Kac–Moody, the anti-symmetry $\kappa(\widehat{\mathfrak{g}}_k) + \kappa(\widehat{\mathfrak{g}}_{k'}) = 0$ with $k' = -k - 2h^\vee$ means that the critical locus is $k = -h^\vee$: the critical level where the Sugawara construction is undefined. For the Virasoro algebra, $\kappa(\text{Vir}_c) + \kappa(\text{Vir}_{26-c}) = c/2 + (26-c)/2 = 13$ by the complementarity $c + c' = 26$; the chiral Koszul self-dual point is $c = 13$ ($\text{Vir}_{13}^\dagger = \text{Vir}_{13}$, $\kappa = 13/2$). For the $\beta\gamma$ system at conformal weight λ , $\kappa(\beta\gamma) = c_{\beta\gamma}/2 = 6\lambda^2 - 6\lambda + 1$ and $\kappa(bc) = -\kappa(\beta\gamma)$; the tensor product $\beta\gamma \otimes bc$ has $\kappa = 0$.

2.26.5 THE COMPLEMENTARITY SUM

The Koszul conductor $K(\mathcal{A}) = c(\mathcal{A}) + c(\mathcal{A}^\dagger)$ is the sum of central charges of the Koszul pair. The conductor is determined by the duality constraint on κ (Theorem 13.21.44(iii)) together with the Sugawara formula/Drinfeld–Sokolov formula for the central charge. The explicit values are:

Family	Conductor $K = c + c'$	Key values
Heisenberg $\mathcal{H}_k$	2	all k
Affine $\widehat{\mathfrak{g}}_k$	$2 \dim \mathfrak{g}$	6 for $\mathfrak{sl}_2$
Principal $\mathcal{W}^k(\mathfrak{g})$	$2r + 4h^\vee d$	26 for $\mathfrak{sl}_2$
$\beta\gamma$	-2	
Virasoro Vir_c	26	$c = 13$ Koszul self-dual

The conductor $K = 26$ for the Virasoro family recovers the bosonic string critical dimension (Theorem 1.3.8).

2.26.6 DUALITY OF THE SHADOW OBSTRUCTION TOWER

The Verdier involution acts on the full MC element by $\mathbb{D}(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}^\dagger}$, and hence on the shadow obstruction tower level by level. For affine Kac–Moody and free-field algebras (where the Verdier involution acts

as sign reversal on each shadow component):

$$\begin{aligned}\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) &= 0, \\ \mathfrak{C}(\mathcal{A}) + \mathfrak{C}(\mathcal{A}^\dagger) &= 0, \\ \mathfrak{Q}(\mathcal{A}) + \mathfrak{Q}(\mathcal{A}^\dagger) &= 0.\end{aligned}$$

For $\mathcal{W}$ -algebras arising from Drinfeld–Sokolov reduction, $\kappa + \kappa'$ is a nonzero constant determined by the root datum (e.g. 13 for Virasoro); see Theorem 13.21.44(iii). The duality of the shadow obstruction tower means that the gravitational complexity of $\mathcal{A}$ and $\mathcal{A}^\dagger$ are the same: $r_{\max}(\mathcal{A}) = r_{\max}(\mathcal{A}^\dagger)$. The gravitational phase space sees both algebras symmetrically.

2.26.7 THE LAGRANGIAN INTERSECTION AND THE CENTER

The intersection of the two Lagrangians,

$$\mathbf{Q}_g(\mathcal{A}) \cap \mathbf{Q}_g(\mathcal{A}^\dagger) = \ker(\sigma - \text{id}) \cap \ker(\sigma + \text{id}) = \ker(\sigma^2 - \text{id}),$$

is nontrivial only when $\sigma^2 \neq \text{id}$; that is, when the Verdier involution has nontrivial higher-order structure. For Koszul pairs on the critical locus ($\kappa = 0$), the involution is strict ($\sigma^2 = \text{id}$) and the intersection is the center $Z(\mathcal{A})$ of the chiral algebra: the space of chiral-central sections that are simultaneously $+1$ and -1 under Verdier involution. Off the critical locus, the intersection is empty (the two Lagrangians are transverse).

2.27 FROM COLLISION TO YANG–BAXTER

The spectral r -matrix $r(z)$ in the holographic datum is extracted from the MC element by a filtration indexed by the depth of collision in the Fulton–MacPherson compactification. The classical Yang–Baxter equation is a formal consequence of the Arnold relation at codimension 2. The Yangian arises as the endomorphism algebra of this construction.

2.27.1 THE COLLISION FILTRATION

Let $\overline{C}_n(X)$ be the Fulton–MacPherson compactification of the configuration space of n distinct points on X . The boundary $\partial\overline{C}_n(X)$ is a normal crossing divisor whose components are indexed by subsets $S \subset \{1, \dots, n\}$ with $|S| \geq 2$: the stratum D_S parametrizes configurations where the points in S collide.

Define the *collision depth* of a boundary stratum as the number of nested collisions:

$$\text{depth}(D_{S_1 \subset \dots \subset S_k}) = k.$$

The collision filtration on the bar complex is

$$F^0 \overline{B}_X(\mathcal{A}) \supset F^1 \overline{B}_X(\mathcal{A}) \supset F^2 \overline{B}_X(\mathcal{A}) \supset \dots,$$

where $F^p \overline{B}_X(\mathcal{A})$ consists of bar elements supported on strata of collision depth $\geq p$. The associated graded is

$$\text{gr}_F^p \overline{B}_X(\mathcal{A}) \cong \bigoplus_{|S|=p+1} \overline{B}_{T_{z_0}X}(\mathcal{A}|_S) \otimes \overline{B}_X(\mathcal{A}|_{S^c \cup \{z_0\}}),$$

where the first factor records the infinitesimal collision pattern (the “screen”) and the second factor records the residual configuration.

The collision filtration is multiplicative: the bar coproduct respects the filtration, and the associated graded inherits a coalgebra structure. The differential on the associated graded is the tree-level approximation to the bar differential: it captures the leading-order OPE at each collision depth.

2.27.2 THE SPECTRAL PARAMETER

At collision depth 1, two points collide: $z_1 \rightarrow z_2$. The screen is $T_{z_0}X \cong \mathbb{C}$, parametrized by the relative coordinate $z = z_1 - z_2$. The bar differential restricted to depth 1 produces the binary OPE, expressed as a Laurent series in z :

$$r(z) = \mathrm{gr}_F^1(d_{\overline{B}})|_{\overline{B}^2} = \sum_{n \geq 0} \frac{r_n}{z^{n+1}},$$

where $r_n \in \mathcal{A}^1 \otimes \mathcal{A}^1$ is the n -th Laurent coefficient, encoding the n -th OPE mode. The element $r(z) \in \mathcal{A}^1 \widehat{\otimes} \mathcal{A}^1((z^{-1}))$ is the *spectral r -matrix*: a meromorphic endomorphism of the tensor square of the Koszul dual, with a pole at $z = 0$ (the collision locus) and regular as $z \rightarrow \infty$ (the separation limit).

The residue of $r(z)$ at $z = 0$ is the leading OPE mode: $\mathrm{Res}_{z=0} r(z) = r_0 \in \mathcal{A}^1 \otimes \mathcal{A}^1$. For affine Kac–Moody, $r_0 = \Omega = \sum_a t^a \otimes t_a$ is the Casimir element. The higher Laurent coefficients $r_1, r_2, \dots$ encode the subleading OPE modes and determine the higher-spin structure of the dg-shifted Yangian.

2.27.3 ARNOLD IMPLIES CYBE

The classical Yang–Baxter equation (CYBE) for $r(z)$ is a formal consequence of the Arnold relation on $\overline{C}_3(X)$. The argument proceeds as follows.

At bar degree 3, the MC equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ restricted to genus 0 and degree 3 gives

$$d_{\overline{B}}(\Theta^{(3)}) + \frac{1}{2}[\Theta^{(2)}, \Theta^{(2)}]^{(3)} = 0,$$

where $\Theta^{(r)}$ denotes the degree- r component. The second term is the operadic composition of two binary operations, which at collision depth 2 produces the triple collision residue.

The collision filtration at depth 2 restricts to the codimension-2 stratum D_{ijk} of triple collision in $\overline{C}_3(X)$. The three pairs (ij) , (jk) , (ik) produce three terms in the iterated residue:

$$\begin{aligned} & [r_{12}(z_1 - z_2), r_{13}(z_1 - z_3)] \\ & + [r_{12}(z_1 - z_2), r_{23}(z_2 - z_3)] \\ & + [r_{13}(z_1 - z_3), r_{23}(z_2 - z_3)] = 0. \end{aligned}$$

Each term corresponds to a boundary stratum of $\overline{C}_3(X)$, and the cyclic sum vanishes because of the Arnold relation $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ at the codimension-2 intersection. The vanishing of this cyclic sum is exactly the CYBE for $r(z)$.

The derivation is Theorem K.7.1. The key point is that no input beyond the geometry of $\overline{C}_3(X)$ is needed: the CYBE is a topological identity, inherited from the Arnold relation on configuration spaces.

2.27.4 FROM r -MATRIX TO YANGIAN

The r -matrix $r(z)$ determines a braided tensor structure on the line-operator category $\mathcal{C}(\mathcal{A}) = \mathcal{A}^1\text{-mod}$. The endomorphism algebra of this tensor structure is the Yangian.

Definition 2.27.1 (The dg-shifted Yangian). The *dg-shifted Yangian* $\mathcal{Y}_T^{\text{dg}}(\mathcal{A})$ is the dg algebra generated by the modes of the r -matrix, with relations imposed by the CYBE and the higher collision conditions:

$$\mathcal{Y}_T^{\text{dg}}(\mathcal{A}) = \text{End}_{\otimes_{r(z)}}(C(\mathcal{A})),$$

the endomorphism algebra of the tensor functor $\otimes_{r(z)}$ on $\mathcal{A}^!$ -mod.

For affine Kac–Moody $\mathcal{A} = \widehat{\mathfrak{g}}_k$, the dg-shifted Yangian recovers the Yangian $Y(\mathfrak{g})$: the rational r -matrix $r(z) = k \Omega/z$ generates the RTT presentation of $Y(\mathfrak{g})$ (Theorem O.2.1), and the CYBE becomes the defining relation of the Yangian. The evaluation homomorphism $\text{ev}_a : Y(\mathfrak{g}) \rightarrow U(\mathfrak{g})$ corresponds to the restriction of the r -matrix to the depth-1 collision stratum.

For the Virasoro algebra, the dg-shifted Yangian is the deformation of $Y(\mathfrak{sl}_2)$ by the Virasoro central charge: the r -matrix has a double pole (from the stress tensor OPE), and the Yangian generators acquire a quadratic correction proportional to c .

2.27.5 THE RTT PRESENTATION

The Yangian admits a presentation through the RTT equation. Define the *monodromy matrix*

$$T(z) = \sum_{n \geq 0} \frac{T_n}{z^{n+1}} \in \text{End}(V) \otimes \mathcal{Y}_T^{\text{dg}}(\mathcal{A})[[z^{-1}]],$$

where V is the evaluation module and T_n are the Yangian generators. The RTT equation is

$$R(z_1 - z_2) T_1(z_1) T_2(z_2) = T_2(z_2) T_1(z_1) R(z_1 - z_2),$$

where $R(z) = 1 + r(z)/z$ is the quantum R -matrix (the classical r -matrix plus the identity), $T_i(z) = T(z)$ acting in the i -th tensor factor, and the equation holds in $\text{End}(V^{\otimes 2}) \otimes \mathcal{Y}[[z_1^{-1}, z_2^{-1}]]$.

The RTT equation is the quantization of the CYBE: the classical limit $\hbar \rightarrow 0$ of $R = 1 + \hbar r + O(\hbar^2)$ gives the CYBE for $r(z)$. From the bar-complex perspective, the RTT equation arises from the collision filtration at depth 3: the depth-3 strata of $\overline{C}_4(X)$ impose relations among the depth-2 generators, and these relations are exactly the RTT equation.

2.27.6 THE MODULAR YANGIAN

The all-genera extension of the Yangian construction is the *modular dg-shifted Yangian* $\mathcal{Y}_T^{\text{dg}, \text{mod}}(\mathcal{A})$ (Definition O.13.112): the pronilpotent completion of the dg-shifted Yangian intended to organize genus corrections. A conjectural modular R -matrix

$$R_T^{\text{mod}}(z; \hbar) = 1 + \sum_{g \geq 0} \hbar^{2g} R_T^{(g)}(z)$$

would be a Maurer–Cartan element in the completed convolution algebra, and the corresponding higher-genus Yang–Baxter condition would be the modular-kernel shadow of the MC equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ at the level of the modular convolution algebra.

At genus 0, the modular R -matrix reduces to the classical r -matrix: $R_T^{(0)}(z) = r(z)$. At genus 1, the correction $R_T^{(1)}(z)$ is intended to encode the elliptic deformation: the r -matrix would acquire a dependence on the modular parameter τ of the torus, controlled by the modular characteristic $\kappa(\mathcal{A})$. The genus expansion of the modular R -matrix is thus only a conjectural higher-genus refinement of the perturbative holographic scattering package on this surface.

2.27.7 THE DRINFELD–KOHNO BRIDGE

The Drinfeld–Kohno theorem connects the KZ connection (a flat connection on the configuration space, with monodromy in the braid group) to the quantum group (a Hopf algebra whose representation category is braided monoidal). From the bar-complex perspective, this bridge is the passage from the shadow connection (§2.24) to the Yangian (§2.27.4):

$$\text{KZ connection } \nabla^{\text{KZ}} \xrightarrow{\text{monodromy}} \text{Braid-group representation} \xrightarrow{\text{DK}} U_q(\mathfrak{g})\text{-mod}$$

The first arrow computes the monodromy of the KZ connection around loops in the configuration space; the second arrow identifies this monodromy representation with the braided tensor category of $U_q(\mathfrak{g})$ -modules. On the affine Kac–Moody comparison surface, the first arrow is classified by the bar complex because the KZ connection is identified there with the genus-0 shadow connection; the second arrow is the Drinfeld–Kohno comparison with the quantum-group side.

The parameter matching is $q = e^{\pi i/(k+h^\vee)}$, where k is the level of the affine Kac–Moody algebra and $h^\vee$ is the dual Coxeter number. This is the Kazhdan–Lusztig equivalence (Theorem 15.2.9): the module category of $\widehat{\mathfrak{g}}_k$ at non-critical level is equivalent to the representation category of $U_q(\mathfrak{g})$, with q determined by the level.

2.28 PERTURBATIVE FINITENESS AND THE CRITICAL STRING

The shadow obstruction tower is an algebraic construction: it lives in the cyclic deformation complex and requires no analysis. The passage to physics (partition functions, amplitudes, modular forms) requires an analytic input: the convergence of the genus tower. This section describes the analytic completion programme and its relation to the critical string.

2.28.1 THE HS-SEWING CRITERION

The analytic convergence of the genus tower is controlled by a Hilbert–Schmidt condition on the sewing amplitudes. Let $\mathcal{A}$ be a conformal vertex algebra with vacuum character $\chi_{\mathcal{A}}(q) = \text{tr}_{\mathcal{A}}(q^{L_0-c/24})$. The *sewing amplitude* at genus g is the functional

$$Z_g(\mathcal{A}; q_1, \dots, q_g) = \text{tr}_{\mathcal{A}^{\otimes g}} \left(\prod_{\alpha=1}^g q_{\alpha}^{L_0-c/24} \cdot S_{\alpha} \right), \quad (2.47)$$

where S_{α} is the sewing operator for the α -th handle.

Definition 2.28.1 (HS-sewing condition). The chiral algebra $\mathcal{A}$ satisfies the *HS-sewing condition* if, for all $0 < |q| < 1$ and all sewing data, the sum

$$\sum_{a,b,c} |q|^{a+b+c} \|m_{a,b}^c\|_{\text{HS}}^2 < \infty,$$

where $m_{a,b}^c$ is the OPE structure constant between states of conformal weight a, b, c , and $\|\cdot\|_{\text{HS}}$ is the Hilbert–Schmidt norm on the finite-dimensional weight spaces.

The HS-sewing condition implies that the sewing amplitude (2.47) converges absolutely and defines a holomorphic function of $(q_1, \dots, q_g)$ in the polydisk $|q_{\alpha}| < 1$. The convergent sum is the genus- g partition function $Z_g(\mathcal{A})$.

THEOREM 2.28.2 (*General HS-sewing criterion*;). Polynomial OPE growth and subexponential sector growth imply the HS-sewing condition at all genera. In particular, the HS-sewing condition holds for every algebra in the standard landscape: Heisenberg, free fermion, lattice, $\beta\gamma$, affine Kac–Moody, Virasoro, $\mathcal{W}$ -algebras. The proof is Theorem K.7.1.

2.28.2 THE HEISENBERG SEWING THEOREM

For the Heisenberg algebra, the sewing reduces to a one-particle computation. The genus- g partition function is a Fredholm determinant of the Bergman sewing operator:

THEOREM 2.28.3 (*Heisenberg sewing*;). The genus- g partition function of $\mathcal{H}_k$ is

$$Z_g(\mathcal{H}_k) = \det\left(1 - S_g^{(1)}\right)^{-k},$$

where $S_g^{(1)}$ is the one-particle Bergman sewing operator, a trace-class operator on the one-particle Hilbert space $\mathcal{H}_k^{(1)} = \bigoplus_{n \geq 1} \mathbb{C} \cdot \alpha_{-n}|0\rangle$. The eigenvalues of $S_g^{(1)}$ are the squares of the Schottky parameters. The proof is Theorem K.7.1.

The Fredholm determinant formula is the Gaussian case of the sewing programme: because the Heisenberg has only a double-pole OPE, the multi-particle sewing operator factorizes into a product of one-particle operators, and the trace over the Fock space reduces to a determinant. For non-Gaussian algebras (Kac–Moody, Virasoro, $\mathcal{W}$ -algebras), the sewing operator does not factorize, and the partition function requires the full HS-sewing machinery of Theorem 2.28.2.

2.28.3 THE $\hat{A}$ -GENUS AND INDEX TRANSGRESSION

The generating function of the genus- g obstruction classes is the $\hat{A}$ -genus (Theorem 13.21.44):

$$\sum_{g \geq 1} \text{obs}_g(\mathcal{A}) \cdot \hbar^{2g} = \kappa(\mathcal{A}) \cdot (\hat{A}(i\hbar) - 1) = \kappa(\mathcal{A}) \cdot \left(\frac{i\hbar/2}{\sinh(i\hbar/2)} - 1 \right).$$

The $\hat{A}$ -genus appears because the obstruction classes $\text{obs}_g = \kappa \cdot \lambda_g$ (proved for uniform-weight algebras at all genera, and unconditionally at $g = 1$) are the Chern characters of the Hodge bundle, and $\text{td}(\mathbb{E}^\vee) = \hat{A}(i\hbar)$ by the Grothendieck–Riemann–Roch theorem applied to the universal curve.

The index transgression is the passage from characteristic classes on $\overline{\mathcal{M}}_g$ to partition functions on curves: the $\hat{A}$ -genus of the Hodge bundle transgresses to the modular discriminant $\Delta(\tau)$ on the moduli of elliptic curves. For the Heisenberg, this gives $Z_1(\mathcal{H}_k) = \eta(\tau)^{-k}$, where $\eta(\tau) = q^{1/24} \prod_{n \geq 1} (1 - q^n)$ is the Dedekind eta function. For the Virasoro at central charge c , the genus-1 partition function is $Z_1(\text{Vir}_c) = q^{-c/24} \prod_{n \geq 2} (1 - q^n)^{-1}$, and the one-loop effective action is $\log Z_1 = -\frac{c}{24} \log q + \sum_{n \geq 2} \log(1 - q^n)^{-1}$.

2.28.4 THE CRITICAL STRING AT $c = 26$

The bosonic string critical dimension emerges from Koszul duality alone. The Virasoro algebra Vir_c is Koszul dual to Vir_{26-c} (Chapter H), and the complementarity sum is

$$c + c' = c + (26 - c) = 26.$$

The anomaly-cancellation condition for the string is $c_{\text{matter}} + c_{\text{ghost}} = 0$, where the ghost contribution is $c_{\text{ghost}} = -26$. From the bar-complex perspective, the Koszul dual of the matter Virasoro is $\text{Vir}_c^\dagger \simeq \text{Vir}_{26-c}$

(Chapter H), and the complementarity sum $c + c' = c + (26 - c) = 26$ recovers the critical dimension. The ghost system (bc at $c = -26$) is the physical implementation of the Koszul dual; the cobar $\Omega(\overline{B}(\text{Vir}_c))$ recovers Vir_c itself by bar-cobar inversion (Theorem B), not the dual (Remark 1.3.9).

The perturbative finiteness of the bosonic string at $c = 26$ is the statement that the total BRST complex has $\kappa = 0$: the genus tower is unobstructed, and the bar complex is nilpotent at all genera. Equivalently, the modular characteristic of the matter-ghost system vanishes:

$$\kappa(\text{Vir}_{26} \otimes bc_{-26}) = \kappa(\text{Vir}_{26}) + \kappa(bc_{-26}) = 13 + (-13) = 0,$$

using the additivity of κ under tensor product: the matter Virasoro at $c = 26$ has $\kappa = 13$, while the bc ghost system at $c = -26$ has $\kappa = -13$. The critical dimension is not an input but a consequence of Koszul duality.

2.28.5 THE SEWING ENVELOPE AND ANALYTIC CONTINUATION

The algebraic bar complex is a dense skeleton of the analytic object. The passage from algebra to analysis is the *sewing envelope* $\mathcal{A}^{\text{sew}}$: the Hausdorff completion of $\mathcal{A}$ in the all-amplitude seminorm topology. The sewing envelope carries the structure of a topological chiral algebra, and the HS-sewing condition ensures that the sewing amplitudes extend from the algebraic core to the completed object.

The analytic bar coalgebra $\overline{B}^{\text{an}}(\mathcal{A})$ is the graph-norm closure of the algebraic bar complex inside the completed tensor algebra of the sewing envelope. The analytic Koszul pair $(\mathcal{A}^{\text{sew}}, (\mathcal{A}^!)^{\text{sew}})$ is the completed version of the algebraic Koszul pair, and the analytic shadow $Q_g^{\text{an}}(\mathcal{A})$ is the genus- g factorization homology of the analytic bar coalgebra.

The platonic chain relating the algebraic and analytic objects is

$$\mathcal{A}_{\text{alg}} \subset \mathcal{A}^{\text{sew}} \rightsquigarrow \mathcal{F}_{\mathcal{A}} \in \text{IndHilb} \rightsquigarrow Q_{\bullet}^{\text{an}}(\mathcal{A}),$$

where $\mathcal{A}_{\text{alg}}$ is the algebraic core, $\mathcal{A}^{\text{sew}}$ is the sewing envelope, $\mathcal{F}_{\mathcal{A}}$ is the factorization algebra valued in ind-Hilbert spaces (in the sense of Moriawaki [323]), and $Q_{\bullet}^{\text{an}}(\mathcal{A})$ is the sequence of analytic shadows. The Heisenberg sewing theorem (Theorem 2.28.3) is the first completed step in this chain. The remaining steps are the subject of the analytic sewing programme.

2.29 GUIDE TO THE DEVELOPMENT

The results of this monograph are organized along ten principal lines, each building on the categorical logarithm of Part I, the nonlinear engine of Part II, and the E_1 wing of Part III, then extending outward through the standard landscape (Part IV), the bridges to mathematical physics (Part .2), and the frontier (Part .2). The holographic datum $\mathcal{H}(\mathcal{A})$ of §2.22.5 provides the unifying thread: each result is a projection or extraction from the single MC element $\Theta_{\mathcal{A}}$.

2.29.1 THE ALGEBRAIC ENGINE

The algebraic engine consists of Theorems A–D and H, proved in Part I. The constructions are:

- (i) The bar-cobar adjunction $\overline{B}_X \dashv \Omega_X$ with Verdier intertwining (Theorem A, Chapter 8).
- (ii) Bar-cobar inversion on the Koszul locus (Theorem B, Chapter 8).

- (iii) The Lagrangian complementarity decomposition $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^\dagger)$ (Theorem C, Chapter 13).
- (iv) The scalar modular characteristic $\kappa(\mathcal{A})$ with $\hat{A}$ -genus generating function (Theorem D, Chapter 13).
- (v) Polynomial chiral Hochschild cohomology on the Koszul locus (Theorem H, Chapter 14).

These five theorems are projections of the single identity $D_{\mathcal{A}}^2 = 0$ at the convolution level.

2.29.2 THE SHADOW OBSTRUCTION TOWER

The nonlinear characteristic layer (Part I, Chapter 18) extends the scalar invariant κ to the full MC element $\Theta_{\mathcal{A}}$:

- (i) Construction of the modular convolution dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ and its cyclic subcomplex $\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A})$ (Chapter 13).
- (ii) The bar-intrinsic MC element $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_{\mathcal{A}}^{(0)}$ (Theorem 13.21.69).
- (iii) Finite-order projections: κ (degree 2), $\mathfrak{C}$ (degree 3), $\mathfrak{Q}$ (degree 4).
- (iv) Shadow archetypes: G/L/C/M classification of the standard landscape.
- (v) Clutching laws for the quartic class (Theorem 18.7.11).
- (vi) Shadow algebra $\mathcal{A}^{\text{sh}} = H_{\bullet}(\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A}))$ as universal home for modular invariants.

2.29.3 THE STANDARD LANDSCAPE

Part IV computes the algebraic engine on every major family. Each chapter produces the bar complex, Koszul dual, genus tower, modular characteristic, and shadow archetype. The families are: Heisenberg, free fermion, lattice, $\beta\gamma$, symplectic fermion, affine Kac–Moody (all types), principal $\mathcal{W}$ -algebras (all types), Virasoro, $\mathcal{W}_N$ ($N \geq 3$), deformation quantization families, Yangians, and toroidal/elliptic algebras.

2.29.4 THE HOLOGRAPHIC TRIANGLE

The holographic programme (§2.23) assembles the engine into the six-fold datum $\mathcal{H}(\mathcal{A})$. The Swiss-cheese factorization (Chapter A.9), the bulk-boundary-line triangle, the collision filtration (§2.27), and the four recovery theorems (§2.23.6) produce a rigid package whose internal consistency is guaranteed by the MC equation.

2.29.5 THE SHADOW CONNECTION

The shadow connection (§2.24) gives the general flat modular connection on the bar-cohomological / derived-coinvariant package. On the affine genus-0 comparison surface it identifies with the KZ connection, and on the Virasoro degenerate-module surface its higher collision residues yield the BPZ equations. The genus-1 extension involves the Hodge bundle and the modular characteristic κ .

2.29.6 THE YANGIAN EXTRACTION

The collision-to-Yang–Baxter programme (§2.27) constructs the dg-shifted Yangian from the bar complex. The CYBE is the Arnold relation at codimension 2. The modular Yangian carries the genus corrections as a pro-MC element. The Drinfeld–Kohno theorem is the affine comparison package from KZ monodromy to the corresponding quantum-group side (Chapter O).

2.29.7 PERTURBATIVE FINITENESS

The analytic completion programme (§2.28) upgrades the algebraic bar complex to convergent partition functions. The HS-sewing criterion (Theorem K.7.1) covers the standard landscape. The Heisenberg sewing theorem is the Gaussian seed. The critical string at $c = 26$ is an output of the Virasoro complementarity sum.

2.29.8 COMPLETION AND THE MC FRONTIER

The MC frontier (§1.7) records the boundary between proved and open territory. MC1 through MC4 are proved; MC5 is partially proved (analytic HS-sewing package at all genera; genuswise BV/BRST/bar identification conjectural). MC3 is proved for all simple types on the evaluation-generated core (Theorem O.9.71, Corollary O.9.73); the residual DK-4/5 problem (extension and completion beyond evaluation modules) is downstream of MC3. The remaining frontiers are non-principal W-algebra duality, analytic completion, and the genuswise BV/BRST/bar comparison. The completed bar-cobar theory (MC4, Theorem 8.1.27) gives a completion-closed homotopy equivalence. The MC4 splitting (positive towers solved, resonant towers reduced to finite problems) is the structural resolution of the completion obstacle.

2.29.9 BRIDGES TO PHYSICS

Part .2 connects the engine to Feynman diagrams, BV-BRST quantization (Chapter R.3.1), Yang–Mills boundary theory, and geometric Langlands. The bar complex is the BRST complex; the MC equation is the quantum master equation $\hbar\Delta S + \frac{1}{2}\{S, S\} = 0$; the shadow connection is the gauge connection of the BV formalism.

2.29.10 VOLUME II AND BEYOND

Volume II applies the engine to the full bulk/boundary/line triangle in 3d holomorphic-topological QFT. The bar complex’s differential is $\mathbb{C}$ -direction factorization; its deconcatenation coproduct is $\mathbb{R}$ -direction factorization; together they make $\overline{B}_X(\mathcal{A})$ an E_1 -chiral coassociative coalgebra on $\mathrm{FM}_k(\mathbb{C}) \times \mathrm{Conf}_k(\mathbb{R})$. The $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ structure emerges on the derived center pair $(C_{\mathrm{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A})$; the recognition theorem, homotopy-Koszulity, PVA descent, and the derived conformal-block line-operator identification are proved in Volume II. The PVA quantization bridge and holographic applications complete the programme.

2.29.11 THE KOSZULNESS CHARACTERIZATION PROGRAMME

The meta-theorem on chiral Koszulness (Theorem 11.1.50) lists twelve characterizations of the Koszul property for chiral algebras: items (i)–(x) are ten *unconditional* equivalences; item (xi), the Lagrangian criterion, is *conditional* on perfectness and nondegeneracy hypotheses; item (xii), D-module purity, is *one-directional* ((xii) $\Rightarrow$ (x) proved, converse open). The conditions range across several mathematical disciplines:

- (i) A_∞ -formality of the bar cohomology.
- (ii) Shadow-formality: the shadow obstruction tower is equivalent to the L_∞ -formality obstruction tower at degrees 2, 3, 4.
- (iii) E_2 -formality of chiral Hochschild cohomology.
- (iv) Genus-0 curve independence: Koszulness on $\mathbb{P}^1$ implies Koszulness on any smooth curve.
- (v) Graph-sum truncation: the graph sum for $\Theta_{\mathcal{A}}^{\leq r}$ terminates at finitely many graphs.
- (vi) Universal Koszulness: $V_k(\mathfrak{g})$ is chirally Koszul for all k .
- (vii) PBW universality: freely strongly generated vertex algebras are chirally Koszul.
- (viii) Barr–Beck–Lurie: the monadic characterization via the bar-cobar monad.
- (ix) Factorization homology concentration: $\int_X \mathcal{A}$ is concentrated in the expected cohomological degrees.
- (x) FM boundary acyclicity: the restriction of the bar complex to the boundary of $\overline{C}_n(X)$ is acyclic.
- (xi) Tropical Koszulness: the tropicalization of the bar complex is acyclic.
- (xii) Lagrangian criterion: the Lagrangian complement $\mathbf{Q}_g(\mathcal{A}^!)$ is concentrated in the expected degrees.
(Conditional on perfectness and nondegeneracy hypotheses.)

The ten unconditional equivalences are proved by chain-level arguments connecting each condition to the degeneration of the bar spectral sequence at E_2 . The Lagrangian criterion requires additional hypotheses on the ambient pairing (see Theorem 8.6.37). The programme is recorded in §K.7.1 of the concordance.

2.29.12 SUMMARY OF DEPENDENCIES

The logical dependencies among the principal constructions are:

Construction	Depends on
Bar complex $\overline{B}_X(\mathcal{A})$	chiral algebra $\mathcal{A}$, FM compactification
Koszul dual $\mathcal{A}^!$	Theorem A (Verdier intertwining)
MC element $\Theta_{\mathcal{A}}$	$D_{\mathcal{A}}^2 = 0$ (formal consequence of $\partial^2 = 0$ on $\overline{\mathcal{M}}_{g,n}$)
Shadow obstruction tower	projections of $\Theta_{\mathcal{A}}$
r -matrix $r(z)$	collision filtration on $\overline{B}_X(\mathcal{A})$
CYBE	Arnold relation on $\overline{C}_3(X)$
Yangian $\mathcal{Y}_T^{\text{dg}}$	r -matrix + RTT equation
Shadow connection ∇^{hol}	$\text{Sh}_{g,n}(\Theta_{\mathcal{A}})$
KZ connection (affine comparison surface)	$\nabla^{\text{hol}} _{g=0}$
BPZ equations (Virasoro degenerate-module surface)	null vectors + shadow connection
HS-sewing	OPE growth bounds
$c = 26$	Virasoro Koszul duality + $\kappa_{\text{tot}} = 0$

Every entry in the right column is either a geometric input (FM compactification, boundary stratification of moduli) or a consequence of the identity $D_{\mathcal{A}}^2 = 0$. The holographic programme is a tree rooted at this single identity.

2.29.13 THE MASTER INVARIANT TABLE

The following table collects the principal numerical invariants produced by the holographic datum for the standard families. Each entry is a projection of $\Theta_{\mathcal{A}}$.

Family	κ	$c + c'$	$r_{\max}$	Class
Heisenberg $\mathcal{H}_k$	k	2	2	G
Free fermion ψ_k	$k/4$	1	2	G
Lattice V_{Λ}	$\text{rank}(\Lambda)$	$2 \text{rank}(\Lambda)$	2	G
$\beta\gamma$	-1	-2	4	C
$\widehat{\mathfrak{sl}}_{2k}$	$\frac{3(k+2)}{4}$	6	3	L
$\widehat{\mathfrak{g}}_k$	$\frac{(k+h^{\vee}) \dim \mathfrak{g}}{2h^{\vee}}$	$2 \dim \mathfrak{g}$	3	L
Vir_c	$c/2$	26	∞	M
$\mathcal{W}^k(\mathfrak{sl}_N)$	$c(H_N - 1)$	$2(N-1)(2N^2+2N+1)$	∞	M
$Y(\mathfrak{sl}_N)$ (Yangian)	$N^2 - 1$	$2(N^2 - 1)$	3	L

The modular characteristic κ determines the one-loop physics; the conductor $c + c'$ determines the anomaly cancellation; the shadow depth $r_{\max}$ determines the gravitational complexity. All three invariants are computable from the bar complex of $\mathcal{A}$, and all three are projections of the holographic datum $\mathcal{H}(\mathcal{A})$.

The seven sections of this supplement, from the Swiss-cheese factorization to the master invariant table, form a self-contained executive summary of the holographic content of the monograph. The full proofs and computations appear in Parts I–IV of Volume I and in Volume II.

Part I

The Bar Complex

Place sections $a_1, \dots, a_n$ of a chiral algebra $\mathcal{A}$ at distinct points $z_1, \dots, z_n$ on a smooth curve X . Wedge the tensor $a_1(z_1) \otimes \dots \otimes a_n(z_n)$ against the logarithmic n -form $\eta = \bigwedge_{i < j} d \log(z_i - z_j)$ on the Fulton–MacPherson compactification $\overline{C}_n(X)$, and extract residues at each collision divisor. The result is a differential. Arnold’s three-term identity

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$$

forces $d^2 = 0$. This is the bar complex $\overline{B}_X(\mathcal{A})$: the categorical logarithm of $\mathcal{A}$.

A logarithm has four properties. Each is a theorem.

- (A) **Existence.** The bar-cobar adjunction $(\overline{B}, \Omega)$, intertwined with Verdier duality on $\text{Ran}(X)$. The logarithm exists and is natural.
- (B) **Invertibility.** On the Koszul locus, $\Omega(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$: the cobar inverts the bar, with the spectral sequence collapsing at E_2 . The logarithm has an exponential.
- (C) **Branch structure.** At genus $g \geq 1$, $\mathcal{Q}_g(\mathcal{A}) \oplus \mathcal{Q}_g(\mathcal{A}^\dagger)$ sit as complementary Lagrangians inside $R\Gamma(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$. The logarithm has monodromy; its sheets are Lagrangian.
- (D) **Leading coefficient.** The modular characteristic $\kappa(\mathcal{A})$ is universal, additive, and duality-constrained; its generating function is the $\hat{A}$ -genus. The leading Taylor coefficient of the logarithm is a topological index.

(H) **The coefficient ring.** $CH^*(\mathcal{A})$ is polynomial on the Koszul locus and dual to $CH^*(\mathcal{A}^\dagger)$. The full Taylor series of the logarithm lives in a polynomial ring.

But $\kappa(\mathcal{A})$ is only the *linear* leading term. Part II develops the full nonlinear structure: the *shadow obstruction tower* $\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \dots$, a hierarchy of finite-order invariants (quadratic, cubic, quartic, and beyond), each proved constructively with obstruction classes $\mathcal{O}_{r+1}(\mathcal{A})$ in the cyclic deformation complex. The all-degree limit of this tower is the universal class $\Theta_{\mathcal{A}}$, proved by the bar-intrinsic construction (Theorem 13.21.69); the constructive content is the finite-order engine.

Chapter 3

Algebraic foundations and bar constructions

The classical bar complex does not see curves. For a quadratic algebra A over a point, $\bar{B}(A) = T^c(s^{-1}\bar{A})$ records the multiplication through the deconcatenation differential and nothing else: the composition $a_1 \cdot a_2$ lives in degree zero, the relations among compositions live in degree one, and the PBW property is a statement about the filtration by word length. No information flows across a spatial separation, because the ground field has no geometry. On a smooth curve X , by contrast, two generators of a chiral algebra $\mathcal{A}$ placed at distinct points z_1, z_2 interact through an OPE whose singular coefficients along the diagonal $z_1 = z_2$ are the data the classical bar construction misses entirely. The pole $1/(z_1 - z_2)^k$ and the logarithmic form $\eta = d \log(z_1 - z_2)$ that absorbs one pole are not combinatorial decorations: they are the degree-two scattering kernel of the algebra, and the whole factorization structure on $\text{Ran}(X)$ is built out of them.

A chiral upgrade of Koszul duality therefore has to add three ingredients that the classical theory cannot supply on its own. First, the tensor product $V^{\otimes n}$ is replaced by the factorization product $\mathcal{A}^{\boxtimes n}$ on the configuration space $C_n(X)$, whose boundary strata record the successive collisions of points. Second, the differential is no longer a sum of face maps but a sum of residues at those strata, weighted by the Arnold forms $\eta_{ij} = d \log(z_i - z_j)$ that organise the E_2 -page of the arrangement cohomology of the diagonal complement. Third, the whole construction has to survive genus-by-genus: at higher genus the propagator picks up period corrections from $H^0(\Sigma_g, \Omega^1)$, and the bar differential becomes curved. Before any of this is possible the classical definitions have to be rephrased in the cohomological grading used throughout the chiral extension, with desuspension s^{-1} lowering degree and the convolution dg Lie algebra $\mathfrak{g}_\tau$ governing the twisting morphism that links bar to cobar. The classical story then becomes the genus-zero, degree-two projection of a larger object whose genus tower and modular extensions are the content of the later chapters.

Given a quadratic algebra $A = T(V)/(R)$ with $R \subset V \otimes V$, the *Koszul dual coalgebra* is the sub-coalgebra $A^\perp \hookrightarrow T^c(sV^*)$ cogenerated by $s^2 R^\perp$, where $R^\perp = \{f \in V^* \otimes V^* : \langle f, r \rangle = 0 \text{ for all } r \in R\}$ is the orthogonal complement under the canonical pairing (Construction 3.1.4). The bar complex $\bar{B}(A)$ is the cofree coalgebra $T^c(s^{-1}\bar{A})$ on the desuspended augmentation ideal, equipped with the differential $d_{\bar{B}} = d_{\text{internal}} + d_{\text{coproduct}}$ whose second component encodes the multiplication of A through the formula $d_{\text{coproduct}}(s^{-1}a_1 \otimes \cdots \otimes s^{-1}a_n) = \sum_i \pm s^{-1}a_1 \otimes \cdots \otimes s^{-1}(a_i \cdot a_{i+1}) \otimes \cdots \otimes s^{-1}a_n$. On the Koszul locus, $H^*(\bar{B}(A))$ is concentrated in bar degree 1 and recovers $A^\perp$ (Definition 3.1.7). The central algebraic object mediating between bar and cobar is the *convolution dg Lie algebra* $\mathfrak{g}_\tau := \text{Hom}(\bar{B}(A), A)$ (Definition 3.1.13), with bracket $[f, g] = \mu_A \circ (f \otimes g) \circ \Delta_{\bar{B}} - (-1)^{|f||g|} \mu_A \circ (g \otimes f) \circ \Delta_{\bar{B}}$ and differential $\partial f = d_A \circ f - (-1)^{|f|} f \circ d_{\bar{B}}$. A *twisting morphism* $\tau : \bar{B}(A) \rightarrow A$ (Definition 3.1.19) is a Maurer–Cartan

element of this Lie algebra: $\partial\tau + \frac{1}{2}[\tau, \tau] = 0$. The bar-cobar adjunction, its inversion on the Koszul locus, and the genus tower are all controlled by τ and its modular extensions.

MOTIVATING GEOMETRY: COLLISIONS AND DUALITY

Why do algebras have duals? The Ran space $\text{Ran}(X)$ (Definition 3.3.2) parameterizes finite nonempty subsets of a smooth curve X . When two points collide, their interaction must be encoded algebraically. The bar construction records collision strata as a graded coalgebra $\bar{B}(\mathcal{A})$ cogenerated by dual generators. The cobar construction inverts: it reassembles the original algebra from collision data via the coalgebra coproduct.

On the Koszul locus (a homological acyclicity condition on the bar complex), this round trip is bijective. Bar and cobar are adjoint projections of a single incidence correspondence on the Fulton–MacPherson compactification $\bar{C}_n(X)$. The geometry is developed in §3.3.2 and Chapter 8; here we focus on the algebraic avatar: *classical Koszul duality*.

3.1 CLASSICAL KOSZUL DUALITY

3.1.1 QUADRATIC ALGEBRAS AND KOSZUL DUALITY

Definition 3.1.1 (Quadratic algebra). A graded algebra $A = T(V)/I$ is *quadratic* if:

1. V is a graded vector space (generators)
2. $I \subset V \otimes V$ is a subspace of relations in degree 2
3. The defining ideal is (I) generated by I

We write $A = A(V, R)$ where $R \subset V \otimes V$ are the relations. The algebra carries a canonical *augmentation* $\varepsilon: A \rightarrow k$ sending all generators to zero; the *augmentation ideal* is $\bar{A} = \ker(\varepsilon) = \bigoplus_{n \geq 1} V^{\otimes n} / (I)$. The bar construction (Definition I.6.3) is built from $\bar{A}$.

Example 3.1.2 (Prototypical examples). The symmetric algebra $\text{Sym}(V)$ has $R = \{v \otimes w - w \otimes v\}$; the exterior algebra $\Lambda(V)$ has $R = \{v \otimes w + w \otimes v\}$. The universal enveloping algebra $U(\mathfrak{g})$ has:

$$\begin{aligned} \text{Generators: } & \mathfrak{g} \\ \text{Relations: } & R_{\mathfrak{g}} = \{x \otimes y - y \otimes x - [x, y] : x, y \in \mathfrak{g}\} \end{aligned}$$

3.1.2 THE KOSZUL DUAL COALGEBRA

Example 3.1.3 (Com–Lie: the coalgebra). The symmetric algebra $\text{Sym}(V)$ has relations $R = \Lambda^2(V) \subset V^{\otimes 2}$ (antisymmetric tensors). Its orthogonal complement is $R^\perp = \text{Sym}^2(V^*) \subset (V^*)^{\otimes 2}$. The Koszul dual coalgebra is the sub-coalgebra $\text{Sym}^! \hookrightarrow T^c(sV^*)$ cogenerated by $s^2 R^\perp$; since the suspended generators sV^* have degree 1, the Koszul sign rule makes graded-symmetric tensors antisymmetric in the unsigned sense, and the result is the exterior coalgebra $\Lambda^c(sV^*)$ with deconcatenation coproduct. When $\dim V < \infty$, the degree-wise linear dual is

$$(\Lambda^c(sV^*))^\vee \cong \Lambda(sV),$$

the Koszul dual algebra (exterior algebra on the suspended generators). The coalgebra $\Lambda^c(sV^*)$ and the algebra $\Lambda(sV)$ are related by degree-wise linear dualizing, which requires $\dim V < \infty$. Separately, the

Chevalley–Eilenberg cochain algebra $C_{\text{CE}}^*(V)$ of the abelian Lie algebra V is $\Lambda(sV^*)$ (exterior algebra on the suspended dual generators); it coincides with $\Lambda(sV)$ only when $V \cong V^*$.

Construction 3.1.4 (Koszul dual coalgebra). Given a quadratic algebra $A = A(V, R)$ with $R \subset V^{\otimes 2}$, define the orthogonal complement

$$R^\perp = \{f \in V^* \otimes V^* : \langle f, r \rangle = 0 \text{ for all } r \in R\}, \quad \langle \alpha \otimes \beta, v \otimes w \rangle = \langle \alpha, v \rangle \langle \beta, w \rangle.$$

The *Koszul dual coalgebra* is the sub-coalgebra

$$A^\dagger \hookrightarrow T^c(sV^*),$$

defined as the *maximal* sub-coalgebra of the cofree coalgebra $T^c(sV^*)$ whose degree-2 component lies in $s^2R^\perp$. Maximality is well-defined: since the sum of any family of sub-coalgebras with degree-2 part in $s^2R^\perp$ again has degree-2 part in $s^2R^\perp$ (the constraint is linear), a unique largest sub-coalgebra with this property exists. It is constructed explicitly: the degree- n component is

$$(A^\dagger)^{(n)} = \bigcap_{i+j=n-2} (sV^*)^{\otimes i} \otimes s^2R^\perp \otimes (sV^*)^{\otimes j}$$

inside $(sV^*)^{\otimes n}$, with comultiplication given by restricting deconcatenation. This intersection formula gives the maximal sub-coalgebra because any sub-coalgebra $C \subset T^c(sV^*)$ with $C^{(2)} \subset s^2R^\perp$ necessarily has $C^{(n)} \subset (A^\dagger)^{(n)}$ for all n : the deconcatenation coproduct on $C^{(n)}$ lands in $\bigoplus_{i+j=n} C^{(i)} \otimes C^{(j)}$, so each “slot” through which a degree-2 factor passes is constrained to $s^2R^\perp$. This is a sub-coalgebra of the cofree coalgebra, not a quotient. When each $(A^\dagger)^{(n)}$ is finite-dimensional (in particular, when $\dim V < \infty$), the graded linear dual $(A^\dagger)^\vee$ is the *Koszul dual algebra*: a quotient of the free algebra on the dual generators, with relations determined by R .

3.1.3 KOSZUL PAIRS: PRECISE DEFINITION

Definition 3.1.5 (Koszul pair). A pair of quadratic algebras (A_1, A_2) is a *Koszul pair* if:

1. $\bar{B}(A_1) \simeq A_2^\dagger$ (as coalgebras)
2. $\bar{B}(A_2) \simeq A_1^\dagger$ (as coalgebras)
3. $\Omega(\bar{B}(A_1)) \simeq A_1$ (cobar inverts bar)
4. $\Omega(\bar{B}(A_2)) \simeq A_2$ (cobar inverts bar)

Definition 3.1.6 (Koszul chiral algebra). Let X be a smooth projective curve over $\mathbb{C}$. An augmented chiral algebra $\mathcal{A}$ (Definition 3.3.3) is *Koszul* if the bar-cobar counit

$$\varepsilon: \Omega_X(\bar{B}_X(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$$

is a quasi-isomorphism at genus 0.

Definition 3.1.7 (Koszul locus). The *Koszul locus* is the full subcategory

$$\text{Kosz}(X) \subset \text{Alg}_{\text{aug}}(\text{Fact}(X))$$

of augmented chiral algebras that are Koszul in the sense of Definition 3.1.6.

Definition 3.1.8 (Modular Koszul chiral algebra). A Koszul chiral algebra $\mathcal{A}$ is *modular Koszul* if it also satisfies axiom (MK₃) of Definition 13.21.9: at each genus $g \geq 1$, the PBW spectral sequence of the genus- g bar construction $\overline{B}_X^{(g)}(\mathcal{A})$ degenerates at E_2 . The *modular Koszul locus* is the full subcategory

$$\text{Kosz}^{\text{mod}}(X) \subset \text{Kosz}(X)$$

of modular Koszul chiral algebras. On the modular Koszul locus, bar-cobar inversion holds at all genera (Theorem 13.18.4) and complementarity decomposes the center local system into Lagrangian summands (Theorem 13.15.14). The full dg model with axioms (MK₁)–(MK₃) and data (D₁)–(D₆) is Definition 13.21.9 (Chapter 13).

Remark 3.1.9 (Equivalent formulations of Koszulness). Definition 3.1.6 is equivalent to each of the following conditions:

- (i) *PBW degeneration*: the PBW spectral sequence, induced by the conformal weight filtration on $\overline{B}_X(\mathcal{A})$, degenerates at E_2 (Theorem 11.1.18);
- (ii) *Concentration*: $H^*(\overline{B}_X(\mathcal{A}))$ is concentrated in bar degree 1;
- (iii) *Acyclicity*: the twisted tensor product $\overline{B}_X(\mathcal{A}) \otimes_{\pi} \mathcal{A}^!$, formed with the universal twisting morphism π (Proposition 3.1.21(i), Definition 3.1.20), is acyclic.

These equivalences are special cases of the ten unconditional equivalences (i)–(x) proved in Theorem 11.1.50 (Chapter 11). Off the Koszul locus, the bar complex is curved and lives in the coderived category (Appendix K.7.1); the categorical logarithm has monodromy.

The definition above identifies Koszulness with the bar-cobar counit being a quasi-isomorphism. Chapter 11 introduces the antecedent recognition data: a chiral twisting datum (Definition 11.1.1) and a Koszul twisting morphism (Definition 11.1.3, Theorem 11.1.9); bar-cobar identifications are then proved as consequences on the Koszul locus. The full chiral Koszul pair is Definition 11.1.15 (previewed in §3.1.5 below); the E_1 -chiral version appears in Theorem 11.5.4.

Remark 3.1.10 (Two phenomena). Conditions (1)–(2) establish *Koszul duality*: bar of A_1 produces the dual coalgebra to A_2 , and vice versa. Conditions (3)–(4) establish *bar-cobar inversion*: $\Omega \circ \overline{B}$ is homotopy equivalent to the identity. These are logically independent.

3.1.4 CLASSICAL EXAMPLES REVISITED

THEOREM 3.1.11 (*Classical Koszul pairs; [359, 41, 299]*). The following are Koszul pairs in the sense of Definition 3.1.5:

1. $(\text{Sym}(V), \Lambda(V^*))$: commutative and exterior algebras
2. $(U(\mathfrak{g}), C_{\text{CE}}^*(\mathfrak{g}))$: universal enveloping and Chevalley–Eilenberg cochains
3. $(T(V), T^c(V^*))$: tensor algebra and tensor coalgebra

Each pair satisfies all four conditions of Definition 3.1.5.

The chiral enhancement appears in Chapter 2 (Heisenberg, double pole), §E.1.1 (free fermions, simple pole), and Chapter G (Kac–Moody, mixed poles).

Definition 3.1.12 (Spectral-parameter classical Yang–Baxter equation). Let $r(z) \in \mathfrak{g} \otimes \mathfrak{g}((z^{-1}))$ be a meromorphic function of a spectral parameter z . The *spectral-parameter CYBE* is

$$[r_{12}(z), r_{13}(z+w)] + [r_{12}(z), r_{23}(w)] + [r_{13}(z+w), r_{23}(w)] = 0.$$

This is distinct from the *constant CYBE* $[r_{12}, r_{13}] + [r_{12}, r_{23}] + [r_{13}, r_{23}] = 0$: the Casimir Ω satisfies the spectral form (with $r(z) = k\Omega/z$) but not the constant form.

3.1.5 CHIRAL KOSZUL PAIRS: PREVIEW

Definition 3.1.5 extends to chiral algebras (Definition 3.3.3) via a two-step formulation: the *construction* of bar and cobar exists for all augmented chiral algebras (Definition 11.1.1), while the Koszul *recognition criterion* identifies when these constructions yield resolutions (Definition 11.1.3; full treatment: Definition 11.1.15, Chapter 11).

The chiral Koszul pair structure has three layers (cf. Definition 11.1.15, Chapter 11):

- (i) *Construction layer*: For every augmented chiral algebra $\mathcal{A}$, the bar construction $\bar{B}^{\text{ch}}(\mathcal{A})$ and cobar construction $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}))$ exist as objects (Definition 11.1.1).
- (ii) *Recognition layer*: A chiral twisting datum $(\mathcal{A}, C, \tau, F_\bullet)$ satisfying PBW degeneration and acyclicity of twisted tensor products provides *antecedent* Koszul recognition data (Definition 11.1.3).
- (iii) *Theorem layer*: For a chiral Koszul pair $(\mathcal{A}_1, \mathcal{A}_2)$, Theorem A (Theorem 11.1.84) proves $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_2^!$ and $\Omega^{\text{ch}}(\mathcal{A}_1^!) \simeq \mathcal{A}_1$ as *consequences* of the recognition data, not as definitions.

Off the Koszul locus, the bar-cobar object persists only in the completed coderived category (Appendix K.7.1).

The correspondence between twisting morphisms and GLZ Maurer–Cartan elements is Proposition 3.1.28(iii).

3.1.6 TWISTING MORPHISMS: THE FUNDAMENTAL OBJECT

The single algebraic structure underlying bar-cobar duality, Koszul resolutions, and the modular genus tower is the convolution algebra $\text{Hom}(C, A)$: at the dg level it is a dg Lie algebra whose Maurer–Cartan elements are the twisting morphisms; at the full homotopy level it carries an L_∞ -structure whose higher brackets encode the homotopy transfer data ([299, Theorem 10.3.8]). More precisely, the convolution dg Lie algebra is a strict model $\text{Conv}_{\text{str}}(C, P)$ of the homotopy-invariant L_∞ -algebra $\text{Conv}_\infty(C, P)$ (Theorem 3.1.24); the strict model suffices for all explicit computations in this monograph. We begin with the classical dg theory ([299, §2.1–2.3]) before the chiral generalization (Chapter 11); the hierarchy from dg through L_∞ to the modular quantum L_∞ appears in Remark 3.1.23.

Definition 3.1.13 (Convolution dg Lie algebra). Let (C, Δ, d_C) be a conilpotent dg coalgebra and (A, μ, d_A) a dg algebra. The *convolution algebra* $\text{Hom}(C, A)$ is the graded vector space of all linear maps $C \rightarrow A$, equipped with:

- (i) the *convolution product* $f \star g := \mu \circ (f \otimes g) \circ \Delta$;
- (ii) the *differential* $\partial(f) := d_A \circ f - (-1)^{|f|} f \circ d_C$;
- (iii) the *Lie bracket* $[f, g] := f \star g - (-1)^{|f||g|} g \star f$.

The triple $(\mathrm{Hom}(C, A), [-, -], \partial)$ is a dg Lie algebra [299, Proposition 2.1.1]. Expanding the $\star$ -product in the bracket recovers the explicit formula $[f, g] = \mu \circ (f \otimes g) \circ \Delta - (-1)^{|f||g|} \mu \circ (g \otimes f) \circ \Delta$ used in the overview above.

Remark 3.1.14 (Strict model versus homotopy-invariant structure). The convolution dg Lie algebra of Definition 3.1.13 is a *strict model* of an underlying homotopy-invariant object: the L_∞ convolution algebra $\mathrm{Conv}_\infty(C, \mathcal{P})$ whose higher brackets ℓ_k ($k \geq 3$) arise from the operadic composition and the A_∞/L_∞ homotopy transfer [299, §10.3]. The two structures have canonically isomorphic Maurer–Cartan moduli:

$$\mathrm{MC}(\mathrm{Conv}_{\mathrm{str}}(C, \mathcal{P})) \cong \mathrm{MC}(\mathrm{Conv}_\infty(C, \mathcal{P})),$$

so for *computing* Maurer–Cartan elements, which is the primary use throughout Part I, the strict dg Lie model suffices. The full L_∞ structure becomes essential for three purposes:

- (i) *Homotopy transfer*: preserving MC data across quasi-isomorphisms (the reason bar-cobar preserves quasi-isos);
- (ii) *Formality*: proving that the deformation complex is formal in the sense of Kontsevich–Soibelman [278];
- (iii) *Gauge equivalence*: classifying deformations up to L_∞ homotopy, not merely up to strict isomorphism.

The hierarchy is:

$$\text{modular } L_\infty \text{ object} \xrightarrow{\text{strictify}} \text{dg Lie model} \xrightarrow{\text{MC}} \text{algebra structures and genus tower.}$$

All constructions in this monograph are functorial with respect to the full L_∞ structure; the strict model is the computational avatar. The full three-pillar architecture (homotopy chiral algebras (Pillar A), convolution sL_∞ (Pillar B), and logarithmic FM geometry (Pillar C)) is developed in §K.7.1; the convolution hierarchy above is the algebraic backbone of Pillar B.

Remark 3.1.15 (Functoriality infrastructure and operadic models). The functoriality claimed in the preceding remark has precise foundations from three sources:

- (i) *Vallette [389]*. The category of P_∞ -algebras carries a model category structure with bar-cobar as Quillen equivalence [389, Theorem 2.1]; every P_∞ -algebra is ∞ -quasi-isomorphic to a strict P -algebra, functorially [389, Theorem 1.2]. The results hold for *any* operad P by using BP in place of the Koszul dual [389, §1.6].
- (ii) *Robert-Nicoud–Wierstra [367]*. Conv is functorial in ∞ -morphisms of either the coalgebra or algebra slot [367, Theorem 5.1], but **not** in both simultaneously [367, Theorem 6.6]. This one-slot constraint is a hard obstruction (explicit counterexample at degree 3), not a gap in the proof. All constructions in this monograph use one-slot functoriality only.
- (iii) *Operadic vs. coalgebraic models*. The homotopy chiral algebra structure of Malikov–Schechtman [309] (algebras over the Eilenberg–Zilber homotopy Lie operad $\mathcal{Y}(n) = \mathcal{Z}(n) \otimes_k \mathrm{Lie}(n)$ in the pseudo-tensor category of $\mathcal{D}$ -modules) and the convolution L_∞ structure of Loday–Vallette [299] (codifferentials on cofree coalgebras) are equivalent models of the same homotopy-theoretic content over fields of characteristic 0. The former encodes homotopy coherence in the operad; the latter in the coalgebra. The translation is the Hinich–Schechtman correspondence: a $\tau_{\leq 0}\mathcal{Y}$ -algebra structure is equivalent to an L_∞ structure with the same MC moduli.

- (iv) *Geometric realisation* (Mok [322]). The planted-forest coefficient algebra $\mathbf{G}_{\text{pf}}$ (Definition 13.22.400) is the tropical skeleton of the logarithmic Fulton–MacPherson space $\text{FM}_n^{\log}(X \mid D)$ (Proposition 13.22.401). The weight filtration on $\mathfrak{g}_{\mathcal{A}}^{\text{amb}}$ is the codimension filtration on log FM boundary strata. This gives the combinatorial heart of the convolution algebra a geometric incarnation.

THEOREM 3.1.16 (*Convolution = master object identification*;). For any cooperadic/operadic pair $(C, \mathcal{P})$ and twisting morphism $\alpha: C \rightarrow \mathcal{P}$, the convolution dg Lie algebra $\text{Conv}_{\text{str}}(C, \mathcal{P})$ of Definition 3.1.13 is the strict model of the convolution sL_{∞} -algebra

$$\text{Conv}_{\text{str}}(C, \mathcal{P}) \hookrightarrow \text{hom}_{\alpha}(C, \mathcal{P})$$

of Robert–Nicoud–Wierstra [367, Theorem 4.1]. The sL_{∞} higher brackets ℓ_k ($k \geq 3$) on hom_{α} arise from the homotopy transfer through the Hom functor (Loday–Vallette [299, Theorem 10.3.8]). In particular, the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ of Definition 13.22.1 is the chiral specialization with $C = C_{\text{ch}}^{\dagger}$, $\mathcal{P} = \mathcal{P}^{\text{ch}}$.

References. The general operadic convolution identification is [367, Theorem 4.1]; the strict model comparison is [299, Theorem 10.3.8]. The chiral specialization follows from identifying the chiral operad as Koszul with the standard chiral twisting morphism (Definition 3.1.19). $\square$

Remark 3.1.17 (*Explicit higher brackets of the convolution sL_{∞} algebra*). For concreteness we record the explicit formulas. Let (C, Δ, d_C) be a conilpotent dg coalgebra and (A, μ, d_A) a dg algebra, with homotopy retract data $h: A \rightrightarrows H: i: H \hookrightarrow A, \pi: A \twoheadrightarrow H, \pi i = \text{id}_H, i\pi - \text{id}_A = \partial h + h\partial$. The homological perturbation lemma [299, Theorem 10.3.1] transfers the dg Lie structure on $\text{Hom}(C, A)$ to an sL_{∞} structure on $\text{Hom}(C, H)$ with brackets:

- (i) *Binary*: $\ell_2(f_1, f_2) = \pi \circ \mu \circ (f_1 \otimes f_2) \circ \Delta - (-1)^{|f_1||f_2|} \pi \circ \mu \circ (f_2 \otimes f_1) \circ \Delta$. This is the projection of the convolution Lie bracket.

- (ii) *Ternary*:

$$\ell_3(f_1, f_2, f_3) = \sum_{\sigma \in \text{UnSh}(1,2)} \pm \pi \circ \mu \circ (\text{id} \otimes h \circ \mu) \circ (f_{\sigma(1)} \otimes f_{\sigma(2)} \otimes f_3) \circ \Delta^{(3)},$$

where $\Delta^{(3)} = (\Delta \otimes \text{id}) \circ \Delta: C \rightarrow C^{\otimes 3}$ is the iterated coproduct, $\text{UnSh}(1, 2)$ denotes $(1, 2)$ -unshuffles, and the sign $\pm$ is the Koszul sign from the permutation. Concretely: ℓ_3 inserts the contracting homotopy h between two successive binary compositions, then projects. It vanishes when $H = A$ (i.e., when $h = 0$): the strict dg Lie algebra has $\ell_k = 0$ for $k \geq 3$.

- (iii) *General*: $\ell_k(f_1, \dots, f_k)$ is a signed sum over planar binary trees with k leaves, each internal edge decorated by the homotopy h , each internal vertex by μ , the root by π , and the leaves by $f_1, \dots, f_k$ [299, Theorem 10.3.8]. Explicitly:

$$\ell_k(f_1, \dots, f_k) = \sum_{T \in \text{PBT}(k)} \pm \pi \circ \mu_T^h \circ (f_1 \otimes \dots \otimes f_k) \circ \Delta^{(k)},$$

where $\text{PBT}(k)$ is the set of planar binary trees with k leaves and μ_T^h denotes the iterated composition along T with μ at each internal vertex and h at each internal edge. The signs are determined by the Koszul sign rule.

The higher brackets ℓ_k ($k \geq 3$) measure the *failure of formality* of the underlying homotopy type. On the Koszul locus (Definition 3.1.7), the bar spectral sequence collapses at E_2 (Theorem 11.1.50(ii)), the bar cohomology $H^*(\bar{B}(\mathcal{A}))$ carries a trivial A_∞ structure ($m_n = 0$ for $n \geq 3$, Theorem 11.1.50(iii)), and consequently the homotopy transfer produces no higher brackets: $\ell_k = 0$ for $k \geq 3$. Off the Koszul locus, the ℓ_k are generically nonzero and encode the L_∞ deformation theory of the algebra.

COROLLARY 3.1.18 (*MC element = twisting morphism*;). The universal class $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ is a twisting morphism:

$$\text{MC}(\text{hom}_\alpha(C, \mathcal{P})) \cong \text{Tw}_\alpha(C, \mathcal{P}).$$

The identification of the chiral algebra structure with the MC element (Proposition 13.22.395) is the chiral instance of this general bijection [367, Theorem 4.6]. The all-degree master equation $\nabla_H(\text{Sh}_r) + o^{(r)} = 0$ is the MC equation $\partial(\Theta) + \frac{1}{2}[\Theta, \Theta] = 0$ projected to degree r via the weight filtration. In particular, the bar complex $\bar{B}(\mathcal{A})$ is the twisting of the modular cyclic deformation complex $\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A})$ (Definition 14.5.12) by the universal MC element $\Theta_{\mathcal{A}}$: the bar differential, the genus tower, the shadow projections, and the Koszul dual $\mathcal{A}^!$ all descend from a single organizing datum.

References. [367, Theorem 4.6] and [299, Theorem 6.5.7]. $\square$

Definition 3.1.19 (*Twisting morphism*). A twisting morphism $\tau: C \rightarrow A$ is a degree-+1 linear map (degree -1 in the homological convention of [299]) satisfying the *Maurer–Cartan equation* in the convolution algebra (Definition 3.1.13):

$$\partial(\tau) + \tau \star \tau = 0, \quad \text{i.e.,} \quad d_A \circ \tau + \tau \circ d_C + \mu_A \circ (\tau \otimes \tau) \circ \Delta_C = 0. \quad (3.1)$$

The set of all twisting morphisms is $\text{Tw}(C, A) := \text{MC}(\text{Hom}(C, A))$ [299, §2.1].

Definition 3.1.20 (*Twisted tensor products*). For a twisting morphism $\tau: C \rightarrow A$, the *left twisted tensor product* $A \otimes_\tau C$ is the graded vector space $A \otimes C$ with differential

$$d_\tau(a \otimes c) = d_A(a) \otimes c + (-1)^{|a|} a \otimes d_C(c) + \sum (-1)^{|a|} a \cdot \tau(c_{(1)}) \otimes c_{(2)},$$

where $\Delta(c) = \sum c_{(1)} \otimes c_{(2)}$ is the Sweedler notation for the coproduct. The *right twisted tensor product* $C \otimes_\tau A$ has differential $d_\tau(c \otimes a) = d_C(c) \otimes a + (-1)^{|c|} c \otimes d_A(a) + \sum c_{(1)} \otimes \tau(c_{(2)}) \cdot a$ (with Koszul signs; [299, 2.1.5]). The MC equation (3.1) is equivalent to $d_\tau^2 = 0$ [299, Lemma 2.1.4].

PROPOSITION 3.1.21 (*Universal twisting morphisms* [299];). (i) *Projection*. Project to bar degree 1 and desuspend to get $\pi: B(A) \rightarrow A$. This is a twisting morphism, and it is *universal*: every twisting morphism $\tau: C \rightarrow A$ factors uniquely through π via a dg coalgebra map $g_\tau: C \rightarrow B(A)$ [299, Theorem 2.2.4].

(ii) *Inclusion*. The composite $\iota: C \xrightarrow{s^{-1}} s^{-1}\bar{C} \hookrightarrow \Omega(C)$ (desuspension into the free algebra $\Omega(C) = T(s^{-1}\bar{C})$) is a twisting morphism. It is *universal*: every $\tau: C \rightarrow A$ factors uniquely as $\tau = f_\tau \circ \iota$ for a dg algebra map $f_\tau: \Omega(C) \rightarrow A$ [299, Theorem 2.2.7].

(iii) *Natural bijection*. The two universal properties yield a natural bijection

$$\text{Hom}_{\text{dg CoAlg}}(C, B(A)) \cong \text{Tw}(C, A) \cong \text{Hom}_{\text{dg Alg}}(\Omega(C), A). \quad (3.2)$$

This is the *bar-cobar adjunction*: the bar functor B is right adjoint to the cobar functor Ω , and the set of twisting morphisms $\text{Tw}(C, A)$ is the adjunction bifunctor [299, Theorem 2.2.9].

- (iv) *Acyclicity*. Both canonical twisted tensor products are acyclic: $B(A) \otimes_\pi A \simeq \mathbb{k}$ and $A \otimes_\pi B(A) \simeq \mathbb{k}$ [299, Corollary 2.2.5].

Remark 3.1.22 (The twisting morphism as geometric propagator). In the chiral setting (Chapter 6), the universal twisting morphism $\pi: \overline{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ is geometrically realized as

$$\pi(c)(z) = \int_{\overline{C}_2(X)} \mathrm{ev}^* c(w) \wedge S(z, w) dw,$$

where $S(z, w)$ is the Szegő propagator on the curve X . On a smooth curve X , the M-level realization of the abstract twisting morphism π is the Szegő propagator integral. The MC equation (3.1) for π is equivalent to $d_{\mathrm{bar}}^2 = 0$ (Theorem 6.1.21): the Fay trisecant identity (Proposition 14.5.24) and the Arnold relations (Theorem 5.1.23) are the analytic and combinatorial incarnations of the single algebraic MC equation.

The chiral generalization of the full bijection (3.2) is the chiral twisting datum (Definition 11.1.1) and the fundamental theorem of chiral twisting morphisms (Theorem 11.1.9).

Remark 3.1.23 (The convolution hierarchy: from $\mathrm{Hom}(C, A)$ to modular homotopy theory). As the genus filtration opens, the convolution algebra enlarges:

<i>Convolution algebra</i>	<i>Homotopy level</i>	<i>MC elements</i>	<i>Genus</i>	<i>MC equation</i>
$\mathrm{Hom}(C, A)$	L_∞ [299, Thm. 10.3.8]	twisting morphisms τ	$g = 0$	$\partial\tau + \tau \star \tau = 0$
$\mathrm{CoDer}(\overline{B}(\mathcal{A}))[1]$	A_∞	A_∞ structures	$g = 0$	$\sum m_i \circ m_j = 0$
$\mathrm{CoDer}^{\mathrm{cyc}}(\widehat{\overline{B}}(\mathcal{A}))[1]$	cyclic L_∞	cyclic L_∞ operations	$g = 0$	$\sum \ell_j \circ \ell_i = 0$
$\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$	quantum L_∞	$\Theta_{\mathcal{A}}$	all g	QME (14.16)

Key point. Every row carries the *full homotopy* structure, not just a strict dg Lie bracket. The L_∞ brackets ℓ_n for $n \geq 3$ at genus 0 arise from the A_∞ coalgebra structure on the bar construction, transported through the Hom functor [299, Theorem 10.3.8]. At genus $g \geq 1$, the quantum L_∞ operations $\ell_n^{(g)}$ come from stable-graph Feynman amplitudes (Theorem 13.22.6). For Koszul chiral algebras, the operadic convolution L_∞ is *formal* (quasi-isomorphic to its cohomology with trivial higher brackets), so the strict dg Lie model suffices for computations; the full L_∞ structure becomes essential for non-Koszul algebras and for homotopy-invariant constructions.

The [1]-shift in rows 2–3 makes the coderivation bracket degree 0, matching the tangent Lie algebra convention. The rows are related by successive enrichments: row 1 $\rightarrow$ row 2 via the bar construction (coalgebra becomes bar coalgebra); row 2 $\rightarrow$ row 3 by completing the bar coalgebra and restricting to cyclic coderivations ($\mathrm{CoDer}^{\mathrm{cyc}} \subset \mathrm{CoDer}$); row 3 $\rightarrow$ row 4 by tensoring with chains on $\overline{\mathcal{M}}_{g,n}$ (Definition 14.5.30). The MC equation specializes at each level as shown in the fourth column. Row 4 is the *master object*: rows 1–3 are obtained by restricting to genus 0 ($\hbar \rightarrow 0$) and truncating to lower homotopy operations. The shadow obstruction tower $\Theta^{\leq r}$ in row 4 is the primary proved content; the five main theorems are read off from this full tower, with Theorem D extracting the scalar level $\Theta^{\leq 2} = \kappa$ (Remark 13.22.94).

Each row admits a *homotopy upgrade*: the dg Lie bracket $[-, -]$ is the shadow of a full L_∞ -structure whose higher brackets ℓ_n ($n \geq 3$) arise from homotopy transfer through the convolution Hom functor ([299, Theorem 10.3.8], van der Laan [390]). At the modular level, this produces a *quantum L_∞ -algebra*

with operations $\ell_n^{(g)}$ indexed by stable type (g, n) (Theorem 13.22.6). The dg level suffices for the existence of MC elements; the full homotopy level is needed for transfer to minimal models and for gauge equivalences (Remark 13.22.9).

THEOREM 3.1.24 (*Operadic identification of the convolution algebra; .*). Let C be a cooperad, $\mathcal{P}$ an operad, and $\alpha: C \rightarrow \mathcal{P}$ an operadic twisting morphism (i.e. $\alpha \in \text{Tw}(C, \mathcal{P})$). Then (Robert-Nicoud–Wierstra [367], Theorem 4.1):

- (i) The convolution operad $\text{hom}(C, \mathcal{P})$ carries a natural $s\mathcal{L}_\infty$ -algebra structure, and the assignment $\alpha \mapsto W_\alpha$ defines a bijection

$$\text{Tw}(C, \mathcal{P}) \cong \text{hom}_{\text{Op}}(s\mathcal{L}_\infty, \text{hom}(C, \mathcal{P})).$$

- (ii) For D a conilpotent C -coalgebra and A a $\mathcal{P}$ -algebra, the chain complex $\text{hom}(D, A)$ carries a natural $s\mathcal{L}_\infty$ -algebra structure $\text{hom}^\alpha(D, A)$ whose Maurer–Cartan elements are precisely the twisting morphisms relative to α :

$$\text{MC}(\text{hom}^\alpha(D, A)) \cong \text{Tw}_\alpha(D, A). \quad (3.3)$$

- (iii) The bifunctor $\text{hom}^\alpha: (\text{conil. } C\text{-cog})^{\text{op}} \times \mathcal{P}\text{-alg} \rightarrow s\mathcal{L}_\infty\text{-alg}$ extends to ∞_α -morphisms in either slot, but not both simultaneously ([367], Theorem 5.1 and §6).

Applied to the chiral setting: the modular convolution dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ of Definition 13.22.1 is the chiral instance of $\text{hom}^\alpha(D, A)$ with $\alpha = \tau_{\text{ch}}$ the chiral twisting morphism (Theorem 11.1.9), $D = \overline{B}^{\text{ch}}(\mathcal{A})$, and $A = \mathcal{A}^\dagger$. The master MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ is a twisting morphism relative to τ_{ch} , and Proposition 13.22.395 is the chiral specialization of (3.3).

Proof. The identification of the dg Lie structure on $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ with $\text{hom}^\alpha(D, A)$ is immediate from comparing Definition 13.22.1 (the product over stable types weighted by $C_\bullet(\overline{\mathcal{M}}_{g,n+1})$) with the general construction [367, Definition 4.4] applied to the chiral cooperad and operad. The bijection (3.3) follows from [367, Theorem 4.6], which was proved independently in [366, Proposition 2.9] and [397, Proposition 7.1]. The one-slot functoriality is [367, Corollary 5.4]. $\square$

COROLLARY 3.1.25 (*Quillen equivalence for chiral bar-cobar; .*). (Vallette [389], Theorem 2.1.) The category of conilpotent dg $\mathcal{P}^\dagger$ -coalgebras admits a model category structure in which:

- (i) weak equivalences are morphisms $f: C \rightarrow D$ such that $\Omega_\kappa f$ is a quasi-isomorphism of dg $\mathcal{P}$ -algebras;
- (ii) cofibrations are degreewise monomorphisms;
- (iii) fibrant objects are quasi-free $\mathcal{P}^\dagger$ -coalgebras.

The bar-cobar adjunction $B_\kappa: \text{dg } \mathcal{P}\text{-alg} \rightleftarrows \text{conil dg } \mathcal{P}^\dagger\text{-coalg}: \Omega_\kappa$ is a Quillen equivalence. In particular, B_κ preserves fibrations and weak equivalences, and Ω_κ preserves cofibrations and weak equivalences ([389], Theorem 2.9).

Specializing to the chiral operad: our bar-cobar adjunction (Theorem A) is a Quillen equivalence in this model structure.

COROLLARY 3.1.26 (*Homotopy invariance of the shadow algebra*;). (Robert–Nicoud–Wierstra [367], §8.) The Maurer–Cartan spaces of the convolution $s\mathcal{L}_\infty$ -algebras are invariant up to homotopy under ∞_α -quasi-isomorphisms. Consequently:

- (i) The shadow algebra $\mathcal{A}^{\text{sh}} = H_\bullet(\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A}))$ is a homotopy invariant: ∞ -quasi-isomorphic chiral algebras have weakly equivalent shadow algebras.
- (ii) The modular characteristic $\kappa(\mathcal{A})$ is an ∞ -quasi-isomorphism invariant.
- (iii) The full shadow obstruction tower $(\kappa, \Delta, \mathfrak{C}, \mathfrak{Q}, \text{Sh}_r)$ is an ∞ -quasi-isomorphism invariant.
- (iv) The master MC element $\Theta_{\mathcal{A}}$ is invariant up to gauge equivalence in the Deligne–Getzler–Hinich ∞ -groupoid $\text{MC}_\infty(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$.

3.1.7 THE GUI–LI–ZENG QUADRATIC DUALITY FRAMEWORK

Definition 3.1.27 (*Gui–Li–Zeng setup*). Gui–Li–Zeng [213] define Koszul duality for chiral algebras through four ingredients.

Chiral quadratic data. A pair (N, P) where N is a sheaf of generators (chiral vector space) and $P \subset j_*j^*(N \boxtimes N)$ is a subsheaf of quadratic relations. The quadratic chiral algebra is

$$\mathcal{A}(N, P) = \frac{\mathcal{A}(N)}{(P)}$$

where $\mathcal{A}(N)$ is the free chiral algebra on N .

Dualizable quadratic data. (N, P) is *dualizable* if $(s^{-1}N^\vee \omega^{-1}, P^\perp)$ is also a chiral quadratic datum, where $N^\vee \omega^{-1}$ is the dual with twist by inverse canonical bundle and $P^\perp$ is the chiral annihilator defined by

$$\mu(\langle P \otimes \omega_{X^2}, P^\perp \otimes s^2 \omega_{X^2} \rangle) = 0$$

under the unit chiral operation μ .

Quadratic dual. For dualizable (N, P) , the quadratic dual is

$$\mathcal{A}^! = \mathcal{A}(s^{-1}N^\vee \omega^{-1}, P^\perp).$$

Maurer–Cartan correspondence. There is a bijection

$$\text{Hom}(\mathcal{A}, \mathcal{B}) \leftrightarrow \text{MC}(\mathcal{A}^! \otimes \mathcal{B})$$

between morphisms of chiral algebras and Maurer–Cartan elements in the tensor product.

PROPOSITION 3.1.28 (*Comparison: our approach vs GLZ*;). The geometric bar-cobar framework of this monograph and the algebraic framework of Gui–Li–Zeng [213] are related as follows:

1. *Quadratic case agreement.* For a quadratic chiral algebra $\mathcal{A}(N, P)$ (generators N , relations $P \subset j_*j^*(N \boxtimes N)$), our bar construction gives $\bar{B}^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}(s^{-1}N^\vee \omega^{-1}, P^\perp)^!$, which coincides with the GLZ dual coalgebra.
2. *Non-quadratic extension.* Our framework extends to non-quadratic algebras via the full configuration space bar complex (Chapter 6), which replaces: quadratic relations P with OPE structure of arbitrary pole order; the annihilator $P^\perp$ with residue extraction at collision divisors; algebraic dualization with geometric Poincaré–Verdier duality.

3. *Maurer–Cartan elements.* The GLZ Maurer–Cartan element $\alpha \in MC(\mathcal{A}^! \otimes \mathcal{B})$ corresponds to our twisting morphism $\tau: \mathcal{A}^! \rightarrow \mathcal{B}$, realized geometrically as an integration kernel on $\overline{C}_2(X)$: $\tau(c)(z) = \int_{\overline{C}_2(X)} \text{ev}^* c(w) \wedge K(z, w)$.
4. *Curved structures.* GLZ’s framework handles curved A_∞ algebras through Maurer–Cartan deformations; our configuration space approach realizes the same data as genus-by-genus quantum corrections (curvature = higher-genus corrections; Maurer–Cartan equation = Stokes’ theorem on $\overline{C}_n(X)$).

Proof. For (i): the bar complex $\bar{B}^{\text{ch}}(\mathcal{A}(N, P))$ has generators $s^{-1}N^\vee$ in bar degree 1 and relations $P^\perp \subset s^{-1}N^\vee \otimes s^{-1}N^\vee$ in bar degree 2, extracted by the double-residue operation on $\overline{C}_3(X)$. The ω^{-1} -twist is substantive: chiral algebras are right $\mathcal{D}$ -modules (sections of ω_X), so desuspension carries a geometric twist $s^{-1}\bar{\mathcal{A}} \simeq \bar{\mathcal{A}} \otimes_{\mathcal{O}_X} \omega_X^{-1}[-1]$ (Appendix G, §G.7). Since the algebra is quadratic, the bar complex is generated in degrees ≤ 2 , so the bar coalgebra is the sub-coalgebra of the cofree coalgebra $T^c(s^{-1}N^\vee \omega^{-1})$ cogenerated by $P^\perp$, which is the definition of the GLZ dual coalgebra ([213], Proposition 3.2). For (iii): the MC equation $d\alpha + \alpha \star \alpha = 0$ translates under the integration kernel to $d\tau + \mu_{\mathcal{B}} \circ (\tau \otimes \tau) \circ \Delta_{\mathcal{A}^!} = 0$, which is the twisting morphism condition (Definition 3.1.19). Items (ii) and (iv) are descriptions of the respective frameworks’ scopes. $\square$

Remark 3.1.29 (Complementarity of the two approaches). The GLZ algebraic framework provides conceptual clarity for quadratic algebras; the geometric framework of this monograph extends to non-quadratic examples (Virasoro, $\mathcal{W}$ -algebras, Yangian) via configuration space integrals, at the cost of more involved compactification and convergence analysis.

3.2 SYMMETRIC SEQUENCES AND OPERADS

We work in $\mathcal{V} = \text{Ch}_{\mathbb{C}}$, cochain complexes over $\mathbb{C}$ with cohomological grading ($|d| = +1$) and Koszul sign rule (Convention 1.10.3).

Definition 3.2.1 (Symmetric sequence). A *symmetric sequence* is a collection $P = \{P(n)\}_{n \geq 0}$ where each $P(n)$ is an object of $\mathcal{V}$ equipped with a right action of the symmetric group S_n . Morphisms of symmetric sequences are collections of S_n -equivariant maps. When $\mathcal{V}$ carries a differential structure, we require that the S_n -action commutes with differentials.

Definition 3.2.2 (Composition product). For symmetric sequences A and B , their composition product is defined by:

$$(A \circ B)(n) = \bigoplus_{k \geq 0} A(k) \otimes_{S_k} \left(\bigoplus_{i_1 + \dots + i_k = n} \text{Ind}_{S_{i_1} \times \dots \times S_{i_k}}^{S_n} (B(i_1) \otimes \dots \otimes B(i_k)) \right)$$

where Ind denotes the induced representation functor, using the block diagonal embedding

$$S_{i_1} \times \dots \times S_{i_k} \hookrightarrow S_n$$

that acts on $\{1, \dots, i_1\} \sqcup \{i_1 + 1, \dots, i_1 + i_2\} \sqcup \dots \sqcup \{i_1 + \dots + i_{k-1} + 1, \dots, n\}$.

PROPOSITION 3.2.3 (Associativity of the composition product). The composition product $\circ$ is associative up to canonical isomorphism: $(A \circ B) \circ C \cong A \circ (B \circ C)$ for any symmetric sequences A, B, C . The unit is $\mathbb{I}$ with $\mathbb{I}(1) = \mathbb{C}$, $\mathbb{I}(n) = 0$ for $n \neq 1$.

Proof. Both $(A \circ B) \circ C$ and $A \circ (B \circ C)$ evaluate at degree n to the same colimit: a sum over *two-level trees* with n leaves, internal vertices labelled by A, B, C respectively. Concretely,

$$((A \circ B) \circ C)(n) \cong \bigoplus_T A(|v_1|) \otimes_{S_{|v_1|}} \left(\bigotimes_j B(|v_{2,j}|) \otimes_{S_{|v_{2,j}|}} \bigotimes_k C(|v_{3,k}|) \right) \otimes_{G_T} \mathbb{C}[S_n]$$

where the sum runs over isomorphism classes of three-level rooted trees T with n labelled leaves, and $|v_\bullet|$ denotes the valence at each internal vertex. Parenthesizing $(A \circ B) \circ C$ versus $A \circ (B \circ C)$ corresponds to grouping the tree summation differently (first by the A - B junction, or first by the B - C junction), but the set of three-level trees is the same. The canonical isomorphism is the identity on each tree summand. The unit property $A \circ \mathbb{I} \cong A \cong \mathbb{I} \circ A$ is immediate: $\mathbb{I}$ contributes a single identity strand at each input ([299, Proposition 5.1.3]). $\square$

3.3 CHIRAL ALGEBRAS AND NON-ABELIAN POINCARÉ DUALITY

3.3.1 FACTORIZATION AS LOCAL-TO-GLOBAL

Remark 3.3.1. The factorization axiom $\mathcal{A}(U \sqcup V) \simeq \mathcal{A}(U) \otimes \mathcal{A}(V)$ is excision for NAP duality: $\int_{M_1 \sqcup M_2} A = \int_{M_1} A \otimes \int_{M_2} A$.

3.3.2 RAN SPACE AND UNIVERSAL RECIPIENTS

Definition 3.3.2 (Ran space). Let X be a smooth algebraic curve over $\mathbb{C}$. The *Ran space* of X is the ind-scheme

$$\mathrm{Ran}(X) = \varinjlim_{I \in \mathrm{fSet}^{\mathrm{surj}}} X^I,$$

where $\mathrm{fSet}^{\mathrm{surj}}$ is the category of non-empty finite sets with surjections. A surjection $\sigma: I \twoheadrightarrow J$ induces a diagonal embedding $\Delta_\sigma: X^J \hookrightarrow X^I$ (inserting the same point at all σ -fibers), identifying configurations where points collide. Concretely, $\mathrm{Ran}(X)$ parameterises finite non-empty subsets $S \subset X$ with the topology in which a family $\{S_t\}$ converges as points coalesce.

- (i) *Stratification by cardinality.* $\mathrm{Ran}(X) = \bigsqcup_{n \geq 1} \mathrm{Ran}^{\leq n}(X)$, where $\mathrm{Ran}^{\leq n}(X) \cong \mathrm{Conf}_n(X)/\Sigma_n$ is the space of subsets of cardinality exactly n . The closure $\mathrm{Ran}^{\leq n}(X) = \bigsqcup_{k=1}^n \mathrm{Ran}^{\leq k}(X)$ is a scheme of finite type.
- (ii) *Union morphism.* The map $\cup: \mathrm{Ran}(X) \times \mathrm{Ran}(X) \rightarrow \mathrm{Ran}(X)$ sending $(S_1, S_2) \mapsto S_1 \cup S_2$ is the structural morphism for factorization. Over the locus $\mathrm{Ran}(X)^{\mathrm{disj}} = \{(S_1, S_2) : S_1 \cap S_2 = \emptyset\}$, the union is disjoint and the factorization isomorphism $\mathcal{F}(S_1 \cup S_2) \cong \mathcal{F}(S_1) \otimes \mathcal{F}(S_2)$ holds.
- (iii) *Diagonal stratification.* The boundary of $\mathrm{Ran}^{\leq n}(X)$ consists of the diagonals $\Delta_\sigma(X^m)$ for $m < n$. At these loci, the factorization structure degenerates and the OPE singularity of a chiral algebra $\mathcal{A}$ is concentrated. The bar complex $\overline{B}_X(\mathcal{A})$ is the sheaf on $\mathrm{Ran}(X)$ whose sections on $\mathrm{Ran}^{\leq n}(X)$ are bar elements of degree n (equation (1.9.1)).

For a detailed treatment of the ind-scheme structure, the precise site (laft prestacks), and the comparison with Beilinson–Drinfeld’s formulation [40, §3.4], see Definition 5.7.2 (Chapter 5).

Definition 3.3.3 (Chiral algebra). A *chiral algebra* on a smooth algebraic curve X is a right $\mathcal{D}_X$ -module $\mathcal{A}$ equipped with a *chiral product*

$$\mu: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \longrightarrow \Delta_!(\mathcal{A}),$$

where $j: X^2 \setminus \Delta \hookrightarrow X^2$ is the complement of the diagonal and $\Delta_! = \Delta_* \circ \mathcal{D}_{X \rightarrow X^2}$ is the $\mathcal{D}$ -module pushforward. The three axioms are:

- (i) *Locality*: μ factors through $j_* j^*$; the product is meromorphic with poles only along the diagonal.
- (ii) *Associativity* (Borcherds identity): for every triple of sections $\phi_i, \phi_j, \phi_\ell$ and every form ω , the cyclic sum of iterated residues along the triple-collision divisor vanishes:

$$\sum_{\text{cyclic}} \text{Res}_{D_{j\ell}} \circ \text{Res}_{D_{ij}} [\mu(\mu(\phi_i, \phi_j), \phi_\ell) \otimes \omega] = 0. \quad (3.4)$$

This couples all OPE pole orders simultaneously: it reduces to the Jacobi identity for the simple-pole bracket but also constrains all higher-pole interactions. The geometric origin of this axiom as the unique condition for the FM bar differential to satisfy $d^2 = 0$ is explained in §1.2.

- (iii) *Unit*: an embedding $\omega_X \hookrightarrow \mathcal{A}$ (the vacuum).

Axiom (ii) is stated as an independent algebraic axiom on μ : it is a constraint on the iterated residues of the chiral product at codimension-2 boundary strata. The geometric perspective (§1.2) reveals that this axiom is exactly the condition forced by the boundary stratification of $\overline{C}_n(X)$ for the FM bar differential to satisfy $d^2 = 0$.

An *augmented* chiral algebra carries a splitting $\varepsilon: \mathcal{A} \rightarrow \omega_X$ of the unit; the augmentation ideal is $\overline{\mathcal{A}} = \ker(\varepsilon)$. The operator product expansion $a(z)b(w) \sim \sum_{n \geq 0} c_n(w)/(z-w)^{n+1}$ is the mode expansion of μ . The *chiral bracket* $\{a, b\} = c_0$ extracts the simple-pole residue; the full product μ involves all pole orders (Convention 6.0.5). The complete formulation, with the twisting datum needed for the Koszul pair structure, is Definition II.1.1 (Chapter II).

THEOREM 3.3.4 (*Chiral algebras on Ran space*;). (Beilinson–Drinfeld [40, Chapter 3])

A chiral algebra $\mathcal{A}$ on X (Definition 3.3.3) determines a $\mathcal{D}$ -module $\mathcal{F}_{\mathcal{A}}$ on $\text{Ran}(X)$ satisfying:

1. Factorization: $\mathcal{F}_{\mathcal{A}}(S \sqcup T) = \mathcal{F}_{\mathcal{A}}(S) \otimes \mathcal{F}_{\mathcal{A}}(T)$
2. Compatibility with embeddings
3. $\mathcal{D}$ -module structure encoding OPEs

The bar-cobar duality acts on these sheaves on Ran space, realizing NAP duality for factorization algebras.

Remark 3.3.5 (Universality as precondition for curve-independence). The $\mathcal{D}$ -module $\mathcal{F}_{\mathcal{A}}$ on $\text{Ran}(X)$ in Theorem 3.3.4 encodes the chiral product on a *single* curve X . For the bar complex and its invariants (κ , shadow obstruction tower, Koszulness) to be *curve-independent*, a stronger condition is needed: the factorization algebra must be *universal* in the sense of Cliff [86], meaning that it extends to a compatible system of factorization algebras over *all* smooth curves simultaneously, with pullback isomorphisms $\varphi_{\text{ch}}^* \mathcal{F}_Y \simeq \mathcal{F}_X$ along all étale morphisms $\varphi: X \rightarrow Y$ satisfying a cocycle condition.

In dimension 1, Cliff [86, Proposition 8.1] proves that universal factorization algebras are equivalent to *quasi-conformal* vertex algebras in the sense of Frenkel–Ben-Zvi [171, Ch. 6]: those carrying an action

of the group $\text{Aut}(\mathcal{O})$ of coordinate changes on the formal disk, with L_{-1} acting as translation, L_0 acting semisimply with integral eigenvalues, and $\text{Der}_+(\mathcal{O})$ acting locally nilpotently. Every conformal vertex algebra (one possessing a Virasoro element) is quasi-conformal, but the converse fails: certain lattice vertex algebras are quasi-conformal without being conformal.

All standard families in the landscape (Heisenberg, affine Kac–Moody, Virasoro, $\mathcal{W}_N$, $\beta\gamma$, lattice VOAs) are quasi-conformal and hence universal. The $\text{Aut}(\mathcal{O})$ -action is the bridge: the OPE is defined on the formal disk (curve-independently), the factorization isomorphisms use only the diagonal stratification of X^I (which is étale-local), and the bar complex inherits universality from the underlying chiral algebra. Proposition 13.22.366 (genus-0 curve-independence of Koszulness) and Theorem 13.22.367 (higher-genus open-stratum curve-independence) both rest on this universality: the bar differential depends only on the formal-disk OPE data, which is the datum that the quasi-conformal structure makes curve-independent.

This remark is foundational: *universality is not an additional hypothesis but a precondition for the entire bar-cobar framework to produce curve-independent invariants*. See Remark 13.22.368 for the explicit connection to shadow invariants and Remark 13.13.17 for the five-level hierarchy controlling genus extension.

Definition 3.3.6 (Operad). An operad P is a monoid for the composition product: composition maps $\gamma : P(k) \otimes P(i_1) \otimes \cdots \otimes P(i_k) \rightarrow P(i_1 + \cdots + i_k)$ and unit $\eta : \mathbb{I} \rightarrow P(1)$, satisfying associativity and S_n -equivariance. In $\mathcal{V} = \text{Ch}_{\mathbb{C}}$, all structure maps are chain maps.

Definition 3.3.7 (Cooperad). A cooperad is a comonoid for the composition product, with structure maps dual to those of an operad. Explicitly, we have decomposition maps $\Delta : C(n) \rightarrow (C \circ C)(n)$ and a counit $\epsilon : C \rightarrow \mathbb{I}$ satisfying coassociativity and coequivariance axioms.

Example 3.3.8 (Endomorphism operad). For any object $V \in \mathcal{V}$, the endomorphism operad End_V has

$$\text{End}_V(n) = \text{Hom}_{\mathcal{V}}(V^{\otimes n}, V)$$

with composition given by substitution of multilinear operations. This is the fundamental example motivating the general theory.

3.4 THE COTRIPLE BAR CONSTRUCTION

An adjunction $F \dashv U : \mathcal{A} \rightleftarrows \mathcal{B}$ yields a comonad $G = FU$ on $\mathcal{B}$ with counit $\epsilon : FU \rightarrow \text{id}$ and comultiplication $\delta : FU \rightarrow FUFU$.

Definition 3.4.1 (Cotriple bar resolution). The cotriple bar resolution of $B \in \mathcal{B}$ is the simplicial object:

$$B_{\bullet}^G(B) : \cdots \rightrightarrows (FU)^3 B \rightrightarrows (FU)^2 B \rightrightarrows FUB \rightarrow B$$

with face maps $d_i = (FU)^i \cdot \epsilon \cdot (FU)^{n-i}$ for $0 \leq i \leq n$ (applying the counit at position i) and degeneracy maps s_i inserting the unit at position i .

Example 3.4.2 (Cotriple bar resolution for a P -algebra). For an augmented operad P , the free-forgetful adjunction $F_P \dashv U : P\text{-Alg} \rightleftarrows \mathcal{V}$ yields the *cotriple* (monadic) bar resolution of a P -algebra A :

$$B_n^{\text{cotr}}(P, A) = \underbrace{P \circ \cdots \circ P \circ A}_{n \text{ copies}}, \quad n \geq 0,$$

with simplicial structure given by the operad multiplication and the counit of the adjunction. The associated total complex is a free P -algebra resolution of A (May [314], Fresse [182]). *This is distinct from the Koszul-dual operadic bar $B_P(A) = (P^i \circ A, d_{\kappa})$ of Theorem 3.6.2:* the cotriple resolution has n copies of P and

is always defined, while the Koszul-dual bar uses the Koszul dual cooperad P^i and requires an operadic twisting morphism $\kappa: P^i \rightarrow P$. On the Koszul locus (Definition 3.7.3), the two constructions are quasi-isomorphic and both compute $\mathrm{Tor}_\bullet^P(\mathbb{I}, A)$; off the Koszul locus they differ, and the Koszul-dual bar lives in the coderived category.

3.4.1 THE FUNDAMENTAL BAR-COBAR ISOMORPHISM

Remark 3.4.3 (Operadic Koszul pairs). The operadic version of Definition 3.1.5 replaces algebras by operads, generator duality by collection duality, and relation orthogonality by the Koszul dual cooperad P^i , the maximal sub-cooperad of $\mathcal{T}^c(s^{-1}E^\vee)$ cogenerated by $R^\perp$ (Definition 3.7.2). See Chapter 11 for the chiral analog.

Example 3.4.4 (Com–Lie: operadic duality and algebra-level bar). *Operad level.* The quadratic generators are $\mu \in \mathrm{Com}(2)$ and $\ell \in \mathrm{Lie}(2)$, paired by $\langle \mu, \ell \rangle = 1$. The Koszul dual cooperads are

$$\mathrm{Com}^i \cong s^{-1}\mathrm{Lie}^c, \quad \mathrm{Lie}^i \cong s^{-1}\mathrm{Com}^c,$$

where Lie^c and Com^c are the Lie and commutative cooperads (Loday–Vallette [299, §13.1.4, §13.1.5]). The operadic bar construction of a quadratic operad is quasi-isomorphic to its Koszul dual cooperad; for the Com–Lie pair,

$$\begin{aligned} \overline{B}(\mathrm{Com}) &\simeq \mathrm{Com}^i \cong s^{-1}\mathrm{Lie}^c && \text{(partition complex; Björner–Wachs [52])} \\ \overline{B}(\mathrm{Lie}) &\simeq \mathrm{Lie}^i \cong s^{-1}\mathrm{Com}^c \\ \Omega(\mathrm{Com}^i) &\xrightarrow{\sim} \mathrm{Com} \\ \Omega(\mathrm{Lie}^i) &\xrightarrow{\sim} \mathrm{Lie}. \end{aligned}$$

Concretely, the degree- n component of $\overline{B}(\mathrm{Com})$ is the (shifted, signed) chain complex of the partition lattice $\overline{\Pi}_n$, whose reduced homology is concentrated in a single degree and carries the Lie representation tensored with sign (Theorem 3.8.1).

Algebra level. For a commutative algebra A , the (Koszul-dual) operadic bar construction is

$$B_{\mathrm{Com}}(A) = (\mathrm{Com}^i \circ \bar{A}, d) \cong (s^{-1}\mathrm{Lie}^c \circ \bar{A}, d),$$

the *cofree Lie coalgebra* on $s^{-1}\bar{A}$ equipped with the Harrison differential. This is NOT a cocommutative coalgebra: it is a *Lie* coalgebra whose cobracket is the deconcatenation-antisymmetrization induced from Lie^c . The resulting complex computes Harrison homology $\mathrm{Harr}_\bullet(A)$ (Loday [297, §4.2]). In characteristic zero there is a quasi-isomorphic *cocommutative* model $(\mathrm{Sym}^c(s^{-1}\bar{A}), d_{\mathrm{CE}})$, the Harrison–André–Quillen / Chevalley–Eilenberg cochain complex, obtained from $\mathrm{Lie}^c \circ \bar{A}$ by antisymmetrization (equivalently, by the Eulerian idempotent decomposition of $T^c(s^{-1}\bar{A})$). These two models are quasi-isomorphic in characteristic 0 but carry genuinely different coalgebra structures: Lie^c is a Lie cooperad, Sym^c is a commutative cooperad, and neither acquires the coassociative coproduct of $T^c(s^{-1}\bar{A})$.

Three distinct bar complexes. For an associative algebra A , the standard Eilenberg–Mac Lane bar is $B_{\mathrm{Ass}}(A) = T^c(s^{-1}\bar{A})$, a tensor coassociative coalgebra; for a commutative algebra, $B_{\mathrm{Com}}(A) = \mathrm{Lie}^c \circ s^{-1}\bar{A}$ is the Harrison coLie coalgebra; for a Lie algebra $\mathfrak{g}$, $B_{\mathrm{Lie}}(\mathfrak{g}) = \mathrm{Com}^c \circ s^{-1}\mathfrak{g} \cong \mathrm{Sym}^c(s^{-1}\mathfrak{g})$ is the Chevalley–Eilenberg cocommutative coalgebra. Each uses the Koszul dual cooperad of the operad controlling the algebra type; the three objects have different underlying symmetric-sequence structures and should not be conflated.

Remark 3.4.5 (Two levels of Koszul duality). Koszul duality operates at two distinct levels:

- (a) *Operadic level:* the operad P has a Koszul dual cooperad P^i (Definition 3.7.2) and a Koszul dual operad $P^! = (P^i)^\vee$. For example, $\text{Com}^! \cong \text{Lie}$ and $\text{Com}^i \cong s^{-1}\text{Lie}^c$. This governs the *type* of algebraic structure.
- (b) *Algebraic level:* a P -algebra A has a bar construction $B_P(A) = P^i \circ \bar{A}$ with the Koszul-twisting differential (Convention 6.0.2). This is a P^i -coalgebra and governs the *specific* duality for a given algebra. For $P = \text{Com}$ the bar is a coLie coalgebra (Harrison); for $P = \text{Ass}$ it is a coassociative coalgebra (Eilenberg–Mac Lane); for $P = \text{Lie}$ it is a cocommutative coalgebra (Chevalley–Eilenberg).

In the chiral setting, both levels are active simultaneously. The operadic structure supplies the geometry (FM compactification, Arnold relation, logarithmic forms); the algebraic structure supplies the OPE data (generators, relations, pole orders). The bar construction weaves them together: it places OPE data on the operadic geometry and extracts residues. The result is a factorization coalgebra that encodes both the type of structure (commutative, associative, Lie) and the specific algebra $\mathcal{A}$. Inversion holds on the Koszul locus (Definition 3.1.7).

3.5 THE OPERADIC BAR-COBAR DUALITY

For an augmented operad P with augmentation $\epsilon : P \rightarrow \mathbb{I}$, we construct the bar and cobar functors:

Definition 3.5.1 (Operadic bar construction). For an augmented operad P with augmentation $\epsilon : P \rightarrow \mathbb{I}$ and augmentation ideal $\bar{P} = \ker(\epsilon)$, the *operadic bar construction* $\bar{B}(P)$ is the cofree conilpotent cooperad on the desuspension $s^{-1}\bar{P}$, in the cohomological convention ($|d| = +1$). Explicitly, writing $\mathcal{T}^c$ for the cofree-cooperad functor on a symmetric sequence,

$$\bar{B}(P) = \mathcal{T}^c(s^{-1}\bar{P}) = \bigoplus_{n \geq 1} (s^{-1}\bar{P})^{\circ n} \Big|_{\text{trees}},$$

where $(-)^{\circ n}$ denotes the n -fold iterated cooperadic composition and the sum runs over rooted trees whose internal vertices are decorated by elements of $s^{-1}\bar{P}$. The differential $d = d_{\text{internal}} + d_{\text{decomposition}}$ combines the internal differential of P with edge contractions: the second component $d_{\text{decomposition}}$ is the unique coderivation whose projection to cogenerators is the operadic composition $s^{-1}\bar{P} \circ_{(1)} s^{-1}\bar{P} \rightarrow s^{-1}\bar{P}$ (Loday–Vallette [299, §6.5]). *Distinction from the associative tensor coalgebra.* The symbol $\mathcal{T}^c$ for the cofree-cooperad functor is distinct from the tensor-coalgebra functor T^c used elsewhere in this chapter (e.g. Construction 3.1.4): $T^c(V)$ is the cofree coassociative coalgebra on a graded vector space V , while $\mathcal{T}^c(M)$ is the cofree cooperad on a symmetric sequence M .

3.6 COTRIPLE RESOLUTION AND CONFIGURATION SPACES

Remark 3.6.1 (Configuration spaces and factorization). By the Ayala–Francis theorem [30], factorization homology $\int_X \mathcal{A}$ of a chiral algebra on a curve X is computed by the colimit $\text{colim}_n [\mathcal{A}^{\otimes n} \otimes \Omega^*(\text{Conf}_n(X))]$. The bar complex is the dual construction.

3.6.1 THE GENUS EXPANSION

THEOREM 3.6.2 (*Operadic bar complex* [299];). For an operad $\mathcal{P}$ and $\mathcal{P}$ -algebra A , the bar complex is:

$$B_{\mathcal{P}}(A) = \bigoplus_{n \geq 1} (\mathcal{P}^{\vee}(n) \otimes_{\Sigma_n} A^{\otimes n})$$

where $\mathcal{P}^{\vee}$ is the Koszul dual cooperad (which already incorporates the appropriate suspension), and the differential combines the cooperad cocomposition with the algebra structure maps of A .

THEOREM 3.6.3 (*Geometric realization*;). For the chiral operad $\mathcal{P}_{\text{ch}}$ on a curve X :

1. $\mathcal{P}_{\text{ch}}(n) \cong \Omega_{\log}^*(\overline{C}_n(X))$ as a complex [278]
2. The operadic composition corresponds to boundary stratification
3. The bar differential becomes residues at collision divisors

This provides a canonical isomorphism:

$$B_{\mathcal{P}_{\text{ch}}}(\mathcal{A}) \cong \bar{B}_{\text{geom}}^{\text{ch}}(\mathcal{A})$$

Proof. We verify the isomorphism in two steps.

Underlying graded objects. The chiral operad has $\mathcal{P}_{\text{ch}}(n) = \Omega_{\log}^*(\overline{C}_n(X))$ by item (1). Its Koszul dual cooperad is obtained by degree-wise linear dualizing the generators and imposing orthogonal relations (Definition 3.7.2): since the generators live in $\Omega_{\log}^*$, the dual generators live in the Borel–Moore homology $H_*^{\text{BM}}(\overline{C}_n(X), \mathbb{C})$ (Poincaré–Verdier duality on the compact manifold with corners $\overline{C}_n(X)$). Thus $\mathcal{P}_{\text{ch}}^{\vee}(n) \cong H_*^{\text{BM}}(\overline{C}_n(X), \mathbb{C})$. Therefore the n -th component of the operadic bar complex is:

$$\mathcal{P}_{\text{ch}}^{\vee}(n) \otimes_{\Sigma_n} \mathcal{A}^{\otimes n} \cong \Gamma(\overline{C}_n(X), j_* j^*(\mathcal{A}^{\boxtimes n}) \otimes \Omega_{\log}^*)^{\Sigma_n}$$

which is the n -th term of the geometric bar complex $\bar{B}_{\text{geom}}^{\text{ch}}(\mathcal{A})$.

Differentials. The operadic bar differential $d = d_{\text{cooperad}} + d_{\text{alg}}$ translates as follows. The cooperad cocomposition $\Delta: \mathcal{P}^{\vee}(n) \rightarrow \bigoplus_k \mathcal{P}^{\vee}(k) \otimes \mathcal{P}^{\vee}(n_1) \otimes \cdots \otimes \mathcal{P}^{\vee}(n_k)$ corresponds to the boundary stratification of $\overline{C}_n(X)$: each codimension-1 boundary divisor D_S (labeled by a subset S of colliding points) contributes a residue term. The algebra structure maps $m_k: \mathcal{A}^{\otimes k} \rightarrow \mathcal{A}$ are the OPE coefficients extracted by these residues. Together, $d_{\text{cooperad}} + d_{\text{alg}}$ becomes $d_{\text{dR}} + d_{\text{res}}$ (the de Rham plus residue differential on the geometric bar complex), matching the differential of Definition 6.1.15. $\square$

3.7 QUADRATIC OPERADS AND KOSZUL DUALITY

Definition 3.7.1 (*Quadratic operad*). A quadratic operad has the form $P = \text{Free}(E)/(R)$ where E is a collection of generating operations in degree 2, $R \subset \text{Free}(E)(3)$ consists of quadratic relations, and (R) is the operadic ideal generated by R .

Definition 3.7.2 (*Koszul dual cooperad*). For a quadratic operad $P = \text{Free}(E)/(R)$, the *Koszul dual cooperad* $P^{\natural}$ is the maximal sub-cooperad of the cofree cooperad $\mathcal{T}^c(s^{-1}E^{\vee})$ cogenerated by the orthogonal relations $R^{\perp} \subset (s^{-1}E^{\vee})^{\otimes 2}$, where the orthogonality is with respect to the natural pairing induced by evaluation. The *Koszul dual operad* is the degree-wise linear dual $P^{\natural} := (P^{\natural})^{\vee}$ (Loday–Vallette [299, §7.2]), an operad in its own right; the two objects are related but not equal, and the cooperad $P^{\natural}$ is the primitive notion.

Definition 3.7.3 (Koszul operad). An operad P is *Koszul* if the canonical map $\Omega(P^i) \rightarrow P$ from the cobar of the Koszul dual cooperad is a quasi-isomorphism. Equivalently, the Koszul complex $K_\bullet(P) = P^i \circ P$ with differential induced by the cooperad and operad structures is acyclic in positive degrees (Loday–Vallette [299, §7.4]).

3.8 DERIVATION OF COM-LIE DUALITY

THEOREM 3.8.1 (*Com–Lie Koszul duality* [203, 299];). There are canonical isomorphisms of operads

$$\mathrm{Com}^! \cong \mathrm{Lie}, \quad \mathrm{Lie}^! \cong \mathrm{Com},$$

and, at the cooperad level, of Koszul dual cooperads

$$\mathrm{Com}^i \cong s^{-1}\mathrm{Lie}^c, \quad \mathrm{Lie}^i \cong s^{-1}\mathrm{Com}^c,$$

where Lie^c and Com^c are the Lie and commutative cooperads. Both Com and Lie are Koszul operads (Definition 3.7.3): the canonical maps

$$\Omega(\mathrm{Com}^i) \xrightarrow{\sim} \mathrm{Com}, \quad \Omega(\mathrm{Lie}^i) \xrightarrow{\sim} \mathrm{Lie}$$

are quasi-isomorphisms.

Proof via partition lattices. By Theorem 15.12.48, $\overline{B}(\mathrm{Com})(n) \simeq s^{n-1}\tilde{C}_*(\overline{\Pi}_n) \otimes \mathrm{sgn}_n$.

Classical results of Björner–Wachs [52] and Stanley [381] establish that the reduced homology of $\overline{\Pi}_n$ is:

- The order complex $|\overline{\Pi}_n|$ has dimension $n - 3$ (maximal chains in $\overline{\Pi}_n$ have length $n - 3$)
- $\tilde{H}_k(\overline{\Pi}_n) = 0$ for $k \neq n - 3$ (homology concentrated in the top degree)
- The S_n -representation on $\tilde{H}_{n-3}(\overline{\Pi}_n)$ is $\mathrm{Lie}(n) \otimes \mathrm{sgn}_n$ where $\mathrm{Lie}(n)$ is the Lie representation

The geometric realization $|\overline{\Pi}_n|$ is homotopy equivalent to a wedge of $(n - 1)!$ spheres of dimension $n - 3$, with the S_n -action on the top homology given by the Lie representation tensored with the sign.

For Com–Lie duality, the bar construction gives ([299, Theorem 7.2.1]):

$$\overline{B}(\mathrm{Com})(n) \simeq s^{n-1}\tilde{C}_*(\overline{\Pi}_n) \otimes \mathrm{sgn}_n.$$

More generally, for any Koszul operad $\mathcal{P}$ the degree- n component of the bar cooperad is the (shifted, twisted) chains on the relevant compactification: $\overline{B}(\mathcal{P})^!(n) \simeq C_*^{\mathrm{BM}}(\overline{C}_n, \partial\overline{C}_n) \otimes_{\mathcal{P}} ([299, §7.1])$. This is the general mechanism by which cooperadic cobar complexes compute configuration-space homology. Taking homology and using that $\overline{\Pi}_n$ has homology concentrated in the single degree $n - 3$:

$$H_*(\overline{B}(\mathrm{Com})(n)) \simeq s^{n-1}\tilde{H}_{n-3}(\overline{\Pi}_n) \otimes \mathrm{sgn}_n = s^{n-1}\mathrm{Lie}(n) \otimes \mathrm{sgn}_n \otimes \mathrm{sgn}_n = s^{n-1}\mathrm{Lie}(n)$$

Since this is concentrated in a single degree, the bar complex is formal and we obtain $\overline{B}(\mathrm{Com}) \simeq \mathrm{Com}^i$, where the Koszul dual cooperad satisfies $\mathrm{Com}^i(n) \cong s^{-1}\mathrm{Lie}^c(n) = s^{n-1}\mathrm{Lie}(n)$ in the Loday–Vallette grading convention ([299, §7.2, §13.1.4]). Applying the cobar functor yields the quasi-isomorphism $\Omega(\mathrm{Com}^i) \xrightarrow{\sim} \mathrm{Com}$. The dual statement $\mathrm{Lie}^! \cong \mathrm{Com}$ (equivalently $\mathrm{Lie}^i \cong s^{-1}\mathrm{Com}^c$) follows by Schur–Weyl duality, using the characterization of Lie as the primitive part of the tensor coalgebra. $\square$

Alternative proof via generating series. The Poincaré series of the operads satisfy:

$$\begin{aligned} P_{\text{Com}}(x) &= e^x - 1 \\ P_{\text{Lie}}(x) &= -\log(1 - x) \end{aligned}$$

These are compositional inverses: $P_{\text{Lie}}(-P_{\text{Com}}(-x)) = x$. This functional equation characterizes Koszul dual pairs, providing an independent verification of the duality. $\square$

3.9 THE QUADRATIC DUAL AND ORTHOGONALITY

For explicit computations, we need the quadratic presentations:

PROPOSITION 3.9.1 (*Quadratic presentations [299];*). The operads Com and Lie have quadratic presentations:

$$\begin{aligned} \text{Com} &= \text{Free}(\mu) / (R_{\text{Com}}) \text{ where } R_{\text{Com}} = \langle \mu_{12,3} - \mu_{1,23}, \mu_{12} - \mu_{21} \rangle \\ \text{Lie} &= \text{Free}(\ell) / (R_{\text{Lie}}) \text{ where } R_{\text{Lie}} = \langle \ell_{12,3} + \ell_{23,1} + \ell_{31,2}, \ell_{12} + \ell_{21} \rangle \end{aligned}$$

where subscripts denote inputs, and composition is denoted by adjacency. Here $\mu_{12,3}$ means $\mu \circ_1 \mu$ and $\mu_{1,23}$ means $\mu \circ_2 \mu$.

PROPOSITION 3.9.2 (*Orthogonality;*). With respect to the natural pairing between $\text{Free}(\mu)(3)$ and $\text{Free}(\ell^*)(3)$ induced by $\langle \mu, \ell^* \rangle = 1$, one has

$$R_{\text{Com}} \perp R_{\text{Lie}}$$

This orthogonality is the concrete manifestation of Koszul duality.

Proof. We compute the pairing explicitly. The spaces have bases:

$$\begin{aligned} \text{Free}(\mu)(3) &= \text{span}\{\mu_{12,3}, \mu_{1,23}, \mu_{13,2}, \mu_{2,13}, \mu_{23,1}, \mu_{3,12}\} \\ \text{Free}(\ell^*)(3) &= \text{span}\{\ell_{12,3}^*, \ell_{1,23}^*, \text{etc.}\} \end{aligned}$$

The pairing $\langle \mu_{ij,k}, \ell_{pq,r}^* \rangle = 1$ if the tree structures match and 0 otherwise. Computing:

$$\begin{aligned} \langle \mu_{12,3} - \mu_{1,23}, \ell_{12,3}^* + \ell_{23,1}^* + \ell_{31,2}^* \rangle &= 1 + 0 + 0 - 0 - 0 - 1 = 0 \\ \langle \mu_{12,3} - \mu_{1,23}, \ell_{13,2}^* + \ell_{32,1}^* + \ell_{21,3}^* \rangle &= 0 - 1 + 0 + 0 + 1 + 0 = 0 \end{aligned}$$

Similar computations for all pairs verify the orthogonality. $\square$

3.10 FACTORIZATION ALGEBRA AXIOMS: VERIFICATION

3.10.1 MOTIVATION

Construction 3.10.1 (*Configuration space realization*). A factorization algebra $\mathcal{F}$ on a manifold M assigns to each open $U \subset M$ a vector space $\mathcal{F}(U)$ satisfying $\mathcal{F}(U \sqcup V) \cong \mathcal{F}(U) \otimes \mathcal{F}(V)$ and the colimit reconstruction

$$\mathcal{F}(U) = \text{colim}_{(x_1, \dots, x_n) \in C_n(U)} \mathcal{F}(\text{disk around } x_1) \otimes \cdots \otimes \mathcal{F}(\text{disk around } x_n)$$

over the configuration space $C_n(M) = \{(x_1, \dots, x_n) \in M^n : x_i \neq x_j\}$. Factorization algebras on $\mathbb{R}^n$ are equivalent to E_n -algebras [303, Theorem 5.4.5.9].

3.10.2 WEISS TOPOLOGY AND FACTORIZATION ALGEBRAS

The cosheaf condition defining factorization algebras requires a topology finer than the ordinary open-cover topology. The correct notion, introduced by Weiss [396] in the context of manifold calculus and adopted by Costello–Gwilliam [92], is the following.

Definition 3.10.2 (Weiss cover). Let M be a topological space. A collection $\{U_i\}_{i \in I}$ of open subsets of M is a *Weiss cover* of an open $V \subset M$ if every *finite* subset $S \subset V$ is contained in some single U_i .

The *Weiss topology* on $\text{Opens}(M)$ is the Grothendieck topology whose covering families are exactly the Weiss covers. We verify the three Grothendieck axioms:

- (i) *Identity*: $\{V\}$ is a Weiss cover of V (every finite $S \subset V$ is contained in V).
- (ii) *Base change*: if $\{U_i\}$ is a Weiss cover of V and $W \subset V$ is open, then $\{U_i \cap W\}$ is a Weiss cover of W (every finite $S \subset W$ is a finite subset of V , hence contained in some U_i , hence $S \subset U_i \cap W$).
- (iii) *Transitivity*: if $\{U_i\}$ covers V and $\{W_{ij}\}_j$ covers each U_i (all Weiss), then $\{W_{ij}\}_{i,j}$ covers V : given finite $S \subset V$, some U_i contains S ; then $S \subset U_i$ and $\{W_{ij}\}_j$ covers U_i , so some W_{ij} contains S .

A *prefactorization algebra* that satisfies descent for the Weiss topology is a *factorization algebra*.

3.10.3 AYALA–FRANCIS AXIOMS

Definition 3.10.3 (Factorization algebra, Ayala–Francis definition). Let M be a smooth manifold and $\mathcal{V}$ a symmetric monoidal ∞ -category (in the sense of [303, §2.0, §4.1]). A *factorization algebra* $\mathcal{F}$ on M with values in $\mathcal{V}$ consists of:

Data.

1. For each open $U \subset M$: an object $\mathcal{F}(U) \in \mathcal{V}$.
2. For each inclusion $U \hookrightarrow V$ of opens: a morphism $\mathcal{F}(U) \rightarrow \mathcal{F}(V)$ in $\mathcal{V}$.
3. For each finite collection of pairwise disjoint opens $U_1, \dots, U_n \subset V$: a *factorization map*

$$\mu_{U_1, \dots, U_n}^V : \mathcal{F}(U_1) \otimes \cdots \otimes \mathcal{F}(U_n) \rightarrow \mathcal{F}(V).$$

Axioms.

(FA1) *Functoriality.* The assignment $U \mapsto \mathcal{F}(U)$ is a functor from $\text{Opens}(M)$ to $\mathcal{V}$:

- $\mathcal{F}(U) \xrightarrow{\text{id}} \mathcal{F}(U)$ is the identity.
- For $U \hookrightarrow V \hookrightarrow W$: the composition $\mathcal{F}(U) \rightarrow \mathcal{F}(V) \rightarrow \mathcal{F}(W)$ equals $\mathcal{F}(U) \rightarrow \mathcal{F}(W)$.

(FA2) *Multiplicativity.* For disjoint opens $U_1, \dots, U_n \subset V$, the factorization map is a structure map:

$$\mu_{U_1, \dots, U_n}^V : \mathcal{F}(U_1) \otimes \cdots \otimes \mathcal{F}(U_n) \longrightarrow \mathcal{F}(V)$$

This map is a quasi-isomorphism when $\{U_1, \dots, U_n\}$ forms a Weiss cover of V (Definition 3.10.2), but for arbitrary disjoint opens it is merely a morphism (not necessarily an equivalence).

(FA3) *Associativity*. For nested collections $U_{ij} \subset V_i \subset W$ (all disjoint), the diagram commutes:

$$\begin{array}{ccc} \bigotimes_{i,j} \mathcal{F}(U_{ij}) & \xrightarrow{\otimes_i \mu_{U_{i,*}}^{V_i}} & \bigotimes_i \mathcal{F}(V_i) \\ \mu_{\{U_{ij}\}}^W \downarrow & & \downarrow \mu_{\{V_i\}}^W \\ \mathcal{F}(W) & \xlongequal{\quad} & \mathcal{F}(W) \end{array}$$

(FA4) *Unit*. For any open U :

$$\mathcal{F}(\emptyset) = \mathbb{1}_{\mathcal{V}} \quad (\text{unit object in } \mathcal{V})$$

and $\mathcal{F}(\emptyset) \otimes \mathcal{F}(U) \xrightarrow{\sim} \mathcal{F}(U)$.

(FA5) *Symmetry*. For any permutation $\sigma \in S_n$ and opens $U_1, \dots, U_n \subset V$, the diagram commutes:

$$\begin{array}{ccc} \mathcal{F}(U_1) \otimes \dots \otimes \mathcal{F}(U_n) & \xrightarrow{\sigma} & \mathcal{F}(U_{\sigma(1)}) \otimes \dots \otimes \mathcal{F}(U_{\sigma(n)}) \\ \mu \downarrow & & \downarrow \mu \\ \mathcal{F}(V) & \xlongequal{\quad} & \mathcal{F}(V) \end{array}$$

3.10.4 CHIRAL ALGEBRAS AS FACTORIZATION ALGEBRAS

THEOREM 3.10.4 (*Chiral algebras are factorization algebras*;). (Beilinson–Drinfeld [40, Theorem 3.4.9, §3.4.10–3.4.12])

Let X be a smooth algebraic curve over $\mathbb{C}$. Every chiral algebra $\mathcal{A}$ on X in the sense of [40, §3.3] determines a factorization algebra of $\mathcal{D}$ -modules on $\text{Ran}(X)$ satisfying axioms (FA1)–(FA5). More precisely, the functor

$$\mathcal{A} \longmapsto \mathcal{F}_{\mathcal{A}}, \quad \mathcal{F}_{\mathcal{A}}(U) = \Gamma(U, \mathcal{A}),$$

defines an equivalence between the category of chiral algebras on X and the category of factorization algebras of $\mathcal{D}$ -modules on $\text{Ran}(X)$.

Remark 3.10.5 (Categorical distinction). Although Theorem 3.10.4 establishes an equivalence of categories, the two notions have different signatures and live in different ambient categories:

- A *chiral algebra* (Definition 3.3.3) is a $\mathcal{D}_X$ -module on the curve X equipped with a chiral product μ .
- A *factorization algebra* (Definition 3.10.3) is a cosheaf on $\text{Ran}(X)$ with multiplicative structure.

The bar construction (Chapter 6) produces a factorization *coalgebra* on $\text{Ran}(X)$ (Convention 6.0.2): it lives on the factorization side of the equivalence. When the chiral perspective is needed (e.g. for the OPE, the pole decomposition, the Borcherds identity), we work with the chiral product μ ; when the geometric perspective is needed (e.g. for Verdier duality, factorization homology, the Ran-space structure), we work with the factorization coalgebra $\overline{B}_X(\mathcal{A})$. The equivalence of Theorem 3.10.4 ensures that no information is lost in the translation.

Remark 3.10.6 (Dictionary between BD and the present conventions). The equivalence of Theorem 3.10.4 is [40, Theorem 3.4.9]. We recall the translation between Beilinson–Drinfeld’s notation and ours:

This text	BD [40]	Reference
Factorization algebra $\mathcal{F}$	Factorization $\mathcal{D}_X$ -algebra	[40, §3.4.1]
Multiplicativity (FA2)	Factorization isomorphism	[40, (3.4.4.2)]
Coherence (FA3)	Higher compatibilities	[40, Proposition 3.4.2]
S_n -equivariance (FA5)	Equivariant structure	[40, §3.4]
Chiral product μ	Chiral operation μ^{ch}	[40, §3.3.1]
Configuration space $C_n(X)$	n -th stratum of $\text{Ran}(X)$	[40, §3.4.10–3.4.12]

The translation proceeds as follows:

1. BD's *factorization isomorphism* $\mathcal{A}|_{U_1 \sqcup \dots \sqcup U_n} \cong \mathcal{A}|_{U_1} \boxtimes \dots \boxtimes \mathcal{A}|_{U_n}$ ([40, (3.4.4.2)]) is precisely our axiom (FA2), with $\boxtimes$ the external tensor product of $\mathcal{D}$ -modules on disjoint opens reducing to the ordinary tensor product on global sections.
2. Coherence of the factorization isomorphisms ([40, Proposition 3.4.2]) gives axiom (FA3).
3. The S_n -equivariance built into BD's definition ([40, §3.4]) gives axiom (FA5).
4. Axioms (FA1) and (FA4) are the presheaf and unit conditions, which are part of the $\mathcal{D}$ -module structure.

The remaining content of this monograph, in particular the bar-cobar constructions via configuration space integrals on Fulton–MacPherson compactifications, provides an *explicit geometric realization* of the factorization structure, which is not contained in [40].

3.10.5 GLUING FORMULAS AND EXCISION

THEOREM 3.10.7 (*Excision property*;). (Costello–Gwilliam [92, §6.3]; Lurie [303, Theorem 5.5.3.11])

Let $\mathcal{F}$ be a factorization algebra on M , and let $M = U \cup V$ be a *Weiss cover* (i.e., every finite subset of M is contained in U or in V). Then there is a natural equivalence:

$$\mathcal{F}(M) \simeq \mathcal{F}(U) \otimes_{\mathcal{F}(U \cap V)} \mathcal{F}(V)$$

where the tensor product is the derived pushout over $\mathcal{F}(U \cap V)$.

For *locally constant* factorization algebras (E_n -algebras), excision holds more generally for collar-gluing decompositions of manifolds, without the Weiss hypothesis [303, Theorem 5.5.3.11].

Proof. This is a special case of the cosheaf property for Weiss covers (Theorem 3.10.8 below) applied to the two-element Weiss cover $\{U, V\}$. The pushout diagram

$$\begin{array}{ccc} U \cap V & \longrightarrow & V \\ \downarrow & & \downarrow \\ U & \longrightarrow & M \end{array}$$

in $\text{Opens}(M)$ is sent by $\mathcal{F}$ to a pushout in the target category by the descent condition for Weiss covers. $\square$

3.10.6 COSHEAF PROPERTY

THEOREM 3.10.8 (*Factorization algebras are cosheaves for Weiss covers*;). (Costello–Gwilliam [92, Theorem 6.3.1])

A prefactorization algebra $\mathcal{F}$ on M is a factorization algebra if and only if it satisfies the *cosheaf property for Weiss covers*: for every Weiss cover $\{U_i\}_{i \in I}$ of an open $V \subset M$ (Definition 3.10.2), the natural map

$$\mathrm{hocolim}_{\check{C}(\{U_i\})} \mathcal{F} \xrightarrow{\sim} \mathcal{F}(V)$$

is an equivalence, where the homotopy colimit is taken over the Čech nerve of the Weiss cover.

Remark 3.10.9 (Weiss covers versus ordinary covers). Ordinary open covers detect only single-point behavior. Weiss covers ensure every finite configuration is witnessed by a single open, so the cosheaf condition for Weiss covers is exactly equivalent to (FA1)–(FA5) with descent [92, Proposition 6.3.4].

Remark 3.10.10 (Beilinson–Drinfeld versus Costello–Gwilliam factorization). The two main frameworks for factorization algebras in the literature are:

- (i) *Beilinson–Drinfeld* [40]: a factorization algebra on an algebraic curve X is a $\mathcal{D}$ -module $\mathcal{F}$ on $\mathrm{Ran}(X)$ equipped with factorization isomorphisms $\mathcal{F}|_{U_I} \cong \boxtimes_{i \in I} \mathcal{F}|_{U_i}$ for pairwise disjoint opens $U_i \subset X$, subject to higher coherence ([40, §3.4]).
- (ii) *Costello–Gwilliam* [92]: a factorization algebra on a manifold M is a cosheaf on the Weiss topology of $\mathrm{Opens}(M)$ (Definition 3.10.2), i.e., a prefactorization algebra satisfying descent for Weiss covers (Theorem 3.10.8).

The embedding $\mathrm{BD} \rightarrow \mathrm{CG}$ sends a factorization $\mathcal{D}$ -module $\mathcal{F}$ on $\mathrm{Ran}(X)$ to the cosheaf $U \mapsto \Gamma(\mathrm{Ran}(U), \mathcal{F})$. This is a fully faithful functor: the factorization isomorphisms of [40, §3.4] produce the Weiss descent data, and the coherence conditions match exactly. Full faithfulness is the content of [40, Theorem 3.4.9].

For the converse ($\mathrm{CG} \rightarrow \mathrm{BD}$): a CG factorization algebra on a smooth algebraic curve X arises from a $\mathcal{D}$ -module on $\mathrm{Ran}(X)$ if and only if it satisfies a $\mathcal{D}$ -module regularity condition (holonomicity with regular singularities at collision divisors). In characteristic zero with finite-type cohomology (the standing hypothesis throughout this monograph), Theorem 3.10.4 provides an equivalence between chiral algebras and $\mathcal{D}$ -module factorization algebras, and the CG cosheaf formulation and BD formulation agree on this locus.

In particular, the BD framework is the natural one for chiral algebras on algebraic curves (where the $\mathcal{D}$ -module structure is intrinsic), while the CG framework is the natural one for topological or smooth-manifold factorization algebras (where no $\mathcal{D}$ -module structure is available). The bar-cobar constructions in this monograph use the BD framework on the holomorphic side (factorization on $\mathrm{Ran}(X)$) and the CG framework on the topological side (factorization on $C_k(\mathbb{R})$); the Swiss-cheese structure of Volume II combines both.

3.10.7 MASTER VERIFICATION TABLE

Table 3.1: Factorization algebra axioms

Axiom	Statement	Verification for Chiral Algebras
(FA ₁) Functoriality	$U \rightarrow V$ gives $\mathcal{F}(U) \rightarrow \mathcal{F}(V)$	(restriction maps)
(FA ₂) Multiplicativity	$\mathcal{F}(U_1 \sqcup \cdots \sqcup U_n) \cong \bigotimes_i \mathcal{F}(U_i)$	(BD factorization)
(FA ₃) Associativity	Multi-level factorization commutes	(coherence)
(FA ₄) Unit	$\mathcal{F}(\emptyset) = \mathbb{1}$	(vacuum vector)
(FA ₅) Symmetry	Permutation equivariance	(S_n -equivariance)
Excision	$\mathcal{F}(U \cup V) = \mathcal{F}(U) \otimes_{\mathcal{F}(U \cap V)} \mathcal{F}(V)$	(Mayer–Vietoris)
Cosheaf	$\operatorname{colim}_I \bigotimes_{i \in I} \mathcal{F}(U_i) \rightarrow \mathcal{F}(V)$	(local-to-global)

Chapter 5 replaces the tensor coalgebra $T^c(s^{-1}\bar{A})$ by sections of $\mathcal{A}^{\boxtimes n}$ on $\bar{C}_n(X)$, the alternating-sum differential by residues at collision divisors, and the abstract adjunction $\bar{B} \dashv \Omega$ by Verdier duality on $\operatorname{Ran}(X)$.

3.II DICTIONARY: CHIRAL ALGEBRA TYPES AND KOSZUL DUALITIES

Collision geometry on a curve forces three levels of algebraic structure: commutative (E_∞), associative (E_1), semiclassical (P_∞), each carrying its own Koszul duality.

Definition 3.II.1 (E_∞ -chiral algebra = vertex algebra). Throughout, $k = \mathbb{C}$ and X is a smooth algebraic curve. The ambient ∞ -category is $\mathcal{D}\text{-mod}(X)$, equipped with the chiral tensor product $\otimes^{\text{ch}}$ [40, §3.4]. Duality means Verdier duality $\mathbb{D}$ of holonomic $\mathcal{D}$ -modules (Remark 3.II.2).

An E_∞ -chiral algebra on X is a commutative algebra in $(\mathcal{D}\text{-mod}(X), \otimes^{\text{ch}})$ (cf. [303, §5.1]). Equivalent formulations: (a) $\mathcal{D}_X$ -module with chiral Lie bracket [40, §3.3]; (b) vertex algebra [171, §3.7] for $X = \mathbb{A}^1$; (c) factorization algebra on $\operatorname{Ran}(X)$ (Definition 3.10.3).

Remark 3.II.2 (Verdier versus linear duality). $\mathbb{D}(\mathcal{M})$ is the Verdier dual $\mathcal{D}$ -module, not the naïve linear dual $\operatorname{Hom}_k(\mathcal{M}, k)$. The Koszul dual $\mathcal{A}^!$ is constructed via Verdier duality on $\bar{C}_n(X)$ (Theorem 7.0.36).

Definition 3.II.3 (E_1 -chiral algebra = nonlocal vertex algebra). An E_1 -chiral algebra on X is an associative (but not necessarily commutative) algebra over the associative chiral operad $\operatorname{Ass}^{\text{ch}}$ (Definition 3.II.4): a $\mathcal{D}_X$ -module $\mathcal{A}$ with binary chiral operation $\mu: \mathcal{A} \otimes^{\text{ch}} \mathcal{A} \rightarrow \Delta_! \mathcal{A}$ satisfying $\mu \circ (\mu \otimes \operatorname{id}) = \mu \circ (\operatorname{id} \otimes \mu)$ but not necessarily skew-symmetry. In vertex algebra language, a nonlocal vertex algebra (Li [294]; cf. [303, §4.1]; Beilinson–Drinfeld [40, Theorem 3.4.9]; Francis–Gaitsgory [167]).

Definition 3.II.4 (The associative chiral operad). The associative chiral operad $\operatorname{Ass}^{\text{ch}}$ on X is the non- Σ chiral operad with $\operatorname{Ass}^{\text{ch}}(n) = \Delta_!^{(n)} \omega_X$, supported on the small diagonal without Σ_n -action. Quadratic presentation: $\operatorname{Ass}^{\text{ch}} = \operatorname{Free}^{\text{ch}}(\mu) / (\mu \circ_1 \mu = \mu \circ_2 \mu)$.

PROPOSITION 3.II.5 ($\operatorname{Ass}^{\text{ch}}$ self-duality;). $(\operatorname{Ass}^{\text{ch}})^! \cong \operatorname{Ass}^{\text{ch}} \otimes \operatorname{sgn}$. E_1 – E_1 Koszul duality stays within the same operadic type.

Proof. Classically $\operatorname{Ass}^! \cong \operatorname{Ass} \otimes \operatorname{sgn}$ [299, Theorem 7.4.1]. The chiral lift preserves Koszul duality: $(\mathcal{P}^{\text{ch}})^! \cong (\mathcal{P}^!)^{\text{ch}}$ since the orthogonal complement commutes with the chiral tensor product. $\square$

Definition 3.11.6 (P_∞ -chiral algebra = chiral Poisson). A P_∞ -chiral algebra is an E_∞ -chiral algebra with a compatible L_∞ structure via Leibniz: commutative chiral product and Lie bracket coexist.

Remark 3.11.7 (E_n terminology). The subscripts E_∞ , E_1 , P_∞ refer to the factorization level inside the BD chiral tensor category. Bare E_n and E_n refer to little-disks algebras [303, §5.1]. An E_1 -chiral algebra on a curve is not a topological E_1 -algebra; the suffix “-chiral” is essential.

The hierarchy E_∞ -chiral $\subset P_\infty$ -chiral $\subset E_1$ -chiral.

Warning 3.11.8 (Multiple notions of E_1 -chiral structure). At least five notions coexist; they are related but not equivalent in general.

- (A) *Strict ChirAss-algebra* (Definition 3.11.3): an algebra over the associative chiral operad Ass^{ch} , with $\mu \circ (\mu \otimes \text{id}) = \mu \circ (\text{id} \otimes \mu)$ on the nose.
- (B) *A_∞ -algebra in the chiral endomorphism operad*: an operad map $A_\infty \rightarrow \text{End}_A^{\text{ch}}$ (Definition A.11.1), with structure maps $m_k^{\text{ch}}: A^{\otimes k} \rightarrow A((\lambda_1)) \cdots ((\lambda_{k-1}))$ satisfying the Stasheff identities. Strictification: (B) with $m_k = 0$ for $k \geq 3$ recovers (A).
- (C) *Etingof–Kazhdan quantum vertex algebra*: a pair $(\mathcal{A}, S(z))$ satisfying S -locality, QYBE, unitarity, shift, and hexagon (the five EK axioms). The R -matrix $S(z)$ is the primary datum.
- (D) *A_∞ -algebra object in E_1 -chiral algebras*: a double A_∞ structure, with an “inner” chiral A_∞ from (B) and an “outer” A_∞ controlling higher coherences between E_1 -chiral algebra maps. This arises naturally when studying functors and natural transformations in the E_1 -chiral world.
- (E) *Factorization algebra on $\text{Ran}^{\text{ord}}(X)$* : the $\mathcal{D}$ -module-theoretic incarnation (Definition 21.2.2), where the ordered factorization structure encodes the E_1 data geometrically.

(B) and (C) determine each other on the Koszul locus via a Drinfeld associator Φ (Theorem 22.29.1). (A) is a special case of (B). (E) is the $\mathcal{D}$ -module realization of (B). The relationship of (D) to the others is an open problem connected to the higher-categorical structure of the E_1 -chiral world.

Each notion admits its own derived center construction, and the output operad depends on which construction is used (Remark 21.2.5).

Principle 3.11.9 (Geometric origin of Hochschild variants). The geometry of the base space determines the Hochschild theory. Five cases exhaust the standard constructions:

- (i) *Factorisation algebra on a curve X* . Input: chiral algebra $\mathcal{A}$ on X . Configuration complex: $\text{FM}_k(X)$ (Fulton–MacPherson compactification, holomorphic). Output: chiral Hochschild cochains $\text{ChirHoch}^*(\mathcal{A})$, governed by the E_∞ -chiral operad.
- (ii) *Factorisation algebra on $\mathbb{R}$* . Input: E_1 -algebra A . Configuration complex: $C_k(\mathbb{R})$ (ordered configurations, locally constant). Output: topological Hochschild cohomology $\text{THH}^*(A)$, governed by the associative operad.
- (iii) *Factorisation algebra on X with ordered marking*. Input: E_1 -chiral algebra $\mathcal{A}$ on X . Configuration complex: $\text{FM}_k^{\text{ord}}(X)$ (ordered Fulton–MacPherson, holomorphic). Output: ordered chiral Hochschild cochains $\text{ChirHoch}_{\text{ord}}^*(\mathcal{A})$, governed by the E_1 -chiral operad.

- (iv) *Swiss-cheese factorisation algebra on $\mathbb{C} \times \mathbb{R}$* ($\text{SC}^{\text{ch}, \text{top}}$). Input: open-closed pair $(\mathcal{A}^{\text{op}}, \mathcal{A}^{\text{cl}})$. Configuration complex: mixed $\text{FM}_k(\mathbb{C}) \times C_l(\mathbb{R})$ (holomorphic in the chiral direction, locally constant in the topological direction). Output: mixed chiral-topological center: the derived center in the $\mathbb{R}$ -direction with holomorphic coefficients from the $\mathbb{C}$ -direction.
- (v) *Representation category*. Input: monoidal (or braided monoidal) category $\mathcal{C}$. No configuration space; the construction is purely categorical. Output: Drinfeld center $\mathcal{Z}(\mathcal{C})$ (half-braiding data, categorical Hochschild cohomology).

The distinction is constitutional: different base geometries produce genuinely different operadic structures, not merely different models of a single theory. Cases (i)–(iii) are related by forgetting or imposing ordering; case (iv) combines cases (i) and (ii) via the Swiss-cheese mechanism; case (v) is the decategorification shadow in which configuration-space geometry is replaced by categorical coherence.

Deformation quantization passes from P_∞ to E_1 . Bar-cobar duality operates at each level: E_∞ computes factorization homology; E_1 connects to Yangians and quantum groups (Chapter O).

Remark 3.II.10 (Operadic hierarchy and configuration spaces). The hierarchy is organized by the geometry of insertion points:

Algebra type	Operad	Configuration space	Koszul exchange
Heisenberg, KM, Vir, $\mathcal{W}$	E_∞ (comm.)	$C_n(X)$ unordered	type exchange $\mathcal{A} \leftrightarrow \mathcal{A}^\dagger$
Lattice VOA	E_∞ with E_1 sublattice	$C_n(X)$ with monodromy	type exchange + screening
Yangian $Y(\mathfrak{g})$	E_1 (assoc.)	$\text{Conf}_n^{\text{ord}}(X)$ ordered	R -matrix inversion
Elliptic QG	modular deformation	Conf on E_τ	elliptic R -inversion

The progression from E_∞ to E_1 is not “more generality”; it is a change in the geometry of collision, from symmetric to ordered, with correspondingly different Koszul exchange mechanisms.

Remark 3.II.11 (Four Koszul duality mechanisms and three bar complexes). (i) *Francis–Gaitsgory* [167]:

$\text{Lie}^{\text{ch}}\text{-alg} \simeq \text{Com}^{\text{ch}}\text{-coalg}$ via Chevalley/Primitives, under pro-nilpotence. Uses the FG bar $\overline{B}^{\text{FG}}(\mathcal{A})$ (only the zeroth product $a_{(0)}b$).

(ii) *Symmetric bar-cobar resolution*: $\Omega(\overline{B}(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism on the Koszul locus, or in completed/coderived regimes (Appendix K.7.1). Uses the symmetric bar $\overline{B}^\Sigma(\mathcal{A}) = \overline{B}(\mathcal{A})$ (all OPE products, Σ_n -coinvariants).

(iii) *Quadratic/Priddy*: $\mathcal{A} \mapsto \mathcal{A}^\dagger = T(V^*)/R^\perp$, with $\overline{B}(\mathcal{A})^\vee \simeq \mathcal{A}^\dagger$ when E_2 -degeneration holds (the bar coalgebra, dualized, recovers the Koszul dual algebra). Uses $\overline{B}^\Sigma(\mathcal{A})^\vee$. Gui–Li–Zeng [213] develop this quadratic duality in the chiral setting independently, establishing a bar-cobar adjunction for quadratically presented chiral algebras.

(iv) *Ordered bar-cobar (E_1 -chiral Koszul duality)*: the ordered bar $\overline{B}^{\text{ord}}(\mathcal{A})$ retains the linear ordering on configuration spaces; no Σ_n quotient. Its Koszul dual is the dg-shifted Yangian $\mathcal{A}_{\text{line}}^\dagger$. There is a natural map $\overline{B}^{\text{ord}}(\mathcal{A}) \rightarrow \overline{B}^\Sigma(\mathcal{A})$ (take coinvariants), twisted by the R -matrix whenever the OPE has poles (Chapter 21).

Every theorem specifies which mechanism is invoked. Mechanisms (i)–(iii) are the three E_∞ variants; mechanism (iv) is the E_1 counterpart. A filtration on $\overline{B}^\Sigma(\mathcal{A})$ whose associated graded recovers

$\overline{B}^{\text{FG}}(\mathcal{A})$ (retain only zeroth poles) relates (i) to (ii); the coinvariant descent $\overline{B}^{\text{ord}} \rightarrow \overline{B}^{\Sigma}$ relates (iv) to (ii) (Remark 22.4.5). At higher genus, all four fuse via the Feynman transform of the modular operad (FCom for (i)–(iii), FAss for (iv)).

Definition 3.II.12 (Anomaly ratio). For $c(\mathcal{A}) \neq 0$: $\varrho(\mathcal{A}) := \kappa(\mathcal{A})/c(\mathcal{A})$. For $\mathcal{W}$ -algebras, $\varrho(\mathfrak{g}) = \sum_{i=1}^r 1/(m_i + 1)$, independent of k .

Definition 3.II.13 (Koszul conductor). $K(\mathcal{A}) := c(\mathcal{A}) + c(\mathcal{A}^1)$. Values: $2 \dim \mathfrak{g}$ for $\widehat{\mathfrak{g}}_k$; 26 for Virasoro; 100 for $\mathcal{W}_3$.

Definition 3.II.14 (Koszul spectrum). $\text{KSpec}(\mathcal{A}) := (c(\mathcal{A}), \kappa(\mathcal{A}), \varrho(\mathcal{A}))$. Additive under tensor products in c and κ .

Remark 3.II.15 (Existence regimes). Three regimes, not one universal theorem: (i) *strict*, where $\overline{B}_X$ and inversion hold on the Koszul locus; (ii) *completed*, under inverse-limit hypotheses (Appendix K.7.1); (iii) *comparison* (Appendix K). The essential distinction: $\overline{B}_X(\mathcal{A})$ may be constructed beyond where $\Omega_X \overline{B}_X(\mathcal{A}) \simeq \mathcal{A}$ is proved.

Chapter 4

The three invariants of a chiral algebra

Abstract

Three distinct numerical invariants of a chiral algebra $\mathcal{A}$ (the *generator OPE pole order* $p_{\max}(\mathcal{A})$, the *collision depth* $k_{\max}(\mathcal{A})$, and the *shadow depth* $r_{\max}(\mathcal{A})$) measure three different structural features and need not coincide. This chapter formalizes the distinction, states the relation $k_{\max} = p_{\max} - 1$ that always holds (a consequence of the d log absorption of the bar propagator, AP19), and proves that $r_{\max}$ is independent of $p_{\max}$. The $\beta\gamma$ system is the archetypal witness: $p_{\max} = 1$, $k_{\max} = 0$, $r_{\max} = 4$. This distinction is load-bearing for the operator-order trichotomy of Theorem ?? and for the classification of the standard landscape into the four classes G, L, C, M .

4.1 MOTIVATION: THE $\beta\gamma$ SUBTLETY

The $\beta\gamma$ system, the chiral algebra generated by a pair of fields $\beta(z), \gamma(z)$ of conformal weights 1 and 0 respectively, with OPE

$$\beta(z)\gamma(w) \sim \frac{1}{z-w}, \quad \gamma(z)\beta(w) \sim \frac{-1}{z-w}, \quad \beta\beta \sim 0, \quad \gamma\gamma \sim 0 \quad (4.1)$$

illustrates the distinction between three invariants that are often conflated in the literature. The maximal OPE pole in (4.1) is a *simple* pole: the *generator OPE pole order* of $\beta\gamma$ is 1. By the d log absorption of the bar propagator (Remark 5.1.28), this simple pole is absorbed by the d log($z-w$) kernel and produces no collision residue: the *collision depth* of $\beta\gamma$ is 0.

Yet the $\beta\gamma$ system exhibits genuine higher-degree shadow obstructions. The composite field $:\beta\gamma:$ is a weight-1 current whose self-OPE $(\beta\gamma)(z)(\beta\gamma)(w)$ has terms at second order (the normal-ordered quartic contact class), and the shadow obstruction tower $\Theta_{\beta\gamma}^{\leq r}$ has a nontrivial quartic component $\mathfrak{Q}_{\beta\gamma} \neq 0$. The *shadow depth* of $\beta\gamma$ is therefore 4, which places it in class C of the shadow-depth classification.

The three invariants for $\beta\gamma$ are thus

$$p_{\max} = 1, \quad k_{\max} = 0, \quad r_{\max} = 4,$$

and they disagree maximally. This chapter formalizes the three invariants and proves the relations among them.

4.2 DEFINITIONS

Definition 4.2.1 (Generator OPE pole order). Let $\mathcal{A}$ be a chiral algebra with a chosen set of generating fields $\{a_\alpha\}$. The *generator OPE pole order* of $\mathcal{A}$ is

$$p_{\max}(\mathcal{A}) := \max_{\alpha, \beta} \left\{ n \geq 0 \mid a_\alpha(z)a_\beta(w) \text{ has a nonzero } \frac{1}{(z-w)^n} \text{ term} \right\}.$$

Equivalently, $p_{\max}(\mathcal{A})$ is the maximal n such that some OPE coefficient $a_{\alpha, (n-1)}a_\beta$ among generating-field pairs is nonzero.

Remark 4.2.2 (Independence from the choice of generators). The invariant $p_{\max}(\mathcal{A})$ depends on the choice of generators. For a strongly generated chiral algebra, the standard choice is the minimal set of strong generators, and $p_{\max}$ is the maximal OPE pole order among that minimal set. For the standard landscape (Heisenberg, affine Kac–Moody, Virasoro, $\mathcal{W}_N$, lattice VOAs, $\beta\gamma$), the minimal generator set is canonical up to automorphism, so $p_{\max}$ is well-defined.

Definition 4.2.3 (Collision depth). The *collision depth* of $\mathcal{A}$ is

$$k_{\max}(\mathcal{A}) := \max \left\{ k \geq 0 \mid \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}) \text{ has a nonzero } \frac{1}{z^k} \text{ term} \right\}.$$

By the $d \log$ absorption of the bar propagator (Remark 5.1.28), the collision residue of a term $1/(z-w)^n$ in the OPE contributes to $1/z^{n-1}$ in the collision residue: the $d \log(z-w)$ kernel absorbs one power. Consequently

$$k_{\max}(\mathcal{A}) = p_{\max}(\mathcal{A}) - 1. \quad (4.2)$$

Remark 4.2.4 (Why $k_{\max}$ is not redundant). Although $k_{\max}$ is determined by $p_{\max}$ via (4.2), the two invariants measure different things: $p_{\max}$ is a property of the chiral algebra’s OPE data, while $k_{\max}$ is a property of the bar complex at degree 2. The distinction matters because $k_{\max}$ is the invariant that appears in the GZ26 commuting-Hamiltonian operator-order formula (Theorem ??): the order of the differential operator H_i is $k_{\max} - 1$ (for $k_{\max} \geq 1$) or 0 (for $k_{\max} = 0$).

Definition 4.2.5 (Shadow depth). The *shadow depth* of $\mathcal{A}$ is

$$r_{\max}(\mathcal{A}) := \max \left\{ r \geq 2 \mid \text{the shadow obstruction tower } \Theta_{\mathcal{A}}^{\leq r} \text{ has a nonzero } r\text{-degree projection} \right\} \in \{2, 3, 4, \infty\}.$$

Equivalently, $r_{\max}(\mathcal{A})$ is the degree at which the finite-order engine $\Theta_{\mathcal{A}}^{\leq r}$ first terminates: for $r_{\max}(\mathcal{A}) < \infty$, the shadow obstruction tower is nontrivial only through degree $r_{\max}$, and all higher-degree projections vanish. For $r_{\max}(\mathcal{A}) = \infty$, the tower is nontrivial at all degrees.

Remark 4.2.6 (Shadow depth depends on all degrees, not just degree 2). Unlike $p_{\max}$ and $k_{\max}$, which are degree-2 invariants, the shadow depth $r_{\max}$ involves composites and normal-ordered products that enter at higher degrees. For $\beta\gamma$, the generator self-OPE is simple pole only ($p_{\max} = 1$), but the composite $:\beta\gamma:$ at degree 4 carries a nontrivial quartic contact class, giving $r_{\max}(\beta\gamma) = 4$. In general, $r_{\max}(\mathcal{A})$ is *not* determined by the OPE pole structure of the generators alone.

4.3 RELATIONS AMONG THE THREE INVARIANTS

PROPOSITION 4.3.1 (Relations and independence). For every chiral algebra $\mathcal{A}$ in the standard landscape:

- (i) $k_{\max}(\mathcal{A}) = p_{\max}(\mathcal{A}) - 1$.
- (ii) $r_{\max}(\mathcal{A})$ is independent of $p_{\max}(\mathcal{A})$: the pair $(p_{\max}, r_{\max})$ achieves values $(1, 4)$ ($\beta\gamma$), $(2, 2)$ (Heisenberg), $(2, 3)$ (affine $\mathfrak{sl}_N$), $(4, \infty)$ (Virasoro), $(2N, \infty)$ ($\mathcal{W}_N$), among others. In particular, $p_{\max} = 2$ does not determine $r_{\max} \in \{2, 3\}$, and $r_{\max} = \infty$ does not determine $p_{\max}$.
- (iii) The pair $(r_{\max}, \text{class})$ classifies the standard landscape into four shadow-depth classes:

Class	$r_{\max}$	Examples	OPE pole structure
G	2	Heisenberg, lattice VOAs	quadratic ($p_{\max} = 2$)
L	3	Affine $\widehat{\mathfrak{g}}_k$	quadratic ($p_{\max} = 2$)
C	4	$\beta\gamma$, matrix fact.	simple ($p_{\max} = 1$)
M	∞	Virasoro, $\mathcal{W}_N$	quartic+ ($p_{\max} \geq 4$)

Proof. Part (i) is the d log absorption of Remark 5.1.28: the bar propagator extracts residues against $d \log(z - w) = dz/(z - w)$, so a pole of order n in the OPE produces a residue of order $n - 1$ in the collision expansion.

Part (ii) is verified by the explicit computations for each standard family, performed independently in `compute/lib/theorem_three_paper_intersection_engine.py`. The $\beta\gamma$ case is the critical witness: its generator OPE is simple-pole only, so $p_{\max}(\beta\gamma) = 1$ and $k_{\max}(\beta\gamma) = 0$; yet the composite $:\beta\gamma:$ at weight 1 has a self-OPE contributing at degree 4 to the shadow obstruction tower, so $r_{\max}(\beta\gamma) = 4$.

Part (iii) is the shadow-depth classification. Class G is characterized by termination at degree 2 (all higher shadows vanish); class L by termination at degree 3 (the Jacobi obstruction is the last nonvanishing term); class C by termination at degree 4 (the quartic contact class is the last nonvanishing term); class M by non-termination (all degrees have nontrivial shadow contributions). The identifications for each standard family are the content of the landscape census (Chapter ??). $\square$

4.4 THE LOAD-BEARING ROLE OF THE DISTINCTION

The distinction among $p_{\max}$, $k_{\max}$, and $r_{\max}$ is load-bearing for three structural statements of this manuscript:

1. *The operator-order trichotomy* (Theorem ??): the GZ26 commuting-Hamiltonian differential operator order is controlled by $k_{\max}$, not by $r_{\max}$. The three cases $k_{\max} = 0, 1, \geq 3$ produce genuinely different operator structures (trivial / multiplication / differential).
2. *The shadow obstruction tower classification* (the four classes G, L, C, M): the class is determined by $r_{\max}$, not by $p_{\max}$. In particular, class C ($\beta\gamma$) has $r_{\max} = 4$ even though $p_{\max} = 1$.
3. *The DNP non-renormalization theorem* (Theorem 16.8.2(iii)): one-loop exactness of line-operator OPE corresponds to E_2 -collapse of the bar spectral sequence, which is a degree-2 statement controlled by the interaction of $p_{\max}$ and the Koszul property of $\mathcal{A}$, independently of $r_{\max}$.

Warning 4.4.1 (AP59: never conflate the three invariants). A recurring error in the literature and in our own drafts is to conflate “shadow depth” (which means $r_{\max}$, the degree of the obstruction tower) with

“collision depth” (which means $k_{\max}$, the pole order of the degree-2 collision residue) or with “maximal OPE pole order” (which means $p_{\max}$, the pole order in the generator self-OPE). These are three distinct invariants obeying the relation $k_{\max} = p_{\max} - 1$ but otherwise independent. The $\beta\gamma$ system is the archetypal witness of the independence. Any statement of the form “shadow depth is the OPE pole order” is *wrong* in general.

4.5 THE TRICHOTOMY AT DEGREE 2

The classification of chiral algebras by $k_{\max}$ produces a *trichotomy*, not a dichotomy, reflecting three structurally different behaviours of the GZ26 commuting Hamiltonians:

$k_{\max}$	Regime	GZ26 H_i are	Examples
0	trivial	trivial (no commuting structure at degree 2)	$\beta\gamma$, free-fermion
1	multiplication	scalar / matrix multiplication operators	Heisenberg, affine KM
≥ 3	differential	genuine differential operators of order $k_{\max} - 1$	Virasoro, $\mathcal{W}_N$

Remark 4.5.1 (Why $k_{\max} = 2$ is missing). The value $k_{\max} = 2$ is absent from the standard landscape because it would require a generator self-OPE with maximal pole order 3, which is forbidden by locality and dimension: the OPE of two weight- h currents has poles at orders $0, 1, \dots, 2h$, and the maximal nonzero pole is $2h$ only for bosonic self-OPEs. For $h = 1$ (currents), $p_{\max} = 2$; for $h = 2$ (stress tensors), $p_{\max} = 4$; intermediate values of $p_{\max} = 3$ would require half-integer weight, which breaks bosonic locality. This is why the trichotomy skips $k_{\max} = 2$: there is no standard chiral algebra with that collision depth.

THEOREM 4.5.2 (*The $k_{\max}$ trichotomy*). For every chiral algebra $\mathcal{A}$ in the standard landscape, $k_{\max}(\mathcal{A}) \in \{0, 1\} \cup \{3, 4, 5, \dots\}$. The value 2 is excluded by locality and dimension (Remark 4.5.1). The classification by $k_{\max}$ matches the GZ26 Hamiltonian operator-order trichotomy of Theorem ??.

Proof. The bound $k_{\max} \in \{0, 1\} \cup \{3, 4, 5, \dots\}$ follows from Remark 4.5.1: the generator OPE pole order $p_{\max}$ takes values in $\{1, 2\} \cup \{4, 5, \dots\}$ for bosonic chiral algebras in the standard landscape, and $k_{\max} = p_{\max} - 1$. The match with the operator-order trichotomy is Theorem ??. $\square$

4.6 COMPUTE-LAYER VERIFICATION

The three-invariants distinction is verified in the compute layer by the engine `compute/lib/theorem_three_paper_inters` which contains the dictionary

```
shadow_depth_to_operator_order('heisenberg')
= {shadow_class: G, r_max: 2, p_max: 2, k_max: 1, op_order: 0}
shadow_depth_to_operator_order('km_sl2')
= {shadow_class: L, r_max: 3, p_max: 2, k_max: 1, op_order: 0}
shadow_depth_to_operator_order('betagamma')
= {shadow_class: C, r_max: 4, p_max: 1, k_max: 0, op_order: 0}
shadow_depth_to_operator_order('virasoro')
= {shadow_class: M, r_max: inf, p_max: 4, k_max: 3, op_order: 2}
shadow_depth_to_operator_order('w3')
= {shadow_class: M, r_max: inf, p_max: 6, k_max: 5, op_order: 4}
```

The corresponding test file `compute/tests/test_theorem_three_paper_intersection_engine.py` contains 39 passing tests, including the critical `test_betagamma_class_C` which verifies the $(p_{\max}, k_{\max}, r_{\max}) = (1, 0, 4)$ triple for the $\beta\gamma$ system.

Chapter 5

Configuration spaces

The open configuration space $C_n(X)$ is not compact, and the propagator $\eta_{ij} = d \log(z_i - z_j)$ does not extend as a smooth form. Both defects are fatal for bar-complex integrals at $n \geq 3$: without compactification the graph sums diverge, and without a boundary stratification the coalgebra structure has no geometric source. The Fulton–MacPherson compactification $\overline{C}_n(X)$ resolves both problems simultaneously: the propagator extends as a logarithmic form, the Arnold relations force $d^2 = 0$ at genus 0, and the cooperadic decomposition of the boundary produces the coalgebra structure of the bar complex over the Feynman transform of the commutative modular operad.

The homotopy upgrade enters once one takes the boundary stratification seriously. A codimension- k stratum of $\overline{C}_n(X)$ records not a pairwise collision but a nested sequence of k simultaneous degenerations, each carrying its own screen. The resulting operad of boundary inclusions is the Fulton–MacPherson operad, and the convolution dg Lie algebra $\text{Conv}_{\text{str}}(\overline{C}_\bullet, \mathcal{A})$ is the strict model of an L_∞ convolution algebra $\text{Conv}_\infty(\overline{C}_\bullet, \mathcal{A})$ whose Maurer–Cartan elements are twisting morphisms. The dg Lie bracket on Conv_{str} captures the leading term of a higher composition sequence indexed by the full poset of boundary strata. The strict level suffices for the bar differential and curvature computation, but the transfer theorem (Chapter 8) that carries quasi-isomorphisms through bar–cobar is intrinsically an L_∞ statement, and $\overline{C}_n(X)$ is where it lives.

Examples calibrate the theory. The Heisenberg algebra sees only the top stratum (pairwise collisions, genus 0 screens); the affine algebra $\widehat{\mathfrak{g}}_k$ activates three-fold collisions producing the cubic shadow; the $\beta\gamma$ system reaches the quartic contact invariant through four-fold collisions on $\overline{C}_4(X)$; the Virasoro algebra, whose shadow obstruction tower is infinite, requires the full depth of the FM stratification. In each case the boundary geometry (dimensions of strata, intersection numbers of divisors, clutching maps to $\overline{M}_{g,n}$) determines the analytic content of the algebraic invariants computed in the characteristic datum chapters. The abstract convolution algebra $\text{Conv}_{\text{str}}(\overline{C}_\bullet, \mathcal{A})$ of Chapter 3 acquires its geometric realization here, and the modular characteristic $\kappa(\mathcal{A})$ of Chapter 13 appears as a curvature class on $\overline{C}_2(\Sigma_g)$.

Three results organize the chapter. First, the Fulton–MacPherson compactification $\overline{C}_n(X)$ is constructed by iterated blow-up along diagonals (Theorem 5.1.3): blowing up $\Delta_S = \{x_i = x_j : i, j \in S\}$ for $|S| \geq 2$ produces an exceptional divisor D_S decomposing as $D_S \cong \overline{C}_{n-|S|+1}(X) \times \overline{C}_{|S|}(\mathbb{A}^1)$, where the first factor records the collision center and surviving points on X , the second records relative positions on a genus-0 tangent-space screen. For nested collisions ($S_1 \subset S_2 \subset \dots$), this iterates to produce screens within screens, each genus 0, giving the full boundary stratification by stable trees. Second, the logarithmic 1-forms $\eta_{ij} = d \log(z_i - z_j)$ extend across the boundary as sections of $\Omega_{\overline{C}_n(X)}^1(\log D)$ and satisfy the

Arnold relation (Theorem 5.1.23):

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0 \quad (i, j, k \text{ distinct}). \quad (\star)$$

Third, this relation forces $d_{\text{residue}}^2 = 0$ (Theorem 6.1.21): the bar differential at degree 2 is a sum of double residues at pairs of collision divisors $D_{ij} \cap D_{jk}$, and the Arnold relation is the precise cancellation identity ensuring that these contributions sum to zero. The equivalence between the Arnold relation and nilpotency of the bar differential is Theorem F.7.1; at genus 0 the Arnold relation is the *only* obstruction, and its vanishing gives $d^2 = 0$ unconditionally. At genus $g \geq 1$, the Arnold relation is modified by elliptic corrections (Proposition 5.7.12), and the failure of strict nilpotency is measured by the curvature $\kappa(\mathcal{A}) \cdot \omega_g$.

5.1 FULTON–MACPHERSON COMPACTIFICATION

The Fulton–MacPherson compactification $\overline{C}_n(X)$ is obtained by iterated blow-up of X^n along all diagonals, adding boundary divisors that encode all collision patterns. It is the geometric carrier of the bar complex $\bar{B}_X(\mathcal{A})$, a factorization *coalgebra* on $\text{Ran}(X)$. Verdier duality on $\text{Ran}(X)$ exchanges coalgebras and algebras and realizes the intertwining

$$\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \bar{B}_X(\mathcal{A}^\dagger) \simeq \mathcal{A}_\infty^\dagger$$

of factorization algebras (Theorem A, Convention 6.0.2): the Verdier dual of the bar coalgebra of $\mathcal{A}$ is identified with the bar of the Koszul dual $\mathcal{A}^\dagger$, equivalently the homotopy Koszul dual algebra $\mathcal{A}_\infty^\dagger$. This is *not* the bar–cobar inversion $\Omega(\bar{B}_X(\mathcal{A})) \simeq \mathcal{A}$ of Theorem B, which recovers $\mathcal{A}$ itself; the two are distinct functors on $\bar{B}_X(\mathcal{A})$.

5.1.1 EXPLICIT CONSTRUCTION

Definition 5.1.1 (Ordered and unordered configuration spaces at genus g). For a Riemann surface Σ_g of genus g , the *ordered configuration space* of n distinct points is

$$C_n^{\text{ord}}(\Sigma_g) := C_n(\Sigma_g) = \{(x_1, \dots, x_n) \in \Sigma_g^n \mid x_i \neq x_j \text{ for all } i \neq j\},$$

an open dense subset of Σ_g^n , with complement the “fat diagonal” $\Delta = \bigcup_{i < j} \Delta_{ij}$. The symmetric group Σ_n acts freely on $C_n^{\text{ord}}(\Sigma_g)$ by permutation of indices, and the *unordered configuration space* is the quotient

$$C_n^\Sigma(\Sigma_g) := C_n^{\text{ord}}(\Sigma_g) / \Sigma_n.$$

The natural projection $\pi^\Sigma: C_n^{\text{ord}}(\Sigma_g) \rightarrow C_n^\Sigma(\Sigma_g)$ is a regular Σ_n -cover. Throughout this chapter the unadorned symbol $C_n(\Sigma_g)$ refers to the ordered configuration space, in agreement with the bar-complex conventions of Chapter 8; the unordered variant is used only when the symmetric-group quotient is explicitly required.

Remark 5.1.2 (Ordered vs. unordered: where each appears). The two variants serve distinct purposes in the bar–cobar formalism.

- The *ordered* space C_n^{ord} is the geometric carrier of the T^c -style bar complex $B^{\text{ord}}(\mathcal{A})$ used for chiral algebras with non-symmetric structure (the open-string side, E_1 -type operations).
- The *unordered* space C_n^Σ is the geometric carrier of the Sym^c -style bar complex $B^\Sigma(\mathcal{A})$ used for factorization *coalgebras* (closed-string, E_∞ -type operations) where the multiplication is symmetric.

- The projection $\pi^\Sigma: C_n^{\text{ord}} \rightarrow C_n^\Sigma$ induces the averaging morphism $\text{av}: B^{\text{ord}}(\mathcal{A}) \rightarrow B^\Sigma(\mathcal{A})$ (taking Σ_n -coinvariants), and the geometric origin of av is precisely the Σ_n -coinvariant projection on configuration spaces.

The Fulton–MacPherson compactification commutes with the Σ_n -quotient: $\overline{C}_n^\Sigma(\Sigma_g) = \overline{C}_n^{\text{ord}}(\Sigma_g)/\Sigma_n$, since the diagonals Δ_S are Σ_n -invariant subvarieties of Σ_g^n and the iterated blowup is performed along Σ_n -equivariant centers.

5.1.2 THE FULTON–MACPHERSON COMPACTIFICATION ACROSS GENERA

The configuration space $C_n(\Sigma_g)$ is non-compact. The Fulton–MacPherson compactification [186] resolves this by iterated blow-ups along diagonals, recording collision rates and angles in exceptional divisors. For a logarithmic variant on punctured and nodal curves, see Mok [322].

5.1.2.1 Iterated blow-up construction

THEOREM 5.1.3 (*Fulton–MacPherson compactification at genus g [186];*). There exists a canonical smooth compactification $\overline{C}_n(\Sigma_g)$ constructed via iterated blow-ups. More precisely:

1. There is a natural open embedding

$$j: C_n(\Sigma_g) \hookrightarrow \overline{C}_n(\Sigma_g)$$

with dense image.

2. The compactification $\overline{C}_n(\Sigma_g)$ is smooth and proper over $\mathbb{C}$; as a blow-up of the smooth projective variety Σ_g^n along smooth centers, it is itself a smooth projective variety.
3. The complement $D = \overline{C}_n(\Sigma_g) \setminus C_n(\Sigma_g)$ is a *normal crossing divisor*, i.e., locally analytically isomorphic to coordinate hyperplanes.
4. The boundary admits a natural stratification:

$$\partial \overline{C}_n(\Sigma_g) = D = \bigcup_{\pi \in \Pi_n^{\geq 2}} D_\pi$$

where $\Pi_n^{\geq 2}$ is the set of partitions $\pi = (S_1, \dots, S_k)$ of $\{1, \dots, n\}$ with each $|S_i| \geq 1$ and at least one $|S_j| \geq 2$.

5. Each codimension-1 boundary divisor D_S (for $S \subset \{1, \dots, n\}$, $|S| \geq 2$) decomposes as a fibre bundle:

$$D_S \cong \overline{C}_{n-|S|+1}(\Sigma_g) \times \overline{C}_{|S|}(\mathbb{A}^1) / \text{Aff}(\mathbb{A}^1),$$

where the first factor records the collision center plus the remaining $n - |S|$ points on Σ_g , and the second factor records relative positions on the tangent-space screen (genus 0), *modulo the affine group* $\text{Aff}(\mathbb{A}^1) = \mathbb{C} \rtimes \mathbb{C}^*$ of translations and dilations on the screen. The translation quotient identifies the screen with the tangent space $T_q \Sigma_g$ at the collision point (eliminating the choice of origin), and the dilation quotient eliminates the overall scale, so that only the projective-shape data remain on the screen. For deeper strata corresponding to nested collisions, this iterates: screens within screens

give products of Aff-quotiented genus-0 configuration spaces. Note: unlike the Deligne–Mumford compactification $\overline{\mathcal{M}}_{g,n}$, the FM compactification of a fixed curve involves no curve degeneration; all screens are genus 0.

6. The construction is *functorial*: smooth maps $\Sigma_g \rightarrow \Sigma_{g'}$ induce maps $\overline{C}_n(\Sigma_g) \rightarrow \overline{C}_n(\Sigma_{g'})$ compatible with stratification.

Construction. The construction proceeds in stages:

Stage 0: Initial Space

Begin with the smooth space Σ_g^n . The configuration space is the complement of the “fat diagonal”:

$$C_n(\Sigma_g) = \Sigma_g^n \setminus \bigcup_{1 \leq i < j \leq n} \Delta_{ij}$$

where $\Delta_{ij} = \{(x_1, \dots, x_n) \in \Sigma_g^n : x_i = x_j\}$ is a smooth divisor of codimension 1.

Stage 1: Blow Up Diagonal

First blow up the full diagonal $\Delta_n = \{x_1 = \dots = x_n\}$ (codimension $n - 1$):

$$\widetilde{\Sigma}_{g,1}^n = \text{Bl}_{\Delta_n}(\Sigma_g^n)$$

Local coordinates near Δ_n . Choose a point $p \in \Delta_n$ and local coordinate z on Σ_g near p . Near p , we have coordinates $(z_1, \dots, z_n)$ on Σ_g^n . The blow-up introduces:

- *Center of mass:* $u = \frac{1}{n} \sum_{i=1}^n z_i$
- *Relative coordinates:* $\zeta_i = z_i - u$ for $i = 1, \dots, n-1$ (with $\zeta_n = -\sum_{i=1}^{n-1} \zeta_i$)
- *Projective directions:* $[\zeta_1 : \dots : \zeta_{n-1}] \in \mathbb{P}^{n-2}$

The exceptional divisor E_n is a $\mathbb{P}^{n-2}$ -bundle over Σ_g (the projectivization of the normal bundle $N_{\Delta_n/\Sigma_g^n} \cong \bigoplus^{n-1} T\Sigma_g$), parametrizing the collision location (the Σ_g factor) and the relative directions of approach (the $\mathbb{P}^{n-2}$ fiber).

Stage 2: Blow Up Partial Diagonals

Next, blow up the proper transform of each partial diagonal Δ_S for $S \subsetneq \{1, \dots, n\}$ with $|S| \geq 2$, proceeding in *decreasing order of $|S|$* (equivalently, decreasing order of codimension, since $\text{codim}(\Delta_S) = |S| - 1$).

For a subset $S = \{i_1, \dots, i_k\}$ with $2 \leq k < n$:

$$\widetilde{\Sigma}_{g,S}^n = \text{Bl}_{\widetilde{\Delta}_S}(\widetilde{\Sigma}_{g,S_{\text{prev}}}^n)$$

where $\widetilde{\Delta}_S$ is the proper transform of Δ_S from the previous blow-up stage.

The ordering matters: we must blow up in order of decreasing codimension to ensure:

1. All centers of blow-up are smooth
2. The final result is independent of choices within each codimension
3. Normal crossings are preserved at each stage

Stage 3: Final Compactification

After all blow-ups, we obtain:

$$\overline{C}_n(\Sigma_g) = \widetilde{\Sigma}_{g, \text{final}}^n$$

The boundary divisors D_S (one for each subset S with $|S| \geq 2$) are the exceptional divisors from blowing up Δ_S .

Verification of Normal Crossings.

To verify that $D = \bigcup_S D_S$ has normal crossings, we check locally. Near a point in $D_{S_1} \cap \cdots \cap D_{S_m}$ (where $S_1, \dots, S_m$ are *nested* subsets: $S_1 \subset S_2 \subset \cdots \subset S_m$), we have local analytic coordinates:

$$(u, \epsilon_1, \theta_1, \dots, \epsilon_m, \theta_m, w_1, \dots, w_k)$$

where:

- $u \in \Sigma_g$ is the common collision point
- (ϵ_j, θ_j) are polar coordinates measuring the j -th stage collision (radial distance and angle)
- $w_1, \dots, w_k$ parametrize points not involved in collisions

The divisors are locally:

$$D_{S_j} = \{\epsilon_j = 0\}$$

These are precisely coordinate hyperplanes, hence normal crossing.

Functoriality.

If $f : \Sigma_g \rightarrow \Sigma_{g'}$ is a smooth map, it induces $f^{(n)} : \Sigma_g^n \rightarrow \Sigma_{g'}^n$ by $(x_1, \dots, x_n) \mapsto (f(x_1), \dots, f(x_n))$. The map $f^{(n)}$ preserves diagonals:

$$f^{(n)}(\Delta_S) \subseteq \Delta_S$$

so it lifts canonically to the blow-ups, giving:

$$\overline{f^{(n)}} : \overline{C}_n(\Sigma_g) \rightarrow \overline{C}_n(\Sigma_{g'})$$

compatible with boundary stratification. □

Remark 5.1.4 (Recording collision data). The blow-up records collision rates $|z_i - z_j| \sim \epsilon(t)$, approach angles $\arg(z_i - z_j) = \theta$, and hierarchies (nested collisions produce screens within screens). These are the data appearing in the OPE $\phi_i(z)\phi_j(w) = \sum_k C_{ij}^k(z, w)/(z - w)^{h_i + h_j - h_k} \cdot \phi_k(w) + \cdots$.

5.1.2.2 Boundary stratification and stable curves

At genus $g \geq 1$, the boundary has additional structure beyond just point collisions:

THEOREM 5.1.5 (*Boundary strata of $\overline{\mathcal{M}}_{g,n}$ [124, 271];*). For the Deligne–Mumford–Knudsen moduli space $\overline{\mathcal{M}}_{g,n}$ (which serves as the universal compactified configuration space), the boundary $\partial \overline{\mathcal{M}}_{g,n}$ consists of:

1. *Collision strata:* D_S where points in subset S collide (as in genus 0)

2. *Degeneration strata:* D_Γ where the curve degenerates to a stable nodal curve of genus g with dual graph Γ

The Fulton–MacPherson compactification $\overline{C}_n(\Sigma_g)$ of a *fixed* smooth curve Σ_g has only collision strata; no curve degeneration occurs. The degeneration strata appear when one works with the universal family over $\overline{\mathcal{M}}_g$, i.e., when the underlying curve is allowed to vary and degenerate.

Proof. There is a natural forgetful map:

$$\overline{\mathcal{M}}_{g,n} \xrightarrow{\pi} \overline{\mathcal{M}}_g$$

that forgets the marked points and stabilizes. Over the interior $\mathcal{M}_g$, the fiber $\pi^{-1}([\Sigma_g])$ is the FM compactification $\overline{C}_n(\Sigma_g)$. The full boundary $\partial\overline{\mathcal{M}}_{g,n}$ decomposes according to two mechanisms.

(1) *Collision strata.* For a subset $S \subseteq \{1, \dots, n\}$ with $|S| \geq 2$, the stratum D_S parameterizes configurations where the points $\{z_i\}_{i \in S}$ have collided. By the Fulton–MacPherson construction applied fiberwise over $\overline{\mathcal{M}}_g$, the blowup along the diagonal $\Delta_S = \{z_i = z_j \text{ for all } i, j \in S\}$ replaces Δ_S by the exceptional divisor $D_S \cong \overline{C}_{|S|}(\mathbb{C}) \times \overline{C}_{n-|S|+1}(\Sigma_g)$, which records the relative positions and directions of approach of the colliding points. This is exactly the genus-0 construction applied to a local coordinate neighborhood of the collision point, and the resulting strata have normal crossings (Theorem 5.1.12).

(2) *Degeneration strata.* These arise from the boundary of $\overline{\mathcal{M}}_g$, not from point collisions. A boundary stratum of $\overline{\mathcal{M}}_{g,n}$ is indexed by a stable graph Γ (Definition 5.1.6) with $\sum_v g(v) + b_1(\Gamma) = g$, where $b_1(\Gamma) = |E(\Gamma)| - |V(\Gamma)| + 1$ is the first Betti number. The corresponding stratum is:

$$D_\Gamma \cong \prod_{v \in V(\Gamma)} \overline{\mathcal{M}}_{g(v), n(v)} \Big/ \text{Aut}(\Gamma)$$

where $n(v)$ counts the half-edges and tails at vertex v . Each edge $e \in E(\Gamma)$ corresponds to a node of the degenerate curve, with local model $xy = t_e$ for a smoothing parameter t_e . When the curve has a fixed complex structure with period matrix $\tau \in \mathbb{H}_g$, the degeneration strata $D_{\Gamma, \tau}$ record how τ approaches the boundary of the Satake compactification of $\mathbb{H}_g/\text{Sp}_{2g}(\mathbb{Z})$.

Exhaustiveness. Every point of $\partial\overline{C}_n(\Sigma_g) = \overline{C}_n(\Sigma_g) \setminus C_n(\Sigma_g)$ belongs to at least one stratum: either some subset of marked points has collided (type 1), or the underlying curve has degenerated (type 2), or both. This follows from the properness of $\overline{\mathcal{M}}_{g,n}$ (Deligne–Mumford–Knudsen [124, 271]): every sequence in $C_n(\Sigma_g)$ has a subsequence converging to a stable n -pointed curve, and the limit is classified by its dual graph and the collision data of the marked points. $\square$

Definition 5.1.6 (Stable graph). A *stable graph* Γ of genus g with n marked points consists of:

- A connected graph with vertices $V(\Gamma)$ and edges $E(\Gamma)$
- A genus function $g : V(\Gamma) \rightarrow \mathbb{Z}_{\geq 0}$
- n marked half-edges (tails) attached to vertices
- *Stability condition:* For each vertex v ,

$$2g(v) - 2 + n(v) > 0$$

where $n(v) = \text{val}(v)$ is the valence (number of incident half-edges and tails)

with total genus:

$$g(\Gamma) = \sum_{v \in V(\Gamma)} g(v) + h^1(\Gamma) = g$$

where $h^1(\Gamma) = |E(\Gamma)| - |V(\Gamma)| + 1$ is the first Betti number.

Example 5.1.7 (Stable graphs at genus 1, $n = 2$). For $\overline{\mathcal{M}}_{1,2}$ (genus 1, two marked points), the stable graphs indexing boundary strata are:

1. *Interior:* Both points distinct on a smooth genus 1 curve

$$\Gamma_0 : \text{one vertex with } g(v) = 1, n(v) = 2$$

2. *Rational tail (bubble):* A genus-0 component carrying both marked points separates off from a genus-1 component

$$\Gamma_1 : \text{two vertices } v_1, v_2 \text{ with } g(v_1) = 1, g(v_2) = 0, \text{ one edge, both tails on } v_2$$

Stability: $2(1) - 2 + 1 = 1 > 0$ for v_1 and $2(0) - 2 + 3 = 1 > 0$ for v_2 . This boundary divisor is isomorphic to $\overline{\mathcal{M}}_{1,1}$ (the attaching point on the genus-1 component).

3. *Node formation:* The torus degenerates to a nodal curve (pinched cycle)

$$\Gamma_3 : \text{one vertex with } g(v) = 0, \text{ one self-loop, two tails}$$

The self-loop contributes $h^1(\Gamma_3) = 1$, giving total genus $g(v) + h^1 = 0 + 1 = 1$. This gives a divisor parametrizing nodal genus 1 curves with 2 marked points.

Remark 5.1.8 (Connection to moduli of stable curves). For a fixed smooth curve Σ_g , stabilization gives a map $\pi : \overline{\mathcal{C}}_n(\Sigma_g) \rightarrow \overline{\mathcal{M}}_{g,n}$ sending $(p_1, \dots, p_n) \mapsto [\Sigma_g; p_1, \dots, p_n]^{\text{st}}$. Its image lies in the closure of the locus of curves isomorphic to Σ_g , and over boundary strata the bubble tree structure maps to the nodal curve structure. This underlies the modular properties of chiral correlators and the identification of conformal anomalies with failure of sections to extend over the boundary.

5.1.2.3 Local coordinates and blow-up charts

THEOREM 5.1.9 (Local coordinates near boundary;). Let $D_S \subset \partial \overline{\mathcal{C}}_n(\Sigma_g)$ be a boundary divisor corresponding to collision of points $S = \{i_1, \dots, i_k\} \subseteq \{1, \dots, n\}$ with $k \geq 2$.

There exist local analytic coordinates near a general point of D_S :

$$(p, \epsilon, \theta_1, \dots, \theta_{k-1}, w_\alpha)_{\alpha \in \{1, \dots, n\} \setminus S}$$

where:

- $p \in \Sigma_g$ is the collision point (where all points in S meet)
- $\epsilon \in \mathbb{R}_{>0}$ is the *collision scale* (overall size of the cluster)
- $\theta_j \in S^1$ for $j = 1, \dots, k-1$ are *relative angles* (directions of approach)
- $w_\alpha \in \Sigma_g$ for $\alpha \notin S$ are locations of the remaining points

In these coordinates:

1. The divisor D_S is defined by $\{\epsilon = 0\}$
2. The original points are recovered as:

$$z_{i_j} = p + \epsilon \cdot e^{2\pi i \theta_j} \cdot (\text{fixed direction in } T_p \Sigma_g)$$

for $j = 1, \dots, k$ (with $\theta_k = 0$ by convention)

3. The normal bundle to D_S is trivialized by $\frac{\partial}{\partial \epsilon}$

Proof. We construct the coordinates using the blow-up description.

Step 1: Center of Mass Coordinate

Remark 5.1.10 (Ordering convention for collisions). When describing collision of points $\{i_1, \dots, i_k\}$, we always order indices so that $i_1 < i_2 < \dots < i_k$. The collision divisor is denoted $D_{i_1 \dots i_k}$ or D_S where $S = \{i_1, \dots, i_k\}$ with the lexicographic ordering understood.

This convention ensures consistency with the residue formulas and sign computations throughout the manuscript.

For points $\{z_{i_1}, \dots, z_{i_k}\} \subset \Sigma_g$ approaching a common point, define:

$$p = \frac{1}{k} \sum_{j=1}^k z_{i_j} \in \Sigma_g$$

This is the center of mass of the colliding cluster.

Step 2: Relative Coordinates

Choose a local coordinate ζ on Σ_g near p (with $\zeta(p) = 0$). Write:

$$\zeta_{i_j} = \zeta(z_{i_j}) \in \mathbb{C}$$

Define relative coordinates:

$$\xi_j = \zeta_{i_j} - \zeta(p) = \zeta_{i_j} - \frac{1}{k} \sum_{\ell=1}^k \zeta_{i_\ell}$$

Note that $\sum_{j=1}^k \xi_j = 0$ (center of mass is at origin).

Step 3: Polar Decomposition

Write each ξ_j in polar form:

$$\xi_j = r_j e^{i\theta_j}$$

The collision scale is:

$$\epsilon = \max_{1 \leq j \leq k} r_j = \text{diameter of the cluster}$$

Normalized directions:

$$\theta_j = \arg(\xi_j) \in S^1$$

Fix one angle (say $\theta_k = 0$) to remove rotational redundancy.

Step 4: Blow-Up Description

The blow-up of Δ_S introduces coordinates:

- $p \in \Sigma_g$: collision point
- ϵ : scale
- $[\xi_1 : \cdots : \xi_{k-1}] \in \mathbb{P}^{k-2}$: projective direction

Using the constraint $\sum \xi_j = 0$, we can express this as:

- p
- ϵ
- $\theta_1, \dots, \theta_{k-1} \in S^1$: angles

Step 5: Verification

To verify $D_S = \{\epsilon = 0\}$:

- When $\epsilon > 0$: points $z_{i_j} = p + \epsilon e^{i\theta_j}(\cdots)$ are distinct
- When $\epsilon \rightarrow 0$: all points approach p , i.e., $z_{i_j} \rightarrow p$ for all j
- The limit $\epsilon \rightarrow 0$ with fixed θ_j describes a point in $D_S \subset \overline{C}_n(\Sigma_g)$

□

Example 5.1.11 (Explicit coordinates for three points). For $n = 3$ on Σ_g , consider the divisor D_{12} where $z_1 \rightarrow z_2$.

Coordinates.

- $p \in \Sigma_g$: collision point
- $\epsilon \in \mathbb{R}_{>0}$: $|z_1 - z_2|$
- $\theta \in S^1$: $\arg(z_1 - z_2)$
- $w = z_3$: third point

Reconstruction.

$$z_1 = p + \frac{\epsilon}{2}e^{i\theta}, \quad z_2 = p - \frac{\epsilon}{2}e^{i\theta}, \quad z_3 = w$$

Divisor.

$$D_{12} = \{\epsilon = 0\} \cong \Sigma_g \times \Sigma_g,$$

parametrized by the collision point p on the first factor and the spectator $w = z_3$ on the second. For a curve, the normal bundle of the diagonal $\Delta \hookrightarrow \Sigma_g \times \Sigma_g$ has complex rank 1, so the projectivized fibre $\mathbb{P}^0$ is a point and the angular coordinate θ contributes no additional moduli; the complex normal direction to D_{12} is the single coordinate ϵ (in real terms, the pair $(\epsilon \cos \theta, \epsilon \sin \theta)$ varies over $\mathbb{C}$, but the projective-shape data have already collapsed).

5.1.2.4 Normal crossing property and residues

THEOREM 5.1.12 (*Normal crossings*). The boundary divisor $D = \partial \bar{C}_n(\Sigma_g)$ is a *strict normal crossing divisor*.

More precisely, if $D = \bigcup_{\alpha} D_{\alpha}$ is the decomposition into irreducible components, then:

1. Each D_{α} is smooth
2. At any point $x \in D_{\alpha_1} \cap \cdots \cap D_{\alpha_k}$ (intersection of k components), there exist local analytic coordinates $(u_1, \dots, u_N)$ near x such that:

$$D_{\alpha_j} = \{u_j = 0\} \text{ for } j = 1, \dots, k$$

3. The components intersect transversely: $\bigcap_{j=1}^k T_x D_{\alpha_j}$ has codimension k in $T_x \bar{C}_n(\Sigma_g)$, equivalently the conormals $du_1, \dots, du_k$ are linearly independent at x

Proof. We verify normal crossings using the blow-up construction.

Single Divisor ($k = 1$).

Each divisor $D_{\alpha} = D_S$ (for some $S \subseteq \{1, \dots, n\}$) is the exceptional divisor of blowing up Δ_S . By the theory of blow-ups, exceptional divisors are smooth.

Multiple Intersections ($k \geq 2$).

Suppose $x \in D_{S_1} \cap \cdots \cap D_{S_k}$ where $S_1, \dots, S_k$ are distinct subsets.

For the divisors to intersect at x , the sets must be *nested*:

$$S_1 \subset S_2 \subset \cdots \subset S_k \quad \text{or some permutation}$$

Indeed, D_{S_i} records the collision of points in S_i , so $D_{S_1} \cap D_{S_2} \neq \emptyset$ requires both collision events to occur simultaneously, which forces one index set to contain the other.

Local coordinates for nested sets.

Assume $S_1 \subsetneq S_2 \subsetneq \cdots \subsetneq S_k$. Near x , we have coordinates:

$$(p, \epsilon_1, \theta_1^{(1)}, \dots, \theta_{|S_1|-1}^{(1)}, \epsilon_2, \theta_1^{(2)}, \dots, \theta_{|S_2|-|S_1|-1}^{(2)}, \dots, \epsilon_k, \dots)$$

where:

- ϵ_j measures the scale at the j -th collision level
- $\theta^{(j)}$ are angular coordinates at level j
- $p \in \Sigma_g$ is the ultimate collision point

The divisors are:

$$D_{S_j} = \{\epsilon_j = 0\}$$

These are coordinate hyperplanes, hence normal crossing.

Transversality.

The tangent spaces satisfy:

$$T_x D_{S_j} = \left\{ \frac{\partial}{\partial \epsilon_j} = 0 \right\} \subset T_x \bar{C}_n(\Sigma_g)$$

Since the ϵ_j are independent coordinates:

$$\dim(T_x D_{S_1} \cap \cdots \cap T_x D_{S_k}) = \dim(T_x \overline{C}_n(\Sigma_g)) - k$$

which is the expected codimension for the intersection, confirming transversality. $\square$

5.1.3 STRATIFICATION

5.1.3.1 Incidence relations and poset structure

Definition 5.1.13 (Stratification poset). Define a partial order on partitions $\pi \in \Pi_n^{\geq 2}$:

$$\pi \leq \pi' \iff \text{every part of } \pi \text{ is contained in some part of } \pi'$$

Equivalently: $\pi \leq \pi'$ means " π is a refinement of π' ."

The boundary strata satisfy:

$$D_\pi \subseteq \overline{D_{\pi'}} \iff \pi \leq \pi'$$

where $\overline{D_{\pi'}}$ is the closure of $D_{\pi'}$.

Example 5.1.14 (Poset for $n = 3$). For $n = 3$, the partitions (with at least one part of size ≥ 2) are:

- $\pi_1 = (12|3)$: points 1,2 collide, 3 separate
- $\pi_2 = (13|2)$: points 1,3 collide, 2 separate
- $\pi_3 = (23|1)$: points 2,3 collide, 1 separate
- $\pi_4 = (123)$: all three collide

The partial order:

$$\pi_1, \pi_2, \pi_3 < \pi_4$$

(any pairwise collision is refined by the triple collision)

The closure relations:

$$\overline{D_{\pi_1}} = D_{\pi_1} \cup D_{\pi_4}$$

$$\overline{D_{\pi_2}} = D_{\pi_2} \cup D_{\pi_4}$$

$$\overline{D_{\pi_3}} = D_{\pi_3} \cup D_{\pi_4}$$

Geometrically: the triple collision D_{π_4} lies in the closure of each pairwise collision divisor.

THEOREM 5.1.15 (Closure relations;). The closure of stratum D_π is:

$$\overline{D_\pi} = \bigcup_{\pi' \geq \pi} D_{\pi'}$$

In particular:

1. $\partial D_\pi = \overline{D_\pi} \setminus D_\pi = \bigcup_{\pi' > \pi} D_{\pi'}$
2. The codimension satisfies: $\text{codim}(D_{\pi'}) > \text{codim}(D_\pi)$ whenever $\pi' > \pi$

3. The intersection $D_{\pi_1} \cap D_{\pi_2}$ is nonempty iff there exists π_3 with $\pi_1, \pi_2 \leq \pi_3$

Proof. The closure relation follows from the blow-up construction:

- D_π corresponds to collision pattern π (certain groups of points colliding)
- $\overline{D_\pi}$ includes limits where colliding groups merge further
- A limit of configurations in D_π where groups merge gives a configuration in $D_{\pi'}$ for some coarser $\pi' > \pi$

For codimension: if $\pi' > \pi$, then π' has fewer parts, meaning more points have collided. Each additional collision increases codimension by 1 (locally, it is one more equation $\epsilon_j = 0$).

For intersections: $D_{\pi_1} \cap D_{\pi_2} \neq \emptyset$ requires configurations satisfying both collision patterns simultaneously. This is possible iff the patterns are compatible, i.e., there is a common refinement π_3 with $\pi_1, \pi_2 \leq \pi_3$. $\square$

COROLLARY 5.1.16 (*Boundary divisors in the FM compactification [186];*). For each subset $S \subset \{1, \dots, n\}$ with $|S| \geq 2$, the boundary divisor $D_S \subset \overline{C}_n(\Sigma_g)$ has *codimension 1*. The divisor D_S parametrizes configurations where the points indexed by S collide, together with the “screen” recording how they approach each other.

In particular:

- Each D_S is a divisor ($\text{codim} = 1, \text{dim} = n - 1$)
- The open stratum of D_S fibers over $C_{n-|S|+1}(\Sigma_g)$ (the collision center replaces the cluster) with fiber $\overline{C}_{|S|}(\mathbb{C}) / \text{Aff}(\mathbb{A}^1)$, the FM screen modulo the affine group of translations and dilations on the tangent space. Equivalently, the screen is the projectivized shape space of $|S|$ points on the tangent line $T_q \Sigma_g$ at the collision point q , with the origin and overall scale removed.
- Deeper strata ($\text{codimension} \geq 2$) arise from intersections $D_{S_1} \cap D_{S_2}$ when $S_1 \subset S_2$ (nested collisions)

THEOREM 5.1.17 (*Boundary stratification [186];*). The boundary has a natural stratification:

$$\partial \overline{C}_n(X) = \bigcup_{\pi} D_\pi$$

where π runs over partitions of $\{1, \dots, n\}$ with at least one part of size ≥ 2 .

5.1.4 LOGARITHMIC DIFFERENTIAL FORMS

Definition 5.1.18 (*Logarithmic forms*). The forms $\eta_{ij} = d \log(z_i - z_j)$ that served as propagators in the Heisenberg bar complex (§2.1) are the simplest instances of the following class.

A differential k -form ω on $\overline{C}_n(\Sigma_g)$ has *logarithmic poles along D* if:

1. ω is smooth on the interior $C_n(\Sigma_g)$

2. Near each divisor D_α defined locally by $\{f_\alpha = 0\}$, we have:

$$\omega = \frac{df_\alpha}{f_\alpha} \wedge \alpha + \beta$$

where α is a $(k-1)$ -form and β is a k -form, both smooth up to D_α

The sheaf of logarithmic k -forms is denoted:

$$\Omega_{C_n(\Sigma_g)}^k(\log D)$$

Remark 5.1.19 (Multi-logarithmic extension). On codimension- k strata where k boundary divisors $D_{S_1}, \dots, D_{S_k}$ intersect, logarithmic forms restrict to *multi-logarithmic* forms with logarithmic poles along each component simultaneously. Since D is a normal crossing divisor (Theorem 5.1.3(3)), the sheaf $\Omega^k(\log D)$ is locally free, so multi-logarithmic extension across higher-codimension strata is automatic.

Remark 5.1.20 (Logarithmic condition). The logarithmic condition is precisely what is needed for well-defined residues.

A general form with poles along D might have:

$$\omega = \frac{\alpha}{f^k}$$

for $k \geq 2$ (higher-order pole). Such forms do not have well-defined residues.

Logarithmic forms have:

$$\omega = \frac{df}{f} \wedge \alpha + \beta$$

which has a *simple pole* with residue $\alpha|_{f=0}$.

For chiral algebras: the OPE has the form

$$\phi_i(z)\phi_j(w) \sim \frac{C_{ij}^k}{(z-w)^\Delta} \phi_k(w)$$

Combined with $\eta_{ij} = \frac{dz-dw}{z-w}$, we get:

$$\frac{1}{(z-w)^\Delta} \cdot \frac{dz-dw}{z-w} = \frac{d(z-w)}{(z-w)^{\Delta+1}}$$

For $\Delta = 0$ (no pole in OPE): this is $\frac{d(z-w)}{z-w} = \text{logarithmic}$.

Logarithmic forms therefore furnish the correct coefficient system for chiral algebras.

Example 5.1.21 (Logarithmic form for two points). The basic logarithmic 1-form for configuration of two points:

$$\eta_{12} = d \log(z_1 - z_2) = \frac{dz_1 - dz_2}{z_1 - z_2}$$

Analysis.

- On $C_2(\Sigma_g)$ (where $z_1 \neq z_2$): η_{12} is smooth

- Near D_{12} (where $z_1 \rightarrow z_2$): Using $\epsilon = z_1 - z_2$, we have:

$$\eta_{12} = \frac{d\epsilon}{\epsilon} + (\text{smooth terms})$$

This is a logarithmic pole.

- The residue:

$$\text{Res}_{D_{12}}(\eta_{12}) = 1 \in \Omega_{D_{12}}^0 = \mathcal{O}_{D_{12}}$$

THEOREM 5.1.22 (*Logarithmic complex;*). The sheaf of logarithmic differential forms $\Omega_{\bar{C}_n(\Sigma_g)}^\bullet(\log D)$ forms a complex under the de Rham differential:

$$d : \Omega^k(\log D) \rightarrow \Omega^{k+1}(\log D)$$

Three properties hold:

1. d preserves logarithmic poles: if ω has log poles along D , then $d\omega$ also has log poles
2. $d^2 = 0$ (as always for de Rham differential)
3. By the logarithmic Poincaré lemma, $H^*(\Omega^\bullet(\log D))$ computes the cohomology of the *open* configuration space $C_n(\Sigma_g) = \bar{C}_n(\Sigma_g) \setminus D$ with coefficients in $\mathbb{C}$

Proof. Part 1: Preservation of log poles.

Locally, if $\omega = \frac{df}{f} \wedge \alpha + \beta$ with α, β smooth, then:

$$d\omega = d\left(\frac{df}{f}\right) \wedge \alpha + \frac{df}{f} \wedge d\alpha + d\beta$$

Compute:

$$d\left(\frac{df}{f}\right) = -\frac{df \wedge df}{f^2} = 0$$

(since $df \wedge df = 0$)

Therefore:

$$d\omega = \frac{df}{f} \wedge d\alpha + d\beta$$

Since $d\alpha$ and $d\beta$ are smooth, this is again a logarithmic form.

Part 2: $d^2 = 0$. This is the fundamental property of the de Rham differential, independent of logarithmic conditions.

Part 3: Cohomology. By the logarithmic Poincaré lemma (Deligne [122]), the logarithmic de Rham complex $\Omega^\bullet(\log D)$ on $\bar{C}_n(\Sigma_g)$ computes the cohomology of the *open* complement $\bar{C}_n(\Sigma_g) \setminus D = C_n(\Sigma_g)$:

$$H^*(\bar{C}_n(\Sigma_g), \Omega^\bullet(\log D)) \cong H^*(C_n(\Sigma_g); \mathbb{C})$$

□

THEOREM 5.1.23 (*Arnold relations;*). In the Heisenberg bar complex (§2.2), the identity $d^2 = 0$ at degree 2 reduced to the three-term relation $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$. We recognized it as the Arnold relation; here we develop it systematically.

The logarithmic 1-forms $\eta_{ij} = d \log(z_i - z_j)$ satisfy fundamental relations:

1. *Symmetry*: $\eta_{ji} = \eta_{ij}$ (as differential forms, since $d \log(z_j - z_i) = d \log(-(z_i - z_j)) = d \log(z_i - z_j)$, using $d \log(-1) = 0$). Antisymmetry $e_{ji} = -e_{ij}$ is imposed at the level of the Orlik–Solomon algebra generators, not the forms themselves.

2. *Arnold relation*: For distinct i, j, k :

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$$

3. *Completeness (genus 0)*: For $\Sigma_0 = \mathbb{C}$, the classes η_{ij} generate $H^*(C_n(\mathbb{C}); \mathbb{C})$ and the Arnold relations generate all relations (the Arnol’d–Brieskorn–Orlik–Solomon theorem). For $g \geq 1$, additional generators from $H^*(\Sigma_g)$ (pulled back via projections $\pi_k : C_n(\Sigma_g) \rightarrow \Sigma_g$) and additional “surface relations” are required.

Proof. Part 1: Symmetry of forms.

$$\eta_{ji} = d \log(z_j - z_i) = \frac{dz_j - dz_i}{z_j - z_i} = \frac{-(dz_i - dz_j)}{-(z_i - z_j)} = \frac{dz_i - dz_j}{z_i - z_j} = \eta_{ij}$$

(The two minus signs cancel. Equivalently, $d \log(z_j - z_i) = d \log(-(z_i - z_j)) = d \log(-1) + d \log(z_i - z_j) = \eta_{ij}$ since $d \log(-1) = 0$. Note: the antisymmetry $e_{ji} = -e_{ij}$ is an Orlik–Solomon *algebra* convention, not a property of the forms.)

Part 2: Arnold relation. Fix any three distinct indices $i, j, k \in \{1, \dots, n\}$. Write $z_{ab} = z_a - z_b$ and $dz_{ab} = dz_a - dz_b$ for the coordinate differences and their differentials. The fundamental identity is:

$$z_{ij} + z_{jk} + z_{ki} = (z_i - z_j) + (z_j - z_k) + (z_k - z_i) = 0 \quad (5.1)$$

and identically $dz_{ij} + dz_{jk} + dz_{ki} = 0$ for the differentials.

Each term in the Arnold relation is:

$$\eta_{ij} \wedge \eta_{jk} = \frac{dz_{ij} \wedge dz_{jk}}{z_{ij} \cdot z_{jk}}, \quad \eta_{jk} \wedge \eta_{ki} = \frac{dz_{jk} \wedge dz_{ki}}{z_{jk} \cdot z_{ki}}, \quad \eta_{ki} \wedge \eta_{ij} = \frac{dz_{ki} \wedge dz_{ij}}{z_{ki} \cdot z_{ij}}.$$

Step 1: the three numerator 2-forms coincide. Using $dz_{ki} = -(dz_{ij} + dz_{jk})$ (from the differential of (5.1)):

$$\begin{aligned} dz_{jk} \wedge dz_{ki} &= dz_{jk} \wedge (-(dz_{ij} + dz_{jk})) = -dz_{jk} \wedge dz_{ij} = dz_{ij} \wedge dz_{jk}, \\ dz_{ki} \wedge dz_{ij} &= (-(dz_{ij} + dz_{jk})) \wedge dz_{ij} = -dz_{jk} \wedge dz_{ij} = dz_{ij} \wedge dz_{jk}, \end{aligned}$$

using $d\alpha \wedge d\alpha = 0$ and $d\alpha \wedge d\beta = -d\beta \wedge d\alpha$ throughout. Thus all three numerators equal $dz_{ij} \wedge dz_{jk}$.

Step 2: the coefficient sum vanishes by partial fractions. Bringing the three terms to the common denominator $z_{ij} \cdot z_{jk} \cdot z_{ki}$:

$$\begin{aligned} \eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} &= \frac{dz_{ij} \wedge dz_{jk}}{z_{ij} \cdot z_{jk} \cdot z_{ki}} (z_{ki} + z_{ij} + z_{jk}) \\ &= \frac{dz_{ij} \wedge dz_{jk}}{z_{ij} \cdot z_{jk} \cdot z_{ki}} \cdot 0 = 0 \end{aligned}$$

by (5.1). This holds for any triple i, j, k and any n .

Alternative direct proof via coordinate reduction. Set $u = z_i - z_j$ and $v = z_j - z_k$, so that $z_k - z_i = -(u + v)$. Since $d \log$ is insensitive to overall sign ($d \log(-f) = d \log(f)$ for any nonvanishing f), the three propagators become

$$\eta_{ij} = \frac{du}{u}, \quad \eta_{jk} = \frac{dv}{v}, \quad \eta_{ki} = \frac{du + dv}{u + v}.$$

(For the third: $\eta_{ki} = d \log(z_k - z_i) = d \log(-(u + v)) = d \log(u + v) = (du + dv)/(u + v)$.) Each wedge product is now immediate:

$$\begin{aligned} \eta_{ij} \wedge \eta_{jk} &= \frac{du \wedge dv}{u \cdot v}, \\ \eta_{jk} \wedge \eta_{ki} &= \frac{dv \wedge (du + dv)}{v(u + v)} = \frac{dv \wedge du}{v(u + v)} = -\frac{du \wedge dv}{v(u + v)}, \\ \eta_{ki} \wedge \eta_{ij} &= \frac{(du + dv) \wedge du}{(u + v) \cdot u} = \frac{dv \wedge du}{(u + v) \cdot u} = -\frac{du \wedge dv}{(u + v) \cdot u}, \end{aligned}$$

using $d\alpha \wedge d\alpha = 0$ throughout. Summing:

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = du \wedge dv \left[\frac{1}{uv} - \frac{1}{v(u + v)} - \frac{1}{u(u + v)} \right].$$

The bracketed expression reduces by partial fractions over the common denominator $uv(u + v)$:

$$\frac{u + v}{uv(u + v)} - \frac{u}{uv(u + v)} - \frac{v}{uv(u + v)} = \frac{(u + v) - u - v}{uv(u + v)} = 0.$$

This completes the proof for any triple of distinct indices and any $n \geq 3$.

Part 3: Completeness. This is the main theorem of [25, 186]. The proof uses intersection theory on $\overline{C}_n(\Sigma_g)$ and is beyond our scope here. $\square$

PROPOSITION 5.1.24 (*Geometric realization of the universal twisting morphism;*). The universal twisting morphism $\pi: \overline{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ (Proposition 3.1.21(i)) is geometrically realized on $\overline{C}_2(X)$ by the propagator:

$$\pi([s^{-1}\bar{a}])(z) = \text{Res}_{w=z} \bar{a}(w) \cdot \eta(z, w), \quad (5.2)$$

where $\eta(z, w) = d \log(z - w)$ is the logarithmic propagator (for genus 0; the Szegő kernel $S(z, w)$ for general genus). The Maurer–Cartan equation $\partial(\pi) + \pi \star \pi = 0$ (Definition 3.1.19) at bar degree 2 is the Arnold relation (Theorem 5.1.23):

$$\underbrace{\text{Res}_{w=z} (\bar{a}_1(w) \bar{a}_2(w) \cdot \eta(z, w))}_{\partial(\pi)} + \underbrace{\text{Res}_{w_1=z} \text{Res}_{w_2=z} \bar{a}_1(w_1) \bar{a}_2(w_2) \cdot \eta(z, w_1) \wedge \eta(w_1, w_2)}_{\pi \star \pi} = 0.$$

Neither term vanishes individually; their sum is zero by $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$. The Arnold relation is the MC equation for the propagator.

Proof. The projection $\pi: \overline{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ sends a bar element $[s^{-1}\bar{a}]$ of bar degree 1 to $\bar{a}$ (the cogenerator projection) and kills all higher bar degrees. Geometrically, bar degree 1 elements correspond to sections of $\mathcal{A}$ on $\overline{C}_1(X) = X$, and the projection extracts the coefficient of the identity operator. The residue

formula (5.2) is the explicit realization: the propagator $\eta(z, w)$ extracts the OPE coefficient by residue at $w = z$, which is precisely the bar differential at bar degree 1 (the collision residue of Theorem 6.1.21).

The MC equation $\partial(\pi) + \pi \star \pi = 0$ at bar degree 2 reads: $\text{Res}_{w=z} d_{\overline{B}}([s^{-1}\bar{a}_1 \mid s^{-1}\bar{a}_2]) \cdot \eta(z, w) + \text{Res}_{w_1=z} \text{Res}_{w_2=z} \bar{a}_1(w_1) \bar{a}_2(w_2) \cdot \eta(z, w_1) \wedge \eta(w_1, w_2) = 0$. The first term is $\partial(\pi)$ (the bar differential applied to π); the second is $\pi \star \pi$ (the convolution square, a double residue at $D_{12} \cap D_{23}$). Their sum vanishes by the Arnold relation (Theorem 5.1.23): $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ applied to the triple (z, w_1, w_2) . At bar degree ≥ 3 , both terms vanish individually (π kills bar degree ≥ 2). $\square$

LEMMA 5.1.25 (*Basic logarithmic form*;). The form $\eta_{ij} = d \log(z_i - z_j)$ has:

- Simple pole along D_{ij}
- Residue 1 along D_{ij}
- No other poles

Proof. We work in the local coordinates of Theorem 5.1.9 applied to the two-point collision divisor $D_{ij} \subset \overline{C}_n(\Sigma_g)$. Choose a local coordinate ζ on Σ_g centered at the collision point, and set $t = \zeta(z_i) - \zeta(z_j)$. In the blow-up chart the divisor D_{ij} is the smooth hypersurface $\{t = 0\}$, and $(t, \zeta(z_j), w_\alpha)$ form part of a local coordinate system on $\overline{C}_n(\Sigma_g)$, where w_α denotes the positions of the remaining $n - 2$ points.

Step 1: Local expression. In these coordinates, the logarithmic form is

$$\eta_{ij} = d \log(z_i - z_j) = d \log(\zeta(z_i) - \zeta(z_j)) = \frac{dt}{t},$$

since $t = \zeta(z_i) - \zeta(z_j)$. This is a section of $\Omega_{C_n}^1(\log D_{ij})$ with a simple (first-order) pole along $D_{ij} = \{t = 0\}$ and no other polar locus, since η_{ij} is smooth on the open configuration space $C_n(\Sigma_g)$ and extends with at worst logarithmic singularity along D_{ij} (the only boundary component where z_i and z_j collide).

Step 2: Residue computation. By the definition of the Poincaré residue for a logarithmic form $\omega = f \cdot dt/t +$ (terms regular in t),

$$\text{Res}_{D_{ij}}(\omega) = f|_{t=0}.$$

Applied to $\eta_{ij} = 1 \cdot dt/t$, this gives

$$\text{Res}_{D_{ij}}(\eta_{ij}) = 1 \in \Omega_{D_{ij}}^0 = \mathcal{O}_{D_{ij}}.$$

Step 3: Coordinate independence. Let $\zeta \mapsto \varphi(\zeta)$ be a holomorphic change of local coordinate on Σ_g (with $\varphi'(0) \neq 0$). Under this change,

$$\zeta(z_i) - \zeta(z_j) \mapsto \varphi(\zeta(z_i)) - \varphi(\zeta(z_j)) = \varphi'(\zeta(z_j)) \cdot t + O(t^2),$$

where $t = \zeta(z_i) - \zeta(z_j)$ as before. Therefore

$$\begin{aligned} d \log(\varphi(\zeta(z_i)) - \varphi(\zeta(z_j))) &= d \log(\varphi'(\zeta(z_j)) \cdot t \cdot (1 + O(t))) \\ &= \frac{dt}{t} + d \log \varphi'(\zeta(z_j)) + d \log(1 + O(t)). \end{aligned}$$

The second term is holomorphic (since $\varphi' \neq 0$), and the third term is $O(t) dt/t + (\text{smooth}) = (\text{smooth})$. Hence the polar part is still dt/t , and the residue is still 1. This confirms that the residue is an intrinsic invariant, independent of the choice of local coordinate on Σ_g . $\square$

THEOREM 5.1.26 (*Residue operations;*). For a normal crossing divisor $D = \bigcup_{\alpha} D_{\alpha}$ in $\overline{C}_n(\Sigma_g)$, there are well-defined residue maps:

$$\text{Res}_{D_{\alpha}} : \Omega_{\overline{C}_n(\Sigma_g)}^{\bullet}(\log D) \rightarrow \Omega_{D_{\alpha}}^{\bullet-1}(\log D_{\alpha}^{\partial})$$

where $D_{\alpha}^{\partial} := D_{\alpha} \cap \bigcup_{\beta \neq \alpha} D_{\beta}$ is the induced boundary on D_{α} .

These satisfy:

1. *Leibniz rule:* $\text{Res}_{D_{\alpha}}(\omega \wedge \eta) = \text{Res}_{D_{\alpha}}(\omega) \wedge \eta|_{D_{\alpha}} + (-1)^{|\omega|} \omega|_{D_{\alpha}} \wedge \text{Res}_{D_{\alpha}}(\eta)$
2. *Commutativity:* If $D_{\alpha} \cap D_{\beta} = \emptyset$, then $\text{Res}_{D_{\alpha}} \circ \text{Res}_{D_{\beta}} = \text{Res}_{D_{\beta}} \circ \text{Res}_{D_{\alpha}}$
3. *Residue theorem:* If $d\omega = 0$, then the residue family $\{\text{Res}_{D_{\alpha}}(\omega)\}_{\alpha}$ satisfies the cocycle condition in the residue sequence of Theorem 5.1.29 (equivalently, its total boundary residue vanishes).

Proof. By Theorem 5.1.12, every point of $\overline{C}_n(\Sigma_g)$ admits local coordinates $(z_1, \dots, z_m)$ in which $D = \{z_1 \cdots z_r = 0\}$ is a simple normal crossing divisor. For $i \leq r$, write $D_i = \{z_i = 0\}$.

In such a chart, every logarithmic form has a unique decomposition

$$\omega = \omega_0 + \sum_{i=1}^r \frac{dz_i}{z_i} \wedge \eta_i,$$

with ω_0 regular and each η_i logarithmic along $D_i^{\partial} = \{z_1 \cdots \widehat{z_i} \cdots z_r = 0\} \subset D_i$, with no dz_i/z_i component. Define

$$\text{Res}_{D_i}(\omega) := \eta_i|_{z_i=0} \in \Omega_{D_i}^{\bullet-1}(\log D_i^{\partial}).$$

Independence of choices follows from uniqueness of the decomposition, so the maps glue sheaf-theoretically.

For the Leibniz rule, write $\omega = \omega_0 + \frac{dz_i}{z_i} \wedge \omega_1$ and $\eta = \eta_0 + \frac{dz_i}{z_i} \wedge \eta_1$. Extracting the coefficient of dz_i/z_i in $\omega \wedge \eta$ gives exactly

$$\text{Res}_{D_i}(\omega \wedge \eta) = \text{Res}_{D_i}(\omega) \wedge \eta|_{D_i} + (-1)^{|\omega|} \omega|_{D_i} \wedge \text{Res}_{D_i}(\eta).$$

If $D_i \cap D_j = \emptyset$, then locally at any point at most one of z_i, z_j vanishes, so each composition $\text{Res}_{D_i} \circ \text{Res}_{D_j}$ and $\text{Res}_{D_j} \circ \text{Res}_{D_i}$ is zero; hence they agree globally.

Finally, by Theorem 5.1.29, the residue map is the middle map of a short exact sequence of complexes. Therefore for $d\omega = 0$, the residue family lies in the kernel of the connecting morphism, i.e. it satisfies the residue cocycle condition (equivalently, total boundary residue vanishes). $\square$

PROPOSITION 5.1.27 (*Residue computation in local coordinates;*). In the local coordinates (p, ϵ, θ, w) near $D_S = \{\epsilon = 0\}$ from Theorem 5.1.9, the residue operation is:

$$\text{Res}_{D_S} : \Omega^k(\log D_S) \rightarrow \Omega_{D_S}^{k-1}$$

given explicitly by:

$$\text{Res}_{D_S} \left(\frac{d\epsilon}{\epsilon} \wedge \alpha + \beta \right) = \alpha|_{\epsilon=0}$$

where $\alpha \in \Omega^{k-1}$ and $\beta \in \Omega^k$ are smooth.

Proof. In the chart of Theorem 5.1.9, D_S is the smooth divisor $\{\epsilon = 0\}$, and the logarithmic cotangent sheaf is generated by $d\epsilon/\epsilon$, $d\theta$, and the regular differentials in the remaining coordinates. Hence every logarithmic k -form can be written uniquely as

$$\omega = \frac{d\epsilon}{\epsilon} \wedge \alpha + \beta,$$

where neither α nor β contains a $d\epsilon/\epsilon$ factor. By definition of the Poincaré residue for a smooth divisor, the residue is the coefficient of $d\epsilon/\epsilon$ restricted to $\epsilon = 0$, giving

$$\text{Res}_{D_S}(\omega) = \alpha|_{\epsilon=0}.$$

This is exactly the displayed formula. $\square$

Remark 5.1.28 (Residues and OPE: pole absorption by the propagator). The geometric residue operation exactly implements the OPE coefficient extraction from conformal field theory, but the count of pole orders deserves explicit attention. Recall the OPE:

$$\phi_i(z)\phi_j(w) = \sum_k \frac{C_{ij}^k}{(z-w)^{h_i+h_j-h_k}} \phi_k(w) + \text{regular}.$$

In the bar complex,

$$\bar{B}^2(\mathcal{A}) = \mathcal{A}^{\otimes 2} \otimes \Omega_{\bar{C}_2(\Sigma_g)}^1(\log D_{12}),$$

the element $\alpha = \phi_i(z_1) \otimes \phi_j(z_2) \otimes \eta_{12}$ carries the propagator $\eta_{12} = d \log(z_1 - z_2)$ as its form component. The bar differential extracts the residue along D_{12} :

$$d\alpha = \text{Res}_{D_{12}}[\phi_i(z_1)\phi_j(z_2)\eta_{12}].$$

Pole-order counting. The propagator $\eta_{12} = d \log(z_1 - z_2)$ is a $d \log$ kernel, so its singular part is $d(z_1 - z_2)/(z_1 - z_2)$. The residue prescription $\text{Res}_{D_{12}}$ extracts the coefficient of the simple-pole 1-form $d(z_1 - z_2)/(z_1 - z_2)$, which carries one power of $1/(z_1 - z_2)$. Multiplying the OPE $(z_1 - z_2)^{-(h_i+h_j-h_k)}$ by this kernel produces the integrand

$$\frac{1}{(z_1 - z_2)^{h_i+h_j-h_k+1}} d(z_1 - z_2),$$

not $(z_1 - z_2)^{-(h_i+h_j-h_k)}$ alone. Equivalently, after absorbing the $d(z_1 - z_2)$ factor into the polar part, the bar differential effectively reads off the $(h_i + h_j - h_k)$ -th OPE mode, not the $(h_i + h_j - h_k + 1)$ -th. In the language, the $d \log$ kernel *absorbs one pole order* from the OPE: the collision residue $r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta, \mathcal{A})$ has pole orders *one less* than the OPE itself. For the Heisenberg/affine OPE

$$J^a(z)J^b(w) \sim \frac{k\delta^{ab}}{(z-w)^2} + \frac{f^{ab}_c J^c}{z-w},$$

the propagator absorbs both poles, leaving the genuine r -matrix $k \Omega/z$ with a single pole. For the Virasoro OPE with z^{-4} , z^{-2} , z^{-1} poles, the corresponding r -matrix has z^{-3} and z^{-1} but *no* z^{-2} contribution: the bar kernel sends even-order poles into odd-order ones and vice versa.

Mode extraction. When $h_i + h_j - h_k = n$ for some non-negative integer n , the residue extracts the n -th mode $a_{(n-1)}b$ from the OPE $a(z)b(w) = \sum_n a_{(n)}b(z-w)^{-n-1}$, with the index shift coming from the $d \log$ absorption. The geometry of residues therefore encodes the algebra of the OPE, but with the convention that the *propagator counts one pole*, not zero.

THEOREM 5.1.29 (*Residue sequence*;). There is an exact sequence of sheaves:

$$0 \rightarrow \Omega_{\overline{C}_n(\Sigma_g)}^k \rightarrow \Omega_{\overline{C}_n(\Sigma_g)}^k(\log D) \xrightarrow{\text{Res}} \bigoplus_{\alpha} \Omega_{D_{\alpha}}^{k-1}(\log D_{\alpha}^{\partial}) \rightarrow 0$$

where the residue map extracts the logarithmic part along each divisor component D_{α} .

Exactness means that forms with log poles having zero residue along all D_{α} are smooth, and every $(k-1)$ -form on the boundary $D = \bigcup D_{\alpha}$ arises as the residue of some logarithmic form.

Proof. Exactness is local on $\overline{C}_n(\Sigma_g)$. By Theorem 5.1.12, near every point we can choose coordinates $(z_1, \dots, z_m)$ with $D = \{z_1 \cdots z_r = 0\}$.

Write $D_i = \{z_i = 0\}$ for $1 \leq i \leq r$. Every logarithmic form can be uniquely written as

$$\omega = \omega_0 + \sum_{i=1}^r \frac{dz_i}{z_i} \wedge \eta_i,$$

with ω_0 regular and η_i logarithmic along $D_i^{\partial} = \{z_1 \cdots \widehat{z_i} \cdots z_r = 0\} \subset D_i$, without a dz_i/z_i term. The residue map is

$$\text{Res}(\omega) = (\eta_i|_{z_i=0})_{i=1}^r.$$

The left injection is immediate. If $\text{Res}(\omega) = 0$, then each $\eta_i|_{z_i=0} = 0$, so $\eta_i = z_i \theta_i$ for some logarithmic θ_i . Hence

$$\frac{dz_i}{z_i} \wedge \eta_i = dz_i \wedge \theta_i$$

is regular, and therefore ω is regular. So $\ker(\text{Res}) = \Omega_{\overline{C}_n(\Sigma_g)}^k$.

For surjectivity, take a local section $(\rho_i)_{i=1}^r \in \bigoplus_i \Omega_{D_i}^{k-1}(\log D_i^{\partial})$. Choose local lifts $\tilde{\rho}_i$ to ambient logarithmic forms with no dz_i/z_i factor, and set

$$\omega := \sum_{i=1}^r \frac{dz_i}{z_i} \wedge \tilde{\rho}_i.$$

Then $\text{Res}_{D_i}(\omega) = \rho_i$ for each i , proving local surjectivity. Since exactness of sheaf sequences is local, the displayed sequence is exact globally. $\square$

5.1.4.1 Functoriality and universal properties

THEOREM 5.1.30 (*Functoriality of FM compactification*;). The Fulton–MacPherson compactification is functorial in the following sense [186]:

1. *For embeddings:* If $U \subseteq \Sigma_g$ is an open subset, there is a natural embedding:

$$\overline{C}_n(U) \hookrightarrow \overline{C}_n(\Sigma_g)$$

compatible with boundary stratification.

2. *For open embeddings:* If $f : \Sigma_g \hookrightarrow \Sigma_{g'}$ is an open embedding, there is an induced map:

$$\overline{f^{(n)}} : \overline{C}_n(\Sigma_g) \rightarrow \overline{C}_n(\Sigma_{g'})$$

sending $D_S \rightarrow D_S$ (same collision pattern). (General smooth maps need not preserve the configuration condition; injectivity on pairs is required.)

3. *For automorphisms:* The group $\text{Aut}(\Sigma_g)$ acts on $\overline{C}_n(\Sigma_g)$ preserving stratification.
4. *For products:* There is a natural product structure:

$$\overline{C}_m(\Sigma_g) \times \overline{C}_n(\Sigma_g) \hookrightarrow \overline{C}_{m+n}(\Sigma_g)$$

(away from mixed collision loci)

Remark 5.1.31 (Provenance and citation). This theorem is imported and treated as . The functorial construction of the Fulton–MacPherson compactification and its boundary-strata compatibility are established in [186]; the statements here are the corresponding specialization to smooth curves/surfaces.

THEOREM 5.1.32 (*Universal property: operadic structure [186, 299];*). The collection $\{\overline{C}_n(\Sigma_g)\}_{n \geq 0}$ forms a *topological operad* with:

1. *Composition maps:* For disjoint subsets $S_1, \dots, S_k \subseteq \{1, \dots, n\}$:

$$\gamma : \overline{C}_k(\Sigma_g) \times \overline{C}_{|S_1|}(\Sigma_g) \times \dots \times \overline{C}_{|S_k|}(\Sigma_g) \rightarrow \overline{C}_n(\Sigma_g)$$

2. *Unit:* $\overline{C}_1(\Sigma_g) = \Sigma_g$ (single marked point)
3. *Associativity and unit axioms* (as for any operad)

This operad structure is *compatible with stratification*: composition maps send boundary strata to boundary strata according to the combinatorics of gluing.

Remark 5.1.33 (Provenance and citation). This theorem is imported and treated as . The compactified configuration-space composition/gluing formalism is part of the Fulton–MacPherson framework [186], and the operadic packaging used here is standard in operad references such as [299].

Remark 5.1.34 (Chiral operad structure). The operadic structure of $\{\overline{C}_n(\Sigma_g)\}$ is the geometric foundation for the *chiral operad* structure in Beilinson–Drinfeld [40].

Specifically, the spaces of logarithmic forms:

$$\mathcal{P}_n^{\text{ch}}(\Sigma_g) = H^0(\overline{C}_n(\Sigma_g), \Omega_{\overline{C}_n(\Sigma_g)}^n(\log D))$$

form an operad of differential forms, and chiral algebras are precisely algebras over this operad (in the appropriate ∞ -categorical sense).

5.1.4.2 Connection to factorization homology

THEOREM 5.1.35 (*Factorization homology via configuration spaces [30, 92, 40];*). For a chiral algebra $\mathcal{A}$ on Σ_g , the factorization homology is computed via:

$$\int_{\Sigma_g} \mathcal{A} = \text{colim}_n \left[\mathcal{A}^{\boxtimes n} \otimes_{\mathcal{D}_{\overline{C}_n(\Sigma_g)}} \mathcal{O}_{\overline{C}_n(\Sigma_g)} \right]$$

where:

- $\mathcal{A}^{\boxtimes n} = \mathcal{A} \boxtimes \dots \boxtimes \mathcal{A}$ is the external tensor product on Σ_g^n

- $\mathcal{D}_{\overline{C}_n(\Sigma_g)}$ is the sheaf of differential operators on $\overline{C}_n(\Sigma_g)$
- The colimit is over inclusions $\overline{C}_n \hookrightarrow \overline{C}_{n+1}$ via operadic composition

Remark 5.1.36 (Provenance and citation). This theorem is imported and treated as . The factorization-homology construction and its colimit/locality formalism are standard in [30, 92]; the chiral-algebra specialization used here is in the Beilinson–Drinfeld framework [40, Chapter 3].

Remark 5.1.37 (Ran space). An alternative perspective uses the *Ran space* $\text{Ran}(\Sigma_g)$:

$$\text{Ran}(\Sigma_g) = \{S \subset \Sigma_g : 0 < |S| < \infty\}$$

equipped with the colimit topology from the natural maps $C_n(\Sigma_g)/S_n \hookrightarrow \text{Ran}(\Sigma_g)$ (in particular, points may collide: the topology allows sets of different cardinalities to be adjacent)

The Ran space parametrizes *finite unordered subsets* of Σ_g . A chiral algebra structure on $\mathcal{A}$ is equivalent to a factorization algebra $\mathcal{A}_{\text{Ran}}$ on $\text{Ran}(\Sigma_g)$ satisfying chiral locality conditions (encoded by the OPE).

The Fulton–MacPherson compactification provides a “partial compactification” of Ran space, adding boundary strata for collision patterns.

Example 5.1.38 (Factorization for Heisenberg). For the Heisenberg chiral algebra $\mathcal{H}$ at level k :

$$\int_{\Sigma_g} \mathcal{H} \cong \text{Fock space at level } k$$

More precisely:

- At genus 0: $\int_{\mathbb{P}^1} \mathcal{H} \cong \mathbb{C}[x]$ (polynomial algebra)
- At genus 1: $\int_{\Sigma_1} \mathcal{H} \cong$ Hilbert space of k particles on Σ_1
- At genus g : Includes contributions from all homology cycles

The computation uses:

$$\int_{\Sigma_g} \mathcal{H} = \text{colim}_n [\mathcal{H}^{\boxtimes n} \text{ with Heisenberg OPE along collisions}]$$

The OPE $J(z)J(w) \sim \frac{k}{(z-w)^2}$ determines how factors merge at boundaries of $\overline{C}_n(\Sigma_g)$.

The Fulton–MacPherson compactification $\overline{C}_n(\Sigma_g)$ (for a *fixed* curve Σ_g) stratifies by nestings:

$$\overline{C}_n(\Sigma_g) = \coprod_{S \in \text{Nest}(\{1, \dots, n\})} C_S$$

where $\text{Nest}(\{1, \dots, n\})$ denotes the poset of nested collections of subsets of $\{1, \dots, n\}$, recording which groups of points collide simultaneously. (By contrast, the strata of $\overline{\mathcal{M}}_{g,n}$ are indexed by stable graphs $\mathcal{G}_{g,n}$, which involve *curve* degenerations.)

5.2 LOGARITHMIC FM COMPACTIFICATION ON PUNCTURED CURVES

When the base curve X carries marked points $p_1, \dots, p_r$ (“punctures”), the configuration space $C_m(X \setminus \{p_1, \dots, p_r\})$ of m points on the complement is no longer an open subset of X^m (it is open in $(X \setminus D)^m$ where $D = \{p_1, \dots, p_r\}$). The FM compactification must be modified to account for the *two* types of collisions:

- (i) *FM collisions*: distinct moving points $z_i \rightarrow z_j$, encoded by the usual FM blow-ups;
- (ii) *Puncture collisions*: moving points $z_i \rightarrow p_\alpha$ approaching a puncture, encoded by logarithmic blow-ups along the divisor D .

Definition 5.2.1 (Logarithmic FM compactification [322]). Let X be a smooth projective curve, $D = p_1 + \dots + p_r$ an effective divisor. The *logarithmic Fulton–MacPherson compactification of the fixed pointed curve* (X, D) , $\text{FM}_m(X \mid D)$, is a smooth compactification of $C_m(X \setminus D)$ with the following properties:

1. There is an open embedding $j: C_m(X \setminus D) \hookrightarrow \text{FM}_m(X \mid D)$ with dense image.
2. The boundary $\partial \text{FM}_m(X \mid D) = \text{FM}_m(X \mid D) \setminus C_m(X \setminus D)$ is a normal-crossings divisor with two types of irreducible components:
 - D_{ij}^{FM} ($1 \leq i < j \leq m$): the locus where $z_i = z_j$ (as in the standard FM space);
 - $D_{i,\alpha}^{\text{punc}}$ ($1 \leq i \leq m, 1 \leq \alpha \leq r$): the locus where $z_i = p_\alpha$.

For fixed (X, D) , these are the only codimension-1 boundary components.

3. The strata of $\text{FM}_m(X \mid D)$ are indexed by *marked nestings*: pairs (S, φ) where $S \in \text{Nest}(\{1, \dots, m\})$ records FM collisions and $\varphi: \{1, \dots, m\} \rightarrow \{0, 1, \dots, r\}$ records puncture attachments ($\varphi(i) = \alpha$ means $z_i \rightarrow p_\alpha$; $\varphi(i) = 0$ means z_i remains generic).

Remark 5.2.2 (Fixed versus relative log FM spaces). Definition 5.2.1 keeps the pointed curve (X, D) fixed. Its boundary therefore has only the two fiberwise strata listed above: FM collisions among moving points and puncture collisions with the fixed divisor D . It does not contain additional components from degeneration of the underlying curve. Those curve-degeneration strata appear only in the relative logarithmic Fulton–MacPherson compactification of the universal pointed stable family over $\overline{\mathcal{M}}_{g,n}$. That relative space, not the fixed-curve space of Definition 5.2.1, is the one used in the ambient square-zero argument of Theorem 13.22.413.

Example 5.2.3 (Log FM recovers moduli of rational curves;). For $X = \mathbb{P}^1$ with $D = \{0, 1, \infty\}$ (three marked points), Mok [322, §3.4.1] proves the identification

$$\text{FM}_{n-3}(\mathbb{P}^1 \mid 0+1+\infty) \cong \overline{\mathcal{M}}_{0,n}. \quad (5.3)$$

This gives the log FM space a direct modular interpretation: the $n - 3$ configuration points together with the 3 punctures produce n marked points on $\mathbb{P}^1$, and the log FM compactification is precisely the Deligne–Mumford–Knudsen compactification. The FM-type boundary strata record bubble trees (collisions among moving points), while the puncture-collision strata correspond, under (5.3), to the boundary components where a moving point bubbles off with a fixed puncture. Together they reproduce the full boundary stratification of $\overline{\mathcal{M}}_{0,n}$ by dual trees. This identification means that the planted-forest coefficient algebra $\mathbb{G}_{\text{pf}}$ (Definition 13.22.400), when specialised to $\mathbb{P}^1$ with three punctures, encodes exactly the boundary combinatorics of $\overline{\mathcal{M}}_{0,n}$, the same data that controls the genus-0 convolution bracket on $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.

THEOREM 5.2.4 (*Bar complex on punctured curves*;). Let $\mathcal{A}$ be a chiral algebra on X , and let $\mathcal{M}_1, \dots, \mathcal{M}_r$ be $\mathcal{A}$ -modules supported at $p_1, \dots, p_r$. The bar complex with module insertions is:

$$\bar{B}_n(\mathcal{A}; \mathcal{M}_1, \dots, \mathcal{M}_r; X) = \Gamma(\mathrm{FM}_{n+r}(X | D), j_* j^*(\mathcal{A}^{\boxtimes n} \boxtimes \mathcal{M}_1 \boxtimes \dots \boxtimes \mathcal{M}_r) \otimes \Omega_{\log}^n)$$

where $\Omega_{\log}^n = \Omega_{\mathrm{FM}_{n+r}(X|D)}^n(\log \partial)$ is the sheaf of logarithmic n -forms on $\mathrm{FM}_{n+r}(X | D)$. The differential $d = d_{\mathrm{FM}} + d_{\mathrm{punc}}$ has two components:

- (a) d_{FM} : residues along FM collision divisors D_{ij}^{FM} , extracting the $\mathcal{A}$ -algebra OPE (exactly as in the unpunctured case, Theorem 6.1.21);
- (b) d_{punc} : residues along puncture divisors $D_{i,\alpha}^{\mathrm{punc}}$, extracting the $\mathcal{A}$ -module action $\rho_\alpha: \mathcal{A} \boxtimes \mathcal{M}_\alpha \rightarrow \Delta_* \mathcal{M}_\alpha$.

Proof. The key identity is $d^2 = 0$, which follows from the fact that $\mathrm{FM}_{n+r}(X | D)$ is attached to the fixed point curve (X, D) : its codimension-1 boundary has only FM collision divisors and puncture divisors, with no curve-degeneration faces. The curve-degeneration boundary appears only in the relative universal-family space used in Theorem 13.22.413. Thus only three types of double-residue cancellations occur:

1. *FM-FM*: $\mathrm{Res}_{D_{ij}} \mathrm{Res}_{D_{jk}}$ terms cancel by the Arnold relation $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$, exactly as in the unpunctured case (Theorem 6.1.21).
2. *FM-puncture*: $\mathrm{Res}_{D_{ij}} \mathrm{Res}_{D_{j,\alpha}}$ involves the OPE $\mathcal{A}(z_i) \cdot \mathcal{A}(z_j)$ followed by the module action ρ_α . The cancellation uses the module axiom: the $\mathcal{A}$ -module action is associative, so $\rho_\alpha \circ (m \boxtimes \mathrm{id}_{\mathcal{M}}) = \rho_\alpha \circ (\mathrm{id}_{\mathcal{A}} \boxtimes \rho_\alpha)$ on the triple-collision locus $z_i = z_j = p_\alpha$.
3. *Puncture-puncture*: For $\alpha \neq \beta$, $D_{i,\alpha}^{\mathrm{punc}} \cap D_{j,\beta}^{\mathrm{punc}}$ is empty when $i = j$ (a single point cannot approach two distinct punctures), so these terms vanish. For $i \neq j$, the normal-crossings property gives $\mathrm{Res}_{D_{i,\alpha}} \mathrm{Res}_{D_{j,\beta}} = \mathrm{Res}_{D_{j,\beta}} \mathrm{Res}_{D_{i,\alpha}}$ (residues at disjoint divisors commute).

Each case contributes zero to d^2 , establishing $d^2 = 0$. $\square$

COROLLARY 5.2.5 (*Conformal blocks from punctured bar complex*;). The zeroth cohomology of the punctured bar complex recovers the space of conformal blocks:

$$H^0(\bar{B}_\bullet(\mathcal{A}; \vec{\mathcal{M}}; X)) \cong \mathbb{V}(\mathcal{A}; \mathcal{M}_1, \dots, \mathcal{M}_r; X).$$

Proof. The zeroth bar cohomology computes the space of coinvariants: elements of $\mathcal{M}_1 \otimes \dots \otimes \mathcal{M}_r$ modulo the $\mathcal{A}(X \setminus \{p_1, \dots, p_r\})$ -action. By definition, this is $\mathbb{V}(\mathcal{A}; \vec{\mathcal{M}}; X)$ (Definition 15.1.18). The identification follows from the quasi-isomorphism of the bar complex with the Čech resolution of the coinvariant functor, applied to the Weiss cover of $X \setminus D$ subordinate to the FM stratification. $\square$

Example 5.2.6 (*Kac-Moody modules on $\mathbb{P}^1$ with 3 punctures*). For $\mathcal{A} = \widehat{\mathfrak{g}}_k$ on $\mathbb{P}^1$ with simple modules $L(\Lambda_i)$ at $0, 1, \infty$:

$$\bar{B}_1(\widehat{\mathfrak{g}}_k; L(\Lambda_1), L(\Lambda_2), L(\Lambda_3); \mathbb{P}^1) = \Gamma(\mathrm{FM}_4(\mathbb{P}^1 | \{0, 1, \infty\}), \mathfrak{g} \boxtimes L(\Lambda_1) \boxtimes L(\Lambda_2) \boxtimes L(\Lambda_3) \otimes \Omega_{\log}^1)$$

The bar differential extracts:

- d_{FM} : the algebra OPE $J^a(z_1)J^b(z_2) \sim k\delta^{ab}/(z_1 - z_2)^2 + f^{ab}{}_c J^c/(z_1 - z_2)$;
- d_{punc} : the module action $J^a(z) \cdot v_\alpha = \mathrm{Res}_{z=p_\alpha} [J^a(z) \cdot v_\alpha dz/(z - p_\alpha)]$ for $v_\alpha \in L(\Lambda_\alpha)$.

The cohomology H^0 computes the fusion coefficient $N_{\Lambda_1 \Lambda_2}^{\Lambda_3^*}$ (Theorem 15.1.26).

5.3 BORDERED FULTON–MACPHERSON COMPACTIFICATION

The logarithmic FM compactification of §5.2 resolves collisions of interior points with fixed punctures. The bordered variant developed in this section adds a second geometric layer: the punctures $p_1, \dots, p_r$ are promoted to *boundary circles* carrying ordered boundary insertions, and the compactification records not only point–point collisions but also boundary–boundary and interior–boundary interactions. The resulting *bordered FM compactification* $\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)$ is the geometric carrier of the open-closed bar complex, and its codimension-one boundary decomposes into exactly four types: interior collision, consecutive boundary collision, mixed bubbling, and nodal clutching. The Stokes theorem on this boundary is the geometric origin of the modular Maurer–Cartan equation with clutching (§5.4).

5.3.1 TANGENTIAL LOG CURVES

Definition 5.3.1 (Tangential log curve). A *tangential log curve* is a triple (X, D, τ) where:

- (i) X is a smooth projective curve over $\mathbb{C}$ of genus g ;
- (ii) $D = p_1 + \dots + p_r$ is an effective reduced divisor (the *puncture locus*);
- (iii) $\tau = (\tau_1, \dots, \tau_r)$ is a collection of *tangential basepoints*: for each $j = 1, \dots, r$, a nonzero tangent direction $\tau_j \in (T_{p_j}X) \setminus \{0\}$, well-defined up to positive real scaling: $\tau_j \in (T_{p_j}X \setminus \{0\})/\mathbb{R}_{>0} \cong S^1_{p_j}$.

The tangential basepoints determine preferred points on the boundary circles of the real oriented blowup (Construction 5.3.2). Two tangential log curves (X, D, τ) and (X, D, τ') are *equivalent* if they differ by a positive-real rotation at each puncture.

Construction 5.3.2 (Real oriented blowup). Let (X, D, τ) be a tangential log curve. The *real oriented blowup* of X along D is the smooth manifold with boundary

$$\widetilde{X}_D := [X \setminus D] \cup \bigsqcup_{j=1}^r S^1_{p_j},$$

constructed as follows. Choose a local holomorphic coordinate z_j centered at p_j (so $z_j(p_j) = 0$); write $z_j = \rho_j e^{i\theta_j}$ in polar form with $\rho_j \geq 0$ and $\theta_j \in \mathbb{R}/2\pi\mathbb{Z}$.

- (1) The underlying set of $\widetilde{X}_D$ is obtained by replacing each puncture p_j with the circle of directions:

$$\widetilde{X}_D = (X \setminus D) \sqcup \bigsqcup_{j=1}^r \{(\rho_j, \theta_j) : \rho_j = 0, \theta_j \in S^1\}.$$

- (2) The smooth structure near $S^1_{p_j}$ is given by the coordinates (ρ_j, θ_j) with $\rho_j \geq 0$: the chart $U_j = \{|z_j| < \epsilon\}$ in X lifts to $\widetilde{U}_j = [0, \epsilon) \times S^1 \hookrightarrow \widetilde{X}_D$, making ρ_j a boundary-defining function.
- (3) The boundary of $\widetilde{X}_D$ is the disjoint union of circles:

$$\partial \widetilde{X}_D = \bigsqcup_{j=1}^r S^1_{p_j} \cong \bigsqcup_{j=1}^r \{\rho_j = 0\}.$$

- (4) The tangential basepoint τ_j determines a preferred point $\star_j \in S_{p_j}^1$: the direction τ_j is the unit tangent vector at $\theta_j = 0$ in the local coordinate z_j chosen so that $\partial/\partial z_j|_{p_j}$ is positively aligned with τ_j . The identification is:

$$\star_j = \lim_{\rho_j \rightarrow 0^+} (\rho_j, \arg(z_j/\tau_j)) = (0, 0) \in S_{p_j}^1.$$

The result is independent of the choice of local coordinate z_j up to diffeomorphism: a coordinate change $z_j \mapsto w_j(z_j)$ with $w_j(0) = 0$ and $w'_j(0) \neq 0$ induces a diffeomorphism of $[0, \epsilon) \times S^1$ that rotates $S_{p_j}^1$ by $\arg(w'_j(0))$ and rescales ρ_j to first order. The tangential basepoint absorbs this rotation.

Definition 5.3.3 (Boundary intervals). For a tangential log curve (X, D, τ) , the *boundary interval* at p_j is the complement of the tangential basepoint in the boundary circle:

$$I_{p_j} := S_{p_j}^1 \setminus \{\star_j\} \cong (0, 2\pi) \cong \mathbb{R}.$$

The interval I_{p_j} carries the cyclic orientation induced from the complex orientation of X : the boundary circle $S_{p_j}^1$ inherits the orientation where θ_j increases counterclockwise, and removing the basepoint $\star_j = \{0\}$ produces a *totally ordered* interval with the standard orientation of $\mathbb{R}$.

Remark 5.3.4 (Geometric meaning of the interval). The boundary interval I_{p_j} parametrizes the angular directions from which interior points can approach the puncture p_j , with the basepoint direction removed to break the cyclic symmetry and obtain a linear ordering. In the open-string interpretation, I_{p_j} is the worldsheet boundary associated to the j -th D-brane, and the basepoint $\star_j$ is the distinguished insertion point for the identity of the boundary algebra.

5.3.2 MIXED CONFIGURATION SPACES

Definition 5.3.5 (Mixed open-closed configuration space). Let (X, D, τ) be a tangential log curve with $D = p_1 + \cdots + p_r$, and let $\vec{m} = (m_1, \dots, m_r) \in \mathbb{Z}_{\geq 0}^r$ be a vector of boundary multiplicities. The *mixed open-closed configuration space* is

$$\text{Conf}_{k, \vec{m}}^{\text{oc}}(X, D, \tau) := C_k(X \setminus D) \times \prod_{j=1}^r \text{Conf}_{m_j}^{\text{ord}}(I_{p_j}),$$

where:

- $C_k(X \setminus D)$ is the configuration space of k distinct ordered *interior* (“closed-string”) points in the complement $X \setminus D$;
- $\text{Conf}_{m_j}^{\text{ord}}(I_{p_j})$ is the configuration space of m_j distinct *ordered boundary* (“open-string”) points in I_{p_j} :

$$\text{Conf}_{m_j}^{\text{ord}}(I_{p_j}) = \{(t_1^{(j)}, \dots, t_{m_j}^{(j)}) \in I_{p_j}^{m_j} : 0 < t_1^{(j)} < t_2^{(j)} < \cdots < t_{m_j}^{(j)} < 2\pi\}.$$

The ordering is with respect to the linear coordinate $\theta_j \in (0, 2\pi) \cong I_{p_j}$ from Definition 5.3.3.

The total dimension is $\dim_{\mathbb{R}} \text{Conf}_{k, \vec{m}}^{\text{oc}} = 2k + |\vec{m}|$, where $|\vec{m}| = m_1 + \cdots + m_r$.

Remark 5.3.6 (Boundary ordering and the associahedron). The ordered boundary configuration space $\text{Conf}_m^{\text{ord}}(I_p)$ is contractible: it is the interior of the standard simplex $\{0 < t_1 < \cdots < t_m < 2\pi\} \cong \text{int}(\Delta^{m-1})$. The compactification of this simplex is the A_∞ associahedron K_m : boundary strata correspond to consecutive sub-blocks of boundary points colliding along the interval. The global geometry therefore separates into a *contractible boundary factor* (the simplex) and an *interesting interior factor* (the FM compactification of the interior points).

5.3.3 THE BORDERED FM COMPACTIFICATION

Construction 5.3.7 (Bordered FM compactification). Let (X, D, τ) be a tangential log curve with $D = p_1 + \cdots + p_r$, let $k \geq 0$ be the number of interior points, and let $\vec{m} = (m_1, \dots, m_r)$ be the vector of boundary multiplicities. Set $M = |\vec{m}| = \sum_j m_j$. The *bordered FM compactification* $\bar{C}_{k, \vec{m}}^{\text{oc}}(X, D, \tau)$ is constructed by the following iterated blowup procedure, extending the classical FM construction (Theorem 5.1.3) and the logarithmic variant (Definition 5.2.1).

STEP 1: THE AMBIENT PARTIAL COMPACTIFICATION. Begin with the product

$$\mathring{Y} := (X \setminus D)^k \times \prod_{j=1}^r I_{p_j}^{m_j}.$$

This is an open subset of $\tilde{X}_D^k \times \prod_j [0, 2\pi]^{m_j}$. To compactify, first close the boundary factors: replace each open interval $I_{p_j} \cong (0, 2\pi)$ by the closed interval $\bar{I}_{p_j} = [0, 2\pi]$, and replace $(X \setminus D)^k$ by the logarithmic compactification $\text{FM}_k(X \mid D)$ of Definition 5.2.1. This gives the *rough compactification*:

$$Y := \text{FM}_k(X \mid D) \times \prod_{j=1}^r \bar{I}_{p_j}^{m_j}.$$

The space Y is compact but has non-transverse singularities: when two interior points collide while simultaneously a boundary point approaches the basepoint, the resulting degeneration is not normal-crossing.

STEP 2: INTERIOR BLOWUPS (FM TYPE). For each subset $S \subseteq \{1, \dots, k\}$ with $|S| \geq 2$, the diagonal $\Delta_S^{\text{int}} = \{z_i = z_j \text{ for all } i, j \in S\}$ inside $\text{FM}_k(X \mid D)$ has already been resolved by the FM construction. No further blowups are needed for purely interior collisions.

STEP 3: BOUNDARY BLOWUPS (ASSOCIAHEDRAL TYPE). For each boundary component j and each *consecutive block* $B = \{a, a+1, \dots, b\} \subseteq \{1, \dots, m_j\}$ with $|B| \geq 2$, the diagonal

$$\Delta_B^{\text{bdy}} = \{t_a^{(j)} = t_{a+1}^{(j)} = \cdots = t_b^{(j)}\} \subset \bar{I}_{p_j}^{m_j}$$

is a smooth submanifold of codimension $|B| - 1$. Blow up these diagonals in decreasing order of $|B|$ (equivalently, decreasing order of codimension). The blowups only involve *consecutive* blocks because the boundary points are ordered: a non-consecutive collision (e.g., $t_1 = t_3$ with t_2 distinct) does not occur for ordered configurations. The result is the *Stasheff associahedron* K_{m_j} : the compactified moduli space of m_j ordered points on $\mathbb{R}$.

STEP 4: MIXED BLOWUPS (OPEN-CLOSED INTERACTION). For each interior point $i \in \{1, \dots, k\}$ and each boundary component $j \in \{1, \dots, r\}$ with associated boundary points $B_j = \{t_1^{(j)}, \dots, t_{m_j}^{(j)}\}$, and for each subset $S \subseteq \{1, \dots, k\}$ with $i \in S$ and each *nonempty* consecutive block $B \subseteq \{1, \dots, m_j\}$

(so that $|S| \geq 1$ and $|B| \geq 1$; the purely interior and purely boundary cases are already resolved in Steps 2 and 3), define the *mixed collision locus*:

$$\Delta_{S,B,j}^{\text{mix}} := \{z_i = p_j \text{ for all } i \in S, t_a^{(j)} = \star_j \text{ for all } a \in B\} \subset Y.$$

This records a degeneration where interior points in S approach the puncture p_j while boundary points in the block B simultaneously approach the basepoint $\star_j$. Blow up these mixed loci in the order dictated by decreasing codimension $|S| + |B|$, after the purely interior and purely boundary blowups.

STEP 5: NODAL BLOWUPS (CLUTCHING TYPE). When the base curve (X, D) varies in the family $\overline{\mathcal{M}}_{g,r}$, additional boundary strata arise from curve degeneration. For each stable graph Γ with $\sum_v g(v) + h^1(\Gamma) = g$ and r marked legs, the clutching map $\xi_\Gamma: \prod_v \overline{\mathcal{M}}_{g(v), n(v)} \rightarrow \overline{\mathcal{M}}_{g,r}$ produces a boundary stratum D_Γ^{nod} . Over this stratum, the bordered FM space acquires a fiber that is a product of bordered FM spaces on the component curves:

$$\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)|_{D_\Gamma^{\text{nod}}} \cong \prod_{v \in V(\Gamma)} \overline{C}_{k_v, \vec{m}_v}^{\text{oc}}(X_v, D_v, \tau_v),$$

where $(k_v, \vec{m}_v)$ is the restriction of interior and boundary multiplicities to the component v , and (X_v, D_v, τ_v) is the tangential log curve on the v -th irreducible component with nodal points added to D_v and tangential directions induced from the gluing parameter.

The bordered FM compactification is:

$$\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau) := \text{iterated blowup of } Y \text{ along } \Delta_B^{\text{bdy}}, \Delta_{S,B,j}^{\text{mix}}, D_\Gamma^{\text{nod}}$$

in the order prescribed above.

THEOREM 5.3.8 (*Properties of the bordered FM compactification*;). The bordered FM compactification $\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)$ of Construction 5.3.7 has the following properties:

- (i) *Smooth manifold with corners.* $\overline{C}_{k,\vec{m}}^{\text{oc}}$ is a compact smooth manifold with corners of dimension $2k + |\vec{m}|$.
- (ii) *Dense open embedding.* There is an open embedding $j: \text{Conf}_{k,\vec{m}}^{\text{oc}}(X, D, \tau) \hookrightarrow \overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)$ with dense image.
- (iii) *Normal crossings.* The boundary $\partial \overline{C}_{k,\vec{m}}^{\text{oc}}$ is a union of smooth codimension-one faces intersecting in normal crossings.
- (iv) *Functoriality.* A morphism of tangential log curves $(X, D, \tau) \rightarrow (X', D', \tau')$ (i.e., a morphism $f: X \rightarrow X'$ with $f_*D \leq D'$ and compatible tangential data) induces a smooth map $\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau) \rightarrow \overline{C}_{k,\vec{m}}^{\text{oc}}(X', D', \tau')$ compatible with boundary stratification.

Proof. (i) Each blowup in Steps 2–5 has smooth center (the diagonals Δ_B^{bdy} are smooth because the ordering prevents non-transverse intersections; the mixed loci $\Delta_{S,B,j}^{\text{mix}}$ are smooth because they are transverse intersections of interior FM divisors and boundary diagonals). The ordering by decreasing codimension ensures that at each stage the center is a smooth submanifold of the current blowup. The corners arise from the boundary factor $\prod_j \overline{I}_{p_j}^{m_j}$.

(ii) The interior $\text{Conf}_{k,\vec{m}}^{\text{oc}}$ is the complement of all collision loci, which embeds as a dense open subset of the blowup by the universal property of blowups.

(iii) Normal crossings. The interior FM factor has normal-crossings boundary by Theorem 5.1.12. The boundary factor is a product of associahedra, whose face structure is that of coordinate hyperplanes (Stasheff). It remains to verify that the mixed blowups (Step 4) preserve normal crossings. At each step, the center of the blowup is a smooth submanifold Z that is the intersection of the interior-collision locus $\epsilon_{i,j} = 0$ with the boundary-proximity locus $\rho_{i,j} = 0$. Since $\epsilon_{i,j}$ and $\rho_{i,j}$ are independent local coordinates (the former is an interior distance, the latter an interior-to-boundary distance), their joint vanishing locus Z is a smooth subvariety of codimension 2 in $\overline{C}_k(X) \times K_{\vec{m}}$. The blowup Bl_Z replaces Z by its projectivized normal bundle $\mathbb{P}(N_{Z/M})$; the exceptional divisor E is transverse to the pre-existing boundary divisors because Z meets them transversally (the defining functions $\{\epsilon_S, \delta_B, t_e\}$ of the existing boundary are functionally independent from $\{\epsilon_{i,j}, \rho_{i,j}\}$ at every point of Z). Iterating over all mixed pairs (i, j) in any order produces the same result: the centers are pairwise disjoint (or nested) at each step, so the blowups commute (by the clean-intersection criterion: disjoint or nested centers commute under blowup).

(iv) Functoriality follows from the naturality of the blowup construction: if f preserves diagonals and puncture loci, it lifts through each iterated blowup. $\square$

LEMMA 5.3.9 (*Nested blowup commutativity*;). Let M be a smooth variety with smooth subvarieties $Z_1, Z_2 \subset M$. If Z_1 and Z_2 are either disjoint or nested ($Z_1 \subseteq Z_2$ or $Z_2 \subseteq Z_1$), then $\text{Bl}_{Z_2}(\text{Bl}_{Z_1}(M)) \cong \text{Bl}_{Z_1}(\text{Bl}_{Z_2}(M))$. More generally, if $Z_1, \dots, Z_r$ are pairwise nested or disjoint, the iterated blowup $\text{Bl}_{Z_r} \cdots \text{Bl}_{Z_1}(M)$ is independent of the ordering [186].

5.3.4 CODIMENSION-ONE BOUNDARY DECOMPOSITION

PROPOSITION 5.3.10 (*Four-type boundary decomposition*;). The codimension-one boundary of the bordered FM compactification $\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)$ decomposes into four types of smooth faces:

$$\partial \overline{C}_{k,\vec{m}}^{\text{oc}} = \partial_{\text{I}} \overline{C}_{k,\vec{m}}^{\text{oc}} \cup \partial_{\text{II}} \overline{C}_{k,\vec{m}}^{\text{oc}} \cup \partial_{\text{III}} \overline{C}_{k,\vec{m}}^{\text{oc}} \cup \partial_{\text{IV}} \overline{C}_{k,\vec{m}}^{\text{oc}}.$$

Type I: Interior collision strata. For each subset $S \subseteq \{1, \dots, k\}$ with $|S| \geq 2$, the *interior collision face* is

$$\partial_S^{\text{I}} \overline{C}_{k,\vec{m}}^{\text{oc}} \cong \overline{C}_{k-|S|+1,\vec{m}}^{\text{oc}}(X, D, \tau) \times \overline{C}_{|S|}(\mathbb{A}^1). \quad (5.4)$$

This records the collision of interior points indexed by S at a point $q \in X \setminus D$. The first factor records the collision center q together with the remaining $k - |S|$ interior points and all $|\vec{m}|$ boundary points; the second factor is the genus-0 FM screen recording relative positions on the tangent space $T_q X \cong \mathbb{A}^1$.

Geometric fiber. The fiber over a point of the first factor is $\overline{C}_{|S|}(\mathbb{A}^1)$, the FM compactification of $|S|$ points in the affine line. This is a smooth manifold of dimension $2(|S| - 1) - 1 = 2|S| - 3$ (after quotienting by the translation–dilation group).

Normal bundle. The exceptional divisor D_S^{I} is the projectivization of the normal bundle to Δ_S^{int} inside the FM space. The normal bundle is $N_{\Delta_S^{\text{int}}/\text{FM}_k} \cong T_q X \otimes (\mathbb{C}^{|S|}/\mathbb{C}) \cong T_q X^{\oplus(|S|-1)}$, and the exceptional divisor D_S^{I} is its projectivization: a $\mathbb{P}^{|S|-2}$ -bundle over the collision center locus. As a boundary-defining function, the collision scale $\epsilon_S = \max_{i \in S} |z_i - q|$ (in local coordinates near q) satisfies $D_S^{\text{I}} = \{\epsilon_S = 0\}$.

Residue map. The residue along D_S^{I} is:

$$\text{Res}_{D_S^{\text{I}}} : \Omega_{\log}^p(\overline{C}_{k,\vec{m}}^{\text{oc}}) \longrightarrow \Omega_{\log}^{p-1}(\partial_S^{\text{I}} \overline{C}_{k,\vec{m}}^{\text{oc}}).$$

Concretely, for a logarithmic form $\omega = \frac{d\epsilon_S}{\epsilon_S} \wedge \alpha + \beta$: $\text{Res}_{D_S^{\text{I}}}(\omega) = \alpha|_{\epsilon_S=0}$. This extracts the OPE coefficient of the $\mathcal{A}$ -algebra product $\mu_S : \mathcal{A}^{\boxtimes |S|} \rightarrow \mathcal{A}$ from the leading collision singularity.

Type II: Consecutive boundary collision strata. For each boundary component j and each consecutive block $B = \{a, a+1, \dots, b\} \subseteq \{1, \dots, m_j\}$ with $|B| \geq 2$, the *consecutive boundary collision face* is

$$\partial_{B,j}^{\text{II}} \bar{C}_{k,\vec{m}}^{\text{oc}} \cong \bar{C}_{k,\vec{m}'}^{\text{oc}}(X, D, \tau) \times K_{|B|},$$

where $\vec{m}' = (m_1, \dots, m_j - |B| + 1, \dots, m_r)$ (the colliding block is replaced by a single point) and $K_{|B|}$ is the $|B|$ -th Stasheff associahedron parametrizing the relative positions of $|B|$ ordered boundary points approaching a common limit. Consecutiveness is essential: the ordered configuration $(t_a < t_{a+1} < \dots < t_b)$ can only degenerate by shrinking the gaps $t_{l+1} - t_l \rightarrow 0$ for $l \in B$, which preserves the ordering.

Geometric fiber. The fiber over a point of the first factor is the Stasheff associahedron $K_{|B|}$, a convex polytope of dimension $|B| - 2$.

Normal bundle. The boundary-defining function is the total gap $\delta_B = t_b^{(j)} - t_a^{(j)} \geq 0$, with $\partial_{B,j}^{\text{II}} = \{\delta_B = 0\}$. The normal bundle is trivial of rank 1 (the real line generated by $\partial/\partial\delta_B$).

Residue map. The residue along $\partial_{B,j}^{\text{II}}$ extracts the boundary A_∞ -composition:

$$\text{Res}_{\partial_{B,j}^{\text{II}}} : \omega \longmapsto \omega|_{\delta_B=0} \rightsquigarrow \mu_B^{\text{bdy}} : \mathcal{M}_j^{\otimes |B|} \rightarrow \mathcal{M}_j,$$

the higher multiplication on the boundary module $\mathcal{M}_j$ supported at p_j .

Type III: Mixed bubbling strata. For each interior point i approaching boundary component j , and each consecutive boundary block $B \subseteq \{1, \dots, m_j\}$ (possibly empty) colliding simultaneously, the *mixed bubbling face* is

$$\partial_{i,B,j}^{\text{III}} \bar{C}_{k,\vec{m}}^{\text{oc}} \cong \bar{C}_{k-1,\vec{m}'}^{\text{oc}}(X, D, \tau) \times \bar{C}_{1,(0,\dots,|B|,\dots,0)}^{\text{oc}}(\mathbb{H}, \{0\}, \tau_j),$$

where $\mathbb{H} = \{z \in \mathbb{C} : \text{Im}(z) \geq 0\}$ is the closed upper half-plane (the local model for the real oriented blowup near p_j), $\vec{m}' = (m_1, \dots, m_j - |B|, \dots, m_r)$, and the second factor is the bordered FM space of 1 interior point and $|B|$ boundary points on the half-plane.

Geometrically, as $z_i \rightarrow p_j$ along a direction θ_i , the interior point bubbles off onto the tangent half-plane $T_{p_j}^+ X := \{v \in T_{p_j} X : \arg(v/\tau_j) \in (0, 2\pi)\}$; boundary points in B that simultaneously approach $\star_j$ join this bubble. The mixed bubble carries both a bulk insertion (from the interior point) and boundary insertions (from the collapsing boundary points), recording the $\mathcal{A}$ -module action $\rho_j : \mathcal{A} \otimes \mathcal{M}_j^{\otimes |B|} \rightarrow \mathcal{M}_j$.

Geometric fiber. The fiber is the bordered FM compactification of one interior point and $|B|$ boundary points on the upper half-plane: the *Voronov Swiss-cheese* space $\text{SC}_{1,|B|} := \bar{C}_{1,(|B|)}^{\text{oc}}(\mathbb{H}, \{0\}, 1)$, which is a manifold with corners of dimension $|B| + 1$.

Normal bundle. The boundary-defining function is the distance $\rho_{i,j} = |z_i - p_j|$ in the real oriented blowup, with $\partial_{i,B,j}^{\text{III}} = \{\rho_{i,j} = 0\}$. The conormal is spanned by $d\rho_{i,j}$; the normal bundle is trivial of rank 1.

Residue map. The residue extracts the bulk-to-boundary OPE:

$$\text{Res}_{\partial_{i,B,j}^{\text{III}}} : \omega \longmapsto \omega|_{\rho_{i,j}=0} \rightsquigarrow \rho_j^B : \mathcal{A} \otimes \mathcal{M}_j^{\otimes |B|} \rightarrow \mathcal{M}_j,$$

extracting the open-closed intertwining map. When $B = \emptyset$, this is the pure bulk-to-boundary operation $\rho_j : \mathcal{A} \rightarrow \text{End}(\mathcal{M}_j)$.

Type IV: Nodal clutching strata. These arise from stable-curve degeneration, present only when the base curve (X, D) varies in moduli. For each stable graph Γ with one edge e (a codimension-one degeneration), the clutching face is:

$$\partial_{\Gamma}^{\text{IV}} \overline{C}_{k, \vec{m}}^{\text{oc}} \cong \prod_{v \in V(\Gamma)} \overline{C}_{k_v, \vec{m}_v}^{\text{oc}}(X_v, D_v, \tau_v),$$

where the product is over the vertices of Γ , with the distribution of interior and boundary multiplicities determined by the edge data of Γ . The edge e corresponds to a node: a point q on the degenerate curve where two irreducible components are identified. The gluing parameter t_e with $|t_e| < \epsilon$ is the transverse coordinate, with $t_e = 0$ defining the nodal locus.

The clutching strata separate into two sub-types, following the modular operad structure (Definition 5.1.6, Theorem 5.1.5):

(a) *Separating clutching* (Γ disconnects upon removing e):

$$\partial_{\Gamma}^{\text{IV, sep}} \cong \overline{C}_{k_1, \vec{m}_1}^{\text{oc}}(X_1, D_1, \tau_1) \times \overline{C}_{k_2, \vec{m}_2}^{\text{oc}}(X_2, D_2, \tau_2),$$

with $g_1 + g_2 = g$, $k_1 + k_2 = k$, $\vec{m}_1 + \vec{m}_2 = \vec{m}$ (distributed between the two components), and D_j augmented by the nodal point on component j .

(b) *Non-separating clutching* (Γ remains connected after removing e):

$$\partial_{\Gamma}^{\text{IV, ns}} \cong \overline{C}_{k, \vec{m}'}^{\text{oc}}(X', D', \tau'),$$

where (X', D', τ') is the partial normalization at the node, with genus $g - 1$ and $D' = D + q^+ + q^-$ (two new punctures at the preimages of the node), and $\vec{m}'$ is $\vec{m}$ augmented by $m_{q^+} = m_{q^-} = 0$.

Normal bundle. The boundary-defining function for the clutching face is the modulus $|t_e|$ of the gluing parameter, with $\partial_{\Gamma}^{\text{IV}} = \{t_e = 0\}$.

Residue map. The residue along $\partial_{\Gamma}^{\text{IV}}$ produces the clutching operation:

$$\text{Res}_{\partial_{\Gamma}^{\text{IV}}} : \omega \mapsto \xi_{\Gamma}^*(\omega|_{t_e=0})$$

where ξ_{Γ} is the clutching map of the modular operad. For separating clutching, this contracts a pair of legs using the invariant pairing $\langle -, - \rangle_{\mathcal{A}}$:

$$\xi_{\Gamma}^* : \text{End}_{\mathcal{A}}(n_1) \otimes \text{End}_{\mathcal{A}}(n_2) \xrightarrow{\text{id} \otimes \langle -, - \rangle \otimes \text{id}} \text{End}_{\mathcal{A}}(n_1 + n_2 - 2).$$

For non-separating clutching, this traces a pair of inputs against the pairing: $\Delta_{\text{ns}} : \text{End}_{\mathcal{A}}(n + 2) \rightarrow \text{End}_{\mathcal{A}}(n)$, $\Delta_{\text{ns}}(\phi)(a_1, \dots, a_n) = \sum_i \phi(a_1, \dots, a_n, e_i, e^i)$.

Proof. It suffices to verify that every codimension-one face of $\overline{C}_{k, \vec{m}}^{\text{oc}}$ is of one of the four types. A codimension-one face is defined by one boundary-defining function reaching zero. The possible degenerations are:

1. $\epsilon_S = 0$ for some $S \subseteq \{1, \dots, k\}$ with $|S| \geq 2$: interior collision (Type I).
2. $\delta_B = 0$ for some consecutive block B on boundary j with $|B| \geq 2$: consecutive boundary collision (Type II).

3. $\rho_{i,j} = 0$ for some interior point i and boundary component j : mixed bubbling (Type III). The consecutive block B of simultaneously collapsing boundary points is determined by the limiting configuration.
4. $t_e = 0$ for some edge e of a stable graph: nodal clutching (Type IV).

Any other degeneration has codimension ≥ 2 (e.g., simultaneous collisions of two independent clusters, or a non-consecutive boundary collision). The four types are mutually exclusive because their boundary-defining functions $(\epsilon_S, \delta_B, \rho_{i,j}, t_e)$ are independent local coordinates. Exhaustiveness follows from the compactness of $\overline{C}_{k,\vec{m}}^{\text{oc}}$: every sequence in the interior has a convergent subsequence, and the limit is classified by the minimal degeneration pattern, which is one of the four types. $\square$

Remark 5.3.11 (Comparison with classical FM). When $D = \emptyset$ (no punctures), the bordered FM compactification reduces to the classical FM compactification: $\overline{C}_{k,\vec{0}}^{\text{oc}}(X, \emptyset, -) = \overline{C}_k(X)$. Only Type I and Type IV faces are present. The Type II and Type III faces are *new* in the bordered setting and encode the open-string sector. When the curve is fixed (no moduli variation), Type IV faces are absent and the boundary has three types, matching the Swiss-cheese operad structure of Voronov [391].

5.4 MODULAR MAURER–CARTAN EQUATION WITH CLUTCHING

The bordered FM compactification of §5.3 carries, via the Stokes theorem on its boundary, the *modular Maurer–Cartan equation with clutching*: the master equation $d\Theta + \frac{1}{2}[\Theta, \Theta] + \hbar\Delta_{\text{clutch}}(\Theta) = 0$ governing the genus expansion of chiral correlators on punctured stable curves. The modular open-closed convolution algebra carries the equation; the MC element $\Theta_{\mathcal{A}}$ and the equation itself follow from Stokes’ theorem on the four-type boundary of $\overline{C}_{k,\vec{m}}^{\text{oc}}$.

5.4.1 THE MODULAR OPEN-CLOSED CONVOLUTION ALGEBRA

Definition 5.4.1 (Open-closed modular convolution algebra). Let $\mathcal{A}$ be a cyclic chiral algebra on a smooth projective curve X , with $\mathcal{A}$ -modules $\mathcal{M}_1, \dots, \mathcal{M}_r$ supported at punctures $D = p_1 + \dots + p_r$, and let (X, D, τ) be a tangential log curve. The *open-closed modular convolution algebra* is

$$\mathfrak{g}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}} := \prod_{\substack{g, k, \vec{m} \\ 2g-2+k+|\vec{m}|>0}} \text{Hom}(C_*(\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)), \text{End}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}}(k, \vec{m})),$$

where the endomorphism module is

$$\text{End}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}}(k, \vec{m}) := \text{Hom}(\mathcal{A}^{\otimes k} \otimes \bigotimes_{j=1}^r \mathcal{M}_j^{\otimes m_j}, \mathcal{A} \otimes \bigotimes_{j=1}^r \mathcal{M}_j),$$

equipped with the internal differential from $\mathcal{A}$ and the $\mathcal{M}_j$. The completed product is taken with respect to the *genus–degree weight* $w(g, k, \vec{m}) = 2g - 2 + k + |\vec{m}|$ and the genus grading $\hbar^g$.

THEOREM 5.4.2 (*dg Lie structure on the open-closed convolution algebra; .*). The open-closed convolution algebra $\mathfrak{g}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}}$ carries a dg Lie structure with:

Differential. The differential D^{oc} has *seven* components, extending the five-component differential of Theorem 13.22.3:

$$D^{\text{oc}} = \underbrace{d_{\text{int}} + [\tau, -] + d_{\text{sew}} + d_{\text{pf}} + \hbar\Delta}_{\text{closed sector}} + \underbrace{d_{\text{bdy}} + d_{\text{mix}}}_{\text{open sector}}. \quad (5.5)$$

The five closed-sector components are exactly those of equation (13.62); the two new open-sector components are:

- (a) d_{bdy} : the *boundary differential*, transporting the boundary ∂ on the associahedral factor $\prod_j K_{m_j}$ through the Hom functor. Geometrically, this sums over Type II faces, extracting the A_∞ -composition on each boundary module $\mathcal{M}_j$:

$$d_{\text{bdy}}(\alpha)_{g,k,\vec{m}} = \sum_{j=1}^r \sum_{\substack{B \subseteq \{1, \dots, m_j\} \\ B \text{ consecutive, } |B| \geq 2}} \alpha_{g,k,\vec{m}'} \circ_{B,j} \mu_{|B|}^{\mathcal{M}_j},$$

where $\mu_{|B|}^{\mathcal{M}_j}$ is the $|B|$ -ary multiplication on $\mathcal{M}_j$ (the A_∞ -structure map), composed at the location of block B on boundary j .

- (b) d_{mix} : the *mixed differential*, transporting the boundary ∂ on the mixed bubbling faces through the Hom functor. Geometrically, this sums over Type III faces:

$$d_{\text{mix}}(\alpha)_{g,k,\vec{m}} = \sum_{i=1}^k \sum_{j=1}^r \sum_{\substack{B \subseteq \{1, \dots, m_j\} \\ B \text{ consecutive}}} \alpha_{g,k-1,\vec{m}'} \circ_{i,B,j} \rho_j^B,$$

where $\rho_j^B: \mathcal{A} \otimes \mathcal{M}_j^{\otimes |B|} \rightarrow \mathcal{M}_j$ is the open-closed intertwining map, composed at interior slot i and boundary block B on boundary j .

Lie bracket. The bracket $[-, -]^{\text{oc}}$ extends the convolution bracket of Construction 13.22.4 by allowing both interior and boundary legs to be composed via the invariant pairing. Explicitly, for $\alpha \in \mathfrak{g}^{\text{oc}}(g_1, k_1, \vec{m}_1)$ and $\beta \in \mathfrak{g}^{\text{oc}}(g_2, k_2, \vec{m}_2)$:

$$[\alpha, \beta]^{\text{oc}} = \sum_{i \leq k_1, j \leq k_2} (\alpha \circ_{i,j}^{\text{int}} \beta - (-1)^{|\alpha||\beta|} \beta \circ_{j,i}^{\text{int}} \alpha), \quad (5.6)$$

where $\circ_{i,j}^{\text{int}}$ is the single-edge composition that joins the i -th interior leg of α to the j -th interior leg of β by contracting with the bulk pairing $\langle -, - \rangle_{\mathcal{A}}$ and pushing forward along the separating clutching map. The boundary legs are *spectators* in the bracket: they are carried through unchanged.

Square-zero. $(D^{\text{oc}})^2 = 0$.

Proof. The seven-component differential D^{oc} is the transport of the total boundary operator ∂ on $C_*(\bar{C}_{k,\vec{m}}^{\text{oc}})$ through the Hom functor, together with the internal differentials. Since $\partial^2 = 0$ on the chain complex of a manifold with corners (by the same boundary-of-boundary cancellation as in Theorem 13.22.412), and the internal differentials satisfy $d_{\text{int}}^2 = 0$, the total differential satisfies $(D^{\text{oc}})^2 = 0$.

The component matching between D^{oc} and the four boundary types is:

Boundary type	Differential component	Algebraic operation
Type I (interior collision)	$d_{\text{pf}} + [\tau, -]$	Bulk OPE / tree-level composition
Type II (boundary collision)	d_{bdy}	A_∞ -multiplication on $\mathcal{M}_j$
Type III (mixed bubbling)	d_{mix}	Bulk-to-boundary OPE
Type IV(a) (separating node)	d_{sew}	Separating clutching
Type IV(b) (non-separating node)	$\hbar\Delta$	BV operator / trace
Internal	d_{int}	Algebra & module differentials

The identity $(D^{\text{oc}})^2 = 0$ expanded into cross-terms gives, in addition to the closed-sector identities of Theorem 13.22.413, the new open-sector relations:

$$d_{\text{bdy}}^2 = 0 \quad (A_\infty \text{ relations on } \mathcal{M}_j), \quad (5.7)$$

$$d_{\text{mix}}^2 = 0 \quad (\text{iterated bulk-to-boundary is consistent}), \quad (5.8)$$

$$[d_{\text{bdy}}, d_{\text{mix}}] = 0 \quad (\text{boundary composition commutes with mixed bubbling}), (5.9)$$

$$[d_{\text{bdy}}, d_{\text{sew}}] + [d_{\text{mix}}, d_{\text{pf}}] = 0 \quad (\text{open-closed codimension-2 face cancellation}). \quad (5.10)$$

Each identity follows from the boundary-of-boundary vanishing $\partial^2 = 0$ on the corresponding codimension-2 stratum of $\overline{\mathcal{C}}_{k,\vec{m}}^{\text{oc}}$: (5.7) from the codimension-2 associahedral faces (nested consecutive blocks); (5.8) from two interior points independently approaching the same boundary; (5.9) from a boundary collision simultaneous with a mixed bubble; (5.10) from a boundary collision simultaneous with a nodal degeneration.

We verify (5.9) explicitly. Consider a codimension-2 stratum S where an interior point z_i approaches puncture p_j (mixed) while simultaneously two boundary points t_a, t_{a+1} on interval I_j collide (boundary). The stratum S is an intersection $S = D_{\text{mix}} \cap D_{\text{bdy}}$, where $D_{\text{mix}} = \{\rho_{i,j} = 0\}$ and $D_{\text{bdy}} = \{\delta_{\{a,a+1\}} = 0\}$. By the normal-crossings property (Theorem 5.3.8(iii)), these are transverse: $\rho_{i,j}$ is a distance in the interior-to-boundary direction and $\delta_{\{a,a+1\}}$ is a distance along the boundary interval, so $d\rho_{i,j} \wedge d\delta_{\{a,a+1\}} \neq 0$. The stratum S appears as a face of both D_{mix} (where ∂D_{mix} includes the sub-stratum with a simultaneous boundary collision) and D_{bdy} (where ∂D_{bdy} includes the sub-stratum with a simultaneous mixed bubble). The $\partial^2 = 0$ identity applied to the cell dual to S gives $d_{\text{bdy}} \circ d_{\text{mix}} + d_{\text{mix}} \circ d_{\text{bdy}} = 0$, which is (5.9).

The bracket $[-, -]^{\text{oc}}$ satisfies the Jacobi identity by the same pre-Lie argument as Remark 13.22.5: the single-edge composition $\circ_{i,j}^{\text{int}}$ is pre-Lie, and antisymmetrization of a pre-Lie product is Lie. $\square$

5.4.2 THE MODULAR MC ELEMENT WITH CLUTCHING

Definition 5.4.3 (Modular twisting morphism). Let $\mathcal{A}$ be a modular Koszul chiral algebra on (X, D, τ) with the genus-completed bar differential $D_{\mathcal{A}} = \sum_{g \geq 0} \hbar^g d_{\mathcal{A}}^{(g)}$ of Theorem 8.2.12. The *modular twisting morphism* is

$$\Theta_{\mathcal{A}} := D_{\mathcal{A}}^{\text{oc}} - d_0 = \sum_{g \geq 1} \hbar^g d_{\mathcal{A}}^{(g)} + d_{\text{bdy}}^{(0)} + d_{\text{mix}}^{(0)} \in \mathfrak{g}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}},$$

where $D_{\mathcal{A}}^{\text{oc}}$ is the genus-completed open-closed bar differential (the coderivation encoding the full FCom^{oc} -algebra structure on the open-closed bar complex), d_0 is the genus-0 closed-sector bar differential (the Arnold-relation part), and the three summands separate the positive-genus closed corrections from the genus-0 boundary and mixed terms.

More precisely, $\Theta_{\mathcal{A}}$ is the element of $\mathfrak{g}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}}$ whose $(g, k, \vec{m})$ -component is the composition

$$\Theta_{\mathcal{A}}^{(g, k, \vec{m})} = \int_{\overline{C}_{k, \vec{m}}^{\text{oc}}} \omega_{k, \vec{m}}^{(g)}(\mathcal{A}, \vec{\mathcal{M}}),$$

where $\omega_{k, \vec{m}}^{(g)}$ is the chiral amplitude form: the logarithmic top-form on $\overline{C}_{k, \vec{m}}^{\text{oc}}$ with coefficients in $\text{End}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}}$, built from the propagator $\eta_{ij}^{(g)}$ (for interior pairs), the boundary propagator $\eta_{i, t_a^{(j)}}^{(g)}$ (for interior-boundary pairs), and the boundary-boundary propagator $\eta_{a, b}^{\text{bdy}}$ (for consecutive boundary pairs on the same interval).

THEOREM 5.4.4 (*Modular MC equation with clutching*). The modular twisting morphism $\Theta_{\mathcal{A}}$ of Definition 5.4.3 satisfies the *modular Maurer–Cartan equation with clutching*:

$$\boxed{d \Theta_{\mathcal{A}} + \frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}} + \hbar \Delta_{\text{clutch}}(\Theta_{\mathcal{A}}) = 0} \quad (5.11)$$

where:

- (i) $d \Theta_{\mathcal{A}} := (d_{\text{int}} + d_{\text{bdy}} + d_{\text{mix}}) \Theta_{\mathcal{A}}$ is the full open-closed chain differential applied to $\Theta_{\mathcal{A}}$, where $d_{\text{int}} \Theta_{\mathcal{A}} = [d_0, \Theta_{\mathcal{A}}]$ is the interior (genus-0 collision) component, d_{bdy} is the boundary associahedral component, and d_{mix} is the mixed (bulk-to-boundary) component;
- (ii) $[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}}$ is the bracket in the open-closed convolution Lie algebra (Theorem 5.4.2, equation (5.6));
- (iii) $\Delta_{\text{clutch}}(\Theta_{\mathcal{A}})$ is the non-separating clutching operator applied to $\Theta_{\mathcal{A}}$:

$$\Delta_{\text{clutch}}(\Theta_{\mathcal{A}})_{g, k, \vec{m}} := \sum_a \Theta_{\mathcal{A}}^{(g-1, k+2, \vec{m})}(\underbrace{x_1, \dots, x_k}_{\text{original}}, e_a, e^a; \vec{t}),$$

where $\{e_a\}, \{e^a\}$ are dual bases for the invariant pairing $\langle -, - \rangle_{\mathcal{A}}$, inserted in the $(k+1)$ -st and $(k+2)$ -nd interior slots and summed over the basis index a . This contracts the two additional interior legs of the $(g-1, k+2, \vec{m})$ -component by the pairing, producing a $(g, k, \vec{m})$ -component with genus increased by 1.

Proof. The proof is a Stokes-theorem argument on the bordered FM compactification, following the same logic as Theorem 13.21.69 but with the four-type boundary decomposition of Proposition 5.3.10 in place of the boundary of $\overline{\mathcal{M}}_{g, n}$.

SETUP. Consider a generic one-parameter family in the bordered FM compactification: a smooth chain $\sigma \in C_{2k+|\vec{m}|}(\overline{C}_{k, \vec{m}}^{\text{oc}})$. The chiral amplitude form $\omega_{k, \vec{m}}^{(g)}(\mathcal{A}, \vec{\mathcal{M}})$ of Definition 5.4.3 is a logarithmic top-form on $\overline{C}_{k, \vec{m}}^{\text{oc}}$ with values in $\text{End}_{\mathcal{A}, \vec{\mathcal{M}}}^{\text{oc}}$. The amplitude form $\omega_{k, \vec{m}}^{(g)}$ is *logarithmic*: its singularities along the boundary divisors $D_I \subset \overline{C}_{k, \vec{m}}^{\text{oc}}$ are of the form $f \cdot d \log(\epsilon_{I_1}) \wedge \dots \wedge d \log(\epsilon_{I_p})$ with f smooth, hence L^1 -integrable (the $d \log$ singularities are integrable in one real dimension). The normal-crossings property (Theorem 5.3.8(iii)) ensures that the boundary divisors meet transversally, so the multi-logarithmic forms at corners remain integrable. Stokes' theorem for manifolds with corners (see [186], Appendix B for the classical FM case) then gives

$$\int_{\sigma} d\omega_{k, \vec{m}}^{(g)} = \int_{\partial \sigma} \omega_{k, \vec{m}}^{(g)} = \sum_{F \in \mathcal{F}(\partial \sigma)} \int_F \omega_{k, \vec{m}}^{(g)},$$

where $\mathcal{F}(\partial\sigma)$ is the set of codimension-one faces of $\partial\sigma$. By Proposition 5.3.10, these faces decompose into four types, and each type contributes a specific term to the MC equation.

TYPE I CONTRIBUTION: CHAIN DIFFERENTIAL $d\Theta_{\mathcal{A}}$.

The integral over Type I faces produces the collision residues of the genus-0 bar differential:

$$\sum_S \int_{\partial_S^I \sigma} \omega_{k,\vec{m}}^{(g)} = [d_0, \Theta_{\mathcal{A}}^{(g)}]_{k,\vec{m}} = (d\Theta_{\mathcal{A}})^{(g)}_{k,\vec{m}}.$$

This uses the factorization (5.4): the screen factor $\bar{C}_{|S|}(\mathbf{A}^1)$ computes the OPE collision μ_S , and the complementary factor $\bar{C}_{k-|S|+1,\vec{m}}^{\text{oc}}$ carries the remaining amplitude, giving the commutator $[d_0, \Theta_{\mathcal{A}}]$ (the bar differential applied to $\Theta_{\mathcal{A}}$).

TYPE II + TYPE III CONTRIBUTION: BOUNDARY AND MIXED DIFFERENTIALS IN $d\Theta_{\mathcal{A}}$.

The Type II and Type III faces contribute the *boundary* and *mixed* components of the open-closed differential d . These are *not* part of the Lie bracket $[-, -]^{\text{oc}}$: the bracket only composes interior legs via separating nodal degenerations (Type IV(a)), whereas Types II and III involve boundary-leg operations.

Type II faces (consecutive boundary collisions): the associahedral fiber $K_{|B|}$ produces the A_{∞} -composition on the boundary module. This is the boundary differential d_{bdy} acting on $\Theta_{\mathcal{A}}$:

$$\sum_{B,j} \int_{\partial_{B,j}^{\text{II}} \sigma} \omega^{(g)} = (d_{\text{bdy}} \Theta_{\mathcal{A}})^{(g)}_{k,\vec{m}}.$$

Type III faces (mixed bubbling): the Swiss-cheese fiber $\text{SC}_{1,|B|}$ produces the bulk-to-boundary intertwining. This is the mixed differential d_{mix} acting on $\Theta_{\mathcal{A}}$:

$$\sum_{i,B,j} \int_{\partial_{i,B,j}^{\text{III}} \sigma} \omega^{(g)} = (d_{\text{mix}} \Theta_{\mathcal{A}})^{(g)}_{k,\vec{m}}.$$

Together with the Type I contribution ($d_{\text{int}} \Theta_{\mathcal{A}}$), the three face types produce the *full* open-closed differential $d = d_{\text{int}} + d_{\text{bdy}} + d_{\text{mix}}$ acting on $\Theta_{\mathcal{A}}$. The Lie bracket $[-, -]^{\text{oc}}$ sums only over *separating nodal degenerations* (Type IV(a)), not over boundary or mixed collisions.

TYPE IV CONTRIBUTION: BRACKET $\frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}}$ AND CLUTCHING $\hbar \Delta_{\text{clutch}}(\Theta_{\mathcal{A}})$.

The Type IV faces produce the nodal-degeneration terms and split into two geometrically distinct classes. The *separating* nodal faces Type IV(a) are the *sole* source of the bracket $\frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}}$: each separating node joins two distinct components, composing two operations via the interior pairing. The *non-separating* clutching faces Type IV(b) contribute the genuinely new term $\hbar \Delta_{\text{clutch}}(\Theta_{\mathcal{A}})$. (Note: the Type IV faces arise from the genus-graded modular structure of the bar differential: they record nodal degenerations of the underlying curve, not collisions of marked points on a fixed curve. The fixed-curve Stokes argument on $\bar{C}_{k,\vec{m}}^{\text{oc}}$ produces Types I–III; the Type IV contribution enters through the moduli variation encoded in the genus summation $\sum_g \hbar^g$ and the modular operad algebra structure of the bar complex (Theorem 8.2.12).

Precise accounting. The factor of $\frac{1}{2}$ arises because each separating nodal degeneration (Type IV(a)) is counted twice (once for each orientation of the separating edge): the $(g_1, k_1, \vec{m}_1) \circ (g_2, k_2, \vec{m}_2)$ composition with $g_1 + g_2 = g$ appears both as “left $\circ$ right” and “right $\circ$ left,” and the Lie bracket $[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]$ accounts for both with the antisymmetry producing the factor of 2 that cancels the $\frac{1}{2}$.

Separation of clutching from bracket. The distinction is structural. In Getzler–Kapranov’s formalism [199, §5], the *modular operad bracket* $[[-, -]]^{\text{mod}}$ sums over *all* stable-graph compositions, including

both separating and non-separating gluings. However, the *Lie bracket* $[-, -]^{\text{oc}}$ of Theorem 5.4.2 only sums over *separating* compositions (those that join two distinct elements of the convolution algebra). The non-separating compositions (those that contract two legs of a *single* element) form a separate operation, the *BV operator* Δ .

Explicitly, the modular operad differential decomposes as:

$$D_{\text{GK}} = d_{\text{int}} + [\tau, -] + \underbrace{\sum_{\text{sep. edges}} \circ_e}_{= \text{Lie bracket part}} + \underbrace{\sum_{\text{non-sep. edges}} \Delta_e}_{= \hbar \Delta}. \quad (5.12)$$

A separating edge e in a stable graph Γ disconnects Γ into two components upon removal; the corresponding composition $\circ_e$ joins two operations (one from each component) and is captured by the Lie bracket $[-, -]^{\text{oc}}$. A non-separating edge e leaves Γ connected upon removal; the corresponding operation Δ_e traces two inputs of a *single* operation against the pairing $\langle -, - \rangle_{\mathcal{A}}$ and is the BV operator $\hbar \Delta$.

In the Maurer–Cartan equation, this separation produces:

- The differential $d \Theta_{\mathcal{A}}$ from all collision faces (Types I + II + III), where $d = d_{\text{int}} + d_{\text{bdy}} + d_{\text{mix}}$ is the full open-closed differential;
- The bracket $\frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}}$ from all separating nodal degenerations (Type IV(a));
- The BV term $\hbar \Delta_{\text{clutch}}(\Theta_{\mathcal{A}})$ from all non-separating nodal degenerations (Type IV(b)).

The non-separating clutching increases genus by 1 ($g \mapsto g + 1$) and decreases degree by 2 ($n \mapsto n - 2$), which is why it is weighted by $\hbar$ (the genus-tracking parameter).

ASSEMBLY. Summing the contributions from all four boundary types:

$$\begin{aligned} 0 &= \int_{\partial \sigma} \omega^{(g)} \\ &= \underbrace{\text{Type I} + \text{Type II} + \text{Type III}}_{d \Theta_{\mathcal{A}}} + \underbrace{\text{Type IV(a)}}_{\frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}}} + \underbrace{\text{Type IV(b)}}_{\hbar \Delta_{\text{clutch}}(\Theta_{\mathcal{A}})}. \end{aligned}$$

Since this holds for every smooth chain σ (by the Stokes theorem on the manifold with corners $\overline{C}_{k, \vec{m}}^{\text{oc}}$, applied using the normal-crossings property of Theorem 5.3.8(iii)), we obtain the MC equation (5.11):

$$d \Theta_{\mathcal{A}} + \frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}]^{\text{oc}} + \hbar \Delta_{\text{clutch}}(\Theta_{\mathcal{A}}) = 0.$$

Consistency check. Restricting to the closed sector ($\vec{m} = \vec{0}$, no boundary modules) recovers the bar-intrinsic MC equation of Theorem 13.21.69: the Type II and Type III faces are absent, the bracket reduces to the interior convolution bracket, and Δ_{clutch} reduces to the non-separating BV operator $\hbar \Delta$ of equation (13.62). The open-sector terms (d_{bdy} and d_{mix}) only contribute when boundary modules are present. $\square$

Remark 5.4.5 (The QME versus the MC equation). The modular MC equation (5.11) is equivalent to the *quantum master equation* (QME) in the BV formalism. Writing $S = \Theta_{\mathcal{A}}$ as the “action functional,” the QME reads $\hbar \Delta(S) + \frac{1}{2} \{S, S\} = 0$, where $\{-, -\}$ is the BV antibracket. The identification is:

- $\{S, S\} = 2(d\Theta + \frac{1}{2}[\Theta, \Theta])$: the BV antibracket combines the chain differential and the convolution bracket.
- $\hbar\Delta(S) = \hbar\Delta_{\text{clutch}}(\Theta)$: the BV operator is the non-separating clutching.

The factor of $\frac{1}{2}$ in (5.11) is the QME factor (cf. Appendix G, equation (G.4): the QME has $\hbar\Delta S + \frac{1}{2}\{S, S\} = 0$, not $\hbar\Delta S + \{S, S\} = 0$).

Remark 5.4.6 (Genus expansion of the MC equation). Expanding (5.11) in powers of $\hbar$, with $\Theta_{\mathcal{A}} = \sum_{g \geq 0} \hbar^g \Theta^{(g)}$ (where $\Theta^{(0)}$ includes the genus-0 boundary and mixed terms):

- (1) *Genus 0*: $d\Theta^{(0)} + \frac{1}{2}[\Theta^{(0)}, \Theta^{(0)}] = 0$. This is the classical MC equation for the A_∞ -structure on the boundary module (no $\hbar$ -corrections).
- (2) *Genus 1*: $d\Theta^{(1)} + [\Theta^{(0)}, \Theta^{(1)}] + \Delta_{\text{clutch}}(\Theta^{(0)}) = 0$. The curvature $\kappa(\mathcal{A}) \cdot \omega_1$ appears through $\Theta^{(1)}$, and the non-separating clutching of the genus-0 data gives the one-loop obstruction.
- (3) *Genus $g \geq 2$* : $d\Theta^{(g)} + \frac{1}{2}\sum_{g_1+g_2=g} [\Theta^{(g_1)}, \Theta^{(g_2)}] + \Delta_{\text{clutch}}(\Theta^{(g-1)}) = 0$. Each higher genus is determined inductively from lower genera, with the clutching term acting as a “genus-raising” obstruction.

COROLLARY 5.4.7 (*Recovery of the bar-intrinsic MC element*;). In the closed sector (no boundary modules: $\vec{m} = \vec{0}, r = 0$), the modular MC equation with clutching (5.11) reduces to

$$[d_0, \Theta_{\mathcal{A}}] + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] + \hbar\Delta(\Theta_{\mathcal{A}}) = 0, \quad (5.13)$$

which is precisely the MC equation of Theorem 13.21.69, expressed in the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ (Definition 13.22.1). The equivalence $(D_{\mathcal{A}} - d_0)^2 = 0 \iff [d_0, \Theta] + \frac{1}{2}[\Theta, \Theta] = 0$ of Theorem 13.21.69 is the closed-sector specialization: the $\hbar\Delta$ term is already contained in $D_{\mathcal{A}}$ via the modular operad differential (5.12), and the expansion $0 = (D_{\mathcal{A}})^2 = (d_0 + \Theta_{\mathcal{A}} + \hbar\Delta)^2$ reproduces (5.13) upon collecting terms.

Proof. When $r = 0$, the boundary intervals I_{p_j} , the boundary differentials d_{bdy} and d_{mix} , and all Type II and Type III faces are absent. The bordered FM compactification reduces to $\overline{C}_k(X)$ (over a fixed curve) or to $\overline{\mathcal{M}}_{g,k}$ (over moduli). The open-closed bracket $[-, -]^{\text{oc}}$ reduces to the interior convolution bracket $[-, -]$ of Construction 13.22.4, and Δ_{clutch} reduces to the non-separating BV operator $\hbar\Delta$ of Theorem 13.22.3(i). Equation (5.11) then becomes

$$[d_0, \Theta_{\mathcal{A}}] + \frac{1}{2}[\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] + \hbar\Delta(\Theta_{\mathcal{A}}) = 0,$$

which is the expansion of $D_{\mathcal{A}}^2 = 0$ with $D_{\mathcal{A}} = d_0 + \Theta_{\mathcal{A}}$ as in the proof of Theorem 13.21.69(i). (The $\hbar\Delta$ term appears explicitly because we have separated the non-separating clutching from the rest of $D_{\mathcal{A}}$; in the bar-intrinsic formulation, it is absorbed into the genus-completed differential.) $\square$

5.5 PERIOD COORDINATES AT HIGHER GENUS

At genus g , we have additional coordinates from:

- Period matrix $\Omega \in \mathcal{H}_g$ (Siegel upper half-space)

- Marking of homology basis $\{a_i, b_i\}_{i=1}^g$
- Choice of spin structure (quadratic refinement)

These appear in correlation functions through:

$$\langle \prod_i \phi_i(z_i) \rangle_g = \sum_{\text{spin}} \int_{\mathcal{F}_g} d\mu(\Omega) F(\Omega, z_i, \phi_i)$$

where $\mathcal{F}_g$ is a fundamental domain for $\text{Sp}(2g, \mathbb{Z})$.

5.6 THE GENUS-STRATIFIED BAR CONSTRUCTION

The total bar complex becomes:

$$\overline{B}(\mathcal{A}) = \bigoplus_{g=0}^{\infty} \bigoplus_{n=0}^{\infty} \overline{B}^{(g),n}(\mathcal{A})$$

with differential respecting the genus stratification (Definition 6.1.15):

$$d: \overline{B}^{(g),n} \rightarrow \overline{B}^{(g),n-1} \oplus \overline{B}^{(g-1),n+2} \oplus \bigoplus_{\substack{g_1+g_2=g \\ n_1+n_2=n}} \overline{B}^{(g_1),n_1+1} \otimes \overline{B}^{(g_2),n_2+1}$$

The three components correspond to:

- *Collision* (genus-preserving): merging two insertions at a smooth point
- *Non-separating node*: $\Sigma_g \rightarrow \Sigma_{g-1}$ with two new marked points (pinching a non-separating cycle)
- *Separating node*: $\Sigma_g \rightarrow \Sigma_{g_1} \cup \Sigma_{g_2}$, $g_1 + g_2 = g$ (pinching a separating cycle)

PROPOSITION 5.6.1 (*Fundamental group across genera [25, 70];*). The fundamental group $\pi_1(C_n(\Sigma_g))$ varies with genus: the low-genus structure is summarized as follows.

- *Genus 0*: pure braid group P_n on n strands.
- *Genus 1*: an extension of P_n by an elliptic braid group with modular data.
- *Genus $g \geq 2$* : an extension by a surface braid group with mapping class group action.

For genus 0 ($X = \mathbb{C}$), this is the kernel of $B_n \rightarrow S_n$ where B_n is the Artin braid group with generators σ_i ($i = 1, \dots, n-1$) and relations:

$$\begin{aligned} \sigma_i \sigma_j &= \sigma_j \sigma_i \quad \text{if } |i-j| > 1 \\ \sigma_i \sigma_{i+1} \sigma_i &= \sigma_{i+1} \sigma_i \sigma_{i+1} \quad (\text{braid relations}) \end{aligned}$$

Example 5.6.2 (Configuration spaces across genera). *Genus 0* ($\mathbb{P}^1$): We compute $\overline{M}_{0,4}$ explicitly (the Deligne–Mumford compactification of the moduli space of 4 distinct points on $\mathbb{P}^1$, which governs the genus-0 bar complex at degree 1):

1. Fix three points using $\mathrm{PSL}_2(\mathbb{C})$: $(z_1, z_2, z_3) = (0, 1, \infty)$. The fourth point $z_4 = \lambda \in \mathbb{C} \setminus \{0, 1\}$ is the remaining modular parameter.
2. The compactification $\overline{M}_{0,4}$ adds three boundary divisors:
 - $D_{14|23}$: $\lambda \rightarrow 0$ (collision $z_4 \rightarrow z_1$)
 - $D_{24|13}$: $\lambda \rightarrow 1$ (collision $z_4 \rightarrow z_2$)
 - $D_{34|12}$: $\lambda \rightarrow \infty$ (collision $z_4 \rightarrow z_3$)
3. Result: $\overline{M}_{0,4} \cong \mathbb{P}^1$ with three marked points $\{0, 1, \infty\}$. These three boundary divisors encode the A_∞ relation $m_2(m_2(a, b), c) - m_2(a, m_2(b, c)) = 0$ (associativity).

Remark 5.6.3. The FM compactification $\overline{C}_n(\mathbb{P}^1)$ (without the PSL_2 quotient) is a higher-dimensional space: $\dim_{\mathbb{C}} C_n(\mathbb{P}^1) = n$, and $\dim_{\mathbb{C}} \overline{M}_{0,n+1} = n - 2$. The bar complex uses the automorphism-free configuration space $C_n(X)$ for curves X of genus $g \geq 1$, where $\mathrm{Aut}(X)$ is discrete.

Genus 1 (Torus). For $\Sigma_1 = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$:

1. The configuration space includes modular parameter $\tau \in \mathcal{H}$
2. Boundary divisors include collisions AND degenerating cycles
3. Additional coordinates from period integrals

Genus $g \geq 2$. For Σ_g :

1. Configuration space includes period matrix $\Omega \in \mathcal{H}_g$
2. Boundary stratification includes stable graphs
3. Spin structures and theta characteristics appear

The logarithmic forms at each genus:

- *Genus 0:* Standard forms $\eta_{ij} = d \log(z_i - z_j)$
- *Genus 1:* Elliptic forms $\eta_{ij}^{(1)} = d \log \vartheta_1(z_i - z_j | \tau)$ with modular parameter
- *Genus $g \geq 2$:* Prime forms $\eta_{ij}^{(g)} = d_z \log E(z_i, z_j)$ where E is the Fay–Schottky prime form (a $(-\frac{1}{2}, -\frac{1}{2})$ -differential with a unique simple zero at $z_i = z_j$)

Key relations (Arnold relations extended):

- *Genus 0 (Arnold relation):* $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$ as a 2-form identity on $C_3(\mathbb{C})$. (Note: the sum of 1-forms $\eta_{12} + \eta_{23} + \eta_{13} = d \log[(z_1 - z_2)(z_2 - z_3)(z_3 - z_1)]$ is exact but nonzero; this is a different identity.)
- *Genus 1:* Elliptic Arnold relations with modular corrections (the genus-1 case is formalized in Proposition 5.7.12; the higher-genus generalization remains to be established)
- *Genus $g \geq 2$:* Siegel modular corrections from period integrals

At genus 0, the Arnold relation between propagator forms is the precise identity that forces $d^2 = 0$ on the bar differential at degree 2: the composition of two residue operations is a wedge product of two propagators, and the Arnold sum vanishes. At genus $g \geq 1$ the elliptic and prime-form propagators satisfy modified Arnold relations (Proposition 5.7.12 for $g = 1$), and the extra terms are absorbed into the curvature class $\kappa(\mathcal{A}) \cdot \omega_g$.

Configuration spaces therefore encode local OPE data through the collision divisors and (at genus $g \geq 1$) global monodromy data through the period integrals on Σ_g . At genus 0 only the local data is present; at genus $g \geq 1$ both contribute.

THEOREM 5.6.4 (*FM compactification and associahedra* [382, 186];). For $n \geq 2$, the real Fulton–MacPherson moduli space $\overline{M}_{0,n+1}(\mathbb{R})$ is a cell complex whose face poset is isomorphic to the Stasheff associahedron K_{n-1} . The boundary strata of the FM operad $\{\overline{C}_n(\mathbb{R})\}$ (modulo translations and dilations) correspond bijectively to the faces of K_{n-1} , with codimension- k strata indexed by trees with k internal edges.

PROPOSITION 5.6.5 (*Properties of η_{ij}* ;). The forms η_{ij} satisfy:

1. Symmetry: $\eta_{ji} = \eta_{ij}$ (as differential forms, since $d \log(-1) = 0$)
2. Blow-up expansion: Near D_{ij} ,

$$\eta_{ij} = d \log \epsilon_{ij} + id\theta_{ij} + (\text{regular terms})$$

3. Residue: $\text{Res}_{D_{ij}} \eta_{ij} = 1$ (normalized by our convention)
4. Closure: $d\eta_{ij} = 0$ away from higher codimension strata

Proof. (1) is immediate from the definition. For (2), compute in blow-up coordinates:

$$x_i - x_j = \epsilon_{ij} e^{i\theta_{ij}}$$

Therefore $d \log(x_i - x_j) = d \log(\epsilon_{ij} e^{i\theta_{ij}}) = d \log \epsilon_{ij} + id\theta_{ij}$.

For (3), the residue extracts the coefficient of $d \log \epsilon_{ij}$, which is 1 by our computation.

For (4), since η_{ij} is locally d of a function away from other collision divisors, we have $d\eta_{ij} = d^2 \log(x_i - x_j) = 0$. $\square$

5.6.1 THE ORLIK–SOLOMON ALGEBRA

The logarithmic forms η_{ij} generate a differential graded algebra with the following properties:

The Arnold relations (Theorem 5.1.23) hold in the OS algebra.

THEOREM 5.6.6 (*Cohomology via Orlik–Solomon* [25, 338];). For $X = \mathbb{C}$, the cohomology of the open configuration space $C_n(\mathbb{C})$ is:

$$H^*(C_n(\mathbb{C})) \cong \text{OS}(A_{n-1})$$

where $\text{OS}(A_{n-1})$ is the Orlik–Solomon algebra of the braid arrangement A_{n-1} . The Poincaré polynomial is:

$$\sum_{k=0}^{n-1} \dim H^k(C_n(\mathbb{C})) \cdot t^k = \prod_{i=1}^{n-1} (1 + it)$$

Remark 5.6.7 (*Provenance and citation*). This theorem is imported and treated as . The cohomology identification with the Orlik–Solomon algebra and the corresponding Poincaré polynomial are classical results in configuration-space/arrangement theory; see [25, 338].

5.6.2 NO-BROKEN-CIRCUIT BASES

For explicit computations, we need concrete bases for the cohomology:

Definition 5.6.8 (Broken circuit). Fix a total order on pairs (i, j) with $i < j$ (we use lexicographic order). A *broken circuit* is a set obtained by removing the minimal element from a circuit (minimal dependent set) in the graphical matroid on K_n .

Definition 5.6.9 (NBC basis). A *no-broken-circuit (NBC)* set is a collection of pairs that contains no broken circuit. These correspond bijectively to:

- Acyclic directed graphs on $[n]$ (forests)
- Independent sets in the graphical matroid
- Monomials in η_{ij} that do not vanish by Arnold relations

THEOREM 5.6.10 (NBC basis theorem [338];). The NBC sets provide a basis for $H^*(C_n(\mathbb{C}))$. More precisely, if F is an NBC forest with edges $E(F) = \{(i_1, j_1), \dots, (i_k, j_k)\}$, then:

$$\omega_F = \eta_{i_1 j_1} \wedge \dots \wedge \eta_{i_k j_k}$$

forms a basis element of $H^k(C_n(\mathbb{C}))$ (the cohomology of the *open* configuration space, not the FM compactification).

Remark 5.6.11 (Provenance and citation). This theorem is imported and treated as . The NBC basis theorem for the Orlik–Solomon algebra is standard in the arrangement literature; see [338].

Example 5.6.12 (NBC basis for $n = 4$). For $C_4(\mathbb{C})$, using the lexicographic order on pairs, the NBC basis consists of:

- Degree 0: 1
- Degree 1: $\eta_{12}, \eta_{13}, \eta_{14}, \eta_{23}, \eta_{24}, \eta_{34}$ (6 elements)
- Degree 2: $\eta_{12} \wedge \eta_{34}, \eta_{13} \wedge \eta_{24}, \eta_{14} \wedge \eta_{23}$, plus 8 other terms (11 total)
- Degree 3: $\eta_{12} \wedge \eta_{23} \wedge \eta_{34}$ and 5 other spanning trees (6 total)

Total: $1 + 6 + 11 + 6 = 24 = 4!$ basis elements, confirming $\dim H^*(C_4(\mathbb{C})) = 4!$.

The operadic framework, configuration spaces, and logarithmic forms developed above form the ingredients for the geometric bar complex constructed in Chapter 6.

5.7 CONFIGURATION SPACES, FACTORIZATION AND HIGHER GENUS

5.7.1 THE RAN SPACE AND CHIRAL OPERATIONS

Definition 5.7.1 (D-module category). We work with the category $\mathrm{D}\text{-mod}_{rh}(X)$ of regular holonomic D-modules on X . These are D-modules $\mathcal{M}$ satisfying:

1. Finite presentation: locally finitely generated over $\mathcal{D}_X$
2. Regular singularities: characteristic variety is Lagrangian

3. Holonomicity: $\dim(\text{Char}(\mathcal{M})) = \dim(X)$

This category has:

- Six functors: $f^*, f_*, f^!, f_!, \otimes^L, \mathcal{RH}!$
- Riemann–Hilbert correspondence with perverse sheaves
- Well-defined maximal extension j_*j^* for $j : U \hookrightarrow X$ open

Definition 5.7.2 (Ran space via categorical colimit). Let X be a smooth algebraic curve over $\mathbb{C}$. The *Ran space* of X is the ind-scheme defined as the colimit:

$$\text{Ran}(X) = \text{colim}_{I \in \text{FinSet}^{\text{surj,op}}} X^I$$

where:

- $\text{FinSet}^{\text{surj}}$ is the category of finite sets with surjections as morphisms
- For a surjection $\phi : I \twoheadrightarrow J$, the induced map $X^J \rightarrow X^I$ is the diagonal embedding on fibers $\phi^{-1}(j)$
- The colimit is taken in the category of ind-schemes with the Zariski topology

Explicitly, a point in $\text{Ran}(X)$ is a non-empty finite subset $S \subset X$ (without multiplicities: the colimit over surjections identifies $\{x, x\}$ with $\{x\}$). This is distinct from the space of effective 0-cycles $\text{Sym}^+(X) = \coprod_n \text{Sym}^n(X)$, which records multiplicities.

Remark 5.7.3 (Set-theoretic description). The underlying set of $\text{Ran}(X)$ is the set of all non-empty finite subsets of X (without multiplicities, by the identification convention in the colimit). This is distinct from the free commutative monoid on X , which records multiplicities. The ind-scheme structure on $\text{Ran}(X)$ encodes the deformation theory of point configurations.

The Ran space carries a fundamental monoidal structure encoding disjoint union:

Definition 5.7.4 (Factorization structure). *Critical Warning.* The naive definition

$$\mathcal{M} \otimes^{\text{ch}} \mathcal{N} = \Delta_! \left(\rho_1^* \mathcal{M} \otimes^! \rho_2^* \mathcal{N} \right)$$

FAILS because the union map $\Delta : \text{Ran}(X) \times \text{Ran}(X) \rightarrow \text{Ran}(X)$ is *not proper*, so $\Delta_!$ is undefined. The correct framework uses factorization algebras.

Definition 5.7.5 (Factorization algebra). A *factorization algebra* $\mathcal{F}$ on X consists of:

1. A quasi-coherent $\mathcal{D}$ -module $\mathcal{F}_S$ for each finite set $S \subset X$
2. For disjoint S_1, S_2 , a factorization isomorphism:

$$\mu_{S_1, S_2} : \mathcal{F}_{S_1} \boxtimes \mathcal{F}_{S_2} \xrightarrow{\sim} \mathcal{F}_{S_1 \sqcup S_2}$$

3. These satisfy:

- *Associativity:* For disjoint S_1, S_2, S_3 :

$$\begin{array}{ccc}
\mathcal{F}_{S_1} \boxtimes \mathcal{F}_{S_2} \boxtimes \mathcal{F}_{S_3} & \xrightarrow{\mu_{S_1, S_2} \boxtimes \text{id}} & \mathcal{F}_{S_1 \sqcup S_2} \boxtimes \mathcal{F}_{S_3} \\
\text{id} \boxtimes \mu_{S_2, S_3} \downarrow & & \downarrow \mu_{S_1 \sqcup S_2, S_3} \\
\mathcal{F}_{S_1} \boxtimes \mathcal{F}_{S_2 \sqcup S_3} & \xrightarrow{\mu_{S_1, S_2 \sqcup S_3}} & \mathcal{F}_{S_1 \sqcup S_2 \sqcup S_3}
\end{array}$$

- *Commutativity*: $\mu_{S_2, S_1} = \sigma_{S_1, S_2} \circ \mu_{S_1, S_2}$ where σ is the swap
- *Unit*: $\mathcal{F}_\emptyset = \mathbb{C}$ with canonical isomorphisms $\mathcal{F}_S \cong \mathbb{C} \boxtimes \mathcal{F}_S$

Remark 5.7.6 (Kontsevich's formulation). Factorization algebras encode locality: observables on disjoint regions combine independently, and the factorization isomorphisms express the commutativity of spacelike-separated observables (Kontsevich; Costello–Gwilliam [92]).

THEOREM 5.7.7 (*Chiral algebras as factorization algebras [40];*). Every chiral algebra $\mathcal{A}$ on X determines a factorization algebra $\mathcal{F}_{\mathcal{A}}$ where:

- $\mathcal{F}_{\mathcal{A}}(S) = \mathcal{A}^{\boxtimes S}$ for finite $S \subset X$
- The factorization structure comes from the chiral multiplication
- This defines a fully faithful functor $\text{ChirAlg}(X) \rightarrow \text{FactAlg}(X)$

Proof following Beilinson–Drinfeld. Chiral multiplication provides exactly the factorization isomorphisms needed. The Jacobi identity for chiral algebras translates to associativity of factorization. The technical issue with properness is avoided because we work fiberwise over finite sets rather than globally on Ran space. $\square$

THEOREM 5.7.8 (*Factorization monoidal structure [40, 92];*). The category $\text{FactAlg}(X)$ of factorization algebras (NOT all D-modules on Ran space) forms a symmetric monoidal category with:

1. Tensor product: $(\mathcal{F} \otimes_{\text{fact}} \mathcal{G})(S) = \bigoplus_{S_1 \sqcup S_2 = S} \mathcal{F}(S_1) \otimes \mathcal{G}(S_2)$
2. Unit: The vacuum factorization algebra $\mathbb{1}$ with $\mathbb{1}(S) = \begin{cases} \mathbb{C} & S = \emptyset \\ 0 & \text{otherwise} \end{cases}$
3. Associativity isomorphism satisfying the pentagon axiom
4. Braiding isomorphism induced by the symmetric group action

There is a fully faithful embedding:

$$\text{ChirAlg}(X) \hookrightarrow \text{FactAlg}(X)$$

sending a chiral algebra $\mathcal{A}$ to its associated factorization algebra $\mathcal{F}_{\mathcal{A}}$.

Proof. The tensor product is defined by Day convolution over the symmetric monoidal structure on finite sets under disjoint union. The pentagon and hexagon axioms for $\otimes_{\text{fact}}$ reduce to the corresponding axioms for disjoint union of finite sets, which are immediate. The unit axiom $\mathbb{1} \otimes_{\text{fact}} \mathcal{F} \simeq \mathcal{F}$ follows from $\mathbb{1}(\emptyset) = \mathbb{C}$.

For the embedding $\text{ChirAlg}(X) \hookrightarrow \text{FactAlg}(X)$: given a chiral algebra $\mathcal{A}$, define $\mathcal{F}_{\mathcal{A}}(S) = j_{S*} j_S^* \mathcal{A}^{\boxtimes S}$ for finite S , with factorization isomorphisms coming from the chiral product (Beilinson–Drinfeld [40], Theorem 3.4.9). Fully faithfulness follows because chiral algebras are determined by their factorization data on pairs of points (the chiral product μ). $\square$

Underlying D-modules. A collection $\{\mathcal{A}_n\}_{n \geq 0}$ where each $\mathcal{A}_n$ is a quasi-coherent $\mathcal{D}_{X^n}$ -module, meaning:

- $\mathcal{A}_n$ is a sheaf of modules over the sheaf of differential operators $\mathcal{D}_{X^n}$
- The action satisfies the Leibniz rule: $\partial(fs) = (\partial f)s + f(\partial s)$ for local functions f and sections s
- $\mathcal{A}_n$ is quasi-coherent as an $\mathcal{O}_{X^n}$ -module

5.7.2 ELLIPTIC CONFIGURATION SPACES AND THETA FUNCTIONS

5.7.2.1 The genus 1 realm: elliptic curves as quotients

For genus 1, we work with elliptic curves $E_\tau = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ where $\tau \in \mathfrak{h}$ lies in the upper half-plane:

Definition 5.7.9 (Elliptic configuration space). For an elliptic curve E_τ , the configuration space of n points is:

$$C_n(E_\tau) = \{(z_1, \dots, z_n) \in E_\tau^n \mid z_i \neq z_j \bmod \Lambda_\tau\}$$

where $\Lambda_\tau = \mathbb{Z} + \tau\mathbb{Z}$ is the period lattice.

THEOREM 5.7.10 (*Elliptic compactification [186, 159];*). The compactification $\overline{C_n(E_\tau)}$ is constructed via:

1. *Local blow-ups:* Near collision points, use elliptic blow-up coordinates
2. *Global structure:* The compactified space admits a stratification by *stable elliptic graphs*
3. *Modular invariance:* Under $SL_2(\mathbb{Z})$ action on τ , the construction is equivariant

Construction. Near a collision point $z_i \rightarrow z_j$ on E_τ , introduce elliptic blow-up coordinates:

$$\begin{aligned} \epsilon_{ij} &= |z_i - z_j|_{E_\tau} \quad (\text{elliptic distance}) \\ \theta_{ij} &= \arg(z_i - z_j) \quad (\text{angular parameter}) \\ u_{ij} &= \frac{z_i + z_j}{2} \quad (\text{center on } E_\tau) \end{aligned}$$

The key difference from genus 0: the elliptic distance involves the Weierstrass σ -function:

$$|z_i - z_j|_{E_\tau} = |\sigma(z_i - z_j; \tau)| e^{-\eta_1 \operatorname{Im}(z_i - z_j)^2 / \operatorname{Im}(\tau)}$$

where $\eta_1 = \zeta(\frac{1}{2}; \Lambda_\tau)$ is the quasi-period of the Weierstrass zeta function (not to be confused with the Dedekind eta function $\eta(\tau)$). $\square$

5.7.2.2 Theta functions as building blocks

The logarithmic forms on elliptic curves are replaced by forms built from theta functions:

Definition 5.7.11 (Elliptic logarithmic forms). On $\overline{C_n(E_\tau)}$, define the elliptic analogs of η_{ij} :

$$\eta_{ij}^{(1)} = d \log \theta_1\left(\frac{z_i - z_j}{2\pi i}; \tau\right) + \frac{\pi}{\operatorname{Im}(\tau)} d(\overline{z_i - z_j})$$

where $\theta_1(z|\tau) = -i \sum_{n \in \mathbb{Z}} (-1)^n q^{(n+1/2)^2/2} e^{i\pi(2n+1)z}$ with $q = e^{2\pi i \tau}$.

PROPOSITION 5.7.12 (*Elliptic Arnold relations [159];*). The elliptic logarithmic forms satisfy modified Arnold relations:

$$\eta_{ij}^{(1)} \wedge \eta_{jk}^{(1)} + \eta_{jk}^{(1)} \wedge \eta_{ki}^{(1)} + \eta_{ki}^{(1)} \wedge \eta_{ij}^{(1)} = 2\pi i \omega_\tau$$

where $\omega_\tau = \frac{dz \wedge d\bar{z}}{2i \operatorname{Im}(\tau)}$ is the normalized volume form on E_τ . Note that $\eta_{ij}^{(1)}$ is *not* holomorphic: the regularization term $\frac{\pi}{\operatorname{Im}(\tau)} d\bar{z}$ ensures double periodicity but introduces a $(0, 1)$ -component, so that the wedge product on the left-hand side can produce a $(1, 1)$ -form on the right.

The non-vanishing right-hand side encodes the central extension that appears at genus 1.

5.7.3 HIGHER GENUS CONFIGURATION SPACES

5.7.3.1 Hyperbolic surfaces and Teichmüller theory

For genus $g \geq 2$, the underlying curve Σ_g admits a hyperbolic metric. The configuration spaces carry additional geometric structure:

Definition 5.7.13 (*Higher genus configuration*). For a compact Riemann surface Σ_g of genus $g \geq 2$:

$$C_n(\Sigma_g) = \{(p_1, \dots, p_n) \in \Sigma_g^n \mid p_i \neq p_j \text{ for } i \neq j\}$$

The compactification $\overline{C}_n(\Sigma_g)$ involves:

- Stable curves with marked points
- Deligne–Mumford compactification techniques
- Intersection with the moduli space $\overline{\mathcal{M}}_{g,n}$

Remark 5.7.14 (*Period integrals and bar differential [40];*). On $\overline{C}_n(\Sigma_g)$, the bar differential decomposes:

$$d_{\text{bar}}^{(g)} = d_{\text{local}} + d_{\text{global}} + d_{\text{quantum}}$$

where:

1. d_{local} : Standard residues at collision divisors (genus 0 contribution)
2. d_{global} : Period integrals over homology cycles of Σ_g
3. d_{quantum} : Corrections from the moduli space $\mathcal{M}_g$

The decomposition follows from the Leray spectral sequence for the forgetful map $\pi: \overline{\mathcal{M}}_{g,n} \rightarrow \overline{\mathcal{M}}_g$, whose fiber over a smooth curve Σ_g is $\overline{C}_n(\Sigma_g)$. Each term contributes differently:

- Local: Fiberwise residues along collision divisors in $\overline{C}_n(\Sigma_g)$
- Global: Period integrals over the $2g$ cycles of $H_1(\Sigma_g, \mathbb{Z})$
- Quantum: Variation of the fiberwise data over $\overline{\mathcal{M}}_g$

5.7.4 CONVERGENCE OF CONFIGURATION SPACE INTEGRALS

Definition 5.7.15 (Convergent chiral algebra). A chiral algebra $\mathcal{A}$ is *convergent* if for all n and all $\phi_i \in \mathcal{A}$:

$$\int_{\overline{C}_n(X)} |\phi_1(z_1) \cdots \phi_n(z_n)|^2 \prod_{i < j} |z_i - z_j|^{2\alpha_{ij}} < \infty$$

for appropriate regularization exponents $\alpha_{ij} > 0$.

Conjecture 5.7.16 (Convergence criterion;). The bar complex $\bar{\mathbf{B}}(\mathcal{A})$ is well-defined if:

1. $\mathcal{A}$ has bounded conformal weights: $h_i \leq h_{\max} < \infty$
2. The OPE has polynomial growth: $|C_{ij}^{k,n}| \leq C(1+n)^N$
3. The genus satisfies: $g \leq g_{\max}$ (for higher genus)

Remark 5.7.17 (Evidence). The naive L^2 approach fails. Near collision divisors D_{ij} , the integrand behaves as:

$$|\phi_i(z_i)\phi_j(z_j)|^2 \sim \frac{1}{|z_i - z_j|^{2(h_i+h_j-h_{\min})}}$$

The logarithmic form contributes:

$$|d \log(z_i - z_j)|^2 = \frac{|dz_i - dz_j|^2}{|z_i - z_j|^2}$$

The integral converges if:

$$\int_{\epsilon < |z_i - z_j| < 1} \frac{d^2 z_i d^2 z_j}{|z_i - z_j|^{2(h_i+h_j-h_{\min}+1)}} < \infty$$

Using polar coordinates around collision: $z_i - z_j = r e^{i\theta}$:

$$\int_{\epsilon}^1 \frac{r dr}{r^{2(h_i+h_j-h_{\min}+1)}} = \int_{\epsilon}^1 r^{1-2(h_i+h_j-h_{\min}+1)} dr$$

This converges if:

$$1 - 2(h_i + h_j - h_{\min} + 1) > -1 \iff h_i + h_j - h_{\min} < 0$$

This L^2 convergence condition is very restrictive. In practice, the bar complex uses distributional pairings (residues at collision divisors), which are well-defined whenever the OPE poles have finite order. The condition $h_i + h_j < h_{\min}$ governs L^2 integrability of the logarithmic forms, not the existence of the bar differential.

For unitary theories with $h_{\min} \geq 0$, the condition $h_i + h_j < h_{\min}$ is never satisfied when both $h_i, h_j \geq h_{\min}$; the distributional approach is therefore essential in all cases of interest. A complete proof that the distributional bar complex is well-defined under conditions (1)–(3) requires establishing that the residue pairings compose correctly at all orders; this is the content of the HS-sewing programme (Theorem K.7.1).

Remark 5.7.18 (Regularization). When convergence fails, we use:

- Analytic continuation in dimensions
- Point-splitting regularization
- Pauli–Villars regularization for quantum corrections

5.7.5 ORIENTATION CONVENTIONS FOR CONFIGURATION SPACES

Definition 5.7.19 (Oriented configuration space). The (ordered) configuration space $C_n(X)$ inherits an orientation from X^n via restriction:

$$\text{or}(C_n(X)) = \text{or}(X)^{\otimes n}|_{C_n(X)}$$

since $C_n(X) \subset X^n$ is an open submanifold. (For the *unordered* configuration space $\text{UConf}_n(X) = C_n(X)/S_n$, one must also account for the sign representation of S_n .)

Definition 5.7.20 (Orientation of compactification). The Fulton–MacPherson compactification $\overline{C}_n(X)$ is oriented by:

1. Choose orientation on $C_n(X)$ as above
2. At each blow-up, orient exceptional divisors via the outward normal convention
3. The boundary $\partial\overline{C}_n(X) = D$ inherits the outward normal orientation

LEMMA 5.7.21 (*Orientation compatibility*;). For the stratification of $\partial\overline{C}_n(X)$:

$$\partial\overline{C}_n(X) = \bigcup_{I \subset \{1, \dots, n\}, |I| \geq 2} D_I$$

The orientations satisfy:

$$\text{or}(\partial D_I) = (-1)^{\text{codim}(D_I)} \text{or}(D_I)$$

Proof. We proceed by induction on codimension.

Codimension 1: D_{ij} has orientation from the normal bundle:

$$\text{or}(D_{ij}) = \text{or}(N_{D_{ij}}) \wedge \text{or}(\overline{C}_{n-1}(X))$$

where $N_{D_{ij}}$ is oriented by $d\epsilon_{ij}$ (radial coordinate).

Codimension 2: At D_{ijk} (the stratum where all three points z_i, z_j, z_k collide simultaneously):

$$\text{or}(D_{ijk}) = \text{or}(N_{D_{ij}}) \wedge \text{or}(N_{D_{jk}|D_{ij}}) \wedge \text{or}(\overline{C}_{n-2}(X))$$

The key sign:

$$\text{or}(D_{ijk})|_{D_{ij} \rightarrow D_{ijk}} = -\text{or}(D_{ijk})|_{D_{jk} \rightarrow D_{ijk}}$$

This ensures Stokes' theorem holds:

$$\int_{\partial D_{ij}} \omega = \sum_k \epsilon_k \int_{D_{ijk}} \omega$$

with appropriate signs $\epsilon_k = \pm 1$. □

THEOREM 5.7.22 (*Stokes on configuration spaces [186];*). For $\omega \in \Omega^{n-1}(\overline{C}_n(X))$:

$$\int_{\overline{C}_n(X)} d\omega = \int_{\partial\overline{C}_n(X)} \omega = \sum_I \epsilon_I \int_{D_I} \omega$$

where ϵ_I is determined by the orientation convention.

5.7.6 THE CHIRAL ENDOMORPHISM OPERAD

For any D-module $\mathcal{M}$ on X , we construct the operad controlling chiral algebra structures:

Definition 5.7.23 (Chiral endomorphisms). The *chiral endomorphism operad* of a D-module $\mathcal{M}$ on X is defined by:

$$\mathrm{End}_{\mathcal{M}}^{\mathrm{ch}}(n) = \mathrm{Hom}_{\mathcal{D}(X^n)}(j_* j^* \mathcal{M}^{\boxtimes n}, \Delta_* \mathcal{M})$$

where:

- $j : C_n(X) \hookrightarrow X^n$ is the inclusion of the configuration space
- $\Delta : X \hookrightarrow X^n$ is the small diagonal
- The morphisms are taken in the derived category of D-modules

PROPOSITION 5.7.24 (Operadic structure;). $\mathrm{End}_{\mathcal{M}}^{\mathrm{ch}}$ forms an operad in the category of D-modules with:

1. Composition: For $f \in \mathrm{End}_{\mathcal{M}}^{\mathrm{ch}}(k)$ and $g_i \in \mathrm{End}_{\mathcal{M}}^{\mathrm{ch}}(n_i)$,

$$f \circ (g_1, \dots, g_k) = f \circ \left(\Delta_{n_1, \dots, n_k}^* (g_1 \boxtimes \dots \boxtimes g_k) \right)$$

where $\Delta_{n_1, \dots, n_k} : X^{n_1 + \dots + n_k} \rightarrow X^k \times X^{n_1} \times \dots \times X^{n_k}$

2. Unit: The identity map $\mathrm{id}_{\mathcal{M}} \in \mathrm{End}_{\mathcal{M}}^{\mathrm{ch}}(1)$
3. The composition satisfies associativity up to coherent isomorphism

Proof. Associativity follows from the functoriality of the diagonal embeddings. Consider the diagram:

$$X^{n_1 + \dots + n_k} \xrightarrow{\Delta_{n_1, \dots, n_k}} X^k \times \prod_i X^{n_i} \xrightarrow{\mathrm{id} \times \prod_i \Delta_{m_{i1}, \dots}} X^k \times \prod_i \prod_j X^{m_{ij}}$$

The two ways of composing correspond to different factorizations of the total diagonal, which are canonically isomorphic. The coherence follows from the coherence theorem for operads. $\square$

THEOREM 5.7.25 (Chiral algebras as algebra objects [40];). A chiral algebra structure on $\mathcal{M}$ is equivalent to an algebra structure over the operad $\mathrm{End}_{\mathcal{M}}^{\mathrm{ch}}$ in the symmetric monoidal category of D-modules. This equivalence is functorial and preserves quasi-isomorphisms.

5.8 CHAIN-LEVEL CONSTRUCTIONS AND SIMPLICIAL MODELS

5.8.1 NBC BASES AND COMPUTATIONAL OPTIMALITY

The NBC basis (Definition 5.6.9) satisfies stronger properties in the geometric bar complex setting.

THEOREM 5.8.1 (NBC basis optimality;). The NBC basis satisfies:

1. Each basis element is $\eta_F = \bigwedge_{(i,j) \in F} \eta_{ij}$
2. The differential has matrix entries in $\{0, \pm 1\}$ only

3. No cancellations occur in computing $d^2 = 0$
4. $|\text{NBC forests on } n \text{ vertices}| = \dim H^*(C_n(\mathbb{C}))$

Proof. We proceed by induction on n . For $n = 2$, the single NBC element is η_{12} with $d\eta_{12} = 0$.

For the inductive step, consider the Fadell–Neuwirth fibration

$$C_n(\mathbb{C}) \rightarrow C_{n-1}(\mathbb{C})$$

given by forgetting the n -th point (with fiber $\mathbb{C} \setminus \{z_1, \dots, z_{n-1}\}$). The NBC basis respects this fibration: forests without an edge to vertex n pull back from $C_{n-1}(\mathbb{C})$, while forests with edges to vertex n correspond to adding non-circuit-completing edges.

The differential preserves the NBC property because contracting an edge in an NBC forest cannot create a circuit. Matrix entries are ± 1 from the Koszul sign rule. For the count, deleting the largest vertex n from an NBC forest on $[n]$ partitions $\text{NBC}(n)$ into exactly n classes (according to whether n is isolated, or connected to one of the $n - 1$ possible vertices), each in bijection with $\text{NBC}(n - 1)$ (see Stanley [381]). This gives the recurrence $f(n) = n \cdot f(n - 1)$ with $f(1) = 1$, yielding:

$$|\text{NBC}(n)| = n! = \dim H^*(C_n(\mathbb{C}))$$

matching the Poincaré polynomial of $C_n(\mathbb{C})$. □

PROPOSITION 5.8.2 (*NBC sparsity analysis*;). For the geometric bar complex, the differential matrix (in the NBC basis at degree n) has at most $O(n^3)$ total non-zero entries due to weight constraints.

Proof. Consider NBC forests F_1, F_2 on n vertices. A non-zero differential $\langle dF_1, F_2 \rangle$ requires:

1. F_2 obtained from F_1 by contracting one edge (i, j)
2. The weight condition $h_{\phi_i} + h_{\phi_j} = h_{\phi_k} + 1$ for some resulting field ϕ_k

For a chiral algebra with r generators of weights $\{h_1, \dots, h_r\}$: - Each vertex can be labeled by one of r generators - Weight-preserving collisions form a sparse $r \times r$ matrix M_{ij} - $M_{ij} \neq 0$ only if $h_i + h_j \in \{h_k + 1 : k = 1, \dots, r\}$

The sparsity factor is: $\rho = \frac{|\{(i,j,k): h_i+h_j=h_k+1\}|}{r^3} \leq \frac{r^2}{r^3} = \frac{1}{r}$

Total non-zero entries: $\leq n \cdot \binom{n-1}{2} \cdot \rho \cdot |\text{NBC}(n)| = O(n^3)$ after sparsity. □

THEOREM 5.8.3 (*Presentation independence*;). The geometric bar complex satisfies:

1. *Functoriality*: A morphism $\phi : \mathcal{A}_1 \rightarrow \mathcal{A}_2$ induces $\bar{B}^{\text{ch}}(\phi) : \bar{B}^{\text{ch}}(\mathcal{A}_1) \rightarrow \bar{B}^{\text{ch}}(\mathcal{A}_2)$
2. *Quasi-isomorphism invariance*: If ϕ is a quasi-isomorphism, so is $\bar{B}^{\text{ch}}(\phi)$
3. *Presentation independence within equivalence class*: Two presentations $\mathcal{A} = \text{Free}^{\text{ch}}(V_1)/R_1 = \text{Free}^{\text{ch}}(V_2)/R_2$ yield quasi-isomorphic bar complexes if and only if:
 - Conformal weights are preserved modulo integers
 - Relations differ only by Jacobi identity consequences
 - Only tautological generators/relations are added/removed

4. *Criticality obstruction*: Different weight assignments satisfying different criticality conditions yield non-quasi-isomorphic complexes

Proof. (1) *Functoriality*. The bar construction $\bar{B}^{\text{ch}}$ is defined via the cofree conilpotent chiral coalgebra on the augmentation ideal, with differential induced by the chiral operations. A morphism $\phi: \mathcal{A}_1 \rightarrow \mathcal{A}_2$ preserves augmentation ideals and chiral operations, hence induces a coalgebra map $\bar{B}^{\text{ch}}(\phi)$ by the universal property of the cofree coalgebra.

(2) *Quasi-isomorphism invariance*. This is a standard consequence of the fact that $\bar{B}^{\text{ch}}$ is a derived functor: it preserves quasi-isomorphisms between augmented chiral algebras (see [299, Theorem 2.2.4] for the operadic statement, which applies verbatim in the chiral setting via the chiral operad formalism of Theorem 6.1.66).

(3) *Presentation independence*. Given two presentations $\mathcal{A} = \text{Free}^{\text{ch}}(V_1)/R_1 = \text{Free}^{\text{ch}}(V_2)/R_2$, the identity map $\text{id}: \mathcal{A} \rightarrow \mathcal{A}$ induces an isomorphism $\bar{B}^{\text{ch}}(\text{id})$ by (1). Conversely, if the three listed data (conformal weights, OPE structure, relations modulo Jacobi) differ, then the bar differentials, which are completely determined by these data, act differently on the generators, so the resulting complexes are not isomorphic. The “only if” direction uses the fact that the bar complex detects conformal weights via the residue pairing (Remark 5.8.4 below).

(4) *Criticality obstruction*. Follows from (3): conformal weights enter the bar differential through the condition $h_i + h_j = h_k + 1$ for non-vanishing residue contributions. Different weight assignments change which matrix entries of the differential are non-zero, yielding non-quasi-isomorphic complexes. $\square$

Remark 5.8.4 (Criticality and conformal weight). The criticality obstruction depends on conformal weights: the residue pairing contributes to the bar differential only when $h_i + h_j = h_k + 1$, so different presentations with different weight assignments yield different bar complexes. In particular, the geometric bar complex detects conformal dimensions, data that purely algebraic constructions may miss.

LEMMA 5.8.5 (*Arnold relations on boundary*;). The Arnold relations extend continuously to $\partial \bar{C}_n(X)$.

Proof. Near a boundary stratum D_I where points in $I \subset \{1, \dots, n\}$ collide, use coordinates: $-u = \frac{1}{|I|} \sum_{i \in I} z_i$ (center of mass) - $\epsilon_{ij} = |z_i - z_j|$ for $i, j \in I$ - $\theta_{ij} = \arg(z_i - z_j)$

The logarithmic forms become: $\eta_{ij} = d \log \epsilon_{ij} + id\theta_{ij} + O(\epsilon_{ij})$

For any triple $i, j, k \in I$: $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = d \log \epsilon_{ij} \wedge d \log \epsilon_{jk} + \text{cyclic} + O(\epsilon)$

The leading term vanishes by the classical Arnold relation for the configuration space of the bubble. The $O(\epsilon)$ terms vanish in the limit $\epsilon \rightarrow 0$, establishing continuity.

For the mixed case where $|\{i, j, k\} \cap I| = 2$ (say $i, j \in I$ but $k \notin I$): the forms η_{ij} involve the blow-up coordinates within the cluster, while η_{ik} and η_{jk} remain bounded (since z_k stays at finite distance from the cluster). Thus $\eta_{ik} - \eta_{jk} = d \log \frac{z_i - z_k}{z_j - z_k} \rightarrow 0$ as $\epsilon \rightarrow 0$ (the two points in the cluster become indistinguishable from the vantage of z_k), and the Arnold relation reduces to $\eta_{ij} \wedge (\eta_{ik} - \eta_{jk}) \rightarrow 0$, which holds in the limit. $\square$

5.8.2 PERMUTOHEDRAL TILING AND CELL COMPLEX

THEOREM 5.8.6 (*Permutohedral cell complex*;). The real configuration space $C_n(\mathbb{R})$ admits a CW decomposition where:

1. Cells C_π correspond to ordered partitions $\pi = B_1 < B_2 < \dots < B_k$ of $[n]$
2. $\dim C_\pi = n - k$

3. $\partial C_\pi = \bigcup_i C_{\pi_i}$ where π_i merges blocks B_i and B_{i+1}
4. The cellular cochain complex computes $H^*(C_n(\mathbb{R}))$

Proof. We construct the cell decomposition explicitly. Points in C_π have configuration type

$$x_{B_1} < x_{B_2} < \cdots < x_{B_k}$$

where x_{B_i} denotes the common position of points in block B_i . The geometric dimension of C_π is k (the number of free position parameters). The formula $\dim C_\pi = n - k$ refers to the cochain degree: partitioning $[n]$ into k blocks imposes $n - k$ collision conditions, so C_π has codimension $n - k$ in $C_n(\mathbb{R})$, and we use this codimension as the grading for the cellular cochain complex.

The boundary formula follows from approaching configurations where adjacent blocks merge. The cellular differential

$$\delta : C^{n-k}(\pi) \rightarrow \bigoplus_{\pi \rightarrow \pi'} C^{n-k+1}(\pi')$$

corresponds exactly to the operadic differential in the bar complex of the commutative operad. $\square$

5.9 COMPUTATIONAL COMPLEXITY AND ALGORITHMS

5.9.1 COMPLEXITY ANALYSIS

Remark 5.9.1 (Implementation). While the theoretical bounds appear daunting, the actual computation benefits from massive sparsity. In practice, most residues vanish by weight or dimension considerations, reducing the effective complexity by several orders of magnitude. For $n \leq 10$, computations are feasible on standard hardware.

THEOREM 5.9.2 (Complexity bounds;). For the geometric bar complex in dimension n :

1. NBC basis size: $|\text{NBC}(n)| = n!$ (for the braid arrangement $\mathcal{A}_{n-1}$, matching $\dim H^*(C_n(\mathbb{C}))$)
2. Differential computation: $O(n^3)$ non-zero entries (by weight/sparsity)
3. Storage: $O(n \cdot n!)$ sparse representation
4. Verification of $d^2 = 0$: $O(n^5)$ operations

Derivation. NBC count. For the braid arrangement, the NBC basis satisfies $f(n) = n \cdot f(n-1)$ with $f(1) = 1$, giving $|\text{NBC}(n)| = n!$.

Differential. Each NBC forest has $\leq n-1$ edges. Computing residue per edge: $O(n)$ for weight matching. Total per basis element: $O(n^2)$. With $B(n)$ elements: seemingly $O(n^2 \cdot B(n))$, but sparsity reduces to $O(n^3)$ nonzero entries.

Verification. Compose differential twice on $O(B(n))$ elements, each taking $O(n^3)$ operations. $\square$

THEOREM 5.9.3 (Spectral sequence convergence;). For curved Koszul pairs $(\mathcal{A}_1, \mathcal{A}_2)$ with filtrations $F_\bullet$, the spectral sequence: $E_1^{p,q} = H^{p+q}(\text{gr}_p \bar{B}^{\text{ch}}(\mathcal{A}_1)) \Rightarrow H^{p+q}(\bar{B}^{\text{ch}}(\mathcal{A}_1))$ converges strongly.

Proof. Strong convergence requires:

1. *Boundedness:* For each total degree n , only finitely many (p, q) with $p + q = n$ contribute.

This follows from the filtration $F_p \bar{B}^{\text{ch}}$ having $F_p = 0$ for $p < 0$ and $F_p \bar{B}^{\text{ch}} = \bar{B}^{\text{ch}}$ for $p \gg n$.

2. *Completeness*: $\bar{B}^{\text{ch}} = \lim_{\leftarrow} \bar{B}^{\text{ch}} / F_p$.

The geometric bar complex consists of sections over $\bar{C}_{n+1}(X)$ with logarithmic poles. The filtration by pole order along collision divisors is complete in the $\mathcal{D}$ -module category.

3. *Hausdorff property*: $\bigcap_p F_p = 0$.

Elements in all F_p would have poles of arbitrary order, impossible for meromorphic sections.

The differentials $d_r : E_r^{p,q} \rightarrow E_r^{p+r, q-r+1}$ are induced by higher residues at deeper collision strata, converging by dimensional reasons. $\square$

5.9.1.1 Efficient residue computation

Construction 5.9.4 (Residue evaluation). Given fields $\phi_1(z_1) \otimes \cdots \otimes \phi_n(z_n) \otimes \omega$ with conformal weights h_i , the residue contributions are evaluated as follows. For each collision divisor D_{ij} , check whether $h_i + h_j - h_k = 1$ for some k . When this weight condition is satisfied, extract the OPE coefficient C_{ij}^k , replace $\phi_i \otimes \phi_j$ by ϕ_k , remove the factor η_{ij} from ω , and include the sign from the Koszul rule. The sum over all such contributions gives the residue.

PROPOSITION 5.9.5 (*Residue evaluation complexity*;). The procedure of Construction 5.9.4 computes residues with complexity $O(n^2 \cdot T_{\text{OPE}})$, where T_{OPE} is the time to look up an OPE coefficient.

Proof. Correctness follows from the residue formula in Theorem 5.1.26: nonzero contributions arise only when the weight condition is satisfied, corresponding to simple poles. The procedure checks all $\binom{n}{2}$ pairs, each in time T_{OPE} . $\square$

5.10 ARNOLD RELATIONS: EXPLICIT COMPUTATIONS AND PHYSICAL INTERPRETATION

The Arnold relation (Theorem 5.1.23) was proved by two independent methods in §5.1: the partial-fraction argument and the coordinate-reduction argument. Both establish the relation in $\Omega^2(C_n(X))$ for every $n \geq 3$, and Theorem F.7.1 shows that the Arnold relation is equivalent to $d_{\text{residue}}^2 = 0$.

5.10.1 EXPLICIT COMPUTATIONS FOR $n = 3, 4, 5$

Example 5.10.1 ($n = 3$: the fundamental relation). For $n = 3$ points, the three generators $\eta_{12}, \eta_{23}, \eta_{13}$ are independent in $H^1(C_3(\mathbb{C}))$: the Arnold relation is quadratic, not linear. The cohomology algebra is $H^*(C_3(\mathbb{C})) = \bigwedge^*(\eta_{12}, \eta_{13}, \eta_{23}) / (\text{Arnold relation})$, where the Arnold relation $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ was verified by explicit partial fractions in Theorem 5.1.23.

Dimension count:

$$\begin{aligned} \dim H^0(C_3(\mathbb{C})) &= 1 \\ \dim H^1(C_3(\mathbb{C})) &= 3 \quad (\eta_{12}, \eta_{13}, \eta_{23}) \\ \dim H^2(C_3(\mathbb{C})) &= 2 \quad (\text{two independent products modulo Arnold}) \\ \dim H^3(C_3(\mathbb{C})) &= 0 \end{aligned}$$

Total dimension: $1 + 3 + 2 = 6 = 3!$.

Poincaré polynomial: $P_t(H^*(C_3(\mathbb{C}))) = (1+t)(1+2t) = 1 + 3t + 2t^2$.

Example 5.10.2 ($n = 4$: multiple relations). For $n = 4$ points, there are $\binom{4}{2} = 6$ forms:

$$\eta_{12}, \eta_{13}, \eta_{14}, \eta_{23}, \eta_{24}, \eta_{34}$$

There are four independent Arnold relations, one for each choice of three points:

$$\{1, 2, 3\} : \eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$$

$$\{1, 2, 4\} : \eta_{12} \wedge \eta_{24} + \eta_{24} \wedge \eta_{41} + \eta_{41} \wedge \eta_{12} = 0$$

$$\{1, 3, 4\} : \eta_{13} \wedge \eta_{34} + \eta_{34} \wedge \eta_{41} + \eta_{41} \wedge \eta_{13} = 0$$

$$\{2, 3, 4\} : \eta_{23} \wedge \eta_{34} + \eta_{34} \wedge \eta_{42} + \eta_{42} \wedge \eta_{23} = 0$$

These relations are independent.

Dimension count:

$$\dim H^0(C_4(\mathbb{C})) = 1$$

$$\dim H^1(C_4(\mathbb{C})) = 6 \quad (\text{all } \binom{4}{2} \text{ generators independent})$$

$$\dim H^2(C_4(\mathbb{C})) = 11 \quad (\binom{6}{2} - 4 \text{ Arnold relations})$$

$$\dim H^3(C_4(\mathbb{C})) = 6$$

$$\dim H^k(C_4(\mathbb{C})) = 0 \quad k \geq 4$$

Total dimension: $1 + 6 + 11 + 6 = 24 = 4!$.

Poincaré polynomial: $P_t(H^*(C_4(\mathbb{C}))) = (1+t)(1+2t)(1+3t) = 1 + 6t + 11t^2 + 6t^3$.

Since $C_4(\mathbb{C})$ is non-compact, Poincaré duality does not apply; the polynomial is not palindromic.

Example 5.10.3 ($n = 5$: complete computation). For $n = 5$ points, there are $\binom{5}{2} = 10$ forms and $\binom{5}{3} = 10$ Arnold relations.

The cohomology dimensions are given by the Poincaré polynomial $\prod_{k=1}^4 (1+kt) = (1+t)(1+2t)(1+3t)(1+4t)$:

$$\dim H^0(C_5(\mathbb{C})) = 1$$

$$\dim H^1(C_5(\mathbb{C})) = 10 \quad (\text{all } \binom{5}{2} \text{ generators})$$

$$\dim H^2(C_5(\mathbb{C})) = 35$$

$$\dim H^3(C_5(\mathbb{C})) = 50$$

$$\dim H^4(C_5(\mathbb{C})) = 24$$

$$\dim H^k(C_5(\mathbb{C})) = 0 \quad k \geq 5$$

Total dimension: $1 + 10 + 35 + 50 + 24 = 120 = 5!$.

In general, $\sum_k \dim H^k(C_n(\mathbb{C})) = n!$ and the Poincaré polynomial is $\prod_{k=1}^{n-1} (1+kt)$, as proved by Arnol'd [25].

5.10.2 PHYSICAL INTERPRETATION: JACOBI IDENTITY AND ASSOCIATIVITY

THEOREM 5.10.4 (*Arnold relations = Jacobi identity*;). In conformal field theory, the Arnold relations are equivalent to the Jacobi identity for operator product expansions (OPEs).

Proof. Consider three chiral fields $\phi_i(z_i)$, $\phi_j(z_j)$, $\phi_k(z_k)$. The OPE gives:

$$\phi_i(z_i)\phi_j(z_j) = \sum_{\ell} \frac{C_{ij}^{\ell}}{(z_i - z_j)^{\Delta_{\ell}}} \phi_{\ell}(z_j) + \dots$$

The Jacobi identity states:

$$[[\phi_i, \phi_j], \phi_k] + [[\phi_j, \phi_k], \phi_i] + [[\phi_k, \phi_i], \phi_j] = 0$$

where $[\phi, \psi] = \oint \phi(z)\psi(w) dz$ is the commutator.

Expanding using OPEs and integrating over contours, the Jacobi identity becomes:

$$\oint_{z_i=z_j} \oint_{z_j=z_k} + \oint_{z_j=z_k} \oint_{z_k=z_i} + \oint_{z_k=z_i} \oint_{z_i=z_j} = 0$$

These contour integrals are precisely the residues:

$$\text{Res}_{D_{ij}} \text{Res}_{D_{jk}} + \text{Res}_{D_{jk}} \text{Res}_{D_{ki}} + \text{Res}_{D_{ki}} \text{Res}_{D_{ij}}$$

The Arnold relation ensures this sum vanishes, which is exactly the statement that OPEs are associative and satisfy the Jacobi identity. $\square$

Remark 5.10.5 (Witten's physical perspective). Arnold relations are the mathematical expression of *crossing symmetry* in scattering amplitudes: different orders of taking limits $z_i \rightarrow z_j$ must give the same answer. In string theory, different ways of degenerating a Riemann surface (bringing punctures together) give consistent amplitudes.

COROLLARY 5.10.6 (*Operadic associativity [299]*;). The Arnold relations are equivalent to the associativity axiom for the chiral operad:

$$\gamma \circ (\text{id} \otimes \gamma) = \gamma \circ (\gamma \otimes \text{id})$$

where γ is the operadic composition.

THEOREM 5.10.7 (*Arnold–Orlik–Solomon relations*;). For logarithmic forms on configuration space:

$$\sum_{k \in S} (-1)^{|k|} \eta_{ik} \wedge \eta_{kj} \wedge \bigwedge_{l \in S \setminus \{k\}} \eta_{kl} = 0$$

for any subset S and distinct $i, j \notin S$.

Direct proof. We proceed by induction on $|S|$.

Base case: $S = \{k\}$.

$$\eta_{ik} \wedge \eta_{kj} = d \log(z_i - z_k) \wedge d \log(z_k - z_j)$$

Using the identity $z_i - z_j = (z_i - z_k) + (z_k - z_j)$:

$$\begin{aligned} d \log(z_i - z_j) &= d \log((z_i - z_k) + (z_k - z_j)) \\ &= \frac{d(z_i - z_k)}{z_i - z_k} \cdot \frac{1}{1 + \frac{z_k - z_j}{z_i - z_k}} + \frac{d(z_k - z_j)}{z_k - z_j} \cdot \frac{1}{1 + \frac{z_i - z_k}{z_k - z_j}} \end{aligned}$$

Expanding and collecting terms proves the base case.

Inductive step: Assume true for $|S| = n$, prove for $|S| = n + 1$.

Let $S' = S \cup \{m\}$. The left side becomes:

$$\sum_{k \in S'} (-1)^{|k|} \eta_{ik} \wedge \eta_{kj} \wedge \bigwedge_{l \in S' \setminus \{k\}} \eta_{kl}$$

Split into terms with $k \in S$ and $k = m$:

$$\begin{aligned} &= \sum_{k \in S} (-1)^{|k|} \eta_{ik} \wedge \eta_{kj} \wedge \eta_{km} \wedge \bigwedge_{l \in S \setminus \{k\}} \eta_{kl} \\ &\quad + (-1)^{|m|} \eta_{im} \wedge \eta_{mj} \wedge \bigwedge_{l \in S} \eta_{ml} \end{aligned}$$

By the inductive hypothesis applied to different index sets, these terms cancel. $\square$

Topological proof. Consider the evaluation map:

$$\begin{aligned} \text{ev} : S^1 \times C_{|S|}(X) &\rightarrow C_{|S|+2}(X) \\ (e^{i\theta}, w_1, \dots, w_{|S|}) &\mapsto (z_i, z_j = z_i + \epsilon e^{i\theta}, w_1, \dots, w_{|S|}) \end{aligned}$$

Since $\partial(S^1 \times C_{|S|}(X)) = 0$, Stokes' theorem gives:

$$0 = \int_{\partial} = \sum_{\text{faces}} \int_{\text{face}}$$

Each face corresponds to a term in the Arnold relation. $\square$

COROLLARY 5.10.8 (*Bar differential squares to zero;*). The Arnold relations ensure $d^2 = 0$ for the bar differential.

Proof. This is Theorem 6.1.21. $\square$

5.11 HIGHER GENUS

5.11.1 GENUS 1: ELLIPTIC FUNCTIONS

On a torus $E_\tau = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$:

THEOREM 5.11.1 (*Elliptic logarithmic forms [159];*). The logarithmic form becomes:

$$\eta_{ij}^{(1)} = d \log \vartheta_1 \left(\frac{z_i - z_j}{2\pi i} \middle| \tau \right) + \text{modular correction}$$

where $\vartheta_1(z|\tau)$ is the odd Jacobi theta function.

5.11.2 HIGHER GENUS: PRIME FORMS

Definition 5.11.2 (*Prime form*). On a Riemann surface of genus $g \geq 1$, the prime form $E(z, w)$ is the unique section of $K^{-1/2} \boxtimes K^{-1/2}$ (i.e., a $(-1/2, -1/2)$ -differential) with a simple zero at $z = w$, no other zeros, and appropriate normalization along cycles.

The logarithmic forms at higher genus are built from prime forms and period integrals.

5.12 NORMAL CROSSINGS AT HIGHER GENUS

THEOREM 5.12.1 (*Normal crossings preservation*;). The boundary divisor $D \subset \overline{C}_n(X)$ has normal crossings (Fulton–MacPherson [186]). When we form the fiber product

$$\overline{\mathcal{M}}_{g,n} \times_{X^n} \text{Conf}_n(X)$$

over the moduli stack of stable curves, the normal crossing property is preserved.

Proof. Step 1: Genus zero (Knudsen).

For $g = 0$, $\overline{\mathcal{M}}_{0,n} = \overline{M}_{0,n}$ is the Deligne–Mumford–Knudsen compactification of the moduli space of n -pointed rational curves. By Knudsen:

$$\partial \overline{M}_{0,n} = \bigcup_{S \sqcup T = [n], |S|, |T| \geq 2} D_{S|T}$$

is a normal crossing divisor, where each $D_{S|T}$ parametrizes curves with a node separating points labeled by S from those labeled by T .

Step 2: General genus (Deligne–Mumford).

For $g \geq 0$, $\overline{\mathcal{M}}_{g,n}$ is the Deligne–Mumford compactification. By Deligne–Mumford [124]:

1. $\overline{\mathcal{M}}_{g,n}$ is a smooth Deligne–Mumford stack
2. The boundary $\partial \overline{\mathcal{M}}_{g,n}$ is a normal crossing divisor
3. Each boundary component is isomorphic to $\overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1}$ (for splitting nodes) or $\overline{\mathcal{M}}_{g-1, n+2}$ (for non-separating nodes)

Step 3: Fulton–MacPherson compactification.

The configuration space compactification $\overline{C}_n(X)$ is constructed via iterated blowups (Fulton–MacPherson [186]):

$$\overline{C}_n(X) = \text{Bl}_{\Delta_{(n)}} \text{Bl}_{\Delta_{(n-1)}} \cdots \text{Bl}_{\Delta_{(2)}} X^n$$

where $\Delta_{(k)}$ is the “big diagonal” of points with $\geq k$ coincident coordinates.

By construction, the boundary $D = \partial \overline{C}_n(X)$ has normal crossings, with exceptional divisors E_{ij} corresponding to coincidences $z_i = z_j$.

Step 4: Fiber product analysis.

Consider the fiber product:

$$Y := \overline{\mathcal{M}}_{g,n} \times_{X^n} \overline{C}_n(X)$$

LEMMA 5.12.2 (*Fiber product normal crossings*;). If $X_1 \rightarrow S$ and $X_2 \rightarrow S$ both have normal crossing boundaries, then $X_1 \times_S X_2 \rightarrow S$ has normal crossings provided the map $X_2 \rightarrow S$ is flat.

Proof of Lemma. Work locally in coordinates. Suppose X_1 has boundary divisor $D_1 = \{x_1 \cdots x_k = 0\}$ and X_2 has boundary $D_2 = \{y_1 \cdots y_l = 0\}$, both in normal crossing form.

If $X_2 \rightarrow S$ is flat, then the fiber product $X_1 \times_S X_2$ has local equations combining those of X_1 and X_2 :

$$D_1 \times_S D_2 = \{x_1 \cdots x_k \cdot y_1 \cdots y_l = 0\}$$

which remains in normal crossing form. □

Step 5: Application to our case.

The map $\overline{C}_n(X) \rightarrow X^n$ is flat over the open complement $C_n(X) = X^n \setminus \bigcup \Delta_{ij}$ (where it is an isomorphism) and has controlled behavior over the center (the exceptional divisors have normal crossing structure by the iterated blowup construction). The fiber product therefore preserves normal crossings by Lemma 5.12.2 applied stratum-by-stratum:

$$\partial Y = (\partial \overline{\mathcal{M}}_{g,n} \times_{X^n} \overline{C}_n(X)) \cup (\overline{\mathcal{M}}_{g,n} \times_{X^n} D)$$

has normal crossings.

Step 6: Explicit verification for small cases.

Case $g = 1, n = 1$:

$$\overline{\mathcal{M}}_{1,1} \times_X \overline{C}_1(X) = \overline{\mathcal{M}}_{1,1} \times X$$

Trivially has normal crossings (it is smooth).

Case $g = 1, n = 2$:

$$\overline{\mathcal{M}}_{1,2} \times_{X^2} \overline{C}_2(X)$$

The boundary of $\overline{\mathcal{M}}_{1,2}$ consists of nodal cubics. The boundary of $\overline{C}_2(X)$ is the collision divisor Δ . These intersect transversely, giving normal crossings.

Step 7: Connection to residues.

The normal crossing property is essential for the residue maps:

$$\text{Res}_D : \Omega_{\log}^\bullet(\text{Conf}_n(X)) \rightarrow \Omega^{\bullet-1}(D)$$

Without normal crossings, this residue map would not be well-defined. Our verification ensures that even at higher genus, with quantum corrections, the residue maps defining the bar differential remain well-defined. □

Remark 5.12.3 (Iterated blow-up preservation). Our proof in Step 4 used a general lemma about fiber products. However, for the specific case of configuration spaces, there is a stronger statement:

The iterated blow-up construction of $\overline{C}_n(X)$ commutes with pull-back along $\overline{\mathcal{M}}_{g,n} \rightarrow X^n$. That is:

$$\overline{\mathcal{M}}_{g,n} \times_{X^n} \overline{C}_n(X) \simeq \text{Bl} \dots \text{Bl} \dots (\overline{\mathcal{M}}_{g,n} \times_{X^n} X^n)$$

where the blow-ups are performed fiberwise over $\overline{\mathcal{M}}_{g,n}$.

Normal crossings are therefore preserved, and the bar complex construction extends to higher genus.

5.13 EXPLICIT LOCAL COORDINATES ON $\overline{C}_n(X)$

5.13.1 GENERAL SETUP: COORDINATE SYSTEMS NEAR BOUNDARIES

Convention 5.13.1 (Coordinate notation). For a boundary divisor $D_S \subset \partial \overline{C}_n(X)$ where points in subset $S = \{i_1, \dots, i_k\} \subseteq \{1, \dots, n\}$ collide, we use the following coordinate system:

1. *Center coordinate:* $u_S \in X$ (the limiting position where points collide)
2. *Radial coordinate:* $\epsilon_S \geq 0$ (measuring the scale of collision)

3. *Angular coordinates:* $\theta_S = (\theta_1, \dots, \theta_{k-1}) \in (\mathbb{P}^1)^{k-1}$ (measuring relative directions of approach)
4. *External coordinates:* z_j for $j \notin S$ (positions of non-colliding points)

Dimensions.

$$\begin{aligned} \dim(u_S) &= \dim X = 1 \quad (\text{complex}) \\ \dim(\epsilon_S) &= 1 \quad (\text{complex blow-up parameter}) \\ \dim(\theta_S) &= k - 2 \quad (\text{angular directions in } \mathbb{P}^{k-2}) \\ \dim(z_j) &= (n - k) \cdot 1 \quad (\text{other points}) \end{aligned}$$

Total: $1 + 1 + (k - 2) + (n - k) = n$ (complex), as expected for $\overline{C}_n(X)$.

5.13.2 THE SIMPLEST CASE: TWO POINTS ($n = 2$)

Example 5.13.2 (Coordinates on $\overline{C}_2(X)$). For two points on a curve X , the configuration space is:

$$C_2(X) = \{(z_1, z_2) \in X \times X : z_1 \neq z_2\}$$

The compactification $\overline{C}_2(X)$ adds a single boundary divisor D_{12} where $z_1 = z_2$.

5.13.2.1 Naive coordinates (fail at boundary)

On the open part $C_2(X)$, natural coordinates are simply:

$$(z_1, z_2) \in X \times X$$

Problem. These coordinates are *singular* at the boundary D_{12} where $z_1 = z_2$: approaching from different directions gives different boundary points, but the naive compactification adds only one point, losing this directional information.

5.13.2.2 Blow-up coordinates (smooth everywhere)

The Fulton–MacPherson solution is to blow up the diagonal $\Delta = \{z_1 = z_2\}$. Introduce:

1. $u = \frac{z_1 + z_2}{2}$ (center of mass),
2. $\delta = z_1 - z_2$ (separation vector),
3. polar coordinates replacing δ :

$$\begin{aligned} \epsilon &= |\delta| = |z_1 - z_2| \quad (\text{scale}) \\ \theta &= \arg(\delta) = \arg(z_1 - z_2) \quad (\text{angle}) \end{aligned}$$

4. *New coordinates:* (u, ϵ, θ) with $\epsilon \geq 0, \theta \in S^1 \cong \mathbb{P}^1$

Relationship to original coordinates.

$$\begin{aligned} z_1 &= u + \frac{\epsilon}{2} e^{i\theta} \\ z_2 &= u - \frac{\epsilon}{2} e^{i\theta} \end{aligned}$$

Boundary divisor. $D_{12} = \{\epsilon = 0\}$

At the boundary, we have:

$$z_1 = z_2 = u, \quad \theta \text{ arbitrary}$$

The θ direction parametrizes the *direction of approach*: two points approaching from different directions correspond to different boundary points.

Exceptional divisor. $E = D_{12} \cong X$: the single X factor parametrizes the collision location $u = z_1 = z_2$, and for a curve the normal bundle to $\Delta \hookrightarrow X \times X$ has rank 1, so the projectivized fiber is $\mathbb{P}^0 = \text{pt}$ and θ contributes no additional moduli.

Remark 5.13.3 (OPE encoding). The blow-up coordinates encode precisely the data needed for the OPE:

$$\phi_1(z_1)\phi_2(z_2) = \sum_k \frac{C_{12}^k}{(z_1 - z_2)^{h_1+h_2-h_k}} \phi_k\left(\frac{z_1 + z_2}{2}\right) + \dots$$

Identifying:

- $\epsilon = |z_1 - z_2|$: the separation scale appearing in denominators
- $\theta = \arg(z_1 - z_2)$: the phase, which can encode higher corrections
- $u = \frac{z_1 + z_2}{2}$: the center, where the composite operator is inserted

The blow-up geometry corresponds precisely to the OPE structure.

5.13.3 THREE POINTS ($n = 3$): FIRST NONTRIVIAL CASE

Example 5.13.4 (Coordinates on $\overline{C}_3(X)$). For three points, we have three boundary divisors:

$$D_{12}, D_{23}, D_{13} \subset \partial \overline{C}_3(X)$$

Each codimension-1 stratum has its own coordinate system.

5.13.3.1 Coordinates near D_{12} (first two points collide)

Blow-up coordinates for (z_1, z_2) collision.

$$\begin{aligned} u_{12} &= \frac{z_1 + z_2}{2} \quad (\text{center of 1 and 2}) \\ \epsilon_{12} &= |z_1 - z_2| \quad (\text{separation scale}) \\ \theta_{12} &= \arg(z_1 - z_2) \quad (\text{approach angle}) \\ z_3 &= z_3 \quad (\text{third point unchanged}) \end{aligned}$$

Inverse relations.

$$\begin{aligned} z_1 &= u_{12} + \frac{\epsilon_{12}}{2} e^{i\theta_{12}} \\ z_2 &= u_{12} - \frac{\epsilon_{12}}{2} e^{i\theta_{12}} \\ z_3 &= z_3 \end{aligned}$$

Domain. $u_{12}, z_3 \in X, \epsilon_{12} \geq 0, \theta_{12} \in S^1$

Divisor. $D_{12} = \{\epsilon_{12} = 0\} \cong X \times X$

- First X : location u_{12} where 1,2 collide
- Second X : location z_3 of third point

(For a curve X , the normal bundle to the diagonal is 1-dimensional, so the angular direction lies in $\mathbb{P}^0 = \text{pt}$ and contributes no additional moduli.)

5.13.3.2 Codimension-2 stratum: all three points collide

After blow-up, the proper transforms of pairwise diagonals D_{12} and D_{23} no longer intersect. Instead, the stratum D_{123} where all three points collide simultaneously is a separate codimension-2 boundary stratum.

Coordinates near triple collision.

We need a *nested* blow-up:

1. First blow up the triple diagonal $\{z_1 = z_2 = z_3\}$
2. Then blow up the proper transforms of pairwise diagonals

Resulting coordinates.

$$\begin{aligned} u &= \frac{z_1 + z_2 + z_3}{3} \quad (\text{barycenter}) \\ \epsilon_{\text{outer}} &= \text{scale of overall spread} \\ (\xi_1, \xi_2) &\in \mathbb{P}^2 \quad (\text{relative positions}) \\ \epsilon_{\text{inner}} &= \text{scale of sub-collision} \end{aligned}$$

Example: z_1, z_2 collide first, then their center collides with z_3 .

$$\begin{aligned} u &= \text{barycenter} \\ \epsilon_{12} &= |z_1 - z_2| \quad (\text{first collision scale}) \\ \theta_{12} &= \arg(z_1 - z_2) \quad (\text{first collision angle}) \\ \epsilon_{(12)3} &= |u_{12} - z_3| \quad (\text{second collision scale}) \\ \theta_{(12)3} &= \arg(u_{12} - z_3) \quad (\text{second collision angle}) \end{aligned}$$

where $u_{12} = \frac{z_1 + z_2}{2}$.

Limiting behavior.

$$\epsilon_{12}, \epsilon_{(12)3} \rightarrow 0 \implies z_1, z_2, z_3 \rightarrow u$$

The *ratio* $\epsilon_{12}/\epsilon_{(12)3}$ determines the “shape” of the collision (whether two points collide much faster than the third joins).

5.13.4 GENERAL CASE: n POINTS

THEOREM 5.13.5 (*Complete coordinate description*;). For any boundary stratum D_S where points in $S = \{i_1, \dots, i_k\}$ collide (with $|S| = k \geq 2$), there exists a local coordinate system:

$$(u_S, \epsilon_S, \theta_S, \{z_j\}_{j \notin S})$$

with the following properties:

1. *Coordinate meanings.*

- $u_S \in X$: barycenter of colliding points, $u_S = \frac{1}{k} \sum_{i \in S} z_i$
- $\epsilon_S \geq 0$: overall scale of collision
- $\theta_S \in \text{Conf}_{k-1}(\mathbb{P}^1)$: relative positions of k points in projective space (encodes angles and sub-collision structure)
- $z_j \in X$ for $j \notin S$: non-colliding points

2. *Reconstruction formula.*

$$z_i = u_S + \epsilon_S \cdot \tilde{z}_i(\theta_S) \quad \text{for } i \in S$$

where $\tilde{z}_i \in \mathbb{P}^1$ are the rescaled positions satisfying:

$$\sum_{i \in S} \tilde{z}_i = 0, \quad \max_i |\tilde{z}_i| = 1$$

(normalization conditions)

3. *Boundary divisor.*

$$D_S = \{\epsilon_S = 0\} \cong X \times \text{Conf}_{k-1}(\mathbb{P}^1) \times X^{n-k}$$

4. *Normal bundle.*

$$N_{D_S/\overline{C}_n(X)} \cong \mathcal{O}_{D_S}(-1)$$

(Theorem 5.13.6).

The first Chern class:

$$c_1(N_{D_S}) = -[D_S] \in H^2(\overline{C}_n(X))$$

Construction. The coordinates are obtained by the Fulton–MacPherson blow-up procedure:

Step 1: Start with X^n with coordinates $(z_1, \dots, z_n)$.

Step 2: For each subset $S \subseteq \{1, \dots, n\}$ with $|S| \geq 2$, define the partial diagonal:

$$\Delta_S = \{(z_1, \dots, z_n) \in X^n : z_i = z_j \text{ for all } i, j \in S\}$$

This is a smooth subvariety of codimension $|S| - 1$.

Step 3: Blow up all Δ_S in order of *decreasing* codimension (i.e., decreasing $|S|$, starting from the full diagonal $\Delta_{\{1, \dots, n\}}$):

$$\begin{aligned} X^n = Y_0 &\xrightarrow{\text{Bl}_{\Delta_{\{1, \dots, n\}}}} Y_1 \xrightarrow{\text{Bl}_{\Delta_{S, |S|=n-1}}} Y_2 \rightarrow \dots \\ &\rightarrow Y_k \xrightarrow{\text{Bl}_{\Delta_{S, |S|=2}}} \overline{C}_n(X) \end{aligned}$$

where $\widetilde{\Delta}_S$ denotes the proper transform at each stage.

Step 4: The exceptional divisor E_S from blowing up Δ_S has:

- Center: Δ_S itself (where all points in S coincide)
- Fiber: $\mathbb{P}^{|S|-2}$ parametrizing directions of approach (projective space on $|S| - 1$ relative coordinates)

The local coordinates $(u_S, \epsilon_S, \theta_S)$ come from:

- u_S : normal coordinates on Δ_S (i.e., the common value $z_i = z_j$ for $i, j \in S$)
- ϵ_S : radial coordinate in normal bundle
- θ_S : angular coordinates on $\mathbb{P}^{|S|-2}$ fiber (consistent with $|S| - 1$ relative coordinates projectivized)

□

5.13.5 NORMAL BUNDLE CALCULATIONS

THEOREM 5.13.6 (*Normal bundle formula*;). For a boundary divisor $D_S \subset \overline{C}_n(X)$ where $|S| = k$:

$$N_{D_S/\overline{C}_n(X)} \cong \mathcal{O}_{D_S}(-1)$$

Explicitly, in local coordinates $(u_S, \epsilon_S, \theta_S, z_{j \notin S})$, the normal direction is $\partial/\partial\epsilon_S$, and scaling:

$$\epsilon_S \mapsto \lambda \epsilon_S$$

induces the line bundle structure.

Geometric proof. Step 1: Blow-up creates $\mathcal{O}(-1)$.

When blowing up a smooth subvariety $Z \subset Y$, the exceptional divisor E has normal bundle:

$$N_{E/\text{Bl}_Z(Y)} = \mathcal{O}_{\mathbb{P}(N_Z)}(-1)$$

This is the *tautological line bundle* on the projectivization of the normal bundle.

Step 2: Our case.

For $\Delta_S \subset X^n$, the normal bundle is:

$$N_{\Delta_S/X^n} = \bigoplus_{i \in S, i \neq i_0} T_X$$

(where i_0 is any fixed element of S)

This has rank $|S| - 1 = k - 1$.

Step 3: Exceptional divisor.

The exceptional divisor $E_S \cong \mathbb{P}(N_{\Delta_S}) \cong \Delta_S \times \mathbb{P}^{k-2}$.

The normal bundle of E_S in the blow-up is:

$$N_{E_S/\text{Bl}_{\Delta_S}(X^n)} = \mathcal{O}_{E_S}(-1)$$

Step 4: After further blow-ups.

Subsequent blow-ups (of proper transforms of other diagonals) do not change this property, because we are blowing up loci that are transverse to E_S .

Therefore, in the final compactification $\overline{C}_n(X)$, the boundary divisor D_S (which is the image of E_S) retains:

$$N_{D_S/\overline{C}_n(X)} \cong \mathcal{O}_{D_S}(-1)$$

□

Example 5.13.7 (Normal bundle for D_{12} in $\overline{C}_3(\mathbb{C})$). Consider $D_{12} \subset \overline{C}_3(\mathbb{C})$ where the first two points collide.

Divisor structure.

$$D_{12} \cong \mathbb{C} \times \mathbb{C}$$

where:

- First $\mathbb{C}$: location u_{12} of collision
- Second $\mathbb{C}$: location z_3 of third point

Normal direction. $\partial/\partial\epsilon_{12}$ (perpendicular to D_{12})

Normal bundle. $N_{D_{12}} = \mathcal{O}_{D_{12}}(-1)$

In coordinates, a section of $N_{D_{12}}$ looks like:

$$s(u_{12}, z_3, \theta_{12}) = f(u_{12}, z_3, \theta_{12}) \cdot \frac{\partial}{\partial\epsilon_{12}}$$

Under rescaling $\epsilon_{12} \mapsto \lambda\epsilon_{12}$:

$$s \mapsto \lambda^{-1}s$$

(hence the “ (-1) ” in $\mathcal{O}(-1)$)

5.13.6 TRANSITION FUNCTIONS BETWEEN CHARTS

PROPOSITION 5.13.8 (*Transition functions [186];*). Consider two overlapping coordinate charts on $\overline{C}_n(X)$:

- Chart U_1 : coordinates $(u_S, \epsilon_S, \theta_S, \dots)$
- Chart U_2 : coordinates $(u_T, \epsilon_T, \theta_T, \dots)$

where $S, T \subseteq \{1, \dots, n\}$ are different subsets.

Case 1: $S \cap T = \emptyset$ (disjoint collisions)

The charts are independent:

$$u_S = u_S(u_T, \epsilon_T, \theta_T, \dots)$$

$$\epsilon_S = \epsilon_S(\dots)$$

$$u_T = u_T(u_S, \epsilon_S, \theta_S, \dots)$$

$$\epsilon_T = \epsilon_T(\dots)$$

Case 2: $S \subset T$ (nested collisions)

Points in S collide first (small scale), then the cluster collides with other points in T (larger scale).

Transition:

$$u_T = \frac{1}{|T|} \sum_{i \in T} z_i = \frac{1}{|T|} \left(|S|u_S + \sum_{i \in T \setminus S} z_i \right)$$

$$\epsilon_T \sim |\text{spread of } S\text{-cluster and } T \setminus S|$$

$$\approx \max(\epsilon_S, |u_S - z_j| \text{ for } j \in T \setminus S)$$

The proper transform means we replace the crude ϵ_T with a more refined version that accounts for the S -cluster structure.

Case 3: $S \cap T \neq \emptyset$, $S \not\subset T$, $T \not\subset S$ (overlapping).

The charts are related by a combination of rotation (changing which subset is viewed as colliding together) and rescaling.

Example 5.13.9 (Transition for D_{12} and D_{23} in $\overline{C}_3(\mathbb{C})$). Charts U_{12} (near D_{12}) and U_{23} (near D_{23}) overlap in the region where all three points are close but not yet colliding.

Chart U_{12} : $(u_{12}, \epsilon_{12}, \theta_{12}, z_3)$

$$z_1 = u_{12} + \frac{\epsilon_{12}}{2} e^{i\theta_{12}}, \quad z_2 = u_{12} - \frac{\epsilon_{12}}{2} e^{i\theta_{12}}, \quad z_3 = z_3$$

Chart U_{23} : $(u_{23}, \epsilon_{23}, \theta_{23}, z_1)$

$$z_2 = u_{23} + \frac{\epsilon_{23}}{2} e^{i\theta_{23}}, \quad z_3 = u_{23} - \frac{\epsilon_{23}}{2} e^{i\theta_{23}}, \quad z_1 = z_1$$

Transition functions. To express U_{23} coordinates in terms of U_{12} :

$$\begin{aligned} u_{23} &= \frac{z_2 + z_3}{2} = \frac{(u_{12} - \frac{\epsilon_{12}}{2} e^{i\theta_{12}}) + z_3}{2} \\ \epsilon_{23} &= |z_2 - z_3| = \left| u_{12} - \frac{\epsilon_{12}}{2} e^{i\theta_{12}} - z_3 \right| \\ \theta_{23} &= \arg(z_2 - z_3) = \arg\left(u_{12} - \frac{\epsilon_{12}}{2} e^{i\theta_{12}} - z_3\right) \end{aligned}$$

These are smooth functions as long as $\epsilon_{12} \neq 0$ and $z_2 \neq z_3$.

5.13.7 VERIFICATION OF NORMAL CROSSINGS

The boundary divisors intersect in *normal crossings*: locally like coordinate hyperplanes.

THEOREM 5.13.10 (*Normal crossings property*;). Let $D_{S_1}, \dots, D_{S_k}$ be boundary divisors of $\overline{C}_n(X)$ that intersect. Then their intersection $D_{S_1} \cap \dots \cap D_{S_k}$ has normal crossings, meaning:

There exist local coordinates $(x_1, \dots, x_d)$ near any point in the intersection such that:

$$D_{S_i} = \{x_i = 0\}$$

for $i = 1, \dots, k$.

Verification for $n = 3$. We verify explicitly for $\overline{C}_3(\mathbb{C})$.

Case: $D_{12} \cap D_{23}$ (all three points collide)

This is a codimension-2 stratum. We need coordinates where:

$$D_{12} = \{\epsilon_{12} = 0\}, \quad D_{23} = \{\epsilon_{23} = 0\}$$

We use nested blow-up coordinates. The first collision brings z_1, z_2 together; the second brings their center toward z_3 .

Coordinates:

$$\begin{aligned} u &= \frac{z_1 + z_2 + z_3}{3} \quad (\text{barycenter}) \\ \epsilon_{12} &= |z_1 - z_2| \quad (\text{first collision}) \\ \theta_{12} &= \arg(z_1 - z_2) \\ \epsilon_{(12)3} &= \left| \frac{z_1 + z_2}{2} - z_3 \right| \quad (\text{second collision}) \\ \theta_{(12)3} &= \arg\left(\frac{z_1 + z_2}{2} - z_3\right) \end{aligned}$$

In these coordinates:

- $D_{12} = \{\epsilon_{12} = 0\}$ (coordinate hyperplane)
- D_{23} is *not* simply $\{\epsilon_{(12)3} = 0\}$, because we need to account for the relationship $z_2 = \frac{z_1 + z_2}{2} - \frac{z_1 - z_2}{2}$.

Refined coordinates. To make D_{23} also a coordinate hyperplane, we use a different parameterization.

Let $\rho_1 = |z_1 - u|$, $\rho_2 = |z_2 - u|$, $\rho_3 = |z_3 - u|$ be distances from barycenter.

Then define:

$$\tilde{\epsilon}_{12} = \rho_1 + \rho_2 - 2\rho_3, \quad \tilde{\epsilon}_{23} = \rho_2 + \rho_3 - 2\rho_1$$

These are linear combinations of the ρ_i , and near the intersection $D_{12} \cap D_{23}$:

$$D_{12} = \{\tilde{\epsilon}_{12} = 0\}, \quad D_{23} = \{\tilde{\epsilon}_{23} = 0\}$$

Since $\tilde{\epsilon}_{12}$ and $\tilde{\epsilon}_{23}$ are independent coordinates (they span a 2-plane in the (ρ_1, ρ_2, ρ_3) space), the divisors intersect in normal crossings. $\checkmark$ $\square$

Remark 5.13.11 (Normal crossings). For general n , the normal crossings property is guaranteed by the Fulton–MacPherson construction itself. The iterated blow-ups are designed precisely to achieve this.

Blowing up in order of decreasing codimension ensures that later blow-ups are transverse to earlier exceptional divisors, preserving normal crossings at each stage.

5.13.8 EXAMPLE: $n = 4$ WITH ALL COORDINATES

Example 5.13.12 (Complete coordinate atlas for $\overline{C}_4(\mathbb{C})$). For four points, we have $2^4 - 4 - 1 = 11$ boundary strata:

- *Codimension 1:* 6 divisors D_{ij} ($1 \leq i < j \leq 4$)
- *Codimension 2:* 4 strata D_{ijk} (three points collide)
- *Codimension 3:* 1 stratum D_{1234} (all four collide)

5.13.8.1 Codimension-1 coordinates

For each D_{ij} :

$$\begin{aligned} u_{ij} &= \frac{z_i + z_j}{2} \\ \epsilon_{ij} &= |z_i - z_j| \\ \theta_{ij} &= \arg(z_i - z_j) \\ z_k, z_\ell &= z_k, z_\ell \quad (k, \ell \notin \{i, j\}) \end{aligned}$$

Example: D_{12} .

Coords: $(u_{12}, \epsilon_{12}, \theta_{12}, z_3, z_4)$

Divisor: $D_{12} = \{\epsilon_{12} = 0\} \cong \mathbb{C} \times \mathbb{C}^2$

(The collision locus $u_{12} \in \mathbb{C}$ times the two free points $z_3, z_4 \in \mathbb{C}^2$. For a curve, the fiber $\mathbb{P}^{|S|-2} = \mathbb{P}^0$ is a point and contributes no factor.)

5.13.8.2 Codimension-2 coordinates

For each D_{ijk} (e.g., D_{123}):

$$\begin{aligned} u_{123} &= \frac{z_1 + z_2 + z_3}{3} \\ \epsilon_{\text{inner}} &= \text{scale of } \{z_1, z_2, z_3\} \text{ spread} \\ \theta_{\text{config}} &\in \text{Conf}_2(\mathbb{P}^1) \text{ (shapes)} \\ z_4 &= z_4 \end{aligned}$$

More precisely, we can use nested blow-up: first two points collide, then third joins:

$$\begin{aligned} u_{123} &= \frac{z_1 + z_2 + z_3}{3} \\ \epsilon_{12} &= |z_1 - z_2| \\ \theta_{12} &= \arg(z_1 - z_2) \\ \epsilon_{(12)3} &= \left| \frac{z_1 + z_2}{2} - z_3 \right| \\ \theta_{(12)3} &= \arg\left(\frac{z_1 + z_2}{2} - z_3\right) \\ z_4 &= z_4 \end{aligned}$$

5.13.8.3 Codimension-3 coordinate (deepest stratum)

D_{1234} : all four points collide.

Nested blow-up with three levels:

$$u = \frac{z_1 + z_2 + z_3 + z_4}{4} \quad (\text{barycenter})$$

$$\epsilon_1 = |z_1 - z_2| \quad (\text{first pair})$$

$$\theta_1 = \arg(z_1 - z_2)$$

$$\epsilon_2 = |u_{12} - z_3| \quad (\text{add third})$$

$$\theta_2 = \arg(u_{12} - z_3)$$

$$\epsilon_3 = |u_{123} - z_4| \quad (\text{add fourth})$$

$$\theta_3 = \arg(u_{123} - z_4)$$

All three $\epsilon_i \rightarrow 0$ simultaneously means all four points converge to u .

The ratios $\epsilon_1 : \epsilon_2 : \epsilon_3$ encode the “shape” of the collision tree.

5.13.9 SUMMARY TABLE: COORDINATE SYSTEMS

Table 5.1: Coordinate systems on $\overline{C}_n(X)$

Stratum	Codim	Coordinates	Divisor Equation
Interior $C_n(X)$	0	$(z_1, \dots, z_n)$	none
D_{ij}	1	$(u_{ij}, \epsilon_{ij}, \theta_{ij}, \{z_k\}_{k \neq i,j})$	$\epsilon_{ij} = 0$
D_{ijk}	2	$(u_{ijk}, \epsilon_{12}, \theta_{12}, \epsilon_{(12)k}, \theta_{(12)k}, \{z_\ell\}_{\ell \notin \{i,j,k\}})$	$\epsilon_{12} = \epsilon_{(12)k} = 0$
General D_S	$ S - 1$	$(u_S, \{\epsilon_{\text{tree}}\}, \{\theta_{\text{tree}}\}, \{z_j\}_{j \notin S})$	All $\epsilon_{\text{tree}} = 0$

5.13.10 CONNECTION TO CHIRAL ALGEBRA AND OPE

Remark 5.13.13 (Geometric encoding of OPE). The Fulton–MacPherson coordinates mirror the structure of the operator product expansion:

Geometry	CFT
ϵ (scale)	$ z_i - z_j $ in OPE denominator
θ (angle)	Phase in $e^{i\theta}$ (monodromy)
u (center)	Location of composite operator
$\mathbb{P}^1$ fiber	Projective structure from operator dimensions
Normal crossings	Consistency of nested OPEs
Nested blow-ups	Associativity of OPE

For example, the OPE

$$\phi_1(z_1)\phi_2(z_2) = \sum_k \frac{C_{12}^k(\theta)}{|z_1 - z_2|^{\Delta_{12}^k}} \phi_k(u)$$

corresponds to the coordinate transformation $(z_1, z_2) \mapsto (u = \frac{z_1 + z_2}{2}, \epsilon = |z_1 - z_2|, \theta = \arg(z_1 - z_2))$. The OPE singularity is resolved by the blow-up introducing the $\mathbb{P}^1$ fiber.

5.14 RAN SPACE: TOPOLOGICAL AND GEOMETRIC STRUCTURE

Remark 5.14.1 (Physical interpretation). In quantum field theory, the Ran space parametrizes multi-particle states with no preferred ordering. Writing $C_n(M) = \{(x_1, \dots, x_n) : x_i \neq x_j\}$ for ordered configurations and $C_n(M)/S_n$ for unordered ones, the Ran space is

$$\mathrm{Ran}(M) = \coprod_{n \geq 0} C_n(M)/S_n.$$

Its topology encodes particle collisions: as particles approach each other, the configuration point in $\mathrm{Ran}(M)$ moves toward a lower-cardinality stratum.

Construction 5.14.2 (Geometric realization). The Ran space has multiple equivalent constructions:

Topological construction.

$$\mathrm{Ran}(M) = \mathrm{colim}_n \mathrm{Sym}^n(M)$$

with colimit topology: $S \in \mathrm{Ran}(M)$ is “close to” T if they differ by finitely many points that are close in M .

Algebraic construction.

$$\mathrm{Ran}(M) = \mathrm{colim}_{\mathrm{surj}} M^{(-)}$$

over the category of finite sets with surjections, where M^J means “ J -indexed family of points in M ”.

Pro-algebraic construction. For M an algebraic variety:

$$\mathrm{Ran}(M) = \text{ind-scheme version of } \coprod_n \mathrm{Sym}^n(M)$$

Each construction has advantages:

- Topological: good for continuous maps and sheaves
- Algebraic: good for functoriality and universal properties
- Pro-algebraic: good for D-modules and chiral algebras

COMPUTATION 5.14.3 (Explicit examples;). We compute Ran space explicitly for basic examples:

$\mathrm{Ran}(\mathbb{R})$.

Points of $\mathrm{Ran}(\mathbb{R})$: finite subsets $S \subset \mathbb{R}$

Topology: $S_n = \{x_1, \dots, x_n\}$ is close to $S_{n-1} = \{x_1, \dots, x_{n-1}\}$ if $x_n \rightarrow x_i$ for some $i \in \{1, \dots, n-1\}$.

$\mathrm{Ran}(\mathbb{C})$.

Points: finite subsets $S \subset \mathbb{C}$

Stratification by cardinality:

- $|S| = 0$: empty set (one point)
- $|S| = 1$: single points (stratum $\cong \mathbb{C}$)
- $|S| = 2$: pairs of points (stratum $\cong \mathrm{Sym}^2(\mathbb{C}) = \mathbb{C}^2/S_2$)
- $|S| = n$: n -tuples (stratum $\cong \mathrm{Sym}^n(\mathbb{C})$)

Boundary: $\overline{\text{Sym}^n(\mathbb{C})} \supset \text{Sym}^{n-1}(\mathbb{C})$ (collision of points)
 $\text{Ran}(S^1)$.

For the circle, we compute:

$$H_*(\text{Ran}(S^1)) = \bigoplus_{n \geq 0} H_*(\text{Sym}^n(S^1))$$

Using the Dold–Thom theorem:

$$H_*(\text{Ran}(S^1)) \cong \mathbb{Z}[t]$$

(polynomial ring in one variable). The polynomial generator t tracks the cardinality of finite subsets, confirming that $\text{Ran}(S^1)$ sees only the combinatorial stratification by particle number.

Remark 5.14.4. The Ran space satisfies a universal property:

$$\text{Hom}_{\text{Top}}(\text{Ran}(M), Y) \cong \text{Hom}_{\text{Fact}}(M, Y)$$

where Hom_{Fact} denotes factorization-preserving maps, i.e., those satisfying $f(S \sqcup T) = f(S) \cdot f(T)$ and $f(\emptyset) = 1$. This characterizes $\text{Ran}(M)$ uniquely. As a consequence, factorization algebras on M are equivalent to sheaves on $\text{Ran}(M)$ with compatible multiplication structure.

5.14.1 RAN SPACE: DEFINITION

Definition 5.14.5 (Ran space). Let M be a topological space (typically a smooth manifold or algebraic variety). The *Ran space* of M , denoted $\text{Ran}(M)$, is defined as:

As a set.

$$\text{Ran}(M) = \{S \subset M : S \text{ is finite and non-empty}\}$$

the set of all finite non-empty subsets of M .

Topological structure. The topology on $\text{Ran}(M)$ is the *colimit topology* from the diagram:

$$\text{Ran}(M) = \text{colim}_{n \geq 1} \text{Sym}^n(M)$$

where $\text{Sym}^n(M) = M^n / S_n$ is the n -th symmetric power with quotient topology.

Explicitly:

- A subset $U \subset \text{Ran}(M)$ is *open* if and only if $U \cap \text{Sym}^n(M)$ is open in $\text{Sym}^n(M)$ for all n
- A map $f : \text{Ran}(M) \rightarrow Y$ is *continuous* if and only if $f|_{\text{Sym}^n(M)} : \text{Sym}^n(M) \rightarrow Y$ is continuous for all n

Example 5.14.6 (Convergence in Ran space). Consider $M = \mathbb{R}$. The sequence of 2-element sets:

$$S_k = \{0, 1/k\} \in \text{Sym}^2(\mathbb{R})$$

As $k \rightarrow \infty$: $1/k \rightarrow 0$, so the two points collide.

In $\text{Ran}(\mathbb{R})$:

$$S_k \rightarrow \{0\} \in \text{Sym}^1(\mathbb{R})$$

This is a sequence in Sym^2 converging to a point in Sym^1 .

The Ran space topology allows points to collide and merge, creating a connection between different cardinality strata.

Example 5.14.7 (Non-Hausdorff phenomenon). The Ran space is *NOT Hausdorff* in general.

Consider $M = \mathbb{R}$. The two points:

$$S_1 = \{0\} \in \text{Ran}^1(\mathbb{R}), \quad S_2 = \{0, 1\} \in \text{Ran}^2(\mathbb{R})$$

Claim: $S_1 = \{0\}$ lies in the closure of $\text{Ran}^{\geq 2}(\mathbb{R})$, so cardinality strata are not closed and $\text{Ran}(\mathbb{R})$ is not Hausdorff.

Proof. In the Ran topology, the sequence $\{0, 1/k\} \in \text{Ran}^2(\mathbb{R})$ converges to $\{0\} \in \text{Ran}^1(\mathbb{R})$ as $k \rightarrow \infty$ (collision of the two points). Hence $S_1 = \{0\}$ is a limit point of $\text{Ran}^2(\mathbb{R})$ but does not lie in it. Since Ran^2 is not closed, $\text{Ran}(\mathbb{R})$ is not T_1 (hence not Hausdorff).

Interpretation. The non-Hausdorff property encodes the physics of particle collisions: one cannot separate configurations with different particle numbers.

5.14.2 D-MODULES AND FACTORIZATION ALGEBRAS ON RAN SPACE

THEOREM 5.14.8 (*Chiral algebras $\leftrightarrow$ D-modules on Ran space [40, 167];*). There is an equivalence of ∞ -categories:

$$\text{ChirAlg}(M) \simeq \text{D-mod}_{\text{fact}}(\text{Ran}(M))$$

where $\text{D-mod}_{\text{fact}}$ denotes D-modules with factorization structure.

Remark 5.14.9 (Provenance and citation). This theorem is imported and treated as . The chiral/Ran-space correspondence is developed in [40, Chapter 3]; the factorization-algebra comparison framework used here is aligned with [167, 92].

5.14.3 CHIRAL HOMOLOGY AS SHEAF COHOMOLOGY ON RAN SPACE

THEOREM 5.14.10 (*Chiral homology via Ran space [40, 92];*). For a chiral algebra $\mathcal{A}$ on M and a closed manifold N with a map $f : N \rightarrow M$, the chiral homology is:

$$\int_N \mathcal{A} = H_*(\text{Ran}(N), f^* \mathcal{F}_{\mathcal{A}})$$

where $\mathcal{F}_{\mathcal{A}}$ is the D-module on $\text{Ran}(M)$ corresponding to $\mathcal{A}$.

Remark 5.14.11 (Provenance and citation). This theorem is imported and treated as . The Ran space interpretation of chiral homology follows the Beilinson–Drinfeld formalism [40, Chapter 3] together with factorization-homology descriptions in [92, 30].

5.14.4 COMPUTATIONAL EXAMPLES

Example 5.14.12 (Homology of $\text{Ran}(S^1)$). For the circle S^1 :

Step 1: Symmetric powers

$$\text{Sym}^n(S^1) = \underbrace{S^1 \times \cdots \times S^1}_n / S_n$$

Topology: $(S^1)^n / S_n$ is a torus quotient.

Step 2: Homology of each stratum. It is a classical fact that $\text{Sym}^n(S^1) \cong S^1$ for all $n \geq 1$: the map sending an unordered n -tuple $\{e^{i\theta_1}, \dots, e^{i\theta_n}\}$ to $e^{i(\theta_1 + \cdots + \theta_n)}$ is a homeomorphism. Hence

$$H_*(\text{Sym}^n(S^1)) \cong H_*(S^1) = \mathbb{Z} \oplus \mathbb{Z} \quad (\text{in degrees 0 and 1})$$

Step 3: Total homology. By the Dold–Thom theorem, $\mathrm{Sym}^\infty(S^1)$ has $\pi_k(\mathrm{Sym}^\infty(S^1)) = H_k(S^1; \mathbb{Z})$, so $\mathrm{Sym}^\infty(S^1) \simeq K(\mathbb{Z}, 0) \times K(\mathbb{Z}, 1)$. The Ran space filtration gives:

$$H_k(\mathrm{Ran}(S^1)) = \mathbb{Z} \quad \text{for } k = 0, 1$$

Example 5.14.13 (Ran space of $\mathbb{P}^1$). For the projective line $\mathbb{P}^1$:

$$\mathrm{Sym}^n(\mathbb{P}^1) \cong \mathbb{P}^n$$

(the symmetric power of $\mathbb{P}^1$ is projective space)

Topology:

- $\mathrm{Sym}^1(\mathbb{P}^1) = \mathbb{P}^1$ (2-sphere)
- $\mathrm{Sym}^2(\mathbb{P}^1) = \mathbb{P}^2$
- $\mathrm{Sym}^n(\mathbb{P}^1) = \mathbb{P}^n$

Cohomology:

$$H^*(\mathrm{Sym}^n(\mathbb{P}^1)) = \mathbb{Z}[h]/(h^{n+1}), \quad |h| = 2$$

Total cohomology of Ran space:

$$H^*(\mathrm{Ran}(\mathbb{P}^1)) = \mathrm{colim}_n \mathbb{Z}[h]/(h^{n+1}) = \mathbb{Z}[h]$$

(polynomial ring in degree 2 generator)

5.14.5 SUMMARY AND MASTER TABLE

Table 5.2: Properties of the Ran space

Property	Description
Definition	$\mathrm{Ran}(M) = \coprod_{n \geq 1} \mathrm{Sym}^n(M)$ (colimit topology)
Topology	Colimit topology: sequences can jump between strata (collisions)
Hausdorff?	NO - configurations with different cardinalities cannot be separated
Stratification	By cardinality: $\mathrm{Ran}(M) = \bigcup_n \mathrm{Sym}^n(M)$
Pro-algebraic	Ind-scheme: $\mathrm{colim}_n \mathrm{Sym}^n(M)$ (when M is algebraic)
Factorization	Factorization algebras $\leftrightarrow$ Sheaves on Ran space
D-modules	$\mathrm{ChiralAlg}(M) \simeq \mathrm{D-mod}_{\mathrm{fact}}(\mathrm{Ran}(M))$
Chiral homology	$\int_N \mathcal{A} = H_*(\mathrm{Ran}(N), \mathcal{F}_{\mathcal{A}})$

Chapter 6

The geometric bar complex

An augmented algebra has exactly one piece of canonical structure beyond its multiplication: the augmentation ideal $\bar{\mathcal{A}} = \ker(\varepsilon)$, the part that the counit forgets. Desuspend it to shift the grading, then form the cofree nilpotent coalgebra $T^c(s^{-1}\bar{\mathcal{A}})$ with deconcatenation coproduct. This object is not a choice; it is the *universal* recipient of coderivations built from the algebra structure maps, and the bar differential is the unique coderivation that encodes them all. The entire construction is forced: given $\mathcal{A}$ and ε , the coalgebra $B(\mathcal{A})$ exists, its differential squares to zero, and every deformation-theoretic invariant of $\mathcal{A}$ is a projection from the resulting Maurer–Cartan element. What follows is the geometric incarnation of this universal object on algebraic curves.

Locality of the chiral product forces a nilpotent coalgebra. The OPE has poles of finite order along the diagonal; the logarithmic kernel $\eta_{ij} = d \log(z_i - z_j)$ on the Fulton–MacPherson compactification $\text{FM}_n(X)$ extracts their residues; and the Arnold relation makes $d^2 = 0$ at genus 0. The primitive construction is the ordered bar $B^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$: the cofree tensor coalgebra with deconcatenation coproduct, carrying the R -matrix, the KZ associator, and the full Yangian deformation. The factorization coalgebra $\bar{B}(\mathcal{A}) = \text{Sym}^c(s^{-1}\bar{\mathcal{A}})$ on $\text{Ran}(X)$ is its Σ_n -coinvariant quotient, the input to the universal MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ governing the genus expansion, the adjunction (Theorem A), and the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$. At genus $g \geq 1$ the fiberwise differential acquires curvature $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ from the Hodge bundle (Chapter 13); on the Koszul locus, the cobar functor inverts the bar: $\Omega \circ \bar{B} \xrightarrow{\sim} \text{id}$ (Theorem 8.6.1). The three-step bar differential $d = d_{\text{internal}} + d_{\text{residue}} + d_{\text{de Rham}}$ that we built by hand for the Heisenberg algebra in Chapter 2 now receives its general formulation. The three components correspond to three types of geometry on the compactified configuration space $\bar{C}_n(X)$:

Component	Geometric origin	Extracts
d_{internal}	Internal differential of $\mathcal{A}$	Algebraic structure
d_{residue}	Residues along collision divisors D_{ij}	OPE coefficients
$d_{\text{de Rham}}$	de Rham differential on $\bar{C}_n(X)$	Configuration geometry

Theorem 6.1.21 assembles these three components into the full genus-0 differential d_0 and proves $d_0^2 = 0$; the key input is the Arnold relation (Theorem 6.1.31, Remark 6.1.3).

Notation. Throughout this chapter, the unadorned differential d on the bar complex denotes the genus-0 collision differential d_0 of Convention 13.0.2; it satisfies $d_0^2 = 0$ (Theorem 6.1.21). The fiberwise curved differential d_{fib} and the total corrected differential D_g appear only in Chapter 13.

Convention 6.o.1 (Set notation and ordering). Throughout this chapter: collision divisors are D_{ij} with $i < j$ (indices in increasing order); the hat notation $\widehat{ij}$ denotes *omission* of both factors ϕ_i and ϕ_j after applying the OPE (we write $\widehat{ij}$ for the collision pattern itself, and $\widehat{\phi_i, \phi_j}$ when listing omitted terms in a tensor product).

Convention 6.o.2 (Bar coalgebra and Koszul dual algebra). The bar construction $\overline{B}_X(\mathcal{A})$ of an augmented chiral algebra $\mathcal{A}$ is a dg factorization *coalgebra* on $\text{Ran}(X)$, the Σ_n -coinvariant quotient of the ordered bar $B_X^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\mathcal{A})$. Throughout this chapter, the unqualified notation $\overline{B}_X(\mathcal{A})$ refers to this symmetric factorization bar on unordered $\text{Ran}(X)$; the ordered tensor coalgebra is always written $B_X^{\text{ord}}(\mathcal{A})$. It is the bar coalgebra of $\mathcal{A}$: the bar complex computes the dual coalgebra

$$\mathcal{A}^i := H^*(\overline{B}_X(\mathcal{A})).$$

Thus $\overline{B}_X(\mathcal{A})$, $\mathcal{A}^i$, and $\mathcal{A}^!$ are distinct objects.

When $\mathcal{A}$ is Koszul, the bar coalgebra has cohomology concentrated in bar degree 1, so $\mathcal{A}^i$ is concentrated there. The Koszul dual *algebra* $\mathcal{A}^! = ((\mathcal{A}^i)^\vee)$ is a separate object: it has generators $\mathcal{V}^\vee = \text{Hom}_{\mathcal{O}_X}(\mathcal{V}, \omega_X)$ ($\mathcal{D}_X$ -module dual of the generators of $\mathcal{A}$) and relations $R^\perp$ (orthogonal complement under the residue pairing). In the classical setting (algebras on a point), $\mathcal{A}^!$ is the graded linear dual of the concentrated dual coalgebra $\mathcal{A}^i$. In the chiral setting, $\mathcal{A}^!$ is characterized by Theorem A (Theorem II.1.84): Verdier duality on $\text{Ran}(X)$ sends the bar *coalgebra* to the homotopy Koszul dual *algebra*,

$$\mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!,$$

Remark 6.o.3 (Verdier side of Theorem A). Theorem A is a statement about the symmetric bar $\overline{B}_X(\mathcal{A})$ on unordered $\text{Ran}(X)$. It is not a statement about the ordered bar $B_X^{\text{ord}}(\mathcal{A})$. The functor $\mathbb{D}_{\text{Ran}}$ is defined on factorization $\mathcal{D}$ -modules on $\text{Ran}(X)$; the expression $\mathbb{D}_{\text{Ran}} B_X^{\text{ord}}(\mathcal{A})$ is therefore not part of the theorem. The ordered bar lives on ordered configuration spaces and does not itself carry the symmetric factorization datum required for this Verdier intertwining. To compare the ordered bar with Theorem A, one must first pass to its Σ_n -coinvariant quotient $\overline{B}_X(\mathcal{A})$.

Remark 6.o.4 (Volume II notation). In Volume II, the Koszul dual splits into two components: $\mathcal{A}_{\text{ch}}^!$ (the chiral dual, arising from Verdier duality on the symmetric bar $\overline{B}_X(\mathcal{A})$) and $\mathcal{A}_{\text{line}}^!$ (the line dual, arising from linear duality on the ordered bar $B_X^{\text{ord}}(\mathcal{A})$). Throughout Volume I, bare $\mathcal{A}^!$ denotes $\mathcal{A}_{\text{ch}}^!$ unless otherwise specified.

The cobar–bar counit $\Omega_X(\overline{B}_X(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ (Theorem 8.6.1) is a *resolution* of $\mathcal{A}$: the cobar of the bar coalgebra recovers $\mathcal{A}$ itself, not its dual.

The bar-dual identity has a precise witness: the *canonical twisting morphism* $\tau: \overline{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$, the degree-+1 map projecting bar generators to their algebra images. The graded vector space $\mathfrak{g}_\tau := \text{Hom}(\overline{B}_X(\mathcal{A}), \mathcal{A})$ carries a natural dg Lie structure, the *convolution Lie algebra*, whose bracket is $[f, g] = \mu_{\mathcal{A}} \circ (f \otimes g) \circ \Delta_{\overline{B}}$ and whose differential is $\partial f = d_{\mathcal{A}} \circ f - (-1)^{|f|} f \circ d_{\overline{B}}$. (This dg Lie algebra is the truncation of a full L_∞ -structure arising from the operadic convolution; the higher brackets ℓ_n for $n \geq 3$ encode homotopy-transfer data and are recovered via graph sums, see Theorem 13.22.6.) The twisting morphism τ is a *Maurer–Cartan element* of this Lie algebra:

$$\partial \tau + \frac{1}{2} [\tau, \tau] = 0 \quad (\text{equivalently: } \partial \tau + \tau \star \tau = 0),$$

and the bar-cobar adjunction is the pair $(\varepsilon_\tau, \eta_\tau)$ it determines. At higher genus, τ extends to a curved MC element $\tau_{\text{mod}} = \tau + \Theta_{\mathcal{A}}$ in the modular convolution algebra $\mathfrak{g}_\tau \widehat{\otimes} R\Gamma(\overline{\mathcal{M}}_g, \bullet)$ (Remark 13.21.67),

whose curvature $\kappa(\mathcal{A}) \cdot \omega_g$ controls the genus tower. The four main theorems are four properties of τ : existence (A), invertibility (B), branch structure (C), leading coefficient (D).

Object	Type	Relationship
$\overline{B}_X(\mathcal{A})$	factorization coalgebra	bar coalgebra
$\mathcal{A}^i = H^*(\overline{B}_X(\mathcal{A}))$	factorization coalgebra	dual coalgebra
$\mathcal{A}^!$	chiral algebra	$= ((\mathcal{A}^i)^\vee)$; generators $= \mathcal{V}^\vee$, relations $= R^\perp$
$\mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A})$	factorization algebra	$\simeq \mathcal{A}_\infty^!$ (Theorem A)
$\Omega_X(\overline{B}_X(\mathcal{A}))$	chiral algebra	$\simeq \mathcal{A}$ (resolution, not $\mathcal{A}^!$)

Convention 6.0.5 (Chiral product vs. chiral bracket). The *chiral product* $\mu: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \rightarrow \Delta_!(\mathcal{A})$ (Definition 3.3.3) encodes all OPE pole orders simultaneously. The *chiral bracket* $\{a, b\} = a_{(0)} b$ extracts the simple-pole residue of μ ; the *invariant pairing* $\kappa(a, b) = a_{(1)} b$ extracts the double-pole residue. The bar differential d_{res} uses the full product μ (Proposition 6.1.24), which decomposes as $d_{\text{res}} = d_{\text{bracket}} + d_{\text{curvature}}$: the bracket component uses $\{, \}$; the curvature component uses κ . Neither component is individually a differential (§1.2).

6.1 THE GEOMETRIC BAR COMPLEX

6.1.1 OPE COEFFICIENTS AS RESIDUES

Remark 6.1.1 (Physical origin). In two-dimensional conformal field theory, the operator product expansion (OPE)

$$\phi_i(z)\phi_j(w) = \sum_k \frac{C_{ij}^k}{(z-w)^{h_i+h_j-h_k}} \phi_k(w) + (\text{less singular})$$

encodes the structure constants C_{ij}^k (fusion rules) and conformal weights h_i ; associativity of multiple OPEs constrains the C_{ij}^k . The bar construction geometrizes this data: $\overline{C}_n(X)$ parametrizes insertion points, D_{ij} encodes the collision $z_i \rightarrow z_j$, $\eta_{ij} = d \log(z_i - z_j)$ carries the singularities, and $\text{Res}_{D_{ij}}$ extracts the OPE coefficients.

Remark 6.1.2 (Parallel track: the BV complex). The bar complex has a second life as the BV complex of a chiral field theory. In the BV formalism (Costello–Gwilliam [92]), a chiral algebra $\mathcal{A}$ determines a classical field theory whose fields are generators of $\mathcal{A}$ and whose *antifields* are cogenerators of $\mathcal{A}^!$; the BV bracket arises from the residue pairing on configuration spaces. The identification

$$\text{bar complex of } \mathcal{A} = \text{BV complex of the chiral field theory of } \mathcal{A}$$

is made precise in Theorem R.3.1. The dictionary is complete:

This chapter	BV reading
Bar differential d_{res}	BRST operator
Logarithmic form η_{ij}	Propagator
Arnold relation $\Rightarrow d^2 = 0$	Quantum master equation
Bar cohomology $H^*(\overline{B}(\mathcal{A}))$	Physical observables
Curvature m_0 (Chapter 13)	Conformal anomaly

This is not an analogy; it is Theorem R.3.1. The algebraic-geometric side comes first because it admits complete proofs; the physical identifications follow as theorems, not heuristics.

Remark 6.1.3 (Holomorphic factorization on $\text{FM}_k(X)$). The bar differential d_{res} , constructed from OPE residues along collision divisors in $\overline{C}_k(X)$, is the factorization algebra structure of Costello–Gwilliam [92] restricted to codimension-1 boundary strata of the Fulton–MacPherson compactification $\text{FM}_k(X)$. Each boundary stratum $D_S \cong \text{FM}_{|S|} \times \text{FM}_{k-|S|+1}$ encodes a cluster of $|S|$ points colliding, and the residue along D_S extracts the factorization product on the cluster. The Arnold relation $\eta_{ij} \wedge \eta_{jk} + \text{cyc.} = 0$ is the codimension-2 cancellation that makes $d_{\text{res}}^2 = 0$ a consequence of the face relations on $\text{FM}_k(X)$. The bar complex is holomorphic factorization on the Fulton–MacPherson compactification.

Example 6.1.4 (OPE as residue: the Heisenberg current). The Heisenberg current $J(z)$ with OPE $J(z)J(w) = k/(z-w)^2 + \text{reg.}$ gives the bar element $J(z_1) \otimes J(z_2) \otimes \eta_{12} \in \overline{B}^1(\mathcal{H})$, where $\eta_{12} = d \log(z_1 - z_2)$. The bar differential extracts the full chiral product μ (Convention 6.0.5): since $J_{(0)}J = 0$ (no simple pole) and $J_{(1)}J = k$ (double pole), the result is

$$d_{\text{res}}(J \otimes J \otimes \eta_{12}) = k \cdot 1.$$

The entire bar differential comes from the curvature component $d_{\text{curvature}}$ (Proposition 6.1.24). One must not multiply the OPE pole by the propagator η_{12} and take a combined residue; the logarithmic form accounts for the bar degree, not an additional pole (Computation 6.1.35).

Remark 6.1.5 (Logarithmic forms are forced). Three requirements distinguish logarithmic forms $\eta_{ij} = d \log(z_i - z_j)$ among meromorphic 1-forms with poles along diagonals, and together determine them uniquely.

Conformal invariance. Under a conformal transformation $z \mapsto f(z)$, a direct computation gives $d \log(f(z_i) - f(z_j)) = \frac{f'(z_i)dz_i - f'(z_j)dz_j}{f(z_i) - f(z_j)}$, which near the diagonal $z_i \approx z_j$ reduces to $(dz_i - dz_j)/(z_i - z_j)$ by cancellation of f' . Thus η_{ij} is conformally invariant up to regular terms.

Well-defined residues. The residue $\text{Res}_{D_{ij}}$ requires a *simple pole* along D_{ij} : forms with higher-order poles (e.g. $dz_i/(z_i - z_j)^2$) do not admit canonical residues. A logarithmic form $\omega = \frac{df}{f} \wedge \alpha + \beta$ with $f = z_i - z_j$ has $\text{Res}_{D_{ij}}(\omega) = \alpha|_{D_{ij}}$, which is canonical.

Arnold relations. The cyclic identity $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$ is the form-level expression of $d^2 = 0$ on configuration spaces; it holds for $d \log$ forms and fails for other meromorphic 1-forms with simple poles.

Conformal invariance, canonical residues, and differential nilpotence together force the logarithmic form uniquely.

6.1.2 NON-ABELIAN POINCARÉ PERSPECTIVE ON BAR CONSTRUCTION

Definition 6.1.6 (Bar as factorization homology). The geometric bar construction is factorization homology of the chiral algebra, following the Beilinson–Drinfeld factorization framework [40, §3.4]:

$$\overline{B}_n^{\text{geom}}(\mathcal{A}) = \int_{\overline{C}_{n+1}(X)/X} \mathcal{A}$$

where we integrate over configuration spaces relative to X .

Remark 6.1.7 (Configuration spaces). Non-abelian Poincaré duality [40, §3.4] integrates over configuration spaces rather than the manifold itself. The compactification $\overline{C}_n(X)$ adds boundary divisors encoding collision data; the key inputs are [40, Theorem 3.4.22, §3.6] (Ran space as the correct geometric setting). Residue extraction is the NAP analogue of the cup product.

THEOREM 6.1.8 (*Bar construction as NAP homology*;). Let $\mathcal{A}$ be a chiral algebra on a smooth curve X satisfying:

- (i) *Holonomicity*: $\mathcal{A}$ is a holonomic $\mathcal{D}_X$ -module (equivalently, locally finitely generated with regular singularities). Concretely, the solution space of the $\mathcal{D}_X$ -equations on any disk is finite-dimensional, the algebraic counterpart of finite-dimensional state spaces at each point.
- (ii) *Excision*: the factorization algebra associated to $\mathcal{A}$ satisfies the Weiss cosheaf condition (Definition 3.10.2), i.e., the factorization structure glues over Weiss covers. This provides the descent data for factorization homology.

Then factorization homology is computed via the geometric bar complex:

$$H_*(\bar{B}^{\text{geom}}(\mathcal{A})) \cong \int_{C_*(X)} \mathcal{A}$$

This is factorization homology of X with coefficients in $\mathcal{A}$ in the sense of Ayala–Francis [30]. Holonomicity guarantees finite-dimensionality of stalks, which is needed for the Ayala–Francis identification [30, Theorem 5.1]; excision provides the descent data.

The coalgebra structure on $\bar{B}^{\text{geom}}(\mathcal{A})$ arises from the coproduct in factorization homology:

$$\int_X A \rightarrow \int_{X_1} A \otimes \int_{X_2} A$$

when X decomposes as $X = X_1 \sqcup X_2$.

Proof. The identification follows from [30] (for the factorization homology framework) and [40] (Section 3.4, for the chiral algebra case). The bar differential $d = d_{\text{int}} + d_{\text{res}} + d_{dR}$ corresponds to the three components of the factorization structure:

- d_{int} : Internal operations in $\mathcal{A}$ (factorization algebra structure)
- d_{res} : Residues at collisions (the full chiral product, realizing the NAP cup product)
- d_{dR} : de Rham differential on logarithmic forms

The key verification is that Weiss covers of $C_n(X)$ compute factorization homology ([30], Theorem 5.1), and the FM compactification provides a canonical system of Weiss covers whose Čech complex is precisely the bar complex (Definition 3.10.2). $\square$

Remark 6.1.9 (*The nilpotence-periodicity correspondence*). The logarithmic form $\eta_{ij} = d \log(z_i - z_j)$ is not an incidental choice of kernel: the bar construction is the *categorical logarithm* for chiral algebras, mapping multiplicative structure (the OPE) to additive/nilpotent structure (the bar differential with $d_0^2 = 0$). The cobar construction is the corresponding *exponential*, reconstructing the algebra from the nilpotent data. The structural principle governing the entire theory is:

Nilpotence is the logarithm of periodicity.

At genus 0, the logarithm η_{ij} is single-valued on $C_2(\mathbb{P}^1)$, the bar differential is nilpotent ($d_0^2 = 0$), and the monodromy is trivial. At genus $g \geq 1$, the logarithm $d \log E(z_i, z_j)$ acquires monodromy around the B -cycles of Σ_g , the fiberwise bar differential fails nilpotence by $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$, and the curvature $\kappa(\mathcal{A})$ is the *infinitesimal generator* of this monodromy: the residue at the branch point of the logarithm. This is the chiral Riemann–Hilbert correspondence: the nilpotent datum κ determines the periodic datum (the monodromy of the bar family over $\overline{\mathcal{M}}_g$) via exponentiation.

The four theorems are four aspects of this correspondence: Theorem A asserts that the categorical logarithm and exponential exist; Theorem B that they are mutually inverse on the convergence domain (the Koszul locus); Theorem C that the failure off the convergence domain decomposes into complementary Lagrangians (the branch structure of the logarithm); and Theorem D that the leading coefficient $\kappa(\mathcal{A})$ of the logarithm determines the genus expansion $F_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g^{\text{FP}}$ (UNIFORM-WEIGHT) at all genera, while the multi-weight extension at genus $g \geq 2$ receives a nonvanishing cross-channel correction (Theorem 13.22.225).

The modular periodicity profile $\Pi(\mathcal{A})$ is the global/exponential counterpart of the infinitesimal/nilpotent characteristic $\kappa(\mathcal{A})$. At the scalar level, the T-matrix eigenvalues $\lambda = \exp(2\pi i(h - c/24))$ are the *exponentials* of conformal weights shifted by the central charge; the modular period N is the smallest positive integer for which $\exp(2\pi i N c/24) = 1$. At the geometric level, the nilpotency $\kappa(\lambda)^{g-1} = 0$ (Theorem 14.6.17) makes the operator $\exp(\kappa(\lambda))$ *unipotent*, not periodic: geometry provides a stabilization threshold, not a period. True periodicity arises from modular and quantum sources whose nilpotent generators have finite-order exponentials.

6.1.3 PRECISE CONSTRUCTION OF THE BAR COMPLEX

Definition 6.1.10 (Genus-graded geometric bar complex, preliminary form). The bar complex at genus g and bar degree n is, in first approximation:

$$\bar{B}^{(g),n}(\mathcal{A}) = \Gamma\left(\overline{C}_{n+1}^{(g)}(\Sigma_g), j_* j^* \mathcal{A}^{\boxtimes(n+1)} \otimes \Omega^n(\log D^{(g)})\right)$$

The total bar complex is $\bar{B}(\mathcal{A}) = \bigoplus_{g \geq 0} \bar{B}^{(g)}(\mathcal{A})$. The complete definition, incorporating the bigrading by bar degree p and form degree q together with the genus-graded orientation bundle $\text{or}_{p+1}^{(g)}$, the sign line that records orientations of the codimension- p collision strata at genus g , is given in Definition 6.1.52 below.

Convention 6.1.11 (Global sections vs. derived global sections). Throughout this chapter, $\Gamma(-)$ denotes *un-derived* global sections: for a sheaf $\mathcal{F}$ on a variety Y , the symbol $\Gamma(Y, \mathcal{F})$ is the vector space $H^0(Y, \mathcal{F})$. When derived global sections are needed (e.g., over moduli stacks or in derived $\mathcal{D}$ -module arguments), we write $R\Gamma$ explicitly. In particular, the bar complex definition above uses honest global sections of a coherent sheaf on the smooth variety $\overline{C}_{n+1}^{(g)}(\Sigma_g)$.

Remark 6.1.12 (Components of the definition). The FM compactification $\overline{C}_{n+1}^{(g)}(\Sigma_g)$ parametrizes $(n+1)$ points on Σ_g with collision patterns (Chapter 5). The degree- n bar complex has $(n+1)$ insertions $\phi_0(z_0) \otimes \cdots \otimes \phi_n(z_n)$, where ϕ_0 is the “output” (operadic structure).

The external tensor product $j_* j^* \mathcal{A}^{\boxtimes(n+1)}$ extends $\mathcal{A}^{\boxtimes(n+1)}$ from the open locus of distinct points across collisions, with the OPE controlling the singularity structure (BD [40, §3.4.14–3.4.22]).

The logarithmic forms $\Omega^n(\log D^{(g)})$ are spanned at genus 0 by wedge products of $\eta_{ij} = d \log(z_i - z_j)$; at genus $g \geq 1$, theta functions ($g = 1$) and prime forms ($g \geq 2$) contribute.

A global section $\alpha \in \bar{B}^{(g),n}(\mathcal{A})$ is a “correlation function”:

$$\alpha = \sum_I a_I(z_0, \dots, z_n) \cdot \phi_{i_0}(z_0) \otimes \cdots \otimes \phi_{i_n}(z_n) \otimes \omega_I(z_0, \dots, z_n)$$

the geometric incarnation of an $(n+1)$ -point function.

Example 6.1.13 (Genus zero, degree 1). At genus 0, degree 1:

$$\bar{B}^{(0),1}(\mathcal{A}) = \Gamma(\bar{C}_2(\mathbb{P}^1), j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \otimes \Omega^1(\log D_{12}))$$

Configuration space. $C_2(\mathbb{P}^1) \subset (\mathbb{P}^1)^2$ has $\dim_{\mathbb{C}} = 2$. The PSL_2 action is transitive on ordered pairs of distinct points, so the quotient $C_2(\mathbb{P}^1)/\mathrm{PSL}_2$ is a point. After fixing the PSL_2 gauge (e.g., $z_2 = \infty$), the residual coordinate is $z_1 \in \mathbb{C}$.

Boundary divisor. $D_{12} = \{z_1 = z_2\}$ is a single point in $\bar{C}_2(\mathbb{P}^1)$.

Logarithmic 1-forms. $\Omega^1(\log D_{12})$ consists of forms:

$$\omega = f(z_1, z_2) \cdot \eta_{12}$$

where $\eta_{12} = \frac{dz_1 - dz_2}{z_1 - z_2}$ and f is a meromorphic function.

Elements. Typical element is:

$$\phi_i(z_1) \otimes \phi_j(z_2) \otimes \eta_{12}$$

Dimension. If $\mathcal{A}$ has N generators, then:

$$\dim \bar{B}^{(0),1}(\mathcal{A}) = N^2 \cdot \dim H^0(\bar{C}_2(\mathbb{P}^1), \Omega^1(\log D_{12}))$$

For $\mathbb{P}^1$, $\dim H^0(\bar{C}_2, \Omega^1(\log D)) = 1$ (only constant coefficient functions after fixing PSL_2).

Hence $\dim \bar{B}^{(0),1}(\mathcal{A}) = N^2$.

Example 6.1.14 (Genus zero, degree 2). At genus 0, degree 2:

$$\bar{B}^{(0),2}(\mathcal{A}) = \Gamma(\bar{C}_3(\mathbb{P}^1), j_* j^*(\mathcal{A}^{\boxtimes 3}) \otimes \Omega^2(\log D))$$

Configuration space. $\bar{C}_3(\mathbb{P}^1)$ has $\dim_{\mathbb{C}} = 3$. Fixing the PSL_2 gauge (e.g., $z_3 = 0, z_2 = 1, z_1 = \infty$ for the normalization), the quotient $\bar{C}_3(\mathbb{P}^1)/\mathrm{PSL}_2 \cong \bar{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$ has $\dim_{\mathbb{C}} = 1$. The PSL_2 -reduced configuration has one free cross-ratio parameter.

Boundary divisor. $D = D_{12} \cup D_{23} \cup D_{13}$ (three divisors, one for each pair of points colliding).

Logarithmic 2-forms. $\Omega^2(\log D)$ is spanned by:

$$\eta_{12} \wedge \eta_{23}, \quad \eta_{23} \wedge \eta_{31}, \quad \eta_{31} \wedge \eta_{12}$$

subject to Arnold relation:

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$$

So the space of 2-forms is 2-dimensional (three generators, one relation).

Elements. Typical element is:

$$\sum_{i,j,k} c_{ijk} \cdot \phi_i(z_1) \otimes \phi_j(z_2) \otimes \phi_k(z_3) \otimes (\eta_{12} \wedge \eta_{23})$$

Dimension.

$$\dim \bar{B}^{(0),2}(\mathcal{A}) = N^3 \cdot 2$$

This grows rapidly with n .

6.1.3.1 The bar differential

Definition 6.1.15 (Bar differential). The bar complex carries a bigrading $\bar{B}_{p,q}(\mathcal{A})$ by *bar degree* p (number of desuspended tensor factors minus one) and *form degree* q . The *cohomological degree* of a homogeneous element $s^{-1}\phi_0 \otimes \cdots \otimes s^{-1}\phi_p \otimes \omega \in \bar{B}_{p,q}$ is

$$n = \sum_{i=0}^p (|\phi_i| - 1) + q = \left(\sum_{i=0}^p |\phi_i| \right) - (p+1) + q,$$

where $|\phi_i|$ is the internal (algebra) cohomological degree and -1 is the desuspension shift. The total differential $d = d_{\text{internal}} + d_{\text{residue}} + d_{\text{form}}$ has $|d| = +1$, verified component by component:

- d_{internal} preserves (p, q) and increases some $|\phi_i|$ by 1: net $n \mapsto n + 1$.
- d_{residue} maps $\bar{B}_{p,q} \rightarrow \bar{B}_{p-1,q}$: bar degree decreases by 1 (two factors merge via μ), form degree is unchanged (the Poincaré residue extracts a scalar, not a form), and the desuspension contribution changes by $-(p) - (-(p+1)) = +1$: net $n \mapsto n + 1$.
- d_{form} maps $\bar{B}_{p,q} \rightarrow \bar{B}_{p,q+1}$: form degree increases by 1 via d_{dR} : net $n \mapsto n + 1$.

The three components are:

$$d = d_{\text{internal}} + d_{\text{residue}} + d_{\text{form}}$$

Component 1: Internal differential d_{internal} .

If $\mathcal{A}$ has an internal differential $d_{\mathcal{A}} : \mathcal{A} \rightarrow \mathcal{A}$ (e.g., from a BRST complex or de Rham differential), we apply it to each tensor factor:

$$d_{\text{internal}}(\phi_0 \otimes \cdots \otimes \phi_n \otimes \omega) = \sum_{i=0}^n (-1)^{\epsilon_i} (\phi_0 \otimes \cdots \otimes d_{\mathcal{A}}(\phi_i) \otimes \cdots \otimes \phi_n \otimes \omega)$$

where ϵ_i is the Koszul sign:

$$\epsilon_i = \sum_{j=0}^{i-1} |\phi_j| + \sum_{j=0}^{i-1} 1 = (\text{total degree before } \phi_i)$$

Component 2: Residue differential d_{residue} .

The main geometric operation extracts OPE coefficients via residues at collision divisors.

$$d_{\text{residue}}(\phi_0 \otimes \cdots \otimes \phi_n \otimes \omega) = \sum_{0 \leq i < j \leq n} (-1)^{\sigma_{ij}} \text{Res}_{D_{ij}} [\mu(\phi_i, \phi_j) \otimes (\text{other factors}) \otimes \omega]$$

where:

- $\mu : \mathcal{A} \otimes \mathcal{A} \rightarrow \mathcal{A}$ is the OPE (chiral product)
- $D_{ij} \subset \bar{C}_{n+1}(\Sigma_g)$ is the divisor where $z_i = z_j$
- $\text{Res}_{D_{ij}}$ is the residue along D_{ij} (see §6.1.14 below)
- σ_{ij} is a sign determined by:

1. Position of i, j in the tensor product (Koszul sign)
2. Orientation of D_{ij} as boundary (geometric sign)
3. Grading of fields ϕ_i, ϕ_j (super sign)

The explicit formula for the sign is:

$$\sigma_{ij} = \left(\sum_{k=0}^{i-1} |\phi_k| \right) + \left(\sum_{k=i+1}^{j-1} |\phi_k| \right) + |\phi_i| + \epsilon_{\text{geom}}(D_{ij})$$

where $\epsilon_{\text{geom}}(D_{ij}) = 0$ or 1 depending on orientation convention (see Convention 6.1.19).

Component 3: Form differential d_{form} .

Apply the de Rham differential to the form component:

$$d_{\text{form}}(\phi_0 \otimes \cdots \otimes \phi_n \otimes \omega) = (-1)^{\sum_{i=0}^n |\phi_i|} (\phi_0 \otimes \cdots \otimes \phi_n \otimes d_{\text{dR}}(\omega))$$

where $d_{\text{dR}} : \Omega^n \rightarrow \Omega^{n+1}$ is the de Rham differential on forms.

LEMMA 6.1.16 (*d_{form} preserves logarithmic forms*). The de Rham differential restricts to a map $d_{\text{dR}} : \Omega_{\overline{C}_{p+1}}^q(\log D) \rightarrow \Omega_{\overline{C}_{p+1}}^{q+1}(\log D)$, so d_{form} is well-defined on the bar complex.

Proof. A logarithmic q -form on a smooth variety Y with normal-crossings divisor D is a section of $\Omega_Y^q(\log D) = \bigwedge^q \Omega_Y^1(\log D)$. The sheaf $\Omega_Y^1(\log D)$ is locally free, generated over $\mathcal{O}_Y$ by $dz_1/z_1, \dots, dz_r/z_r, dz_{r+1}, \dots, dz_n$ where $D = \{z_1 \cdots z_r = 0\}$. Since $d_{\text{dR}}(f \cdot dz_i/z_i) = df \wedge dz_i/z_i$ and df is a section of $\Omega_Y^1(\log D)$ (regular functions have logarithmic differentials), the wedge product remains in $\Omega_Y^{q+1}(\log D)$. This applies with $Y = \overline{C}_{p+1}(\Sigma_g)$ and $D = \partial \overline{C}_{p+1}(\Sigma_g)$, which is normal-crossings by the Fulton–MacPherson construction ([186, Theorem 2]). $\square$

Remark 6.1.17 (*Three components*). Each component has a geometric source and a physical identity: d_{internal} is the BRST operator on $\mathcal{A}$; d_{residue} extracts OPE coefficients via residues at collision divisors D_{ij} ; d_{form} is the de Rham differential on configuration space, enforcing Ward identities (Lemma 6.1.16).

Nilpotency $d^2 = 0$ is *not* automatic. Among the nine cross-terms in $(d_1 + d_2 + d_3)^2$, the critical one is $d_{\text{residue}}^2 = 0$: this requires the full Borchers identity, not merely Jacobi (Proposition 6.1.24). The remaining cross-terms vanish by Stokes ($\{d_{\text{form}}, d_{\text{residue}}\} = 0$) and the derivation property.

Example 6.1.18 (*Heisenberg degree-1 bar differential*). The Heisenberg algebra $\mathcal{H}_k$ with OPE $J(z)J(w) = k/(z-w)^2 + \text{regular}$ has bar differential $d_{\text{res}}(J \otimes J \otimes \eta_{12}) = J_{(1)}J = k \cdot \mathbf{1}$ at degree 1: the full chiral product extracts the double-pole mode $J_{(1)}J = k$. Since $J_{(0)}J = 0$ (no simple pole), only the curvature component $d_{\text{curvature}}$ contributes (Proposition 6.1.24). The level k is visible at genus 0 through the bar differential; at genus $g \geq 1$, it acquires a topological partner $\kappa(\mathcal{H}_k) \cdot \omega_g$ from the Hodge bundle (Chapter 13). See Chapter 2, §2.1 for the full computation.

6.1.4 SIGN CONVENTIONS

Convention 6.1.19 (*Enhanced sign system*). The bar complex requires three types of sign conventions:

Type 1: Koszul signs (algebraic).

The standard Koszul sign rule (Appendix G, §G.7; see also §G.7.10) applies with total degree $|\phi| + k$ for a field $\phi \in \mathcal{A}$ tensored with a form in Ω^k .

Type 2: Orientation signs (geometric).

Configuration spaces and their boundary divisors carry orientations:

1. *Configuration space orientation*: $\overline{C}_{n+1}(\Sigma_g)$ is oriented via the complex structure:

$$\text{or}(\overline{C}_{n+1}) = dz_1 \wedge d\bar{z}_1 \wedge \cdots \wedge dz_n \wedge d\bar{z}_n$$

(after modding out by automorphisms; see §6.1.4 below)

2. *Divisor orientation*: Each boundary divisor D_{ij} is oriented by the *outward normal* convention:

$$\text{or}(D_{ij}) = d\epsilon_{ij} \wedge \text{or}(\text{tangent to } D_{ij})$$

where $\epsilon_{ij} = |z_i - z_j|$ points outward (into the interior).

3. *Codimension-2 strata*: At intersections $D_{ij} \cap D_{jk} = D_{ijk}$:

$$\text{or}(D_{ijk}) = d\epsilon_{ij} \wedge d\epsilon_{jk} \wedge \text{or}(\text{tangent})$$

The key identity (Lemma 6.1.56, item (3)):

$$\text{or}(D_{ijk})|_{D_{ij}} = -\text{or}(D_{ijk})|_{D_{jk}}$$

This sign difference ensures Stokes' theorem holds with correct cancellations.

4. *Residue orientation*: When computing $\text{Res}_{D_{ij}}$, we use:

$$\text{Res}_{D_{ij}} \left(\frac{d\epsilon_{ij}}{\epsilon_{ij}} \wedge \alpha \right) = (+1) \cdot \alpha|_{D_{ij}}$$

(no extra sign for residue extraction)

Type 3: Operadic signs.

The bar complex has an operadic structure (composition of operations). When composing two operations, the sign arises from three sources: *grafting trees* (reordering edges when attaching one tree to another), *shuffle signs* (permuting tensor factors to bring colliding fields together), and the *Koszul sign* (moving differential forms past fields).

The formula (for operads): if we compose operations of degree m and n at the i -th input:

$$\text{sign} = (-1)^\epsilon$$

where:

$$\epsilon = \sum_{j=1}^{i-1} |p_j| \cdot |q|$$

($|p_j|$ are degrees of inputs before position i , $|q|$ is degree of the composed operation)

Compatibility condition.

These three types of signs must be compatible to ensure $d^2 = 0$. The key relations are:

1. *Koszul-Orientation compatibility*:

$$\text{sign}_{\text{Koszul}}(\phi_i \leftrightarrow \phi_j) \cdot \text{sign}_{\text{orient}}(D_{ij} \leftrightarrow D_{ji}) = (-1)^1$$

(fields anticommute up to orientation sign)

2. *Orientation-Residue compatibility:*

$$\text{Res}_{D_{ij}} \circ \text{Res}_{D_{jk}} + \text{Res}_{D_{jk}} \circ \text{Res}_{D_{ij}} = 0 \quad (\text{with correct signs})$$

(residues anticommute at codimension-2 strata)

3. *Koszul-Operadic compatibility:*

$$\text{sign}_{\text{Koszul}}(\text{reorder}) = \text{sign}_{\text{operadic}}(\text{compose})$$

(both give the same sign for the same operation)

LEMMA 6.1.20 (*Sign compatibility*). The three types of signs (Koszul, orientation, operadic) are mutually compatible in the sense required for $d^2 = 0$.

Proof. We verify each compatibility relation:

Relation 1: Koszul-Orientation.

Consider swapping two fields $\phi_i \otimes \phi_j \rightarrow \phi_j \otimes \phi_i$: - Koszul sign: $(-1)^{|\phi_i| \cdot |\phi_j|}$ - This corresponds to swapping collision divisors $D_{ij} \leftrightarrow D_{ji}$ - Orientation sign: $\text{or}(D_{ji}) = -\text{or}(D_{ij})$ (from antisymmetry of differentials)

The product:

$$(-1)^{|\phi_i| \cdot |\phi_j|} \cdot (-1) = (-1)^{|\phi_i| \cdot |\phi_j| + 1}$$

For bosonic fields ($|\phi_i|, |\phi_j|$ even), this is $(-1)^{0+1} = -1$. For fermionic fields ($|\phi_i|, |\phi_j|$ odd), this is $(-1)^{1+1} = +1$.

This yields the correct commutation and anticommutation relations for super-objects.

Relation 2: Orientation-Residue.

At a codimension-2 stratum $D_{ijk} = D_{ij} \cap D_{jk}$:

Approach from D_{ij} side:

$$\text{or}(D_{ijk})|_{D_{ij}} = d\epsilon_{jk} \wedge \text{or}(D_{ij})$$

Approach from D_{jk} side:

$$\text{or}(D_{ijk})|_{D_{jk}} = d\epsilon_{ij} \wedge \text{or}(D_{jk})$$

By Lemma 6.1.56(3), these differ by a sign: $\text{or}(D_{ijk})|_{D_{ij}} = -\text{or}(D_{ijk})|_{D_{jk}}$.

Now compute double residue:

$$\begin{aligned} \text{Res}_{D_{ij}} \text{Res}_{D_{jk}}(\omega) + \text{Res}_{D_{jk}} \text{Res}_{D_{ij}}(\omega) &= \int_{D_{ijk}} \omega|_{D_{ijk}} \text{ (from } \text{or}(D_{ijk})|_{D_{ij}} \text{)} \\ &\quad + \int_{D_{ijk}} \omega|_{D_{ijk}} \text{ (from } \text{or}(D_{ijk})|_{D_{jk}} \text{)} \\ &= (+1) \int + (-1) \int = 0 \end{aligned}$$

The orientations differ by exactly the sign needed for cancellation.

Relation 3: Koszul-Operadic.

Consider composing two operations $\mu_1 : V_1 \otimes V_2 \rightarrow W_1$ and $\mu_2 : W_1 \otimes V_3 \rightarrow W_2$.

Koszul sign for moving V_2 past W_1 :

$$(-1)^{|V_2| \cdot |W_1|}$$

Operadic sign for grafting:

$$(-1)^\epsilon$$

where $\epsilon = |V_1| + |V_2|$ (degrees of inputs before the graft point)

These match when we account for the suspension in the bar construction (W_1 has degree shifted by 1). More precisely, the sign convention on the desuspension $s^{-1}\bar{\mathcal{A}}$ is *chosen* so that the Koszul and operadic signs are compatible; we verify that this choice is consistent.

General case. Let T be the rooted tree labeling the given bar element. Each of the three sign sources defines a parity character on $\text{Aut}(T)$: Koszul signs come from permuting tensor factors, orientation signs come from permuting configuration-space coordinates, and operadic signs come from grafting odd inputs through the operad composition.

The key identity is checked on an adjacent transposition of two inputs ϕ_i, ϕ_j . On the desuspension $s^{-1}\bar{\mathcal{A}}$, that transposition contributes

$$(-1)^{(|\phi_i|-1)(|\phi_j|-1)} = (-1)^{|\phi_i||\phi_j|}(-1)^{|\phi_i|+|\phi_j|}(-1).$$

The first factor is the Koszul sign, the second is the operadic sign, and the last factor is the orientation sign from swapping the two coordinates. Hence the combined action on $s^{-1}\bar{\mathcal{A}}$ already contains all three sign sources.

Because every tree automorphism is generated by adjacent transpositions, compatibility for generators implies

$$\epsilon_{\text{Koszul}} \cdot \epsilon_{\text{orient}} \cdot \epsilon_{\text{operad}} = +1$$

for every rooted tree T . The degree-2 computation above supplies the base case, and induction on tree depth propagates the identity to all graftings. $\square$

6.1.5 PROOF THAT $d^2 = 0$: NINE-TERM VERIFICATION

THEOREM 6.1.21 (*Nilpotency of bar differential*;). [Regime: quadratic, genus-0 (Convention I.10.2).]

The differential $d = d_{\text{internal}} + d_{\text{residue}} + d_{\text{form}}$ on the bar complex satisfies:

$$d^2 = 0$$

More precisely, all nine cross-terms arising from $(d_1 + d_2 + d_3)^2$ cancel.

Proof. Write $d = d_1 + d_2 + d_3$ where $d_1 = d_{\text{int}}$ is the internal differential on $\mathcal{A}$, $d_2 = d_{\text{res}}$ extracts residues at collision divisors, and $d_3 = d_{\text{dR}}$ is the de Rham differential on forms. Expanding $(d_1 + d_2 + d_3)^2$, we obtain six terms (three diagonal and three anticommutators) which we verify separately.

Diagonal terms. The identity $d_1^2 = 0$ holds because $d_{\mathcal{A}}^2 = 0$ on $\mathcal{A}$: diagonal terms vanish by hypothesis, and cross-terms (where d_1 hits two different tensor factors ϕ_i and ϕ_j) cancel in pairs by the Koszul sign rule. The identity $d_3^2 = 0$ is the standard relation $d_{\text{dR}}^2 = 0$ for differential forms.

The identity $d_2^2 = 0$ is the most substantial. In the double sum

$$d_2^2 = \sum_{i < j} \sum_{k < \ell} (-1)^{\sigma_{ij} + \sigma'_{k\ell}} \text{Res}_{D_{k\ell}} \circ \text{Res}_{D_{ij}},$$

three cases arise according to how the index sets $\{i, j\}$ and $\{k, \ell\}$ overlap.

Case (i): Disjoint pairs ($\{i, j\} \cap \{k, \ell\} = \emptyset$). The divisors D_{ij} and $D_{k\ell}$ intersect transversally in $\partial \overline{C}_{n+1}(X)$. Since the divisors are disjoint (no shared indices), the residue operations themselves commute:

$$\text{Res}_{D_{ij}} \circ \text{Res}_{D_{k\ell}} = \text{Res}_{D_{k\ell}} \circ \text{Res}_{D_{ij}}.$$

The cancellation comes from the signed sum in d_2 : the ordered pairs (i, j) , (k, ℓ) and (k, ℓ) , (i, j) contribute with opposite signs $(-1)^{\sigma_{ij} + \sigma'_{k\ell}}$ and $(-1)^{\sigma_{k\ell} + \sigma'_{ij}}$ (Lemma 6.1.20), and these signs differ by (-1) , so the two terms cancel.

Case (ii): One overlap (say $j = k$). This is the case that produced the Arnold relation in the Heisenberg degree-2 computation (§2.2): three boundary strata meet at a triple collision, and their contributions cancel cyclically. We give the complete argument.

Step (a): Identify the codimension-2 locus. When $|\{i, j\} \cap \{k, \ell\}| = 1$, say $j = k$, the double residue $\text{Res}_{D_{j\ell}} \circ \text{Res}_{D_{ij}}$ approaches the locus $D_{ij\ell} \subset \overline{C}_{n+1}(X)$ where all three points z_i, z_j, z_ℓ collide simultaneously. In the FM compactification, $D_{ij\ell}$ is a smooth codimension-2 stratum obtained by blowing up the triple diagonal. Exactly three codimension-1 boundary divisors contain $D_{ij\ell}$, corresponding to the three ways of performing the triple collision in two stages:

$$D_{ij} \cap D_{j\ell}, \quad D_{j\ell} \cap D_{i\ell}, \quad D_{i\ell} \cap D_{ij}.$$

The first collapses $z_i \rightarrow z_j$ and then $z_j \rightarrow z_\ell$; the second collapses $z_j \rightarrow z_\ell$ and then $z_i \rightarrow z_\ell$; the third collapses $z_i \rightarrow z_\ell$ and then $z_j \rightarrow z_\ell$.

Step (b): Extract the three iterated-residue terms. Each codimension-1 stratum through $D_{ij\ell}$ contributes one iterated residue to d_2^2 . The chiral product μ determines the algebra element produced at each stage:

- (1) *First D_{ij} , then $D_{j\ell}$.* Collapsing $z_i \rightarrow z_j$ applies $\mu(\phi_i, \phi_j)$; collapsing the result with z_ℓ applies $\mu(-, \phi_\ell)$. This gives:

$$\text{Res}_{D_{j\ell}} \circ \text{Res}_{D_{ij}} [\mu(\mu(\phi_i, \phi_j), \phi_\ell) \otimes \omega].$$

- (2) *First $D_{j\ell}$, then D_{ij} .* Collapsing $z_j \rightarrow z_\ell$ applies $\mu(\phi_j, \phi_\ell)$; collapsing with z_i applies $\mu(\phi_i, -)$. This gives:

$$\text{Res}_{D_{ij}} \circ \text{Res}_{D_{j\ell}} [\mu(\phi_i, \mu(\phi_j, \phi_\ell)) \otimes \omega].$$

- (3) *First $D_{i\ell}$, then D_{ij} .* Collapsing $z_i \rightarrow z_\ell$ applies $\mu(\phi_i, \phi_\ell)$; collapsing the result with z_j applies $\mu(-, \phi_j)$. This gives:

$$\text{Res}_{D_{i\ell}} \circ \text{Res}_{D_{ij}} [\mu(\mu(\phi_i, \phi_\ell), \phi_j) \otimes \omega].$$

These are the only terms in d_2^2 that access the codimension-2 locus $D_{ij\ell}$. (All other pairs in the double sum either have disjoint indices or identical indices, handled by Cases (i) and (iii).) The total contribution of Case (ii) at the triple $\{i, j, \ell\}$ is thus:

$$\sum_{\text{cyclic}} \text{Res}_{D_{j\ell}} \circ \text{Res}_{D_{ij}} [\mu(\mu(\phi_i, \phi_j), \phi_\ell) \otimes \omega] = 0, \quad (6.1)$$

where the cyclic sum runs over the three terms (1)–(3).

Step (c): The geometric origin: boundary of boundary. The relation $\partial^2 = 0$ on the cellular chain complex of $\overline{C}_{n+1}(X)$ (Lemma 6.1.56) implies that the signed sum of the codimension-2 faces arising from any codimension-2 stratum vanishes. Applied to $D_{ij\ell}$: the three codimension-1 strata D_{ij} , $D_{j\ell}$, $D_{i\ell}$ each pair

to give a codimension-2 face through $D_{ij\ell}$, and the boundary-of-boundary relation $\partial^2 = 0$ asserts that these three faces, with their orientation signs, sum to zero. Since each face carries the corresponding iterated residue of $\mu(\mu(\phi?, \phi?), \phi?) \otimes \omega$, the relation $\partial^2 = 0$ translates directly into the algebraic identity (6.1).

Step (d): Equivalence with the Borchers identity. The vanishing (6.1) is precisely axiom (ii) of Definition 3.3.3: the associativity of the chiral product μ , i.e., the Borchers identity. This identity couples *all* OPE pole orders simultaneously, unlike the Jacobi identity, which governs only the simple-pole bracket $\{-, -\} = (-)_{(0)}(-)$. The Borchers identity is both necessary and sufficient for the vanishing: any meromorphic product μ satisfying locality (i) and producing $d_2^2 = 0$ must satisfy (ii), and conversely any chiral algebra (satisfying (ii) by definition) gives $d_2^2 = 0$ in Case (ii) (cf. §1.2).

Step (e): Conclusion. By the Borchers identity (axiom (ii) of $\mathcal{A}$), the cyclic sum (6.1) vanishes for every triple $\{i, j, \ell\}$ and every choice of sections and forms. Therefore $d_2^2 = 0$ on all Case (ii) contributions.

Case (iii): Same pair $\{i, j\} = \{k, \ell\}$. Since $\text{Res}_{D_{ij}}$ extracts a simple pole along D_{ij} , applying it once produces a section regular along D_{ij} , and a second application yields zero: $\text{Res}_{D_{ij}}^2 = 0$.

Mixed terms. The anticommutator $\{d_1, d_2\} = 0$ follows because the chiral product μ is a morphism of complexes: as a map of $\mathcal{D}_X$ -modules, $\mu: j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \rightarrow \Delta_!(\mathcal{A})$ satisfies

$$d_{\mathcal{A}} \circ \mu = \mu \circ (d_{\mathcal{A}} \boxtimes \text{id} + \text{id} \boxtimes d_{\mathcal{A}}),$$

the Leibniz rule (this is an axiom of a *differential graded* chiral algebra: the chiral product intertwines the internal differential). Since d_{residue} is built from μ via $\text{Res}_{D_{ij}}$, the commutativity $d_{\text{internal}} \circ \text{Res}_{D_{ij}} = \text{Res}_{D_{ij}} \circ d_{\text{internal}}$ follows: $\text{Res}_{D_{ij}}$ is a $\mathcal{D}_X$ -module operation, and $d_{\mathcal{A}}$ is $\mathcal{D}_X$ -linear.

For $\{d_1, d_3\} = 0$: the operators d_1 and d_3 act on the algebra and form tensor factors respectively. The Koszul sign accompanying d_3 includes a factor $(-1)^{\sum_i |\phi_i|}$ from passing the de Rham differential past the algebra elements. After d_1 increases one algebra degree by 1, the sign acquires an extra factor of (-1) . Thus $d_3 \circ d_1 = -d_1 \circ d_3$, and the anticommutator vanishes.

For $\{d_2, d_3\} = 0$: this follows from the residue exact sequence for logarithmic forms. On a normal crossing divisor $D = \bigcup D_{ij} \subset \overline{C}_{n+1}(X)$, the residue map fits into the exact sequence $0 \rightarrow \Omega^k \rightarrow \Omega^k(\log D) \xrightarrow{\text{Res}} \bigoplus_{D_{ij}} \Omega_{D_{ij}}^{k-1}(\log D') \rightarrow 0$, and the de Rham differential is compatible with the residue map: $\text{Res}_{D_{ij}} \circ d_{\text{dR}} = d_{\text{dR}}|_{D_{ij}} \circ \text{Res}_{D_{ij}}$. Since d_2 is a signed sum of residues and $d_3 = d_{\text{dR}}$, they anticommute (with signs from Convention 6.1.19). $\square$

Remark 6.1.22 (Sign-level verification). For a complete sign-by-sign verification of $d^2 = 0$ at low degrees (including the explicit computation for degree-3 elements $[a|b|c]$ in a graded associative algebra), see Verification G.5.7 and Proposition G.5.5 in Appendix G.

Remark 6.1.23 (Synthesis). The three mechanisms entering the proof of $d^2 = 0$, the Borchers identity (algebra), Stokes' theorem (topology), and residue calculus (analysis), all arise from the boundary stratification of $\overline{C}_n(X)$. For the Heisenberg algebra, this reduced to the Arnold relation (§2.2); in general, the factorization structure on $\text{Ran}(X)$ forces the compatibility (Beilinson–Drinfeld [40]; see §1.2 for the selection principle).

PROPOSITION 6.1.24 (Pole decomposition of the bar differential;). The residue differential d_{res} decomposes according to OPE pole order:

$$d_{\text{res}} = d_{\text{bracket}} + d_{\text{curvature}}$$

where d_{bracket} extracts residues from simple poles (Lie bracket terms $a_{(0)}b$) and $d_{\text{curvature}}$ extracts residues from double poles (metric/level terms $\kappa(a, b)|0\rangle$).

This decomposition has the following properties:

1. $d_{\text{bracket}}^2 \neq 0$ in general: the obstruction is the Borchers associator, which involves iterated residues mixing both pole orders.
2. $d_{\text{curvature}}^2 = 0$: double-pole residues produce scalars (vacuum vectors), and a second residue applied to a scalar vanishes.
3. $d_{\text{res}}^2 = d_{\text{bracket}}^2 + \{d_{\text{bracket}}, d_{\text{curvature}}\} + d_{\text{curvature}}^2 = 0$, so the cross-term $\{d_{\text{bracket}}, d_{\text{curvature}}\}$ exactly compensates the failure of $d_{\text{bracket}}^2 = 0$.

In particular, the Lie-bracket Jacobi identity (which would give $d_{\text{bracket}}^2 = 0$ for a Lie algebra) is *insufficient* for nilpotency of the chiral bar differential. The full Borchers identity (associativity of the chiral product μ , involving all pole orders simultaneously) is required.

Proof. For a chiral algebra $\mathcal{A}$ with OPE $a(z)b(w) \sim \sum_{n \geq 0} a_{(n)}b \cdot (z-w)^{-n-1}$, the residue differential at the divisor D_{ij} extracts:

$$\text{Res}_{D_{ij}}[\mu(\phi_i, \phi_j) \otimes \omega] = \text{Res}_{\epsilon=0} \left[\sum_{n \geq 0} \frac{(\phi_i)_{(n)} \phi_j}{\epsilon^{n+1}} \otimes \omega \right]$$

where $\epsilon = z_i - z_j$ is the local coordinate normal to D_{ij} .

The simple-pole contribution ($n = 0$) gives:

$$d_{\text{bracket}}(\cdots) = \sum_{i < j} (-1)^{\sigma_{ij}} \text{Res}_{\epsilon=0} \left[\frac{(\phi_i)_{(0)} \phi_j}{\epsilon} \otimes \omega \right],$$

which extracts the Lie bracket $[\phi_i, \phi_j] = (\phi_i)_{(0)} \phi_j$ via the simple-pole residue of ω .

The double-pole contribution ($n = 1$) gives:

$$d_{\text{curvature}}(\cdots) = \sum_{i < j} (-1)^{\sigma_{ij}} \text{Res}_{\epsilon=0} \left[\frac{(\phi_i)_{(1)} \phi_j}{\epsilon^2} \otimes \omega \right],$$

which extracts the invariant bilinear form $(\phi_i)_{(1)} \phi_j = \kappa(\phi_i, \phi_j)|0\rangle$. For Kac–Moody algebras, this is the level: $(J^a)_{(1)} J^b = k \delta^{ab} |0\rangle$.

Property (2). Since $d_{\text{curvature}}$ replaces a pair (ϕ_i, ϕ_j) by a scalar multiple of the vacuum $|0\rangle$, the output of $d_{\text{curvature}}$ at position i is proportional to $|0\rangle$. A subsequent application of $d_{\text{curvature}}$ (or d_{bracket}) involving this vacuum position produces $|0\rangle_{(n)} \phi_k = 0$ for $n \geq 0$, hence $d_{\text{curvature}}^2 = 0$.

Property (1). In the double sum d_{bracket}^2 , the one-overlap terms (Case (ii) of Theorem 6.1.21) produce iterated residues $\text{Res}_{D_{j\ell}} \text{Res}_{D_{ij}} [(\phi_i)_{(0)} (\phi_j)_{(0)} \phi_\ell \otimes \omega]$. The Borchers identity for the chiral product asserts:

$$\sum_{\text{cyclic}} \text{Res}_{D_{j\ell}} \circ \text{Res}_{D_{ij}} [\mu(\mu(\phi_i, \phi_j), \phi_\ell) \otimes \omega] = 0. \quad (6.2)$$

Decomposing μ by pole order, the bracket–bracket contributions $(\phi_i)_{(0)} ((\phi_j)_{(0)} \phi_\ell)$ give the Jacobi identity, but there are additional bracket–curvature cross-terms $(\phi_i)_{(0)} ((\phi_j)_{(1)} \phi_\ell \cdot |0\rangle)$ and curvature–bracket terms that arise from the Taylor expansion of the OPE near the triple collision locus $D_{ij\ell}$. The Jacobi identity cancels only the pure bracket terms; the cross-terms remain, giving $d_{\text{bracket}}^2 \neq 0$.

Property (3). The full Borchers identity (6.2) cancels *all* iterated residue terms simultaneously, regardless of pole decomposition. Since $d_{\text{res}} = d_{\text{bracket}} + d_{\text{curvature}}$, the identity $d_{\text{res}}^2 = 0$ (Theorem 6.1.21) together with $d_{\text{curvature}}^2 = 0$ gives $d_{\text{bracket}}^2 = -\{d_{\text{bracket}}, d_{\text{curvature}}\}$. $\square$

Remark 6.1.25 (Bicomplex obstruction). Proposition 6.1.24 shows that the pair $(d_{\text{bracket}}, d_{\text{curvature}})$ does *not* form a bicomplex (which would require $d_{\text{bracket}}^2 = d_{\text{curvature}}^2 = \{d_{\text{bracket}}, d_{\text{curvature}}\} = 0$). Instead, $d_{\text{bracket}}^2 = -\{d_{\text{bracket}}, d_{\text{curvature}}\} \neq 0$: the curvature (level/central charge) is the *obstruction* to the Lie-bracket differential being nilpotent.

For *free fields* (Heisenberg, free fermion), the OPE has only a double pole ($a_{(0)}b = 0$), so $d_{\text{bracket}} = 0$ and $d_{\text{res}} = d_{\text{curvature}}$, which squares to zero automatically. This explains the simpler algebraic structure of free-field bar complexes (Corollary K.7.1).

For Kac–Moody algebras, the failure of $d_{\text{bracket}}^2 = 0$ is controlled by the level- k double-pole OPE coefficient $k \cdot (\ , \)$, which gives rise to the curved A_∞ curvature element m_0 with scalar projection $\kappa(\widehat{\mathfrak{g}}_k) = \dim(\mathfrak{g}) \cdot (k + h^\vee)/(2h^\vee)$ (Chapter 14).

COROLLARY 6.1.26 (*Functoriality*;). Since $d^2 = 0$, the bar complex $(\bar{B}^\bullet(\mathcal{A}), d)$ is a chain complex for every chiral algebra $\mathcal{A}$. (The collision residue $r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}})$ is the universal twisting morphism; see Theorem ?? for its genus-0 realization as commuting Hamiltonians.) Morphisms of chiral algebras induce chain maps (apply f to algebra factors, leave forms unchanged); the resulting functor $\bar{B}^{\text{geom}}: \text{ChiralAlg}_X^{\text{aug}} \rightarrow \text{dgCoalg}_X$ is stated and proved in full generality in Theorem 6.1.43.

Proof. The first sentence is the square-zero statement already proved for the total bar differential. If $f: \mathcal{A} \rightarrow \mathcal{A}'$ is a morphism of chiral algebras, applying f to each algebra factor commutes with the internal differential, with the collision residues, and with the de Rham differential, so $\bar{B}^{\text{geom}}(f)$ is a chain map. Compatibility with the coproduct, identities, and composition is checked on the same tensor factors, yielding the stated functor. $\square$

6.1.6 STOKES' THEOREM ON CONFIGURATION SPACES

THEOREM 6.1.27 (*Stokes' theorem on configuration spaces*;). For the Fulton–MacPherson compactification $\bar{C}_{n+1}(\Sigma_g)$ with boundary divisor $D = \bigcup_{i < j} D_{ij}$:

For any $\omega \in \Omega^k(\bar{C}_{n+1}(\Sigma_g))$ (a smooth k -form):

$$\int_{\bar{C}_{n+1}(\Sigma_g)} d_{\text{dR}}(\omega) = \sum_{i < j} \epsilon_{ij} \int_{D_{ij}} \omega|_{D_{ij}}$$

where $\epsilon_{ij} = \pm 1$ is the orientation sign.

For logarithmic forms $\omega \in \Omega^k(\log D)$:

$$\int_{\bar{C}_{n+1}} d_{\text{dR}}(\omega) = \sum_{i < j} \epsilon_{ij} \int_{D_{ij}} \text{Res}_{D_{ij}}(\omega)$$

Proof. The configuration space $\bar{C}_{n+1}(\Sigma_g)$ is a *manifold with corners*. The boundary consists of multiple smooth divisors D_{ij} meeting transversely along higher codimension strata.

Stokes' theorem for manifolds with corners (Theorem of Melrose, Mazzeo, et al.) states:

$$\int_M d\omega = \sum_{\text{faces } F} \epsilon_F \int_F \omega|_F$$

where faces are the codimension-1 boundary components.

Step 1: Identify faces

The faces of $\bar{C}_{n+1}(\Sigma_g)$ are precisely the divisors D_{ij} for $i < j$.

Codimension: Each D_{ij} has codimension 1 in $\overline{C}_{n+1}$:

$$\dim_{\mathbb{C}} D_{ij} = \dim_{\mathbb{C}} \overline{C}_{n+1} - 1 = (n+1) - 1 = n$$

Step 2: Orientation of faces

Each face D_{ij} inherits an orientation from the *outward normal* convention (Convention 6.1.19):

$$\text{or}(D_{ij}) = d\epsilon_{ij} \wedge \text{or}_{\text{tangent}}$$

where $\epsilon_{ij} = |z_i - z_j|$ increases towards the interior.

The sign ϵ_{ij} in Stokes' theorem is:

$$\epsilon_{ij} = +1 \quad \text{if } \text{or}(D_{ij}) = \text{outward normal orientation}$$

$$\epsilon_{ij} = -1 \quad \text{if opposite}$$

With our conventions: $\epsilon_{ij} = +1$ for all $i < j$.

Step 3: Corners

The divisors D_{ij} and $D_{k\ell}$ (for distinct pairs) intersect along codimension-2 strata:

$$D_{ij} \cap D_{k\ell} = D_{ijk\ell}$$

At these corners, we must verify that contributions from different faces cancel appropriately.

Consider the corner $D_{ijk} = D_{ij} \cap D_{jk}$ (where three points collide). Approaching from different faces:

From D_{ij} :

$$\text{contribution} = \int_{D_{ijk}} \omega|_{D_{ij}}|_{D_{ijk}} \cdot \epsilon_{jk}|_{D_{ij}}$$

From D_{jk} :

$$\text{contribution} = \int_{D_{ijk}} \omega|_{D_{jk}}|_{D_{ijk}} \cdot \epsilon_{ij}|_{D_{jk}}$$

By Lemma 6.1.56 (orientation consistency), these have opposite signs:

$$\epsilon_{jk}|_{D_{ij}} = -\epsilon_{ij}|_{D_{jk}}$$

So the corner contributions cancel.

Step 4: Apply Stokes' theorem

With corners handled correctly:

$$\int_{\overline{C}_{n+1}} d_{\text{dR}}(\omega) = \sum_{i < j} \int_{D_{ij}} \omega|_{D_{ij}}$$

For logarithmic forms, $\omega|_{D_{ij}}$ is not well-defined (it has a pole), but $\text{Res}_{D_{ij}}(\omega)$ is:

$$\int_{\overline{C}_{n+1}} d_{\text{dR}}(\omega) = \sum_{i < j} \int_{D_{ij}} \text{Res}_{D_{ij}}(\omega)$$

□

Example 6.1.28 (Stokes for three points). Consider $\overline{C}_3(\mathbb{C})$ (three points on the complex plane, compactified).

Boundary. $D = D_{12} \cup D_{23} \cup D_{13}$ (three divisors)

2-form. $\omega = \eta_{12} \wedge \eta_{23}$ (logarithmic 2-form)

Differential.

$$\begin{aligned} d_{\text{dR}}(\eta_{12} \wedge \eta_{23}) &= d(\eta_{12}) \wedge \eta_{23} - \eta_{12} \wedge d(\eta_{23}) \\ &= 0 \end{aligned}$$

(since $d(\eta_{ij}) = 0$ for logarithmic 1-forms)

Stokes.

$$\int_{\overline{C}_3} d_{\text{dR}}(\omega) = 0 = \int_{D_{12}} \text{Res}_{D_{12}}(\omega) + \int_{D_{23}} \text{Res}_{D_{23}}(\omega) + \int_{D_{13}} \text{Res}_{D_{13}}(\omega)$$

Residues. $-\text{Res}_{D_{12}}(\eta_{12} \wedge \eta_{23}) = \eta_{23}|_{D_{12}} - \text{Res}_{D_{23}}(\eta_{12} \wedge \eta_{23}) = -\eta_{12}|_{D_{23}}$ (sign from wedge order) -
 $\text{Res}_{D_{13}}(\eta_{12} \wedge \eta_{23}) = 0$ (no pole along D_{13})

Therefore

$$0 = \int_{D_{12}} \eta_{23} - \int_{D_{23}} \eta_{12} + 0$$

This is the *Arnold relation*:

$\eta_{12} \wedge \eta_{23}$ integrates to zero around boundaries

COROLLARY 6.1.29 (*Residues anticommute at corners*;). For transverse divisors D_{ij} and $D_{k\ell}$ meeting at a codimension-2 stratum:

$$\text{Res}_{D_{ij}} \text{Res}_{D_{k\ell}} + \text{Res}_{D_{k\ell}} \text{Res}_{D_{ij}} = 0$$

(up to sign)

Proof. Since D_{ij} and $D_{k\ell}$ meet transversally at the codimension-2 stratum $D_{ij} \cap D_{k\ell}$, we may choose local coordinates $(u, v, \dots)$ near the intersection with $D_{ij} = \{u = 0\}$ and $D_{k\ell} = \{v = 0\}$. For a logarithmic form ω with at most simple poles along both divisors, the iterated residue $\text{Res}_{v=0} \text{Res}_{u=0} \omega$ extracts the coefficient of $d \log u \wedge d \log v$, while $\text{Res}_{u=0} \text{Res}_{v=0} \omega$ extracts the coefficient of $d \log v \wedge d \log u = -d \log u \wedge d \log v$. Hence $\text{Res}_{D_{ij}} \circ \text{Res}_{D_{k\ell}} = -\text{Res}_{D_{k\ell}} \circ \text{Res}_{D_{ij}}$. $\square$

6.1.7 ARNOLD RELATIONS: PROOFS FROM THREE PERSPECTIVES

Convention 6.1.30 (Set ordering and position notation). Throughout this manuscript, we adopt the following conventions for ordered sets:

1. *Natural Ordering:* For any finite subset $S \subseteq \mathbb{N}$, we always use the ordering inherited from $\mathbb{N}$:

$$S = \{k_1, k_2, \dots, k_m\} \quad \text{where} \quad k_1 < k_2 < \dots < k_m$$

2. *Position Function:* For $k \in S$, we denote by $|k|_S$ (or simply $|k|$ when S is clear from context) the *position* of k in this ordering:

$$k = k_{|k|} \quad \Longleftrightarrow \quad |k| = i \text{ where } k \text{ is the } i\text{-th smallest element of } S$$

3. *Sign Convention:* Signs arising from reordering are computed via the Koszul rule. Moving an element k past position $|k|$ introduces sign $(-1)^{|k|-1}$.
4. *Multi-indices:* For multi-index sets (e.g., in partitions), we use lexicographic ordering.

Example. For $S = \{2, 5, 7\}$:

- $|2|_S = 1$ (first position)
- $|5|_S = 2$ (second position)
- $|7|_S = 3$ (third position)

In Arnold relations, the notation $(-1)^{|k|}$ means $(-1)^{|k|_S}$ where S is the index set of the collision divisor under consideration.

THEOREM 6.1.31 (*Arnold relations*;). We encountered these relations concretely in the Heisenberg bar complex (§2.2), where they appeared as the identity forcing $d^2 = 0$ at degree 2. In full generality:

For distinct indices $i, j, k \in \{1, \dots, n\}$, the logarithmic 1-forms $\eta_{ij} = d \log(z_i - z_j)$ satisfy:

Formulation 1 (basic).

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$$

Formulation 2 (Orlik–Solomon). The algebra $H^*(C_n(\mathbb{C}); \mathbb{Q})$ is the quotient of the exterior algebra $\wedge \langle \eta_{ij} \mid 1 \leq i < j \leq n \rangle$ by the ideal generated by the three-term Arnold relations of Formulation 1. All higher-degree relations in the Orlik–Solomon algebra follow from these by repeated application; there is no independent “general Arnold relation” beyond the three-term version.

Formulation 3 (cohomological). The cohomology ring $H^*(\overline{C}_n(X); \mathbb{Q})$ is generated by classes $[\eta_{ij}]$ subject to the Arnold relations.

Proof. See Theorem 5.1.23 for the partial-fractions proof. The topological, combinatorial, and operadic perspectives are developed in §5.10. $\square$

Remark 6.1.32 (Arnold relations = Jacobi identity). The geometric content of $d_0^2 = 0$ at degree 3 is precisely the Jacobi identity: the three boundary strata of $\overline{C}_4(\mathbb{P}^1)$ that contribute to d_0^2 correspond to the three terms of the Jacobi identity for the chiral bracket. Concretely, the Arnold relation $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ forces

$$f^{ab}_d f^{dc}_e + f^{bc}_d f^{da}_e + f^{ca}_d f^{db}_e = 0,$$

which is the Jacobi identity for the structure constants extracted by residues. The implication is bidirectional: the Arnold relations *are* the Jacobi identity via the residue dictionary. See Computation K.7.1 for the complete term-by-term verification in $\widehat{\mathfrak{sl}}_{2,k}$ and Theorem 5.10.4 for the general CFT formulation.

COROLLARY 6.1.33 (*Cohomology of configuration spaces* [25];). The cohomology ring $H^*(C_n(\mathbb{C}); \mathbb{Q})$ of the open configuration space is:

$$H^*(C_n(\mathbb{C})) \cong \mathbb{Q}[\eta_{ij} : 1 \leq i < j \leq n] / \mathcal{I}_{\text{Arnold}}$$

where $\mathcal{I}_{\text{Arnold}}$ is the ideal generated by Arnold relations.

Proof. By Arnol’d [25], the 1-forms $\eta_{ij} = d \log(z_i - z_j)$ generate $H^*(C_n(\mathbb{C}); \mathbb{Q})$ and satisfy the Arnold relations $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$. That these generate *all* relations follows from Cohen’s computation of $H^*(C_n(\mathbb{C}))$ as the cohomology of the Arnol’d–Brieskorn braid arrangement complement [85]. See also Appendix F for the three proofs of the Arnold relations used in this monograph. $\square$

6.1.8 LOW-DEGREE EXPLICIT COMPUTATIONS

6.1.8.1 Degree 0: the vacuum

COMPUTATION 6.1.34 (*Degree 0*;). In degree 0:

$$\bar{B}^0(\mathcal{A}) = \Gamma\left(\bar{C}_1(\Sigma_g), \mathcal{A} \otimes \Omega^0(\log D)\right)$$

But $\bar{C}_1(\Sigma_g) = \Sigma_g$ (single point, no collisions), and $\Omega^0(\log D) = \mathcal{O}_{\Sigma_g}$ (functions).
Therefore

$$\bar{B}^0(\mathcal{A}) = \Gamma(\Sigma_g, \mathcal{A}) = H^0(\Sigma_g, \mathcal{A})$$

This is the space of global sections of the chiral algebra.

Physical interpretation. This is the vacuum sector: states with no operator insertions.

Differential. $d : \bar{B}^0 \rightarrow \bar{B}^{-1}$. But there is no $\bar{B}^{-1}$ (negative degree), so $d|_{\bar{B}^0} = 0$.

6.1.8.2 Degree 1: two-point functions

COMPUTATION 6.1.35 (*Degree 1*;). In degree 1:

$$\bar{B}^1(\mathcal{A}) = \Gamma\left(\bar{C}_2(\Sigma_g), j_* j^*(\mathcal{A} \boxtimes \mathcal{A}) \otimes \Omega^1(\log D_{12})\right)$$

Configuration space. $\bar{C}_2(\Sigma_g)$ parametrizes two points on Σ_g . - At genus 0: After modding out PSL_2 , $\bar{C}_2(\mathbb{P}^1) \cong \mathbb{P}^1$ - At genus $g \geq 1$: $\bar{C}_2(\Sigma_g)$ is more complex (includes period matrix data)

Logarithmic 1-forms. $\Omega^1(\log D_{12})$ is 1-dimensional, spanned by:

$$\eta_{12} = \frac{dz_1 - dz_2}{z_1 - z_2} = d \log(z_1 - z_2)$$

Basis. A basis for $\bar{B}^1(\mathcal{A})$ is:

$$\{\phi_i(z_1) \otimes \phi_j(z_2) \otimes \eta_{12} : \phi_i, \phi_j \in \mathcal{A}\}$$

If $\mathcal{A}$ has N generators, then:

$$\dim \bar{B}^1(\mathcal{A}) = N^2$$

Differential. $d : \bar{B}^1 \rightarrow \bar{B}^0$

$$d(\phi_i \otimes \phi_j \otimes \eta_{12}) = \text{Res}_{D_{12}}[\mu(\phi_i, \phi_j) \otimes \eta_{12}]$$

where μ is the chiral product (OPE).

If the OPE is:

$$\phi_i(z)\phi_j(w) = \sum_k \frac{C_{ij}^k}{(z-w)^{\Delta_k}} \phi_k(w) + \text{regular}$$

then the bar differential acts by extracting the full chiral product μ (Convention 6.0.5):

$$d_{\text{res}}(\phi_i \otimes \phi_j \otimes \eta_{12}) = \mu(\phi_i, \phi_j) = \sum_{n \geq 0} (\phi_i)_{(n)} \phi_j.$$

The decomposition $\mu = d_{\text{bracket}} + d_{\text{curvature}}$ (Proposition 6.1.24) separates the contributions:

- $\Delta_k = 1$ (simple pole): the bracket component d_{bracket} extracts $(\phi_i)_{(0)}\phi_j = C_{ij}^k\phi_k$
- $\Delta_k = 2$ (double pole): the curvature component $d_{\text{curvature}}$ extracts the invariant pairing $(\phi_i)_{(1)}\phi_j$
- $\Delta_k \geq 3$ (higher pole): higher modes contribute to secondary operations
- $\Delta_k = 0$ (regular): no pole, zero contribution

Warning. One must *not* multiply the OPE pole by the propagator $\eta_{12} = d\epsilon/\epsilon$ and take the combined residue; the logarithmic form η_{12} accounts for the *degree* in the bar complex, not an additional pole.

Remark 6.1.36 (Iterated residues as A_∞ operations). The iterated residues on FM boundary strata are the A_∞ operations m_k . The k -th boundary stratum of $\overline{\text{Conf}}_{k+1}(\mathbb{C})$ contributes to m_k via the HPL transfer (Proposition 11.1.27). The Arnold relations (the sum of iterated residues at a codimension-2 stratum vanishes) are the Stasheff A_∞ identity $\sum_{i+j=n+1} m_i \circ m_j = 0$. This is the geometric content of $d^2 = 0$: the Borchers identity at the algebraic level and the codimension-2 boundary cancellation at the geometric level produce the same quadratic relations that Gaiotto–Kulp–Wu [193] derive from Wess–Zumino consistency of higher operations in the holomorphic-topological framework.

Example 6.1.37 (Heisenberg at degree 1). The Heisenberg OPE $J(z)J(w) \sim k/(z-w)^2$ has no simple pole ($J_{(0)}J = 0$); the entire bar differential at degree 1 comes from the double-pole extraction $J_{(1)}J = k$:

$$d_{\text{res}}(J \otimes J \otimes \eta_{12}) = k \cdot 1 \quad \in \bar{B}^0 = \mathbb{C}.$$

The level k is visible at genus 0 through $d_{\text{curvature}}$ (Proposition 6.1.24); at genus ≥ 1 it acquires a topological component $m_0 = \kappa \cdot \omega_g$ (Chapter 13).

Example 6.1.38 ($\beta\gamma$ system at degree 1). For the $\beta\gamma$ system with generators $\beta(z), \gamma(z)$ and OPE:

$$\beta(z)\gamma(w) = \frac{1}{z-w} + \text{regular}, \quad \beta(z)\beta(w) = 0, \quad \gamma(z)\gamma(w) = 0$$

Bar degree 1.

$$\bar{B}^1(\mathcal{FG}) = \text{span}\{\beta \otimes \beta \otimes \eta, \beta \otimes \gamma \otimes \eta, \gamma \otimes \beta \otimes \eta, \gamma \otimes \gamma \otimes \eta\}$$

Differential. Only the $\beta \otimes \gamma$ term contributes:

$$\begin{aligned} d(\beta \otimes \gamma \otimes \eta_{12}) &= \text{Res}_{D_{12}} [\mu(\beta, \gamma) \otimes \eta_{12}] \\ &= [\text{Res}_{\epsilon=0} \eta_{12}] \cdot \mu(\beta, \gamma) \Big|_{z_1=z_2} \end{aligned}$$

Setting $\epsilon = z_1 - z_2$, the propagator is $\eta_{12} = d\epsilon/\epsilon$, which has $\text{Res}_{\epsilon=0} [d\epsilon/\epsilon] = 1$. The chiral product $\mu(\beta, \gamma)$ extracts the simple-pole OPE coefficient $\beta(z)\gamma(w) \sim 1/(z-w)$, giving $\mathbb{1}$ (the unit element). Hence $d(\beta \otimes \gamma \otimes \eta_{12}) = \mathbb{1}$.

(Note: the residue is of the *logarithmic* 1-form $d\epsilon/\epsilon$, not of $d\epsilon/\epsilon^2$; one must not multiply the OPE pole by the propagator pole.)

Similarly: $d(\gamma \otimes \beta \otimes \eta_{12}) = -\mathbb{1}$ (the sign arises from the OPE $\gamma(z)\beta(w) \sim -1/(z-w)$, which carries a sign relative to $\beta(z)\gamma(w) \sim +1/(z-w)$ from the ordering convention for the chiral product, not from any fermionic anticommutativity; the $\beta\gamma$ system is bosonic).

Cohomology. $H^1(\bar{B}^\bullet(\mathcal{FG})) = \text{span}\{\beta \otimes \beta, \gamma \otimes \gamma\}$ (2-dimensional).

Remark 6.1.39 (Particle interpretation of low bar cohomology). For the reduced ordered bar complex

$$B^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}}), \quad \bar{\mathcal{A}} = \ker(\varepsilon),$$

the low-degree generators-and-relations truncation admits a particle/scattering interpretation on the quadratic-dual side:

$$\dim H^1(B^{\text{ord}}(\mathcal{A})) = \text{number of single-particle species},$$

$$\dim H^2(B^{\text{ord}}(\mathcal{A})) = \text{number of independent scattering channels},$$

where the second count records the independent quadratic relations. For the standard families:

- Heisenberg: $\dim H^1 = 1$, corresponding to one boson, and $\dim H^2 = 0$, reflecting the absence of quadratic interaction channels in the free theory.
- $\widehat{\mathfrak{sl}}_{2,k}$: $\dim H^1 = 3 = \dim \mathfrak{sl}_2$ and $\dim H^2 = 5$. The degree-2 count is 5, not 6.
- $\widehat{\mathfrak{sl}}_{3,k}$: $\dim H^1 = 8 = \dim \mathfrak{sl}_3$ and $\dim H^2 = 36$. This is the chiral bar value; the Chevalley–Eilenberg count gives 20 and does not include the extra chiral Orlik–Solomon contribution.

Remark 6.1.40 (Intuition à la Witten across genera). In two-dimensional CFT, correlation functions of chiral operators $\phi_1(z_1), \dots, \phi_n(z_n)$ are computed by the genus expansion:

$$\langle \phi_1(z_1) \cdots \phi_n(z_n) \rangle = \sum_{g=0}^{\infty} \lambda^{2g-2} \int_{\text{field space}} \mathcal{D}\phi e^{-S[\phi]} \phi_1(z_1) \cdots \phi_n(z_n)$$

The singularities as $z_i \rightarrow z_j$ encode the operator algebra structure at each genus. The configuration space $C_n(\Sigma_g) = \Sigma_g^n \setminus \{\text{diagonals}\}$ parametrizes non-colliding insertion points; its FM compactification $\bar{C}_n(\Sigma_g)$ adds collision strata and degenerating cycles; logarithmic forms $d \log(z_i - z_j)$ carry OPE singularities with genus corrections; the bar differential computes quantum corrections via residues and period integrals, each genus contributing specific modular forms.

Definition 6.1.41 (Orientation line bundle). The orientation line bundle $\text{or}_{p+1}^{(g)}$ on $\bar{C}_{p+1}(\Sigma_g)$ is

$$\text{or}_{p+1}^{(g)} = \det(T\bar{C}_{p+1}(\Sigma_g)) \otimes \text{sgn}_{p+1} \otimes \mathcal{L}_g$$

where:

- $\det(T\bar{C}_{p+1}(\Sigma_g))$ is the top exterior power of the tangent bundle
- sgn_{p+1} is the sign representation of $\mathfrak{S}_{p+1}$
- $\mathcal{L}_g$ is the genus-dependent orientation bundle from period matrix
- The tensor product ensures that exchanging two points introduces a sign and modular covariance

This ensures $d^2 = 0$ with consistent signs across all face maps and genus levels.

6.1.9 EXPLICIT LOW-DEGREE TERMS

Example 6.1.42 (Unreduced bar complex in low degrees; orientation only). *Warning.* The display in this example uses the full algebra $\mathcal{A}$ (not the augmentation ideal $\bar{\mathcal{A}}$); it is the *unreduced* bar complex, included only as an orientation device. The canonical bar complex used everywhere else in this monograph is the *reduced* bar $\bar{B}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$ built on the augmentation ideal; see the clarification after the display.

In the unreduced presentation:

$$\begin{aligned}\bar{B}_{\text{unred}}^0(\mathcal{A}) &= \mathcal{A} \\ \bar{B}_{\text{unred}}^1(\mathcal{A}) &= \Gamma(C_2(X), \mathcal{A} \boxtimes \mathcal{A} \otimes \eta_{12}) \\ \bar{B}_{\text{unred}}^2(\mathcal{A}) &= \Gamma(\bar{C}_3(X), \mathcal{A}^{\boxtimes 3} \otimes \Omega_{\log}^2).\end{aligned}$$

Bar degree n uses sections over $C_{n+1}(X)$; the bar differential lowers bar degree. The *reduced* bar complex, used from §6.1.10 onward and throughout the monograph, replaces $\mathcal{A}$ by its augmentation ideal $\bar{\mathcal{A}} = \ker(\varepsilon: \mathcal{A} \rightarrow \omega_X)$ and starts at $\bar{B}^0 = \mathbb{C}$. Augmentation separates generators from scalars: the map ε extracts the component of each operator proportional to the identity (the vacuum expectation value), and the reduced complex $T^c(s^{-1}\bar{\mathcal{A}})$ tensors together only the non-scalar modes. Without this splitting, the reduced coproduct on the bar coalgebra would fail conilpotence, and the cofree coalgebra structure that drives the bar-cobar adjunction (Theorem 7.0.51) would be unavailable. Every theorem stated later in this chapter refers to the reduced complex $T^c(s^{-1}\bar{\mathcal{A}})$; the unreduced display above has no independent content.

$$\begin{aligned}d : \bar{B}^1 &\rightarrow \bar{B}^0 \\ a_1 \otimes a_2 \otimes \eta_{12} &\mapsto \text{Res}_{z_1=z_2} [a_1(z_1) \cdot a_2(z_2) \cdot \eta_{12}]\end{aligned}$$

This residue extraction computes the OPE product, contracting two operator insertions via the singular part of their operator product.

6.1.10 FUNCTORIALITY OF THE BAR CONSTRUCTION

THEOREM 6.1.43 (*Bar construction is functorial*;). The geometric bar construction defines a functor:

$$\bar{B}^{\text{geom}} : \text{ChirAlg}_X^{\text{aug}} \rightarrow \text{dgCoalg}_X$$

from augmented chiral algebras to dg coalgebras, that is:

1. *Well-defined on objects:* For each augmented chiral algebra $\mathcal{A}$, $\bar{B}^{\text{geom}}(\mathcal{A})$ is a differential graded coalgebra
2. *Well-defined on morphisms:* For each morphism $f : \mathcal{A} \rightarrow \mathcal{B}$ of augmented chiral algebras, there is an induced coalgebra morphism $\bar{B}^{\text{geom}}(f) : \bar{B}^{\text{geom}}(\mathcal{A}) \rightarrow \bar{B}^{\text{geom}}(\mathcal{B})$
3. *Preserves identities:* $\bar{B}^{\text{geom}}(\text{id}_{\mathcal{A}}) = \text{id}_{\bar{B}^{\text{geom}}(\mathcal{A})}$
4. *Preserves composition:* $\bar{B}^{\text{geom}}(g \circ f) = \bar{B}^{\text{geom}}(g) \circ \bar{B}^{\text{geom}}(f)$

Proof. Well-definedness on objects is Theorem 6.1.21. For a morphism $f : \mathcal{A} \rightarrow \mathcal{B}$ of augmented chiral algebras, define $\bar{B}^{\text{geom}}(f)(a_0 \otimes \cdots \otimes a_n \otimes \omega) = f(a_0) \otimes \cdots \otimes f(a_n) \otimes \omega$ (apply f to algebra factors, leave forms unchanged).

Chain map property. Since f commutes with the internal differential (f is a $\mathcal{D}$ -module map), with the residue differential (f preserves the chiral product), and does not affect the de Rham component, $\bar{B}^{\text{geom}}(f)$ commutes with $d = d_{\text{int}} + d_{\text{res}} + d_{\text{dR}}$.

Coalgebra morphism. The coproduct Δ is defined by restricting to collision divisors; since f acts on algebra factors and Δ acts on the indexing set, $\Delta \circ \bar{B}(f) = (\bar{B}(f) \otimes \bar{B}(f)) \circ \Delta$. The counit compatibility and preservation of identities and composition are immediate from the definition. $\square$

COROLLARY 6.1.44 (*Natural transformation property*;). A commutative diagram of chiral algebras induces a commutative diagram of bar complexes: if $k \circ f = g \circ h$ in ChirAlg_X , then $\bar{B}(k) \circ \bar{B}(f) = \bar{B}(g) \circ \bar{B}(h)$ in dgCoalg_X . This is immediate from functoriality.

Proof. By Corollary 6.1.26, the bar construction is a functor. Applying that functor to the equality $k \circ f = g \circ h$ gives $\bar{B}(k \circ f) = \bar{B}(g \circ h)$, and functoriality expands this as $\bar{B}(k) \circ \bar{B}(f) = \bar{B}(g) \circ \bar{B}(h)$. $\square$

PROPOSITION 6.1.45 (*Model independence*;). Let $\mathcal{A}$ be a chiral algebra on X . Any two admissible¹ dg presentations of the bar object $\mathcal{B}_X(\mathcal{A})$ are connected by a contractible space of quasi-isomorphisms. In particular, any two such models give canonically isomorphic cohomology, spectral sequences, and generating functions.

Proof. Both presentations are cofibrant-fibrant objects in the model structure on conilpotent dg coalgebras over $\text{Ran}(X)$ (that is, dg coalgebras whose iterated reduced coproduct vanishes on every section; see Definition ??) (Positselski [350], Theorem 8.1). Cofibrant-fibrant replacements in this model structure are unique up to a contractible space of weak equivalences: the mapping space $\text{Map}(B_1, B_2)$ between two such replacements is contractible whenever both compute the same homotopy object. The configuration-space model $\bar{B}_X(\mathcal{A})$ is cofibrant by freeness of the coalgebra generators and fibrant by the Cousin filtration (Theorem 13.16.6). Any other admissible model shares these properties by the same arguments, whence the mapping space between them is contractible. $\square$

6.1.11 COALGEBRA STRUCTURE

THEOREM 6.1.46 (*Bar coalgebra*;). The bar complex carries a natural coalgebra structure:

$$\Delta : \bar{B}^{\text{geom}}(\mathcal{A}) \rightarrow \bar{B}^{\text{geom}}(\mathcal{A}) \otimes \bar{B}^{\text{geom}}(\mathcal{A})$$

induced by the diagonal map $X \rightarrow X \times X$. This is the coshuffle coproduct on the symmetric bar $\text{Sym}^c(s^{-1}\bar{\mathcal{A}})$, summing over all 2^n unordered bipartitions (Theorem 6.1.62(ii)). The ordered bar $T^c(s^{-1}\bar{\mathcal{A}})$ carries a distinct deconcatenation coproduct with $n + 1$ terms (Theorem 6.1.62(iii)); the coshuffle is its Σ_n -symmetrization.

Proof. Define Δ on tensors by summing over ordered bipartitions of the input index set and restricting the logarithmic form to the corresponding boundary factorization stratum, as in the explicit formula used in Theorem 6.1.47. This defines a morphism $\bar{B}^{\text{geom}}(\mathcal{A}) \rightarrow \bar{B}^{\text{geom}}(\mathcal{A}) \otimes \bar{B}^{\text{geom}}(\mathcal{A})$.

Coassociativity of this coproduct is proved in Theorem 6.1.47; counit compatibility is proved in Theorem 6.1.48. Hence the stated coproduct gives a coalgebra structure on $\bar{B}^{\text{geom}}(\mathcal{A})$. $\square$

¹An admissible presentation is a dg factorization coalgebra computing $\bar{B}_X(\mathcal{A})$ in the homotopy category: it is built from sections of $\mathcal{A}^{\boxtimes(n+1)}$ over open substacks of $\text{Ran}(X)$ and its differential restricts to the collision-residue map on each boundary stratum.

6.1.12 COALGEBRA AXIOMS: VERIFICATION

THEOREM 6.1.47 (*Coassociativity*). The coproduct $\Delta : \bar{B}_n(\mathcal{A}) \rightarrow \bigoplus_{p+q=n} \bar{B}_p(\mathcal{A}) \otimes \bar{B}_q(\mathcal{A})$ is coassociative:

$$(\Delta \otimes \text{id}) \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$$

Proof. Step 1: Definition of coproduct.

Recall that the coproduct on $\bar{B}_n(\mathcal{A})$ is defined by: for $(a_0 \otimes \cdots \otimes a_n \otimes \omega) \in \bar{B}_n(\mathcal{A})$,

$$\Delta(a_0 \otimes \cdots \otimes a_n \otimes \omega) = \sum_{I \sqcup J = [0, n]} (a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J)$$

where:

- $I, J \subseteq [0, n]$ partition the index set
- $a_I = a_{i_0} \otimes \cdots \otimes a_{i_p}$ for $I = \{i_0, \dots, i_p\}$
- ω_I is the restriction of ω to the configuration space $\bar{C}_{|I|}(X)$

Step 2: Left side, $(\Delta \otimes \text{id}) \circ \Delta$.

Apply Δ first:

$$\Delta(a_0 \otimes \cdots \otimes a_n \otimes \omega) = \sum_{I \sqcup J = [0, n]} (a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J)$$

Now apply $\Delta \otimes \text{id}$ to each term:

$$\begin{aligned} & (\Delta \otimes \text{id})((a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J)) \\ &= \Delta(a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J) \\ &= \left(\sum_{I' \sqcup I'' = I} (a_{I'} \otimes \omega_{I'}) \otimes (a_{I''} \otimes \omega_{I''}) \right) \otimes (a_J \otimes \omega_J) \\ &= \sum_{I' \sqcup I'' = I} (a_{I'} \otimes \omega_{I'}) \otimes (a_{I''} \otimes \omega_{I''}) \otimes (a_J \otimes \omega_J) \end{aligned}$$

Summing over all partitions $I \sqcup J = [0, n]$:

$$(\Delta \otimes \text{id}) \circ \Delta = \sum_{I' \sqcup I'' \sqcup J = [0, n]} (a_{I'} \otimes \omega_{I'}) \otimes (a_{I''} \otimes \omega_{I''}) \otimes (a_J \otimes \omega_J)$$

Step 3: Right side, $(\text{id} \otimes \Delta) \circ \Delta$.

Apply Δ first (same as before):

$$\Delta(a_0 \otimes \cdots \otimes a_n \otimes \omega) = \sum_{I \sqcup J = [0, n]} (a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J)$$

Now apply $\text{id} \otimes \Delta$:

$$\begin{aligned}
 & (\text{id} \otimes \Delta)((a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J)) \\
 &= (a_I \otimes \omega_I) \otimes \Delta(a_J \otimes \omega_J) \\
 &= (a_I \otimes \omega_I) \otimes \left(\sum_{J' \sqcup J'' = J} (a_{J'} \otimes \omega_{J'}) \otimes (a_{J''} \otimes \omega_{J''}) \right) \\
 &= \sum_{J' \sqcup J'' = J} (a_I \otimes \omega_I) \otimes (a_{J'} \otimes \omega_{J'}) \otimes (a_{J''} \otimes \omega_{J''})
 \end{aligned}$$

Summing over all partitions $I \sqcup J = [0, n]$:

$$(\text{id} \otimes \Delta) \circ \Delta = \sum_{I \sqcup J' \sqcup J'' = [0, n]} (a_I \otimes \omega_I) \otimes (a_{J'} \otimes \omega_{J'}) \otimes (a_{J''} \otimes \omega_{J''})$$

Step 4: Comparison.

LHS. Sum over ordered partitions (I', I'', J) with $I' \sqcup I'' \sqcup J = [0, n]$

RHS. Sum over ordered partitions (I, J', J'') with $I \sqcup J' \sqcup J'' = [0, n]$

These are the same set of ordered triples, in different notation.

Relabeling $I' \rightarrow K_1, I'' \rightarrow K_2, J \rightarrow K_3$ on LHS and $I \rightarrow K_1, J' \rightarrow K_2, J'' \rightarrow K_3$ on RHS:

Both sides equal:

$$\sum_{K_1 \sqcup K_2 \sqcup K_3 = [0, n]} (a_{K_1} \otimes \omega_{K_1}) \otimes (a_{K_2} \otimes \omega_{K_2}) \otimes (a_{K_3} \otimes \omega_{K_3})$$

Therefore: $(\Delta \otimes \text{id}) \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$. □

THEOREM 6.1.48 (*Counit axioms*;). The counit $\epsilon : \bar{B}_n(\mathcal{A}) \rightarrow \mathbb{C}$ satisfies:

1. *Left counit*: $(\epsilon \otimes \text{id}) \circ \Delta = \text{id}$
2. *Right counit*: $(\text{id} \otimes \epsilon) \circ \Delta = \text{id}$

Proof. The counit ϵ is:

$$\epsilon(a_0 \otimes \cdots \otimes a_n \otimes \omega) = \begin{cases} \langle a_0, 1 \rangle & n = 0 \\ 0 & n > 0 \end{cases}$$

Left counit axiom.

For $(a_0 \otimes \cdots \otimes a_n \otimes \omega) \in \bar{B}_n(\mathcal{A})$:

$$\begin{aligned}
 & (\epsilon \otimes \text{id})(\Delta(a_0 \otimes \cdots \otimes a_n \otimes \omega)) \\
 &= (\epsilon \otimes \text{id}) \left(\sum_{I \sqcup J = [0, n]} (a_I \otimes \omega_I) \otimes (a_J \otimes \omega_J) \right) \\
 &= \sum_{I \sqcup J = [0, n]} \epsilon(a_I \otimes \omega_I) \cdot (a_J \otimes \omega_J)
 \end{aligned}$$

Now $\epsilon(a_I \otimes \omega_I) = 0$ unless $|I| = 0$ (i.e., $I = \emptyset$).

When $I = \emptyset$, we have $J = [0, n]$ and:

$$\epsilon(1 \otimes \omega_\emptyset) \cdot (a_0 \otimes \cdots \otimes a_n \otimes \omega) = 1 \cdot (a_0 \otimes \cdots \otimes a_n \otimes \omega)$$

Therefore:

$$(\epsilon \otimes \text{id}) \circ \Delta = \text{id}$$

Right counit axiom.

Similarly:

$$\begin{aligned} & (\text{id} \otimes \epsilon)(\Delta(a_0 \otimes \cdots \otimes a_n \otimes \omega)) \\ &= \sum_{I \sqcup J = [0, n]} (a_I \otimes \omega_I) \cdot \epsilon(a_J \otimes \omega_J) \end{aligned}$$

$\epsilon(a_J \otimes \omega_J) = 0$ unless $|J| = 0$ (i.e., $J = \emptyset$).

When $J = \emptyset$, we have $I = [0, n]$ and:

$$(a_0 \otimes \cdots \otimes a_n \otimes \omega) \cdot \epsilon(1 \otimes \omega_\emptyset) = (a_0 \otimes \cdots \otimes a_n \otimes \omega) \cdot 1$$

Therefore:

$$(\text{id} \otimes \epsilon) \circ \Delta = \text{id}$$

□

COROLLARY 6.1.49 (*Bar complex is DG-coalgebra;*). The bar complex $\bar{B}^{\text{geom}}(\mathcal{A})$ with:

- Differential $d = d_{\text{int}} + d_{\text{res}} + d_{\text{dR}}$ (satisfying $d^2 = 0$)
- Coproduct Δ (coassociative)
- Counit ϵ (satisfying counit axioms)

is a differential graded coalgebra.

Proof. This assembles Theorem 6.1.21 ($d^2 = 0$), Theorem 6.1.47 (coassociativity of Δ), and Theorem 6.1.48 (counit axioms). The compatibility $d \circ \Delta = \Delta \circ d$ is Theorem 6.1.46. □

Remark 6.1.50 (Geometric meaning of coassociativity). Coassociativity asserts that the order of splitting is immaterial: $(\Delta \otimes \text{id}) \circ \Delta$ (split left first) equals $(\text{id} \otimes \Delta) \circ \Delta$ (split right first). Geometrically, corners of $\bar{C}_n(X)$ where multiple divisors intersect admit approach from different directions, yielding consistent boundary data.

THEOREM 6.1.51 (*Differential is coderivation;*). [Regime: genus-0 (Convention 1.10.2); at genus $g \geq 1$ the curved differential d_{fb} fails the coderivation property, see Chapter 13.]

The differential d on $\bar{B}(\mathcal{A})$ is a coderivation:

$$\Delta \circ d = (d \otimes \text{id} + \text{id} \otimes d) \circ \Delta$$

Proof. The coderivation identity $\Delta \circ d = (d \otimes \text{id} + \text{id} \otimes d) \circ \Delta$ is verified for each component of $d = d_{\text{int}} + d_{\text{res}} + d_{\text{dR}}$ separately.

For d_{int} : the internal differential acts on each tensor factor ϕ_i independently, and the coshuffle coproduct $\Delta(a_0 \otimes \cdots \otimes a_n) = \sum_{I \sqcup J = [0, n]} \pm (a_I) \otimes (a_J)$ (sum over all 2^{n+1} ordered bipartitions, as defined in Theorem 6.1.47) splits the tensor factors. The Leibniz rule $\Delta \circ d_{\text{int}} = (d_{\text{int}} \otimes \text{id} + \text{id} \otimes d_{\text{int}}) \circ \Delta$ follows because d_{int} acts within each factor and commutes with the splitting.

For d_{res} : the residue at D_{ij} (collision of points i and j) produces a term in bar degree $n - 1$. The coproduct restricts to boundary strata: $\Delta|_{D_{ij}}$ splits the remaining points into two groups, and the residue extraction commutes with this splitting because the divisor D_{ij} lies entirely within the factor containing both i and j .

For d_{dR} : the exterior derivative satisfies $d_{\text{dR}}(\omega_I \wedge \omega_J) = d_{\text{dR}}\omega_I \wedge \omega_J + (-1)^{|\omega_I|}\omega_I \wedge d_{\text{dR}}\omega_J$, which is the Leibniz rule with respect to the Künneth decomposition $\Omega^*(C_{n+1}(X)) \cong \bigoplus_{I \sqcup J} \Omega^*(C_{|I|}(X)) \otimes \Omega^*(C_{|J|}(X))$ used by Δ .

This is the standard coderivation property for bar differentials; see [299], Proposition 2.2.1 for the algebraic version. $\square$

Definition 6.1.52 (Genus-graded geometric bar complex). For a chiral algebra $\mathcal{A}$ on a Riemann surface Σ_g of genus g , the *genus-graded geometric bar complex* is the bigraded complex:

$$\bar{B}_{p,q}^{(g)}(\mathcal{A}) = \Gamma\left(\bar{C}_{p+1}(\Sigma_g), j_* j^* \mathcal{A}^{\boxtimes(p+1)} \otimes \Omega_{\bar{C}_{p+1}(\Sigma_g)}^q(\log D^{(g)}) \otimes \text{or}_{p+1}^{(g)}\right)$$

where:

- $\bar{C}_{p+1}(\Sigma_g)$ is the Fulton–MacPherson compactification at genus g
- $D^{(g)} = \bar{C}_{p+1}(\Sigma_g) \setminus C_{p+1}(\Sigma_g)$ is the boundary divisor with genus-dependent stratification
- $j : C_{p+1}(\Sigma_g) \hookrightarrow \bar{C}_{p+1}(\Sigma_g)$ is the open inclusion
- $\Omega_{\bar{C}_{p+1}(\Sigma_g)}^q(\log D^{(g)})$ includes logarithmic forms and period integrals
- $\text{or}_{p+1}^{(g)}$ is the genus-graded orientation bundle

The total bar complex is:

$$\bar{B}(\mathcal{A}) = \bigoplus_{g=0}^{\infty} \bar{B}^{(g)}(\mathcal{A})$$

Remark 6.1.53 (Orientation bundle). The orientation bundle $\text{or}_{p+1}^{(g)}$ is necessary because configuration spaces are not naturally oriented at each genus. It is the determinant line of $T_{C_{p+1}(\Sigma_g)}$ with genus-dependent corrections, ensuring consistent signs across all face maps. At genus 0, this guarantees $d_0^2 = 0$ (Theorem 6.1.21); at genus $g \geq 1$, the fiberwise differential satisfies $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ and the total corrected differential $D_g^2 = 0$ is established in Chapter 13.

6.1.13 THE DIFFERENTIAL: DETAILED COMPONENTS

The three-component decomposition $d = d_{\text{internal}} + d_{\text{residue}} + d_{\text{form}}$ of Definition 6.1.15 is now expanded at genus g .

6.1.13.1 Internal differential

Definition 6.1.54 (Internal differential). For $\alpha = \alpha_1 \otimes \cdots \otimes \alpha_{n+1} \otimes \omega \otimes \theta \in \bar{B}_{\text{geom}}^{n,q}(\mathcal{A})$ where $\theta \in \text{or}_{n+1}$:

$$d_{\text{int}}(\alpha) = \sum_{i=1}^{n+1} (-1)^{|\alpha_1| + \cdots + |\alpha_{i-1}|} \alpha_1 \otimes \cdots \otimes d_{\mathcal{A}}(\alpha_i) \otimes \cdots \otimes \alpha_{n+1} \otimes \omega \otimes \theta$$

where $d_{\mathcal{A}}$ is the internal differential on $\mathcal{A}$ (if present) and $|\alpha_i|$ denotes the cohomological degree.

6.1.13.2 Factorization differential

Definition 6.1.55 (Factorization differential). The factorization differential encodes the chiral algebra structure:

$$d_{\text{fact}} = \sum_{1 \leq i < j \leq n+1} (-1)^{\sigma(i,j)} \text{Res}_{D_{ij}}(\mu_{ij} \otimes (\eta_{ij} \wedge -))$$

where the sign is:

$$\sigma(i, j) = i + j + \left(\sum_{k=1}^{i-1} |\alpha_k| \right) \cdot |\eta_{ij}|$$

(Here $|\alpha_k|$ denotes the cohomological degree of the k -th element and $|\eta_{ij}| = 1$ for the logarithmic 1-form.)

Geometric meaning. This extracts the “color” C_{ij}^k from the “composite light” of $\mathcal{A}$:

$$\phi_i \otimes \phi_j \otimes \eta_{ij} \xrightarrow{d_{\text{fact}}} \text{Res}_{D_{ij}}[\text{OPE}(\phi_i, \phi_j)] = \sum_k C_{ij}^k \phi_k$$

Each residue reveals one structure coefficient, with the totality forming the complete “spectrum.” This accounts for:

- Koszul sign from moving η_{ij} past the fields α_k
- Orientation of the divisor D_{ij}
- Parity of the permutation after collision

LEMMA 6.1.56 (*Orientation convention*;). Fix orientations on boundary divisors by:

1. For D_{ij} where $z_i = z_j$:

$$\text{or}_{D_{ij}} = dz_1 \wedge \cdots \wedge \widehat{dz_i} \wedge \cdots \wedge dz_{n+1}$$

(omit dz_i , keep others including dz_j)

2. For codimension-2 strata $D_{ijk} = D_{ij} \cap D_{jk}$:

$$\text{or}_{D_{ijk}} = \text{or}_{D_{ij}} \wedge \text{or}_{D_{jk}}$$

3. This implies the relation:

$$\text{or}_{D_{ijk}} = -\text{or}_{D_{ik}} \wedge \text{or}_{D_{jk}} = \text{or}_{D_{jk}} \wedge \text{or}_{D_{ik}}$$

These choices ensure $\partial^2 = 0$ for the boundary operator on $\bar{C}_{n+1}(X)$.

Proof. The FM compactification $\overline{C}_{n+1}(X)$ is constructed by iterated real blow-up along diagonals ([186], §2). After blow-up, each codimension-1 boundary stratum D_S (indexed by subsets $S \subset [n+1]$ with $|S| \geq 2$) is a smooth divisor, and distinct divisors D_S, D_T meet transversally when $S \subset T$ or $T \subset S$ (nested), and are disjoint otherwise. A codimension-2 stratum therefore arises as $D_S \cap D_T$ where $S \subsetneq T$ (a two-step degeneration), and the two orderings of the iterated boundary (first collapse S , then collapse T/S , versus directly collapsing T and then refining to S) yield opposite orientations by the antisymmetry of the normal bundle orientations (Corollary 6.1.29). $\square$

Remark 6.1.57 (Significance of signs). The sign conventions are forced by $d^2 = 0$, following Kontsevich's principle: "signs should be determined by geometry, not combinatorics."

LEMMA 6.1.58 (*Residue properties*;). The residue operation satisfies:

1. $\text{Res}_{D_{ij}}^2 = 0$ (extracting residue lowers pole order)
2. For disjoint pairs: $\text{Res}_{D_{ij}} \circ \text{Res}_{D_{k\ell}} = -\text{Res}_{D_{k\ell}} \circ \text{Res}_{D_{ij}}$
3. For overlapping pairs with $j = k$: contributions combine via Jacobi identity

Proof. Part (1): A section $\omega \in \Omega_{\log}^*(\overline{C}_{n+1}(X))$ has at most a simple pole along D_{ij} . In a local coordinate u with $D_{ij} = \{u = 0\}$, write $\omega = f(u) d \log u + g(u)$ (terms regular in u) where $f(0) = \text{Res}_{D_{ij}} \omega$. The residue $\text{Res}_{D_{ij}} \omega = f(0)$ is a section on D_{ij} with no pole along D_{ij} , so $\text{Res}_{D_{ij}}^2 \omega = \text{Res}_{D_{ij}}(f(0)) = 0$.

Part (2): This is Corollary 6.1.29: for disjoint index pairs, the divisors D_{ij} and $D_{k\ell}$ are transverse, and the anticommutativity follows from the antisymmetry of $d \log u \wedge d \log v$.

Part (3): For overlapping pairs with $j = k$, three codimension-1 strata D_{ij} , D_{jk} , and D_{ik} meet at the triple collision stratum D_{ijk} . The sum of iterated residues:

$$\text{Res}_{D_{jk}} \circ \text{Res}_{D_{ij}} + \text{Res}_{D_{ij}} \circ \text{Res}_{D_{jk}} + \text{Res}_{D_{ik}} \circ \text{Res}_{D_{ij}}$$

vanishes by the associativity of the chiral product, as verified in Case (ii) of Theorem 6.1.21. $\square$

6.1.13.3 Configuration differential

Definition 6.1.59 (Configuration differential). The configuration differential is the de Rham differential on forms:

$$d_{\text{config}} = d_{\text{config}}^{\text{dR}} + d_{\text{config}}^{\text{Lie}^*}$$

where the de Rham component $d_{\text{config}}^{\text{dR}} = \text{id}_{\mathcal{A}^{\boxtimes(n+1)}} \otimes d_{\text{dR}} \otimes \text{id}_{\text{or}}$ acts on the differential forms, and the Lie^* component $d_{\text{config}}^{\text{Lie}^*} = \sum_{I \subset [n+1]} (-1)^{\epsilon(I)} d_{\text{Lie}}^{(I)} \otimes \text{id}_{\Omega^*}$ acts via the Lie^* algebra structure (when present).

For general chiral algebras without Lie^* structure, $d_{\text{config}}^{\text{Lie}^*} = 0$.

Remark 6.1.60 (Geometric meaning). The configuration differential captures how $\mathcal{A}$ varies over configuration space: d_{dR} measures variation of insertion points, d_{Lie^*} encodes infinitesimal symmetries. This parallels the Cartan model for equivariant cohomology.

6.1.14 EXPLICIT RESIDUE COMPUTATIONS

Remark 6.1.61 (Sign conventions: comparison with Loday–Vallette). Our sign conventions for the bar construction follow the geometric approach, which differs slightly from the operadic conventions in Loday–Vallette [299].

The differences are as follows.

1. *Koszul sign rule:* We use the *geometric* Koszul rule where moving a differential form of degree p past an operator of degree q introduces $(-1)^{pq}$.
2. *Residue orientation:* Our residues include an orientation factor from the normal bundle to collision divisors. This introduces signs when collision divisors intersect.
3. *Suspension:* Loday–Vallette use operadic suspension $s : V \rightarrow sV$ with $|s| = 1$. We work with geometric forms directly, so suspension is implicit in the degree shift of $\Omega^n(\log D)$.

Translation between conventions.

Loday–Vallette (Operadic)	Ours (Geometric)
$d_{op}(sa_1 \otimes \cdots \otimes sa_n)$	$d_{geom}(a_1 \otimes \cdots \otimes a_n \otimes \omega_n)$
Sign: $(-1)^{ a_1 + \cdots + a_{i-1} }$	Sign: $(-1)^{\epsilon_i}$ (from form degree)
Suspension degree $ sa_i = a_i + 1$	Form degree $ \omega = n$

The two conventions agree up to an overall normalization constant, absorbed into the definition of the pairing.

The nine-term proof of $d^2 = 0$ (Theorem 6.1.21) uses geometric signs throughout. Translating to operadic conventions via the dictionary above preserves $d^2 = 0$.

THEOREM 6.1.62 (*Three bar complexes and their inclusions*;). Work in characteristic zero. Let $\mathcal{A}$ be an augmented chiral algebra on X with augmentation ideal $\bar{\mathcal{A}} = \ker(\varepsilon)$. There is a chain of coalgebra inclusions

$$\mathrm{Lie}^c(s^{-1}\bar{\mathcal{A}}) \hookrightarrow \mathrm{Sym}^c(s^{-1}\bar{\mathcal{A}}) \hookrightarrow T^c(s^{-1}\bar{\mathcal{A}}) \quad (6.3)$$

whose three terms are:

- (i) (Harrison/coLie bar.) $\mathrm{Lie}^c(s^{-1}\bar{\mathcal{A}})$: the cofree conilpotent coLie coalgebra on $s^{-1}\bar{\mathcal{A}}$. In degree n the component is the cofree Lie^c -coalgebra on $s^{-1}\bar{\mathcal{A}}$, with $\dim \mathrm{Lie}(n) = (n-1)!$ as an S_n -representation. The coproduct is the coLie cobracket. This is the Koszul dual cooperad of $\mathrm{Com}^{\mathrm{ch}}$.
- (ii) (Symmetric/coshuffle bar.) $\mathrm{Sym}^c(s^{-1}\bar{\mathcal{A}})$: the cofree cocommutative coassociative conilpotent coalgebra on $s^{-1}\bar{\mathcal{A}}$. In degree n the component is $((s^{-1}\bar{\mathcal{A}})^{\otimes n})_{S_n}$, with the coshuffle coproduct

$$\Delta(a_1 \cdots a_n) = \sum_{I \sqcup J = [n]} \pm (a_I) \otimes (a_J),$$

a sum over all 2^n unordered bipartitions.

- (iii) (Tensor/deconcatenation bar.) $T^c(s^{-1}\bar{\mathcal{A}})$: the cofree conilpotent coassociative (non-cocommutative) coalgebra on $s^{-1}\bar{\mathcal{A}}$. In degree n the component is $(s^{-1}\bar{\mathcal{A}})^{\otimes n}$, with the deconcatenation coproduct

$$\Delta(a_1 \otimes \cdots \otimes a_n) = \sum_{i=0}^n (a_1 \otimes \cdots \otimes a_i) \otimes (a_{i+1} \otimes \cdots \otimes a_n),$$

a sum over the $n + 1$ consecutive cuts. This is the Koszul dual cooperad of Ass^{ch} .

The inclusions in (6.3) are strict in each degree $n \geq 2$: coshuffle has 2^n terms vs deconcatenation's $n + 1$; coLie is the weight-1 Eulerian summand of coshuffle. The following structural results hold.

- (a) (PBW decomposition.) The Eulerian idempotent decomposition gives a direct-sum splitting of graded coalgebras

$$\text{Sym}^c(s^{-1}\bar{\mathcal{A}}) \cong \bigoplus_{r \geq 1} (\text{Lie}^c(s^{-1}\bar{\mathcal{A}}))^{\odot r}$$

as S_n -modules, where $\odot$ denotes the symmetric product of cooperads. The first summand ($r = 1$) is the Harrison complex; the higher summands are its symmetric decomposables.

- (b) (Symmetrization quasi-isomorphism.) The symmetrization map $\text{sym}: T^c(s^{-1}\bar{\mathcal{A}}) \twoheadrightarrow \text{Sym}^c(s^{-1}\bar{\mathcal{A}})$ is a surjective quasi-isomorphism of dg coalgebras. Its kernel is the space of non-symmetric tensors.

- (c) (R-matrix descent.) The R -matrix tower on T^c descends to the shadow obstruction tower on Sym^c via sym , and the Harrison subcomplex Lie^c detects the primitives. In the notation of §1.4: at degree r , $\text{sym}(r_r) = S_r$ is the E_∞ -shadow at degree r (κ at $r = 2$; the cubic shadow $\mathfrak{C}$ at $r = 3$).

Proof. The three coalgebras are the cofree constructions on $s^{-1}\bar{\mathcal{A}}$ for the cooperads $\text{Lie}^c \subset \text{Sym}^c \subset T^c$, and the inclusions in (6.3) are inherited from the cooperad inclusions $\text{Lie}^c \hookrightarrow \text{Com}^c \hookrightarrow \text{Ass}^c$ (Loday–Vallette [299, Theorem 1.3.6, Proposition 8.6.9]).

Part (a). The Eulerian idempotents $e_n^{(r)} \in \mathbb{Q}[S_n]$ ($r = 1, \dots, n$) form a complete set of orthogonal idempotents that decompose the regular representation into weight spaces for the descent algebra. The weight-1 idempotent $e_n^{(1)}$ projects onto the Lie representations in $\mathbb{Q}[S_n]$; its image is precisely the space of primitive elements of the coshuffle coalgebra, i.e. the Harrison component $\text{Lie}^c(s^{-1}\bar{\mathcal{A}})$ in degree n . The direct-sum decomposition $\text{Sym}^c \cong \bigoplus_{r \geq 1} (\text{Lie}^c)^{\odot r}$ follows from the PBW theorem for Lie coalgebras in characteristic zero (Reutenauer [480, Chapter 9]; Loday–Vallette [299, §1.3.4]): the symmetric coalgebra on a Lie algebra is the universal enveloping cocommutative coalgebra, and the grading by Eulerian weight supplies the splitting.

Part (b). The symmetrization map $\text{sym}(a_1 \otimes \cdots \otimes a_n) = \frac{1}{n!} \sum_{\sigma \in S_n} \epsilon(\sigma) a_{\sigma(1)} \cdots a_{\sigma(n)}$ intertwines the deconcatenation coproduct on T^c with the coshuffle coproduct on Sym^c : both reduce to the same combinatorial identity after S_n -averaging. Surjectivity is immediate (every symmetric tensor is in the image). The map is a quasi-isomorphism because both sides compute $\text{Ext}_{\bar{\mathcal{A}}}^*(\mathbf{1}, \mathbf{1})$ (the derived Hom from the unit); equivalently, the cohomology comparison follows from the Loday–Quillen–Tsygan theorem in characteristic zero (Loday [297, Theorem 3.3.2]).

Part (c). The R -matrix $r_r \in \text{End}(V^{\otimes r}) \otimes \mathcal{O}(*\Delta)$ is the degree- r genus-0 component of the E_1 MC element $\Theta_{\bar{\mathcal{A}}}^{E_1}$ on the tensor bar T^c (Proposition 21.1.13). Under symmetrization, the S_r -coinvariant of r_r is the degree- r shadow S_r on the symmetric bar Sym^c : this is the content of the coinvariant shadow theorem (Theorem 21.3.3). At $r = 2$: $\text{sym}(r(z)) = \frac{1}{2} \text{tr}[\text{Res}_{z=0} r(z)] = \kappa(\mathcal{A})$. The Harrison subcomplex Lie^c

detects the primitives of Sym^c under the coshuffle coproduct; these are the weight-1 Eulerian components, which carry the essential algebraic content (higher Eulerian weights are symmetric decomposables determined by the primitives). $\square$

Remark 6.1.63 (Primacy direction). Information flows in one direction through the chain (6.3): from T^c to Sym^c to Lie^c . The symmetrization map $\text{sym}: T^c \twoheadrightarrow \text{Sym}^c$ is a surjective quasi-isomorphism (part (b)), but its kernel contains the R -matrix's non-coinvariant Fourier modes: the ordered bar is strictly richer. Theorems A–D use the symmetric bar because their statements are Σ_n -invariant; the seven-faces development of the collision residue uses the ordered bar because the quantum-group and Yangian structures it carries are not.

Remark 6.1.64 (Topological factorization on the $\mathbb{R}$ -direction). The $n + 1$ terms of the deconcatenation coproduct on T^c correspond to the $n + 1$ ways of cutting $C_n^<(\mathbb{R}) = \{t_1 < \dots < t_n\}$ into two consecutive segments $\{t_1, \dots, t_p\} \sqcup \{t_{p+1}, \dots, t_n\}$. This is topological factorization on the $\mathbb{R}$ -direction of $\mathbb{C} \times \mathbb{R}$ in the Costello–Gwilliam framework [92, §5.4]: the bar differential is holomorphic factorization on $\text{FM}_k(\mathbb{C})$ (Remark 6.1.3); the bar coproduct is topological factorization on $C_n^<(\mathbb{R})$. Together they exhibit the two geometric directions that later feed the Swiss-cheese story. On the bar complex itself they still form only the single-coloured E_1 dg coalgebra $T^c(s^{-1}\bar{\mathcal{A}})$; the actual $\text{SC}^{\text{ch}, \text{top}}$ datum appears only on the derived-center pair $(C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A})$.

Remark 6.1.65 (Conventions for this chapter). In this chapter, the unadorned notation $\bar{B}^{\text{geom}}(\mathcal{A})$ denotes the symmetric bar $\text{Sym}^c(s^{-1}\bar{\mathcal{A}})$ (Theorem 6.1.62(ii)); the coproduct (Theorems 6.1.46–6.1.47) is the coshuffle on Sym^c , matching the geometric decomposition of $\bar{C}_{n+1}(X)$ into unordered collision strata. Every theorem in this chapter is Σ_n -invariant (Remark 6.1.63).

THEOREM 6.1.66 (Geometric bar = operadic bar;). Let $\mathcal{P}^{\text{ch}}$ be a chiral operad on X (either Com^{ch} or Ass^{ch}) and let $\mathcal{A}$ be an augmented $\mathcal{P}^{\text{ch}}$ -algebra. Then the geometric bar complex $\bar{B}_{\text{geom}}(\mathcal{A})$ (Definition 6.1.15) is naturally quasi-isomorphic to the operadic bar construction $B_{\mathcal{P}^{\text{ch}}}(\mathcal{A})$ in the sense of [299, §6.5]:

$$\bar{B}_{\text{geom}}(\mathcal{A}) \xrightarrow{\sim} B_{\mathcal{P}^{\text{ch}}}(\mathcal{A}).$$

The quasi-isomorphism is natural in $\mathcal{A}$ and compatible with the coalgebra structures on both sides.

Proof. The operadic bar construction $B_{\mathcal{P}}(\mathcal{A}) = (\mathcal{P}^{!,c} \circ \bar{\mathcal{A}}, d_{\bar{B}})$ is a cofree $\mathcal{P}^!$ -coalgebra on the augmentation ideal $\bar{\mathcal{A}} = \ker(\varepsilon)$, with differential $d_{\bar{B}}$ encoding the algebra structure of $\mathcal{A}$ via the twisting morphism $\kappa: \mathcal{P}^{!,c} \rightarrow \mathcal{P}$ [299, Theorem 6.5.7].

Step 1 (Geometric realization of $\mathcal{P}^{!,c}$). For $\mathcal{P} = \text{Com}$ (the E_∞ -chiral case), $\mathcal{P}^{!,c} = \text{Lie}^c$, and the cooperad $\text{Lie}^c(n)$ is computed by the cohomology of the Fulton–MacPherson compactification $\bar{C}_n(X)$: the Arnold relations on $H^*(\bar{C}_n)$ generate the Lie cooperad. For $\mathcal{P} = \text{Ass}$, $\mathcal{P}^{!,c} = \text{Ass}^c$ (the associative cooperad), realized by ordered configurations.

Step 2 (Identification of differentials). The operadic differential $d_{\bar{B}}$ decomposes into d_1 (the cooperadic cocomposition $\mathcal{P}^{!,c}(n) \xrightarrow{\Delta} \mathcal{P}^{!,c}(k) \otimes \mathcal{P}^{!,c}(n_1) \otimes \dots \otimes \mathcal{P}^{!,c}(n_k)$) and d_2 (the twisting morphism applied to pairs of consecutive inputs). Under the geometric realization, d_1 corresponds to the de Rham differential d_{dR} on $\Omega^*(\log D)$ (which detects the codimension-one boundary strata of $\bar{C}_n(X)$), and d_2 corresponds to the residue differential d_{res} (which extracts OPE data at collision divisors). The sign comparison of Remark 6.1.61 shows these agree up to the suspension isomorphism $s\bar{\mathcal{A}} \cong \bar{\mathcal{A}} \otimes \Omega^1(\log D)|_{\text{codim-1}}$.

Step 3 (Quasi-isomorphism). The comparison map sends a geometric bar element $a_1 \otimes \dots \otimes a_n \otimes \omega \in \bar{B}_{\text{geom}}^n(\mathcal{A})$ to the operadic bar element $[sa_1 | \dots | sa_n] \in B_{\mathcal{P}}(\mathcal{A})_n$ by evaluating the logarithmic form

ω at the fundamental class of the fiber. This evaluation is a chain map by Stokes's theorem (boundary terms match the residue differential by Step 2). It is a quasi-isomorphism by the logarithmic comparison theorem: the complex $\Omega_{C_{n+1}(X)}^*(\log D)$ computes $H^*(C_{n+1}(X); \mathbb{C})$ (the cohomology of the open configuration space), and the operadic bar differential encodes precisely the combinatorics of the boundary divisor stratification of $\overline{C}_{n+1}(X)$; both are controlled by the operad structure on $\{C_{n+1}(X)\}_{n \geq 0}$ (cf. [40, Theorem 3.7.4], [201, Theorem 5.1]). $\square$

THEOREM 6.1.67 (*Residue formula*;). Following Beilinson–Drinfeld [40, §3.7.4, p.228], let $\mathcal{A}$ be generated by fields $\phi_\alpha(z)$ with conformal weights h_α and OPE:

$$\phi_\alpha(z)\phi_\beta(w) \sim \sum_\gamma \sum_{n=0}^{N_{\alpha\beta}} \frac{C_{\alpha\beta}^{\gamma,n} \partial^n \phi_\gamma(w)}{(z-w)^{h_\alpha+h_\beta-h_\gamma-n}} + \text{regular}$$

where the sum is finite (quasi-finite OPE). Then:

$$\text{Res}_{D_{ij}} [\phi_{\alpha_1}(z_1) \otimes \cdots \otimes \phi_{\alpha_{n+1}}(z_{n+1}) \otimes \eta_{i_1 j_1} \wedge \cdots \wedge \eta_{i_k j_k}]$$

equals:

- If $(i, j) \notin \{(i_r, j_r)\}_{r=1}^k$: zero (no pole along D_{ij})
- If $(i, j) = (i_r, j_r)$ for unique r and $h_{\alpha_i} + h_{\alpha_j} - h_\gamma - n = 1$:

$$(-1)^r C_{\alpha_i \alpha_j}^{\gamma,n} \phi_{\alpha_1} \otimes \cdots \otimes \partial^n \phi_\gamma \otimes \cdots \otimes \widehat{\phi_{\alpha_j}} \otimes \cdots \otimes \eta_{i_1 j_1} \wedge \cdots \wedge \widehat{\eta_{ij}} \wedge \cdots$$

where the hat denotes omission

- Otherwise: zero from the bracket component (wrong pole order for simple-pole extraction)

The *criticality condition* $h_{\alpha_i} + h_{\alpha_j} - h_\gamma - n = 1$ characterises the *bracket component* d_{bracket} (Proposition 6.1.24): the Poincaré residue along D_{ij} extracts the simple-pole coefficient. The full bar differential $d_{\text{res}} = d_{\text{bracket}} + d_{\text{curvature}}$ (Convention 6.0.5) also receives the double-pole contribution $d_{\text{curvature}}$ from the chiral product μ ; at the double pole ($h_{\alpha_i} + h_{\alpha_j} - h_\gamma - n = 2$), the curvature component extracts the invariant pairing $(\phi_i)_{(1)} \phi_j$. For algebras whose OPE has no simple pole (e.g. the Heisenberg algebra), $d_{\text{bracket}} = 0$ and $d_{\text{res}} = d_{\text{curvature}}$ (Remark 6.1.25).

Proof. Near D_{ij} , we use blow-up coordinates (u, ϵ, θ) where:

$$z_i = u + \frac{\epsilon}{2} e^{i\theta}, \quad z_j = u - \frac{\epsilon}{2} e^{i\theta}$$

The logarithmic form becomes:

$$\eta_{ij} = d \log(\epsilon e^{i\theta}) = d \log \epsilon + i d\theta$$

²The distributional nature of operator products requires care in defining products of distributions. We follow Hörmander's theory of wavefront sets: the OPE is well-defined when wavefront sets are in general position. See Hörmander, *Analysis of Linear Partial Differential Operators I*, Theorem 8.2.10, or Costello–Gwilliam Vol. 1, §2.4 for the QFT perspective.

The OPE gives:

$$\phi_{\alpha_i}(z_i)\phi_{\alpha_j}(z_j) = \sum_{\gamma,n} \frac{C_{\alpha_i\alpha_j}^{\gamma,n} \partial^n \phi_\gamma(u)}{(\epsilon e^{i\theta})^{h_{\alpha_i}+h_{\alpha_j}-h_\gamma-n}} + O(\epsilon^0)$$

The residue $\text{Res}_{D_{ij}}$ extracts the coefficient of $\frac{d \log \epsilon}{\epsilon}$, which is nonzero only when the pole order equals 1, i.e., when $h_{\alpha_i} + h_{\alpha_j} - h_\gamma - n = 1$. This is the *criticality condition* for the residue pairing. The sign $(-1)^r$ comes from moving η_{ij} past $r - 1$ other 1-forms via the Koszul rule for graded commutativity. $\square$

6.1.15 UNIQUENESS AND FUNCTORIALITY

THEOREM 6.1.68 (*Uniqueness and functoriality*;). The geometric bar construction is the unique functor

$$\bar{B}_{\text{geom}} : \text{ChiralAlg}_X \rightarrow \text{dgCoalg}$$

satisfying:

1. *Locality*: For $j : U \hookrightarrow X$ open, $j^* \bar{B}_{\text{geom}}(\mathcal{A}) \cong \bar{B}_{\text{geom}}(j^* \mathcal{A})$
2. *External product*: $\bar{B}_{\text{geom}}(\mathcal{A} \boxtimes \mathcal{B}) \cong \bar{B}_{\text{geom}}(\mathcal{A}) \boxtimes \bar{B}_{\text{geom}}(\mathcal{B})$
3. *Normalization*: $\bar{B}_{\text{geom}}(\mathcal{O}_X) = \Omega^*(\bar{C}_{*+1}(X))$

up to unique natural isomorphism.

It defines a functor from chiral algebras to filtered conilpotent chiral coalgebras, with essential image the coalgebras having logarithmic coderivations supported on collision divisors.

Definition 6.1.69 (*Conilpotent chiral coalgebra*). A chiral coalgebra C is *filtered conilpotent* if the iterated comultiplication $\Delta^{(n)} : C \rightarrow C^{\otimes(n+1)}$ satisfies: For each $c \in C$, there exists N such that $\Delta^{(n)}(c) = 0$ for all $n \geq N$. This ensures the cobar construction $\Omega^{\text{ch}}(C)$ is well-defined without completion.

Proof. Step 1: Existence. We verify each axiom explicitly:

- *Locality*: For $j : U \hookrightarrow X$ open, we have $C_n(U) = j^{-1}(C_n(X))$. The maximal extension $j_* j^*$ commutes with sections over configuration spaces:

$$\begin{aligned} j^* \bar{B}_{\text{geom}}(A) &= j^* \Gamma(\bar{C}_{n+1}(X), \dots) \\ &= \Gamma(\bar{C}_{n+1}(U), \dots) = \bar{B}_{\text{geom}}(j^* A) \end{aligned}$$

- *External product*: For disjoint open subsets $U_1, U_2 \subset X$, the identification $C_n(U_1 \sqcup U_2) \cong \bigsqcup_{k+l=n} C_k(U_1) \times C_l(U_2)$ induces a natural isomorphism

$$\bar{B}_{\text{geom}}(\mathcal{A}|_{U_1 \sqcup U_2}) \cong \bigoplus_{k+l=n} \bar{B}_k(\mathcal{A}|_{U_1}) \otimes \bar{B}_l(\mathcal{A}|_{U_2}),$$

compatible with boundary stratifications.

- *Normalization*: For $A = \mathcal{O}_X$, there are no nontrivial OPEs, so $d_{\text{fact}} = 0$, and we are left with just the de Rham complex on configuration spaces.

Step 2: Uniqueness. Let F, G be two such functors.

For the structure sheaf: By normalization,

$$F(\mathcal{O}_X) = G(\mathcal{O}_X) = \Omega^*(\bar{C}_{*+1}(X))$$

For the free chiral algebra $\text{Free}^{\text{ch}}(V)$ on a vector bundle V , the locality and external product axioms determine:

$$F(\text{Free}^{\text{ch}}(V)) \cong \text{Sym}^*(s^{-1}V) \otimes \Omega^*(\bar{C}_{*+1}(X))$$

(here $s^{-1}V$ is the desuspension $|s^{-1}v| = |v| - 1$ of Convention 6.0.2, matching the desuspension in $T^c(s^{-1}\bar{\mathcal{A}})$), and similarly for G , giving a canonical isomorphism $\eta_V : F(\text{Free}^{\text{ch}}(V)) \xrightarrow{\sim} G(\text{Free}^{\text{ch}}(V))$.

$$\begin{aligned} F(\text{Free}^{\text{ch}}(V)) &= F(V^{\otimes_{\text{ch}} \bullet}) \\ &\cong F(V)^{\otimes \bullet} \quad (\text{external product}) \\ &\cong (s^{-1}V \otimes F(\mathcal{O}_X))^{\otimes \bullet} \quad (\text{locality}) \\ &\cong \text{Sym}^*(s^{-1}V) \otimes \Omega^*(\bar{C}_{*+1}(X)) \end{aligned}$$

Similarly for G , giving a canonical isomorphism $\eta_V : F(\text{Free}^{\text{ch}}(V)) \xrightarrow{\sim} G(\text{Free}^{\text{ch}}(V))$.

For general $\mathcal{A} = \text{Free}^{\text{ch}}(V)/R$: The relations R determine boundaries via the same residue formulas in both $F(\mathcal{A})$ and $G(\mathcal{A})$:

- Each relation $r \in R$ maps to $d_{\text{fact}}(r)$ computed via residues
- The residue formula is determined by the OPE structure
- Locality ensures these agree on all affine charts

Step 3: Natural isomorphism. For morphism $\phi : \mathcal{A} \rightarrow \mathcal{B}$, the diagram

$$\begin{array}{ccc} F(\mathcal{A}) & \xrightarrow{\eta_{\mathcal{A}}} & G(\mathcal{A}) \\ \downarrow F(\phi) & & \downarrow G(\phi) \\ F(\mathcal{B}) & \xrightarrow{\eta_{\mathcal{B}}} & G(\mathcal{B}) \end{array}$$

commutes by construction of η using universal properties.

Verification that relations map to boundaries: Let $r \in R \subset \text{Free}^{\text{ch}}(V) \otimes \text{Free}^{\text{ch}}(V)$. Under F , we have:

$$\begin{aligned} F(r) &\in F(\text{Free}^{\text{ch}}(V) \otimes \text{Free}^{\text{ch}}(V)) = F(\text{Free}^{\text{ch}}(V))^{\otimes 2} \\ &= (V[1] \otimes \Omega^*(C_{*+1}(X)))^{\otimes 2} \end{aligned}$$

The differential d_F maps r to the boundary because:

$$d_F(r) = d_{\text{fact}}(r) + d_{\text{config}}(r) + d_{\text{int}}(r)$$

where d_{fact} implements the relation via residue extraction. Similarly for G . The agreement $F(r) = G(r)$ in cohomology follows from the universal property of free chiral algebras and the uniqueness of residue extraction.

Step 4: Uniqueness of isomorphism. Any other natural isomorphism $\eta' : F \Rightarrow G$ must agree on $\mathcal{O}_X$ by normalization, hence on free algebras by external product, hence on all algebras by locality. $\square$

6.1.16 BAR COMPLEX AS CHIRAL COALGEBRA

THEOREM 6.1.70 (*Bar complex is chiral*;). The geometric bar complex $\bar{B}^{\text{ch}}(\mathcal{A})$ naturally carries the structure of a differential graded chiral coalgebra. The coproduct is the coshuffle coproduct on $\text{Sym}^c(s^{-1}\bar{\mathcal{A}})$; the ordered refinement on $T^c(s^{-1}\bar{\mathcal{A}})$ with deconcatenation coproduct (Theorem 6.1.62(iii)) carries strictly richer data, including the R -matrix tower.

Proof. We construct the chiral coalgebra structure explicitly:

Comultiplication. The map $\Delta : \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \bar{B}^{\text{ch}}(\mathcal{A}) \otimes \bar{B}^{\text{ch}}(\mathcal{A})$ is induced by:

$$\Delta : \bar{C}_{n+1}(X) \rightarrow \bigcup_{I \sqcup J = [n+1]} \bar{C}_{|I|}(X) \times \bar{C}_{|J|}(X)$$

where the union is over ordered partitions with $0 \in I$. Explicitly:

$$\Delta(\phi_0 \otimes \cdots \otimes \phi_n \otimes \omega) = \sum_{I \sqcup J} \pm \left(\bigotimes_{i \in I} \phi_i \otimes \omega|_I \right) \otimes \left(\bigotimes_{j \in J} \phi_j \otimes \omega|_J \right)$$

Counit. $\epsilon : \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathbb{C}$ is given by projection onto degree 0:

$$\epsilon(\phi_0 \otimes \cdots \otimes \phi_n \otimes \omega) = \begin{cases} \int_X \phi_0 & \text{if } n = 0 \\ 0 & \text{if } n > 0 \end{cases}$$

Coassociativity. Follows from the associativity of configuration space stratifications (the stratification $\bar{C}_{n_1+n_2}(X) \supset C_{n_1}(X) \times C_{n_2}(X)$ is associative in the sense that iterated boundary extraction $(I_1, I_2, I_3) \mapsto (I_1 \mid I_2 \mid I_3)$ is independent of the order of extraction, by the transversality of the strata):

$$(\Delta \otimes \text{id}) \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$$

Compatibility with differential. The comultiplication is a chain map:

$$\Delta \circ d = (d \otimes \text{id} + \text{id} \otimes d) \circ \Delta$$

This follows from the compatibility of residues with the stratification of configuration spaces (the residue of $d\omega$ along a boundary stratum equals the residue of ω on the induced stratum, by the compatibility of the Leray residue with the boundary map in the long exact sequence of the pair). $\square$

Chapter 7

The geometric cobar complex

Opening notation. In the overview below, $\overline{B}(\mathcal{A})$ denotes the symmetric factorization bar coalgebra of $\mathcal{A}$; a conilpotent chiral coalgebra means a factorization coalgebra whose iterated reduced coproduct vanishes on every local section; and $\Omega^{\text{ch}}(C) = \bigoplus_{n \geq 0} \Omega_n^{\text{ch}}(C)$ denotes the geometric cobar complex obtained by Verdier duality on configuration spaces. Definitions 7.0.9, 7.0.8, and 7.0.10 give the formal versions used in the rest of the chapter.

The bar functor destroys the algebra: it encodes $\mathcal{A}$ as a factorization coalgebra $\overline{B}(\mathcal{A})$ from which no multiplication is directly visible. The cobar complex $\Omega(C)$ is the reconstruction machine that recovers $\mathcal{A}$ from this coalgebraic residue, realizing the inversion $\Omega(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ (Theorem B) and proving that the MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ determines $\mathcal{A}$ up to quasi-isomorphism on the Koszul locus. Both functors are projections of a single universal twisting morphism $\tau \in \text{MC}(\text{Conv}(C, \mathcal{A}))$ (Definition 3.1.19): bar records collision residues via the logarithmic propagator $\eta_{ij} = d \log(z_i - z_j)$; cobar integrates distributional duals over the open configuration space $C_n(X)$. The duality between them (residues versus delta functions, j_* versus $j_!$) is the Verdier exchange on $\text{Conv}(C, \mathcal{A})$.

Concretely, given a conilpotent chiral coalgebra C on X valued in holonomic $\mathcal{D}$ -modules, the *geometric cobar complex* is $\Omega_n^{\text{ch}}(C) := \mathbb{D}_{\overline{C}_{n+1}(X)}(j_* j^*(C^{\vee, \boxtimes(n+1)}) \otimes \Omega^n(\log D))$ (Definition 7.0.10), where $C^{\vee} = \mathbb{D}_X(C)$ is the $\mathcal{D}$ -module Verdier dual and $j: C_{n+1}(X) \hookrightarrow \overline{C}_{n+1}(X)$ is the open inclusion. The cobar differential is the Verdier transport of the bar differential through the Hom functor: $d_{\text{cobar}} := \mathbb{D}(d_{\text{bar}})$. The exchange $\mathbb{D} \circ j_* \cong j_! \circ \mathbb{D}$ (Lemma 7.0.13) identifies the cobar kernel as the distributional partner of the logarithmic propagator: the Schwartz kernel $K \in \mathcal{D}'(C_n(X) \times C_m(X))$ of Theorem 7.0.7 is the $j_!$ -side of the same MC element τ whose j_* -side is the bar propagator. This is the geometric content of the representability theorem $\text{Tw}(C, \mathcal{A}) = \text{MC}(\text{Conv}(C, \mathcal{A}))$ (Theorem 7.0.51).

At genus $g \geq 1$ the fiberwise differential satisfies $d_{\text{fib}}^2 = \kappa \cdot \omega_g$, reflecting the curved A_{∞} structure $\mu_1^2 = [\mu_0, -]$ (Chapter 8). The total bar differential $d_{\text{bar}}^2 = 0$ remains nilpotent. The cobar functor applied to the bar coalgebra viewed as an FCom-algebra (Theorem 8.2.12) encodes the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ (Proposition 7.0.46). Strict inversion may require completion or coderived contexts at higher genus.

7.0.1 MOTIVATION: REVERSING THE PRISM

Remark 7.0.1 (Three functors on the bar coalgebra: cobar is NOT the Koszul dual). Before entering the construction, we fix a critical distinction that pervades the chapter. Three functors act on the bar coalgebra $\overline{B}(\mathcal{A})$, producing three different objects; confusing any two produces false statements.

(i) *Cobar / bar-cobar inversion* (Theorem B, Corollary 7.o.37):

$$\Omega^{\text{ch}}(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A} \quad (\text{recovers } \mathcal{A} \text{ itself: a round-trip, not a duality}).$$

(ii) *Verdier duality on $\text{Ran}(X)$* (Theorem A, Convention 6.o.2):

$$\mathbb{D}_{\text{Ran}}(\overline{B}(\mathcal{A})) \simeq (\mathcal{A})_{\infty}^! \quad (\text{gives the homotopy Koszul dual factorization algebra}).$$

(iii) *Chiral derived centre / Hochschild cochains* (Theorem H):

$$Z_{\text{ch}}^{\text{der}}(\mathcal{A}) = C_{\text{ch}}^{\bullet}(\mathcal{A}, \mathcal{A}) \quad (\text{the universal bulk / closed-string observables}).$$

Cobar is the inverse, not the dual. Throughout this chapter Ω^{ch} denotes the bar-cobar inverse functor of (i); it recovers the algebra from its bar coalgebra. The homotopy Koszul dual factorization algebra $\mathcal{A}_{\infty}^!$ is obtained by Verdier duality on $\text{Ran}(X)$, and on the Koszul locus Theorem A identifies $\mathcal{A}_{\infty}^! \simeq \mathcal{A}^!$. This is a *different* operation on $\overline{B}(\mathcal{A})$. A statement such as “the cobar of the bar gives the Koszul dual” is false; the correct statement is “the cobar of the bar gives $\mathcal{A}$, and Verdier duality of the bar gives the homotopy Koszul dual factorization algebra.”

Remark 7.o.2 (Which bar complex does the cobar invert?). The manuscript distinguishes three bar complexes on a chiral algebra $\mathcal{A}$:

- (i) $\overline{B}^{\text{FG}}(\mathcal{A}) = \text{Lie}^c(s^{-1}\overline{\mathcal{A}})$, the *Francis–Gaitsgory* bar using the cofree coLie coalgebra on the augmentation coideal (the Harrison complex);
- (ii) $\overline{B}^{\Sigma}(\mathcal{A}) = \text{Sym}^c(s^{-1}\overline{\mathcal{A}})$, the *symmetric / factorization* bar whose underlying coalgebra is cofree cocommutative coassociative with the coshuffle coproduct (2^n terms; the factorization coalgebra of Definition 7.o.9);
- (iii) $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\overline{\mathcal{A}})$, the *ordered* bar using the cofree coassociative (non-cocommutative) coalgebra with the deconcatenation coproduct ($n + 1$ terms).

The cobar functor of this chapter is the left adjoint to $\overline{B}^{\Sigma}$ (the factorization/symmetric bar): given a factorization coalgebra C on X , $\Omega^{\text{ch}}(C)$ is the free chiral algebra on the desuspension $s^{-1}\overline{C}$ with differential extending the reduced comultiplication (Theorem 7.o.50). Bar-cobar inversion (Theorem B, Corollary 7.o.37) is stated for this symmetric/factorization bar: $\Omega^{\text{ch}}(\overline{B}^{\Sigma}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$. The ordered bar $\overline{B}^{\text{ord}}(\mathcal{A})$ carries more information (it tracks point order) and its cobar is a related but distinct construction; we work exclusively with the symmetric cobar except where explicitly noted.

Remark 7.o.3 (Inverse prism principle). The bar construction extracts residues at collision divisors; the cobar integrates over configuration spaces. Their duality is the residue-integration pairing on logarithmic forms.

Physical intuition (Witten). Off-shell amplitudes with infrared cutoffs are classified by the bar complex (compactification provides the cutoff); on-shell propagators with ultraviolet regularization are classified by the cobar complex (delta functions provide the regulator); the bar-cobar pairing computes S-matrix elements by integrating off-shell wavefunctions against on-shell propagators.

Geometric picture (Kontsevich).

	Bar	Cobar
Space	Compactified $\overline{C}_n(X)$	Open $C_n(X)$
Forms	Logarithmic (residues)	Distributional (delta functions)
Operation	Extract (analyze)	Insert (synthesize)
Boundary	Normal crossing divisors	Diagonal singularities
Physics	Off-shell states	On-shell propagators

7.0.2 DISTRIBUTION THEORY PREREQUISITES

Definition 7.0.4 (Test function space). For the open configuration space $C_n(X)$, define the test function space:

$$\mathcal{D}(C_n(X)) = C_c^\infty(C_n(X), \mathbb{C})$$

consisting of smooth, compactly supported functions. This is equipped with the inductive limit topology from exhaustion by compact sets.

Definition 7.0.5 (Distribution space). The space $\mathcal{D}'(C_n(X))$ of *distributions* on $C_n(X)$ is the continuous dual:

$$\mathcal{D}'(C_n(X)) = \mathcal{D}(C_n(X))^*$$

equipped with the weak-* topology. A distribution $T \in \mathcal{D}'(C_n(X))$ is a continuous linear functional:

$$\langle T, \phi \rangle \in \mathbb{C} \quad \text{for all } \phi \in \mathcal{D}(C_n(X))$$

Example 7.0.6 (Fundamental distributions). *Dirac delta.* For $p \in C_n(X)$:

$$\langle \delta_p, \phi \rangle = \phi(p)$$

Principal value. For the diagonal $\Delta_{ij} \subset C_n(X)$:

$$\langle \text{PV}\left(\frac{1}{z_i - z_j}\right), \phi \rangle = \lim_{\epsilon \rightarrow 0} \int_{|z_i - z_j| > \epsilon} \frac{\phi(z_1, \dots, z_n)}{z_i - z_j} dz_1 \cdots dz_n$$

Hadamard finite part. For higher-order poles:

$$\text{FP}\left(\frac{1}{(z_i - z_j)^k}\right) = \lim_{\epsilon \rightarrow 0} \left[\int_{|z_i - z_j| > \epsilon} \frac{\phi}{(z_i - z_j)^k} - \frac{(\text{divergent terms})}{\epsilon^{k-1}} \right]$$

THEOREM 7.0.7 (Schwartz kernel theorem for cobar [221];). Every continuous linear operator:

$$K : \mathcal{D}(C_n(X)) \rightarrow \mathcal{D}'(C_m(X))$$

is represented by a distribution kernel:

$$K \in \mathcal{D}'(C_n(X) \times C_m(X))$$

such that:

$$(K\phi)(z_1, \dots, z_m) = \int_{C_n(X)} K(z_1, \dots, z_m; w_1, \dots, w_n) \phi(w_1, \dots, w_n)$$

Proof. This is a special case of the Schwartz kernel theorem for distributions on smooth manifolds (Hörmander [221], Theorem 5.2.1). The configuration spaces $C_n(X)$ and $C_m(X)$ are smooth manifolds, and continuity of K in the distributional topology guarantees the existence of the integral kernel $K \in \mathcal{D}'(C_n(X) \times C_m(X))$. $\square$

7.0.3 INTRINSIC COBAR VIA VERDIER DUALITY

Definition 7.0.8 (Conilpotent coalgebra). A coalgebra C with comultiplication $\Delta: C \rightarrow C \otimes C$ is *conilpotent* if for each element $c \in C$, there exists $N = N(c) \in \mathbb{N}$ such that the N -fold iterated comultiplication vanishes:

$$\Delta^{(N)}(c) = 0.$$

Equivalently, $C = \bigcup_{N \geq 0} F_N C$ where $F_N C = \ker(\Delta^{(N)})$ is the *coradical filtration*. The condition ensures that for any element, only finitely many terms appear in the cobar differential, making infinite sums unnecessary and convergence automatic.

A coalgebra is *cocomplete* if the natural map $C \rightarrow \varprojlim C/F_N C$ is an isomorphism. Both conditions guarantee that the cobar construction produces a well-defined chain complex (Theorem 7.0.14). See also Definition 8.1.17 for the filtered formulation.

Definition 7.0.9 (Factorization coalgebra). A *factorization coalgebra* on a smooth curve X is a $\mathcal{D}_X$ -module C equipped with:

- (i) a comultiplication $\Delta: C \rightarrow j_* j^*(C \boxtimes C)$, where $j: X^2 \setminus \Delta_X \hookrightarrow X^2$;
- (ii) a counit $\varepsilon: C \rightarrow \omega_X$;
- (iii) the *factorization* (colocality) property: Δ factors through $j_* j^*$, so the comultiplication is comonomorphic with copoles only along the diagonal;
- (iv) coassociativity: the Borchers co-identity (the dual of equation (3.4)) holds for the iterated comultiplication on codimension-2 strata.

This is the Verdier dual of a chiral algebra: if $\mathcal{A}$ is a chiral algebra, then $C = \overline{B}(\mathcal{A})$ (the bar coalgebra) is a factorization coalgebra, and conversely the cobar $\Omega(C)$ recovers a chiral algebra structure.

Definition 7.0.10 (Intrinsic geometric cobar complex). Let C be a conilpotent chiral coalgebra on a smooth algebraic curve X , valued in holonomic $\mathcal{D}$ -modules, with comultiplication $\Delta: C \rightarrow C \boxtimes C$ and coaugmentation $\eta: \omega_X \rightarrow C$. Write $C^\vee := \mathbb{D}_X(C)$ for the $\mathcal{D}$ -module Verdier dual on X , which is a chiral algebra with multiplication dual to Δ .

The *geometric cobar complex* is the graded object:

$$\Omega_n^{\text{ch}}(C) := \mathbb{D}_{\overline{C}_{n+1}(X)} \left(j_* j^* ((C^\vee)^{\boxtimes (n+1)}) \otimes \Omega_{\overline{C}_{n+1}(X)}^n(\log D) \right)$$

where $j: C_{n+1}(X) \hookrightarrow \overline{C}_{n+1}(X)$ is the inclusion, $D = \partial \overline{C}_{n+1}(X)$ is the boundary divisor, and $\mathbb{D}_{\overline{C}_{n+1}(X)}$ is the Verdier duality functor on the compactified configuration space.

The *cobar differential* is:

$$d_{\text{cobar}} := \mathbb{D}(d_{\text{bar}})$$

the Verdier dual of the bar differential (Definition 6.1.15).

Remark 7.0.11. The definition says: *to build the cobar of a coalgebra C , first form the bar of its dual algebra $C^\vee$, then apply Verdier duality on the configuration space.* Concretely, the bar uses j_* (maximal extension across diagonals) and logarithmic forms; the cobar uses $j_!$ (extension by zero) and distributional sections. This is precisely the exchange effected by Verdier duality: $\mathbb{D} \circ j_* \cong j_! \circ \mathbb{D}$ (Lemma 7.0.13).

LEMMA 7.0.12 (Holonomicity of the bar complex;). Let $\mathcal{A}$ be a chiral algebra on a smooth projective curve X , finitely generated over $\mathcal{D}_X$ with regular singularities. Then for each $n \geq 0$:

- (a) The n -th bar component $\bar{B}_n^{\text{ch}}(\mathcal{A})$ is a regular holonomic $\mathcal{D}$ -module on the Fulton–MacPherson compactification $\bar{C}_n(X)$.
- (b) The bar differential $d_{\text{bar}}: \bar{B}_n^{\text{ch}}(\mathcal{A}) \rightarrow \bar{B}_{n-1}^{\text{ch}}(\mathcal{A})$ is a morphism of holonomic $\mathcal{D}$ -modules.

Proof. Step 1: External tensor product. Since $\mathcal{A}$ is a holonomic $\mathcal{D}_X$ -module by hypothesis, the external tensor product $\mathcal{A}^{\boxtimes n}$ is a holonomic $\mathcal{D}_{X^n}$ -module [226, Theorem 3.2.3].

Step 2: Pullback to the FM compactification. The blowdown morphism $\pi: \bar{C}_n(X) \rightarrow X^n$ is proper and birational, so $\pi^! \mathcal{A}^{\boxtimes n}$ is a holonomic $\mathcal{D}_{\bar{C}_n(X)}$ -module [226, Theorem 3.2.3].

Step 3: Logarithmic extension. The bar sheaf on the open configuration space $C_n(X)$ is $j^* \pi^! \mathcal{A}^{\boxtimes n} \otimes \Omega_{\log}^*(D)$, where $j: C_n(X) \hookrightarrow \bar{C}_n(X)$ is the inclusion and $D = \bar{C}_n(X) \setminus C_n(X)$ is a normal crossings divisor (Theorem 5.1.3). The logarithmic differential forms $\Omega_{\log}^*(D)$ define a regular integrable connection on the NCD complement, so j_* of the resulting regular holonomic module on $C_n(X)$ is regular holonomic on $\bar{C}_n(X)$ by Deligne’s regularity theorem [226, Theorem 5.2.17]. This identifies $\bar{B}_n^{\text{ch}}(\mathcal{A})$ as a regular holonomic $\mathcal{D}_{\bar{C}_n(X)}$ -module.

Step 4: Bar differential. The bar differential $d_{\text{bar}} = d_{\text{internal}} + d_{\text{residue}} + d_{\text{form}}$ (Definition 6.1.15). The internal differential d_{internal} is induced by the chiral algebra structure, which is a $\mathcal{D}_X$ -module morphism by definition. The form differential d_{form} is the de Rham differential on $\Omega_{\log}^*(D)$, which is a $\mathcal{D}$ -module morphism. The residue differential $d_{\text{residue}} = \sum_D \text{Res}_D$ is the composition of restriction to a boundary divisor D followed by the trace map, both of which are morphisms of $\mathcal{D}$ -modules [250, Chapter 4]. Hence d_{bar} is a morphism of holonomic $\mathcal{D}$ -modules. $\square$

LEMMA 7.0.13 (*Verdier duality exchanges extensions;*). Let Y be a smooth variety, $U \xhookrightarrow{j} Y$ an open inclusion with complement a normal crossings divisor, and $\mathcal{M}$ a holonomic $\mathcal{D}_U$ -module. Then there is a canonical isomorphism in the derived category of holonomic $\mathcal{D}_Y$ -modules:

$$\mathbb{D}_Y(j_* \mathcal{M}) \cong j_! \mathbb{D}_U(\mathcal{M}).$$

Proof. This is a standard consequence of the theory of holonomic $\mathcal{D}$ -modules; we recall the argument. By adjunction, j_* is right adjoint to j^* and $j_!$ is left adjoint to $j^!$. For j an open inclusion we have $j^! = j^*$, so:

$$j_! \dashv j^* \dashv j_*.$$

Verdier duality exchanges left and right adjoints: for any holonomic $\mathcal{M}$ on U ,

$$\mathbb{D}_Y(j_* \mathcal{M}) = \mathbb{D}_Y(j_* \mathbb{D}_U \mathbb{D}_U \mathcal{M}) \cong j_! (\mathbb{D}_U \mathcal{M})$$

where the last step uses the identity $\mathbb{D}_Y \circ j_* \circ \mathbb{D}_U \cong j_!$, which holds because j_* preserves holonomicity (the complement is a normal crossings divisor) and Verdier duality is involutive on the holonomic category [226, Theorem 2.6.1]. $\square$

THEOREM 7.0.14 (*Distributional model of the cobar;*). Let C be a factorization coalgebra that is conilpotent (Definition 8.1.17) or complete with respect to its coaugmentation ideal. Since each bar component is holonomic (Lemma 7.0.12), the intrinsic cobar (Definition 7.0.10) admits a canonical isomorphism:

$$\Omega_n^{\text{ch}}(C) \cong \Gamma\left(C_{n+1}(X), \text{Hom}_{\mathcal{D}}\left(\pi^* C^{\otimes(n+1)}, \mathcal{D}_{C_{n+1}(X)}\right) \otimes \Omega_{C_{n+1}(X), \text{dist}}^*\right)$$

That is, the intrinsic cobar is represented by distributional sections of $C^{\boxtimes(n+1)}$ over the *open* configuration space.

The three components of the cobar differential correspond to Verdier duals of the bar differential components:

- (i) $d_{\text{extend}} = \mathbb{D}(d_{\text{res}})$: Verdier-dual of the residue differential. Residues at boundary divisors (extracting OPE poles) dualize to delta-function insertions at diagonals (enforcing coincidence constraints).
- (ii) $d_{\text{comult}} = \mathbb{D}(d_{\text{fact}})$: Verdier-dual of the factorization differential. Configuration-splitting in the bar dualizes to comultiplication in the cobar.
- (iii) $d_{\text{internal}} = \mathbb{D}(d_{\text{int}})$: The internal differential is self-dual.

Proof. Step 1: Identification of the underlying graded object. By Lemma 7.0.13,

$$\mathbb{D}_{\overline{C}_{n+1}}(j_* j^*(C^\vee)^{\boxtimes(n+1)} \otimes \Omega_{\log}^n) \cong j_! j^* \mathbb{D}((C^\vee)^{\boxtimes(n+1)}) \otimes \mathbb{D}(\Omega_{\log}^n).$$

Since $\mathbb{D}_X(C^\vee) = C$ (Verdier duality is involutive on holonomic $\mathcal{D}$ -modules) and $\mathbb{D}(\Omega_{\log}^n)$ is the sheaf of distributional $(d - n)$ -currents on $\overline{C}_{n+1}(X)$ (where $d = \dim_{\mathbb{R}} C_{n+1}(X)$), we obtain distributional sections of $C^{\boxtimes(n+1)}$ with $j_!$ -support; that is, sections on $C_{n+1}(X)$ extended by zero across the boundary. Passing to global sections gives the distributional model.

Step 2: Differential components. The bar differential $d_{\text{bar}} = d_{\text{int}} + d_{\text{res}} + d_{\text{config}}$ is a morphism of holonomic $\mathcal{D}$ -modules. Since $\mathbb{D}$ is an exact functor on the holonomic category, each component dualizes individually.

For (i): the residue differential d_{res} acts by $\text{Res}_{z_i=z_j}[\omega \cdot \eta_{ij}]$ (extracting the residue along the boundary divisor D_{ij}). Under the Verdier pairing $\langle \eta_{ij}, \delta(z_i - z_j) \rangle = 1$ (Theorem 7.0.36, Step 3), the dual operation is $K \mapsto \delta(z_i - z_j) \otimes K|_{\Delta_{ij}}$: inserting a delta function at the diagonal. This is exactly the extension differential d_{extend} .

For (ii): the factorization differential splits configurations by restricting to strata where subsets of points collide. Its dual reassembles configurations by applying the comultiplication Δ of C .

For (iii): the internal differential d_{int} acts coefficient-wise by the differential of $\mathcal{A}$ (resp. C) and does not interact with configuration space geometry; it is self-dual under $\mathbb{D}_X(C^\vee) = C$. $\square$

COROLLARY 7.0.15 ($d_{\text{cobar}}^2 = 0$ via Verdier duality;). The cobar differential satisfies $d_{\text{cobar}}^2 = 0$.

Proof. The bar differential satisfies $d_{\text{bar}}^2 = 0$ (Theorem 8.2.10). Since $d_{\text{cobar}} = \mathbb{D}(d_{\text{bar}})$ and Verdier duality is an exact functor on holonomic $\mathcal{D}$ -modules, we have $d_{\text{cobar}}^2 = \mathbb{D}(d_{\text{bar}}^2) = \mathbb{D}(0) = 0$. $\square$

Remark 7.0.16 (Resolution of delta-function products). A classical objection to the distributional cobar is that products of delta distributions may be ill-defined: the product $\delta(z_1 - z_2) \cdot \delta(z_2 - z_3)$ requires a renormalization choice in the analytic category. The intrinsic definition (Definition 7.0.10) dissolves this objection: the cobar is a Verdier dual in the $\mathcal{D}$ -module category, where compositions are governed by the calculus of nearby and vanishing cycles. The normal crossings condition on $D \subset \overline{C}_n(X)$ ensures transversality of all relevant compositions, making them well-defined without renormalization.

The distributional representation (Theorem 7.0.14) is a *consequence*: it describes how the intrinsic $\mathcal{D}$ -module object looks when evaluated on test sections, but the differential and its nilpotence are established at the $\mathcal{D}$ -module level, where no analytic subtleties arise.

7.0.4 EXPLICIT DISTRIBUTIONAL MODEL

Definition 7.0.17 (Geometric cobar complex). The bar complex used logarithmic forms on *compactified* configuration spaces; the cobar uses distributions on *open* configuration spaces. For the Heisenberg algebra (§2.5), the cobar of $\text{coLie}^{\text{ch}}(V^*)$ produced $\text{Sym}^{\text{ch}}(V^*)$; the following definition gives the general construction.

For a conilpotent chiral coalgebra C on X with coaugmentation $\eta : \omega_X \rightarrow C$ and comultiplication $\Delta : C \rightarrow C \boxtimes C$, the *geometric cobar complex* is:

$$\Omega_{p,q}^{\text{ch}}(C) = \Gamma\left(C_{p+1}(X), \text{Hom}_{\mathcal{D}}(\pi^* C^{\otimes(p+1)}, \mathcal{D}_{C_{p+1}(X)}) \otimes \Omega_{C_{p+1}(X), \text{dist}}^q\right)$$

where:

- $C_{p+1}(X)$ is the *open* configuration space (no compactification)
- $\pi : C_{p+1}(X) \rightarrow X^{p+1}$ is the projection
- $\Omega_{C_{p+1}(X), \text{dist}}^q$ are distributional q -forms: currents with prescribed singularities along diagonals $\{z_i = z_j\}$
- $\text{Hom}_{\mathcal{D}}$ denotes $\mathcal{D}$ -module homomorphisms

Equivalently, using the Schwartz kernel theorem (Theorem 7.0.7):

$$\Omega_n^{\text{ch}}(C) = \text{Dist}\left(C_n(X), C^{\boxtimes n}\right) \otimes \Omega_{C_n(X)}^*$$

consisting of distributional sections of $C^{\boxtimes n}$ over the open configuration space with differential forms.

Remark 7.0.18 (Distributions). The cobar differential inserts delta functions $\delta(z_i - z_j)$, forcing the complex to consist of distributions. Geometrically, distributions on $C_n(X)$ are Verdier-dual to logarithmic forms on $\overline{C}_n(X)$. Physically, cobar operations implement propagator composition: $(\square - m^2)G(z, w) = \delta^{(2)}(z - w)$.

Example 7.0.19 (Simplest cobar element). For $n = 2$ with trivial coalgebra $C = \omega_X$, the basic cobar element is:

$$K_2(z_1, z_2) = \delta(z_1 - z_2) \otimes (dz_1 \wedge d\bar{z}_1)$$

This acts on test functions $\phi \in \mathcal{D}(C_2(X))$ by:

$$\langle K_2, \phi \rangle = \int_X \phi(z, z) dz \wedge d\bar{z}$$

enforcing the diagonal constraint.

Physical meaning. This is the propagator for a free scalar field with δ -function source at coinciding points.

THEOREM 7.0.20 (Cobar differential;). The cobar differential is a degree +1 operator:

$$d_{\text{cobar}} : \Omega_{p,q}^{\text{ch}}(C) \rightarrow \Omega_{p-1,q+1}^{\text{ch}}(C) \oplus \Omega_{p,q}^{\text{ch}}(C) \oplus \Omega_{p+1,q}^{\text{ch}}(C)$$

It decomposes into three components:

$$d_{\text{cobar}} = d_{\text{comult}} + d_{\text{internal}} + d_{\text{extend}}$$

where each component has precise meaning:

Component 1: Comultiplication differential.

$$d_{\text{comult}} : \Omega_{p,q}^{\text{ch}}(C) \rightarrow \Omega_{p-1,q}^{\text{ch}}(C)$$

Uses the comultiplication $\Delta : C \rightarrow C \boxtimes C$ to split configurations. For $K \in \Omega_n^{\text{ch}}(C)$ represented as:

$$K = \int_{C_n(X)} k(z_1, \dots, z_n) \otimes c_1(z_1) \otimes \dots \otimes c_n(z_n)$$

We have:

$$(d_{\text{comult}}K)(c_0, \dots, c_{n-2}) = \sum_{i=0}^{n-2} (-1)^{\epsilon_i} K(c_0, \dots, \Delta(c_i), \dots, c_{n-2})$$

where $\epsilon_i = |c_0| + \dots + |c_{i-1}|$ is the Koszul sign.

Component 2: Internal differential.

$$d_{\text{internal}} : \Omega_{p,q}^{\text{ch}}(C) \rightarrow \Omega_{p,q}^{\text{ch}}(C)$$

Applies the internal differential of C coefficient-wise:

$$(d_{\text{internal}}K)(c_0, \dots, c_n) = \sum_{i=0}^n (-1)^{\epsilon_i} K(c_0, \dots, d_C(c_i), \dots, c_n)$$

Component 3: Extension differential.

$$d_{\text{extend}} : \Omega_{p,q}^{\text{ch}}(C) \rightarrow \Omega_{p+1,q}^{\text{ch}}(C)$$

This extends distributions across collision divisors and is the *inverse* of taking residues in the bar complex.

For a distribution K on $C_n(X)$ with singularities along $\Delta_{ij} = \{z_i = z_j\}$:

$$(d_{\text{extend}}K)(z_0, \dots, z_n) = \sum_{i < j} \delta(z_i - z_j) \otimes K|_{\Delta_{ij}}$$

Proof. We construct each component explicitly with all signs and conventions.

Step 1: Comultiplication component.

For $K \in \Omega_n^{\text{ch}}(C)$, write:

$$K = \sum_{\sigma \in \mathfrak{S}_n} K_\sigma \otimes c_{\sigma(1)} \otimes \dots \otimes c_{\sigma(n)}$$

where $K_\sigma \in \mathcal{D}'(C_n(X))$ and $c_i \in C$.

The comultiplication differential acts by:

$$(d_{\text{comult}}K)(c_1, \dots, c_{n-1}) = \sum_{i=1}^{n-1} \sum_{\Delta(c_i) = \sum c'_i \otimes c''_i} (-1)^{\epsilon_i} K(c_1, \dots, c_{i-1}, c'_i, c''_i, c_{i+1}, \dots, c_{n-1})$$

Sign convention. $\epsilon_i = |c_1| + \dots + |c_{i-1}|$ accounts for moving c_i past previous elements.

Geometric picture. In local coordinates $(z_1, \dots, z_n)$ on $C_n(X)$:

$$(d_{\text{comult}}K)(z_1, \dots, z_{n-1}) = \int_X K(z_1, \dots, z_i, w, z_{i+1}, \dots, z_{n-1}) \otimes \Delta_w$$

where Δ_w is the coproduct evaluated at point $w \in X$, and we sum over all insertion positions i .

Step 2: Internal component.

$$(d_{\text{internal}}K)(c_1, \dots, c_n) = \sum_{i=1}^n (-1)^{|c_1| + \dots + |c_{i-1}|} K(c_1, \dots, d_C(c_i), \dots, c_n)$$

Step 3: Extension component.

The extension differential:

$$d_{\text{extend}} : \mathcal{D}'(C_n(X)) \rightarrow \mathcal{D}'(C_{n+1}(X))$$

extends distributions by inserting delta functions at collision loci.

Local coordinate formula. Near the diagonal $\Delta_{ij} = \{z_i = z_j\} \subset C_n(X)$, introduce coordinates:

$$\epsilon = z_i - z_j, \quad \zeta = \frac{z_i + z_j}{2}, \quad z_k \text{ for } k \neq i, j$$

A distribution K singular along Δ_{ij} has Laurent expansion:

$$K(\epsilon, \zeta, \{z_k\}) = \sum_{m=-\infty}^M \frac{K_m(\zeta, \{z_k\})}{\epsilon^m} + (\text{regular terms})$$

The extension across Δ_{ij} is:

$$(d_{\text{extend}}K)(z_1, \dots, z_n, w) = \sum_{i < j} \delta(z_i - z_j) \otimes \text{Res}_{\epsilon=0}[K] \otimes \delta(w - \zeta)$$

Explicit formula using regularization.

$$\langle d_{\text{extend}}K, \phi \rangle = \lim_{\epsilon_0 \rightarrow 0} \int_{|z_i - z_j| < \epsilon_0} K \cdot \phi - (\text{regularization counterterms})$$

The regularization removes divergences, leaving a finite distributional value.

Example. For $K = \frac{1}{(z_1 - z_2)^2}$, let $\epsilon = z_1 - z_2$. The $d \log$ kernel $\eta_{12} = d\epsilon/\epsilon$ of the bar complex absorbs one power of ϵ (pole-order absorption), so the Verdier dual of a double pole is a *single* distribution of order 2 supported on $\Delta_{12} = \{z_1 = z_2\}$, not a tensor product of distributions:

$$d_{\text{extend}} \left[\frac{1}{(z_1 - z_2)^2} \right] = -\delta'(z_1 - z_2)$$

where δ' is the derivative of the delta distribution, paired with test functions by $\langle \delta', \phi \rangle = -\phi'(0)$. In general, a pole of order k in ϵ dualizes to $(-1)^{k-1} (k-1)!^{-1} \delta^{(k-1)}(\epsilon)$, a derivative of order $k-1$: one less than the pole order, because the $d \log$ kernel on the bar side has already absorbed one pole. $\square$

THEOREM 7.0.21 (*Distributional verification of $d_{\text{cobar}}^2 = 0$;*). **Note.** The rigorous proof of $d_{\text{cobar}}^2 = 0$ is Corollary 7.0.15, which deduces nilpotence from Verdier duality without distributional products. The present verification is a *distributional consistency check*: it shows that the distributional model, where defined, gives the same answer. At Term 3 below, the product $\delta(z_i - z_j)^2$ is formally undefined (Schwartz impossibility); the cancellation mechanism via Arnold relations is heuristic in the distributional setting and rigorous only via Verdier duality. The cobar differential satisfies $d_{\text{cobar}}^2 = 0$. This requires verifying nine cross-term cancellations (mirroring the bar complex from Section 6.1.5):

$$d_{\text{cobar}}^2 = (d_{\text{comult}} + d_{\text{internal}} + d_{\text{extend}})^2 = \sum_{i,j} d_i \circ d_j = 0$$

The nine terms to verify.

1. $d_{\text{comult}}^2 = 0$ (coassociativity)
2. $d_{\text{internal}}^2 = 0$ (differential property)
3. $d_{\text{extend}}^2 = 0$ (Stokes' theorem on distributions)
4. $d_{\text{comult}} \circ d_{\text{internal}} + d_{\text{internal}} \circ d_{\text{comult}} = 0$ (chain map property)
5. $d_{\text{comult}} \circ d_{\text{extend}} + d_{\text{extend}} \circ d_{\text{comult}} = 0$ (compatibility)
6. $d_{\text{internal}} \circ d_{\text{extend}} + d_{\text{extend}} \circ d_{\text{internal}} = 0$ (compatibility)

Proof. We verify each term systematically, providing the geometric and algebraic reasoning.

Term 1: $d_{\text{comult}}^2 = 0$

This follows from coassociativity of the comultiplication Δ . By definition:

$$(\Delta \otimes \text{id}) \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$$

Applied twice:

$$\begin{aligned} d_{\text{comult}}^2(K)(c_1, \dots, c_{n-2}) &= \sum_{i < j} (-1)^{\epsilon_i + \epsilon_j} K(\dots, \Delta(c_i), \dots, \Delta(c_j), \dots) \\ &= \sum_{i < j} (-1)^{\epsilon_i + \epsilon_j} K(\dots, (\Delta \otimes \text{id})\Delta(c_i), \dots) \end{aligned}$$

By coassociativity, terms with different orderings cancel pairwise. This completes term 1.

Term 2: $d_{\text{internal}}^2 = 0$

The internal differential acts on each tensor factor independently:

$$d_{\text{internal}}(K)(c_1, \dots, c_n) = \sum_i K(c_1, \dots, d_C(c_i), \dots, c_n).$$

Applying d_{internal} twice, each c_i contributes $d_C^2(c_i) = 0$ (since (C, d_C) is a cochain complex), and cross-terms $d_C(c_i) \otimes d_C(c_j)$ for $i \neq j$ appear with equal signs in both applications, hence cancel:

$$d_{\text{internal}}^2(K) = \sum_i K(\dots, d_C^2(c_i), \dots) + \sum_{i < j} (\dots) - \sum_{i < j} (\dots) = 0.$$

This completes term 2.

Term 3: $d_{\text{extend}}^2 = 0$

The extension differential inserts delta functions. Applied twice:

$$\begin{aligned} d_{\text{extend}}^2(K) &= d_{\text{extend}} \left(\sum_{i < j} \delta(z_i - z_j) \otimes K|_{\Delta_{ij}} \right) \\ &= \sum_{i < j} \sum_{k < \ell} \delta(z_i - z_j) \otimes \delta(z_k - z_\ell) \otimes K|_{\Delta_{ij} \cap \Delta_{k\ell}} \end{aligned}$$

The product $\delta(z_i - z_j) \otimes \delta(z_k - z_\ell)$ is well-defined *only if* the supports are disjoint or coincide. When supports coincide (e.g., $i = k, j = \ell$), we get $\delta(z_i - z_j)^2$, which is *not* a distribution (multiplication of distributions is undefined unless one is smooth).¹

Resolution via dimensional regularization. Introduce a regulator:

$$\delta_\epsilon(z) = \frac{1}{\pi \epsilon^2} e^{-|z|^2/\epsilon^2}$$

Then:

$$\delta_\epsilon(z)^2 = \frac{1}{\pi^2 \epsilon^4} e^{-2|z|^2/\epsilon^2}$$

As $\epsilon \rightarrow 0$, this concentrates at $z = 0$ but with coefficient:

$$\int \delta_\epsilon(z)^2 dz = \frac{1}{\epsilon^2} \rightarrow \infty$$

The divergence is canceled by the *Arnold relation among delta functions*:

$$\delta(z_i - z_j) \wedge \delta(z_j - z_k) = -\delta(z_i - z_k) \wedge \delta(z_j - z_k)$$

When summing over all pairs (i, j) and (k, ℓ) , the Arnold relations cause all terms to cancel pairwise, giving $d_{\text{extend}}^2 = 0$. This is the distributional analogue of the Arnold–Orlik–Solomon relations from the bar complex (Section 6.1.5): collision loci have a combinatorial structure (partial order of collisions), and the Arnold relations encode this structure.

Rigorous alternative. A clean proof avoiding distributional issues entirely is given in Corollary 7.0.15 above, which deduces $d^2 = 0$ from Verdier duality on the Fulton–MacPherson compactification without reference to distributional products.

This completes term 3.

Term 4: $d_{\text{comult}} \circ d_{\text{internal}} + d_{\text{internal}} \circ d_{\text{comult}} = 0$

¹Hörmander’s Distributional Multiplication Theory: Products of distributions like $\delta(z_i - z_j) \wedge \delta(z_j - z_k)$ are generally undefined (Schwartz impossibility theorem). However, our products are well-defined via:

(1) *Microlocal analysis.* By Hörmander [221, Theorem 8.2.10], two distributions u, v can be multiplied if their wave front sets satisfy $\text{WF}(u) + \text{WF}(v) \cap \text{zero section} = \emptyset$. In our case, $\text{WF}(\delta_{D_{ij}}) = N^*(D_{ij})$ (conormal bundle), and these are either disjoint or coincide with controlled intersection.

(2) *Dimensional regularization.* Replace $\delta(z)$ with $\delta_\epsilon(z) = \frac{1}{\pi \epsilon^2} e^{-|z|^2/\epsilon^2}$ and take $\epsilon \rightarrow 0$ after integration.

(3) *Arnold relation cancellations.* Divergences cancel via the Arnold relations (Theorem 6.1.31). The condition $d^2 = 0$ is equivalent to this cancellation.

See Hörmander [221] Chapter 8, Melrose [315] on b-calculus, Kashiwara–Schapira [250] Chapter VII, and Costello–Gwilliam [92] Volume 1, §2.4 for the complete theory. We adopt the Verdier duality approach (Theorem 7.0.36) as the rigorous foundation; the distributional formulas serve as computational guides.

This states that $\Delta : C \rightarrow C \boxtimes C$ is a chain map (compatible with the differential). By hypothesis:

$$\Delta \circ d_C = (d_C \otimes \text{id} + \text{id} \otimes d_C) \circ \Delta$$

Applied to cobar elements:

$$\begin{aligned} (d_{\text{comult}} \circ d_{\text{internal}})(K) &= d_{\text{comult}} \left(\sum_i K(\dots, d_C(c_i), \dots) \right) \\ &= \sum_{i,j} K(\dots, \Delta(d_C(c_i)), \dots) \end{aligned}$$

By the chain map property:

$$\Delta(d_C(c_i)) = (d_C \otimes \text{id} + \text{id} \otimes d_C)(\Delta(c_i))$$

Substituting and using Koszul signs, this precisely cancels $(d_{\text{internal}} \circ d_{\text{comult}})(K)$. This completes term 4.

Term 5: $d_{\text{comult}} \circ d_{\text{extend}} + d_{\text{extend}} \circ d_{\text{comult}} = 0$

Calculation.

$$\begin{aligned} (d_{\text{comult}} \circ d_{\text{extend}})(K) &= d_{\text{comult}} \left(\sum_{i < j} \delta(z_i - z_j) \otimes K|_{\Delta_{ij}} \right) \\ &= \sum_{i < j} \sum_k \delta(z_i - z_j) \otimes \Delta_k(K|_{\Delta_{ij}}) \end{aligned}$$

where Δ_k applies the coproduct at position k .

Similarly:

$$\begin{aligned} (d_{\text{extend}} \circ d_{\text{comult}})(K) &= d_{\text{extend}} \left(\sum_k \Delta_k(K) \right) \\ &= \sum_k \sum_{i < j} \delta(z_i - z_j) \otimes (\Delta_k(K))|_{\Delta_{ij}} \end{aligned}$$

By the Leibniz rule for distributions:

$$\delta(z_i - z_j) \otimes \Delta_k(K) = \Delta_k(\delta(z_i - z_j) \otimes K) \quad \text{if } k \notin \{i, j\}$$

For $k \in \{i, j\}$, the coproduct *splits the collision point*, and the contributions from the two orderings cancel by coassociativity.

All terms cancel pairwise, completing term 5.

Term 6: $d_{\text{internal}} \circ d_{\text{extend}} + d_{\text{extend}} \circ d_{\text{internal}} = 0$

Calculation.

$$\begin{aligned} (d_{\text{internal}} \circ d_{\text{extend}})(K)(c_1, \dots, c_n) &= d_{\text{internal}} \left(\sum_{i < j} \delta(z_i - z_j) \otimes K|_{\Delta_{ij}} \right) \\ &= \sum_{i < j} \sum_k (-1)^{\epsilon_k} \delta(z_i - z_j) \otimes K|_{\Delta_{ij}}(c_1, \dots, d_C(c_k), \dots) \end{aligned}$$

Similarly:

$$\begin{aligned} (d_{\text{extend}} \circ d_{\text{internal}})(K) &= d_{\text{extend}} \left(\sum_k (-1)^{\epsilon_k} K(\dots, d_C(c_k), \dots) \right) \\ &= \sum_k \sum_{i < j} (-1)^{\epsilon_k} \delta(z_i - z_j) \otimes (K(\dots, d_C(c_k), \dots))|_{\Delta_{ij}} \end{aligned}$$

The differential d_C acts coefficient-wise, while $\delta(z_i - z_j)$ acts geometrically. They commute as operators:

$$[\delta(z_i - z_j), d_C(c_k)] = 0$$

The two compositions differ by a Koszul sign: commuting the degree-1 operator d_C past the geometric factor $\delta(z_i - z_j)$ introduces $(-1)^1$, so $d_{\text{internal}} \circ d_{\text{extend}} = -d_{\text{extend}} \circ d_{\text{internal}}$, and the anticommutator vanishes.

This completes the verification of $d^2 = 0$. All nine cross-terms vanish:

	d_{comult}	d_{internal}	d_{extend}
d_{comult}	coassoc.	chain map	Leibniz
d_{internal}	chain map	$d^2 = 0$	commute
d_{extend}	Leibniz	commute	Arnold

Therefore:

$$d_{\text{cobar}}^2 = 0$$

This completes the nilpotency verification, establishing the cobar construction as a valid chain complex, and more precisely as a differential graded algebra with the A_∞ structure. $\square$

Remark 7.0.22 (Duality with bar $d^2 = 0$ proof). The structure of this proof *mirrors exactly* the bar $d^2 = 0$ proof from Section 6.1.5:

Bar (Section 6.1.5)	Cobar (this section)
Residues at divisors	Delta functions at diagonals
Compactified space $\overline{C}_n(X)$	Open space $C_n(X)$
Logarithmic forms	Distributional currents
Stratification by collisions	Singular support on diagonals
Arnold–Orlik–Solomon relations	Arnold relations for distributions
Extract (analyze)	Insert (synthesize)

The proofs are dual under Verdier duality, as is the bar-cobar adjunction itself.

7.0.5 SIGN CONVENTIONS FOR COBAR OPERATIONS

Convention 7.0.23 (Cobar sign system). The cobar complex inherits signs from three sources. Throughout the monograph the signs appendix (Appendix G, §G.7) is authoritative; this convention records the chapter-local shorthand.

Desuspension sign (from s^{-1}). The cobar complex uses desuspension: $|s^{-1}v| = |v| - 1$ (lowers cohomological degree by one). In particular, a degree- h generator $v \in \bar{C}$ becomes a degree- $(h-1)$ generator $s^{-1}v \in \Omega^{\text{ch}}(C)$, and the cobar differential d_Ω has degree $+1$. The cofree-algebra structure on $\Omega^{\text{ch}}(C)$ is on the desuspension $s^{-1}\bar{C}$, never on $\bar{C}$ itself. This is the same convention as the bar complex (both bar and cobar use desuspension in this monograph; see the signs appendix).

Koszul signs (from grading). The standard Koszul sign rule (Appendix G, §G.7).

Symmetry signs (from permutations). The symmetric group $\mathfrak{S}_n$ acts on $C_n(X)$ and $C^{\boxtimes n}$. For $\sigma \in \mathfrak{S}_n$ and elements $c_1, \dots, c_n$:

$$\sigma(c_1 \otimes \dots \otimes c_n) = (-1)^{\epsilon(\sigma, c)} c_{\sigma(1)} \otimes \dots \otimes c_{\sigma(n)}$$

where $\epsilon(\sigma, c)$ is the Koszul sign for moving graded elements according to σ .

Distributional signs (from convolution). When convolving distributions, there are signs from interchanging integrals:

$$(K_1 * K_2)(z, w) = \int K_1(z, u) K_2(u, w) du$$

Interchanging the order introduces sign $(-1)^{|K_1| \cdot |K_2|}$.

LEMMA 7.0.24 (*Sign consistency for cobar differential;*). The sign conventions above ensure that for any two operations in the cobar differential, the double application produces consistent signs that allow cancellations in the $d^2 = 0$ proof.

Proof. Consider the prototypical case: applying d_{extend} twice. This inserts two delta functions $\delta(z_i - z_j)$ and $\delta(z_k - z_\ell)$.

Case 1: Disjoint collisions $(i, j) \cap (k, \ell) = \emptyset$

The delta functions commute with sign:

$$\delta(z_i - z_j) \wedge \delta(z_k - z_\ell) = (-1)^{1 \cdot 1} \delta(z_k - z_\ell) \wedge \delta(z_i - z_j)$$

The sign $(-1)^{1 \cdot 1} = -1$ comes from both delta functions being 1-forms (in the distributional sense). Summing over orderings $(i < j, k < \ell)$ vs $(k < \ell, i < j)$ gives cancellation.

Case 2: Nested collisions (e.g., $i = k, j \neq \ell$)

We have:

$$\delta(z_i - z_j) \wedge \delta(z_i - z_\ell) = (-1) \delta(z_j - z_\ell) \wedge \delta(z_i - z_\ell)$$

This is the distributional analog of the Arnold relation. *Caveat:* products of delta functions supported on intersecting submanifolds require wavefront set conditions for rigorous definition; the argument here is heuristic. The rigorous proof of $d^2 = 0$ for the cobar complex is provided by Verdier duality (Corollary 7.0.15).

In all cases, the signs are chosen so that the Arnold relations hold, ensuring $d_{\text{extend}}^2 = 0$. $\square$

Example 7.0.25 (*Explicit sign computation: three-point function*). Consider cobar complex for $n = 3$ with $C = \omega_X$ (trivial). Elements are:

$$K_3(z_1, z_2, z_3) = \sum_{\text{perms}} k_\sigma(z_1, z_2, z_3) \cdot \text{sgn}(\sigma)$$

Apply d_{extend} :

$$\begin{aligned} d_{\text{extend}}(K_3) &= \delta(z_1 - z_2) \otimes K_3|_{z_1=z_2} \\ &\quad + \delta(z_2 - z_3) \otimes K_3|_{z_2=z_3} \\ &\quad + \delta(z_1 - z_3) \otimes K_3|_{z_1=z_3} \end{aligned}$$

Apply again:

$$\begin{aligned} d_{\text{extend}}^2(K_3) &= \delta(z_1 - z_2) \wedge \delta(z_2 - z_3) \otimes K_3|_{z_1=z_2=z_3} \\ &\quad + \delta(z_2 - z_3) \wedge \delta(z_1 - z_3) \otimes K_3|_{z_1=z_2=z_3} \\ &\quad + \delta(z_1 - z_3) \wedge \delta(z_1 - z_2) \otimes K_3|_{z_1=z_2=z_3} \end{aligned}$$

The three-term Arnold relation (applied heuristically to delta functions, cf. the caveat in Case 2 above) gives:

$$\delta(z_1 - z_2) \wedge \delta(z_2 - z_3) + \delta(z_2 - z_3) \wedge \delta(z_1 - z_3) + \delta(z_1 - z_3) \wedge \delta(z_1 - z_2) = 0$$

directly, so the three terms in $d_{\text{extend}}^2(K_3)$ sum to zero:

$$\text{term}_1 + \text{term}_2 + \text{term}_3 = 0$$

Hence $d_{\text{extend}}^2(K_3) = 0$.

7.0.6 LOW-DEGREE EXPLICIT COMPUTATIONS

Example 7.0.26 (Cobar of linear coalgebra through degree 5). Let $C = T_{\text{ch}}^c(V)$ be the cofree coalgebra on $V = \text{span}\{v\}$ with $|v| = h$. The comultiplication is:

$$\Delta(v^n) = \sum_{k=0}^n \binom{n}{k} v^k \otimes v^{n-k}$$

Cobar complex.

$$\Omega^{\text{ch}}(T_{\text{ch}}^c(V)) = \text{Free}_{\text{ch}}(s^{-1}V^{\otimes n} : n \geq 1)$$

Generators. $s^{-1}v, s^{-1}v^2, s^{-1}v^3, s^{-1}v^4, s^{-1}v^5, \dots$ in degrees $h-1, 2h-1, 3h-1, 4h-1, 5h-1, \dots$ respectively.

Differential formulas.

Degree 1 ($h-1$):

$$d(s^{-1}v) = 0$$

(Primitive element, no coproduct.)

Degree 2 ($2h-1$): The cobar differential uses the *reduced* coproduct $\bar{\Delta}$, which excludes the counit terms:

$$\begin{aligned} d(s^{-1}v^2) &= -\bar{\Delta}(v^2) = -\sum_{k=1}^1 \binom{2}{k} (s^{-1}v^k) \cdot (s^{-1}v^{2-k}) \\ &= -\binom{2}{1} (s^{-1}v) \cdot (s^{-1}v) \\ &= -2(s^{-1}v)^2 \end{aligned}$$

Degree 3 (3b-1):

$$\begin{aligned} d(s^{-1}v^3) &= -\bar{\Delta}(v^3) = -\sum_{k=1}^2 \binom{3}{k} (s^{-1}v^k) \cdot (s^{-1}v^{3-k}) \\ &= -3(s^{-1}v) \cdot (s^{-1}v^2) - 3(s^{-1}v^2) \cdot (s^{-1}v) \end{aligned}$$

In a commutative setting:

$$d(s^{-1}v^3) = -6(s^{-1}v) \cdot (s^{-1}v^2)$$

Degree 4 (4b-1):

$$d(s^{-1}v^4) = -4(s^{-1}v) \cdot (s^{-1}v^3) - 6(s^{-1}v^2) \cdot (s^{-1}v^2)$$

Degree 5 (5b-1):

$$d(s^{-1}v^5) = -5(s^{-1}v) \cdot (s^{-1}v^4) - 10(s^{-1}v^2) \cdot (s^{-1}v^3)$$

General pattern. For generator $s^{-1}v^n$:

$$d(s^{-1}v^n) = -\sum_{k=1}^{n-1} \binom{n}{k} (s^{-1}v^k) \cdot (s^{-1}v^{n-k})$$

Geometric interpretation. These formulas encode how a single insertion point with “charge” v^n splits into two insertion points with charges v^k and v^{n-k} , weighted by binomial coefficients. In CFT, this corresponds to the OPE expansion.

Cohomology. Since all generators except $s^{-1}v$ are exact (boundaries of products), the cohomology is:

$$H^*(\Omega^{\text{ch}}(T_{\text{ch}}^c(V))) = \text{Free}_{\text{ch}}(s^{-1}v)$$

This recovers the original generator V , as expected from bar-cobar inversion.

Example 7.0.27 (Cobar of exterior coalgebra: free fermions). Let $C = \Lambda_{\text{ch}}^*(V)$ be the chiral exterior coalgebra on $V = \text{span}\{\psi\}$ with $|\psi| = \frac{1}{2}$ (fermionic). The comultiplication:

$$\Delta(\psi) = \psi \otimes 1 + 1 \otimes \psi, \quad \Delta(\psi^2) = 0$$

(since $\psi^2 = 0$ by anticommutativity).

Cobar complex.

$$\Omega^{\text{ch}}(\Lambda_{\text{ch}}^*(V)) = \text{Free}_{\text{ch}}(s^{-1}\psi)$$

Generator. $s^{-1}\psi$ in degree $-\frac{1}{2}$.

Differential. The reduced comultiplication $\bar{\Delta}$ removes the $1 \otimes \psi + \psi \otimes 1$ term. For the reduced coproduct:

$$\bar{\Delta}(\psi) = 0$$

Therefore:

$$d(s^{-1}\psi) = 0$$

Cohomology.

$$H^*(\Omega^{\text{ch}}(\Lambda_{\text{ch}}^*(V))) = \text{Free}_{\text{ch}}(s^{-1}\psi)$$

The desuspension s^{-1} converts the fermionic generator ψ (with anticommuting multiplication) into a bosonic generator $s^{-1}\psi$ (with commuting multiplication in the free algebra).

Physical interpretation. This is the *Koszul duality* of free fermions (not to be confused with the boson-fermion correspondence/bosonization, which identifies $\mathcal{F} \cong V_{\mathbb{Z}}$ as a lattice vertex algebra). The cobar construction converts fermionic generators ψ into bosonic generators $\phi = s^{-1}\psi$ via desuspension.

Example 7.0.28 (Free fermion to beta-gamma via bar-cobar). The Koszul duality chain.

$$\text{Free fermion algebra } \mathcal{F} \xrightarrow{\text{bar}} \text{Exterior coalgebra } \bar{B}(\mathcal{F}) \xrightarrow{(-)^\vee} \beta\gamma \text{ system}$$

(The second arrow is linear duality of the coalgebra, yielding the Koszul dual algebra $\mathcal{F}^\dagger = \bar{B}(\mathcal{F})^\vee$. The cobar construction $\Omega(\bar{B}(\mathcal{F}))$ would instead recover $\mathcal{F}$ itself by bar-cobar inversion.)

Explicit construction.

THEOREM 7.0.29 (Fermion-boson Koszul duality;). [Regime: quadratic (Convention 1.10.2).] The $\beta\gamma$ system is the *Koszul dual* of free fermions. This is the chiral analog of classical $\text{Sym}(V) \leftrightarrow \Lambda(V^*)$ Koszul duality (see Part II for the complete bar-cobar computation).

The Koszul duality correspondence exchanges:

1. *Relations:* anticommuting fields $\{\psi, \psi\} = 0 \leftrightarrow$ symplectic bosons $[\beta, \gamma] = 1$; exterior relation $\psi \boxtimes \psi = 0 \leftrightarrow$ symplectic pairing $\langle \beta, \gamma \rangle = \frac{1}{z_1 - z_2}$.
2. *Algebra structure:* exterior algebra $\Lambda^*(\psi) \leftrightarrow$ polynomial-type algebra; bar complex $\bar{B}(\mathcal{F}) = \Lambda^*(\psi, \partial\psi, \dots) \leftrightarrow \bar{B}(\beta\gamma)$ with symplectic differential.
3. *Statistics:* fermionic $\leftrightarrow$ bosonic.

Proof. The free fermion algebra $\mathcal{F} = \Lambda^{\text{ch}}(V)$ is generated by V with the exterior (anticommutative) chiral product. By the classical Koszul duality $\Lambda(V)^\dagger = \text{Sym}(V^*)$ (Loday–Vallette [299], Theorem 3.2.1), the chiral Koszul dual is $\mathcal{F}^\dagger = \text{Sym}^{\text{ch}}(V^*)$, the commutative chiral algebra on V^* , which is the $\beta\gamma$ system with $\beta \in V^*, \gamma \in V$. The complete bar-cobar computation verifying the Koszul property (acyclicity of $B(\mathcal{F}) \otimes_\tau \mathcal{F}^\dagger$) is carried out in Part II. $\square$

Propagator: The bosonic $\beta\gamma$ system has propagator:

$$\langle \beta(z)\gamma(w) \rangle = \frac{1}{z - w}$$

This matches the fermion two-point function via Koszul duality (not to be confused with bosonization, which is a distinct equivalence $\mathcal{F} \cong V_{\mathbb{Z}}$).

Example 7.0.30 (Cobar A_∞ operations: explicit formulas through n_5). The cobar construction carries a canonical A_∞ structure. We compute the first five operations explicitly.

Operation n_1 : The differential

$$n_1 = d_{\text{cobar}} : \Omega^n(C) \rightarrow \Omega^{n+1}(C)$$

(Already computed above.)

Operation n_2 : Convolution product

$$n_2 : \Omega^p(C) \otimes \Omega^q(C) \rightarrow \Omega^{p+q}(C)$$

(In cohomological grading, m_k has degree $2 - k$; for $k = 2$, degree 0: $p + q \mapsto p + q$.)

Formula. For integration kernels K_1, K_2 :

$$(n_2(K_1, K_2))(z_1, \dots, z_{p+q-1}) = \int_X K_1(z_1, \dots, z_p; w) \cdot K_2(w, z_{p+1}, \dots, z_{p+q-1}) dw$$

Geometric interpretation. Glue two configuration spaces at a common point w , then integrate over w .

Sign. $(-1)^{|K_1| \cdot |K_2|}$ from Koszul rule.

Example. For $K_1 = \frac{1}{z_1 - w}$, $K_2 = \frac{1}{w - z_2}$, using partial fractions:

$$\begin{aligned} n_2(K_1, K_2)(z_1, z_2) &= \oint \frac{1}{z_1 - w} \cdot \frac{1}{w - z_2} dw \\ &= \frac{1}{z_1 - z_2} \oint \left[\frac{1}{w - z_2} - \frac{1}{w - z_1} \right] dw \\ &= \frac{2\pi i}{z_1 - z_2} \quad (\text{residue at } w = z_2) \end{aligned}$$

This reproduces the expected propagator $1/(z_1 - z_2)$ (up to normalization $2\pi i$).

Operation n_3 : Triple propagator

$$n_3 : \Omega^{p_1}(C) \otimes \Omega^{p_2}(C) \otimes \Omega^{p_3}(C) \rightarrow \Omega^{p_1+p_2+p_3-2}(C)$$

Formula.

$$(n_3(K_1, K_2, K_3))(z_1, \dots, z_N) = \int_{X \times X} K_1(\dots; w_1) \cdot K_2(w_1, \dots; w_2) \cdot K_3(w_2, \dots) dw_1 dw_2$$

Geometric interpretation. Glue three configuration spaces in a chain, then integrate over the two gluing points.

Operation n_4 : Four-point function

$$n_4 : \bigotimes_{i=1}^4 \Omega^{p_i}(C) \rightarrow \Omega^{\sum p_i - 3}(C)$$

Formula. Similar, but integrate over three intermediate points w_1, w_2, w_3 .

Operation n_5 : Five-point function

$$n_5 : \bigotimes_{i=1}^5 \Omega^{p_i}(C) \rightarrow \Omega^{\sum p_i - 4}(C)$$

General pattern.

$$n_k : \bigotimes_{i=1}^k \Omega^{p_i}(C) \rightarrow \Omega^{\sum p_i - (k-2)}(C)$$

Geometric realization. Integrate over the moduli space $\overline{M}_{0,k+1}$ of stable curves:

$$n_k(K_1, \dots, K_k) = \int_{\overline{M}_{0,k+1}} K_1 \wedge \dots \wedge K_k \wedge \omega_{0,k+1}$$

Physical interpretation. The operation n_k computes k -point correlation functions in CFT. The integration over $\bar{M}_{0,k+1}$ sums over all Feynman diagrams (tree-level for genus 0).

A_∞ relations. These operations satisfy:

$$\sum_{i+j=n+1} \sum_k (-1)^\epsilon n_i(\text{id}^{\otimes k} \otimes n_j \otimes \text{id}^{\otimes(n-k-j)}) = 0$$

This encodes associativity up to homotopy, with n_3 measuring the failure of n_2 to be associative, n_4 measuring the failure of n_3 to be coherent, etc.

7.0.7 PHYSICAL INTERPRETATION: ON-SHELL PROPAGATOR AND FEYNMAN-RULE TEMPLATES

Conjecture 7.0.31 (Cobar elements as on-shell propagator templates;). Elements of the cobar complex $\Omega^{\text{ch}}(C)$ should be read as *algebraic shadow data for on-shell propagators* in the sense of quantum field theory.

Precise statement. For a chiral coalgebra C corresponding to a 2d CFT, elements $K \in \Omega^n(C)$ are distributions satisfying:

1. *Ultraviolet behavior:* Singularities along diagonals $\{z_i = z_j\}$ encode short-distance behavior (UV divergences).
2. *On-shell condition:* The cobar differential $d_{\text{cobar}}(K) = 0$ should model the equations of motion (e.g., $\square\phi = 0$ for free fields).
3. *S-matrix elements:* The cohomology $H^*(\Omega^{\text{ch}}(C))$ should model physical on-shell scattering amplitudes.

Remark 7.0.32 (Physical motivation). Step 1: Cobar as Green's-function template

A propagator $G(z, w)$ in QFT is a Green's function satisfying:

$$(\square_z - m^2)G(z, w) = \delta^{(2)}(z - w)$$

This is the Green's-function template in which G extends across the diagonal $z = w$ as a distribution with a delta function singularity. In the conjectural cobar/QFT dictionary this is modeled by:

$$d_{\text{extend}}(G) = \delta(z - w)$$

Step 2: Cobar differential as equations-of-motion template

For a field ϕ satisfying equations of motion $\square\phi = 0$, the propagator G satisfies:

$$d_{\text{cobar}}(G) = 0$$

This is the template for the *on-shell condition*. Elements in the cohomology $H^*(\Omega^{\text{ch}})$ should therefore be read as algebraic shadows of on-shell propagators.

Step 3: A_∞ operations as Feynman-rule template

The operation n_k in the cobar A_∞ structure should model tree-level k -point correlation functions:

$$\langle \phi(z_1) \cdots \phi(z_k) \rangle = n_k(G, \dots, G)(z_1, \dots, z_k)$$

The A_∞ relations encode (all at genus zero, hence tree-level):

- n_2 = binary vertex (standard product)
- n_3 = ternary vertex (measures failure of strict associativity)
- n_k = k -ary vertex (higher associahedra corrections)

Loop corrections (genus $g \geq 1$) arise from the higher-genus bar complex, not from higher n_k at genus zero.

This gives the conjectural algebraic template for genus-zero Feynman rules.

Remark 7.0.33 (Scope). Conjecture 7.0.31 is tagged because the identification of cobar elements with on-shell propagators requires external physics input (equations of motion, path integral measure) that lies outside the algebraic framework of this monograph.

Homotopy template (Convention 1.10.1): Type VII (physics-dictionary). The conjecture treats cobar complex elements as algebraic shadow data for QFT on-shell propagators, with the A_∞ operations furnishing the genus-zero Feynman-rule template.

Example 7.0.34 (Free scalar field: complete cobar analysis). Consider the free scalar field with action:

$$S = \int \frac{1}{2} (\partial\phi)^2 dz \wedge d\bar{z}$$

Equation of motion. $\square\phi = 0$

Propagator.

$$G(z, w) = -\frac{1}{2\pi} \log |z - w|^2$$

This satisfies:

$$\square_z G(z, w) = \delta^{(2)}(z - w)$$

Cobar interpretation.

$$d_{\text{extend}}(G) = \delta(z - w)$$

Two-point function. Already on-shell, so:

$$\langle \phi(z_1) \phi(z_2) \rangle = G(z_1, z_2) = -\frac{1}{2\pi} \log |z_1 - z_2|^2$$

Four-point function. Computed using n_4 :

$$\begin{aligned} \langle \phi(z_1) \phi(z_2) \phi(z_3) \phi(z_4) \rangle &= n_4(G, G, G, G) \\ &= \int_{X \times X} G(z_1, w_1) G(w_1, z_2) G(z_3, w_2) G(w_2, z_4) dw_1 dw_2 \end{aligned}$$

This is the Wick contraction formula. The cobar A_∞ structure automatically implements Wick's theorem.

Remark 7.0.35 (CFT vertex operators from cobar). In conformal field theory, vertex operators $V_\alpha(z)$ create states $|\alpha\rangle$ at position z . These correspond to cobar elements:

$$V_\alpha \leftrightarrow K_\alpha \in \Omega^1(C)$$

The OPE of vertex operators:

$$V_\alpha(z)V_\beta(w) \sim \sum_\gamma \frac{C_{\alpha\beta}^\gamma}{(z-w)^{h_\gamma-h_\alpha-h_\beta}} V_\gamma(w)$$

corresponds to the cobar product:

$$n_2(K_\alpha, K_\beta) = \sum_\gamma C_{\alpha\beta}^\gamma K_\gamma$$

The structure constants $C_{\alpha\beta}^\gamma$ are precisely the cobar A_∞ structure constants.

The cobar construction thus provides a geometric derivation of the OPE algebra in CFT.

7.0.8 VERDIER DUALITY ON BAR AND COBAR

THEOREM 7.0.36 (*Bar-cobar Verdier*;). [Regime: quadratic, genus-0 (Convention 1.10.2).]

Let $\mathcal{A}$ be on the Koszul locus and write $\mathcal{A}^!$ for its Koszul dual.

Write

$$(\mathcal{A})_\infty^! := \mathbb{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\mathcal{A}))$$

for the homotopy Koszul dual factorization algebra. There is a perfect pairing:

$$\langle \cdot, \cdot \rangle : \bar{B}_n^{\text{ch}}(\mathcal{A}) \otimes (\mathcal{A})_{\infty,n}^! \rightarrow \mathbb{C}$$

given by:

$$\langle \omega_{\text{bar}}, K_{\text{Verdier}} \rangle = \int_{\bar{C}_n(X)} \omega_{\text{bar}} \wedge \iota^* K_{\text{Verdier}}$$

where:

- $\omega_{\text{bar}} \in \Gamma(\bar{C}_n(X), \mathcal{A}^{\boxtimes n} \otimes \Omega_{\log}^*)$ is a bar element (logarithmic form on compactified space)
- $K_{\text{Verdier}} \in (\mathcal{A})_{\infty,n}^!$ is represented on $C_n(X)$ by distributional sections with values in $(\mathcal{A}^!)^{\boxtimes n}$; this is the post-Verdier factorization-algebra side of Theorem A, not a pre-Verdier coalgebra
- $\iota : C_n(X) \hookrightarrow \bar{C}_n(X)$ is the inclusion of the open configuration space
- The integration is well-defined because logarithmic forms pair with distributions

Properties of the pairing.

1. *Perfect pairing*: Non-degenerate in both arguments (by Lemma 7.0.12: each graded piece is a holonomic $\mathcal{D}$ -module on $\bar{C}_n(X)$, hence has finite-dimensional stalks, and Verdier duality for holonomic $\mathcal{D}$ -modules is an involution [250])
2. *Differential compatibility*: $\langle d_{\text{bar}}\omega, K \rangle = -\langle \omega, d_{\text{cobar}}K \rangle$ (graded Leibniz rule)
3. *Residue-distribution duality*: $\langle \text{Res}_D[\omega], \delta_D \rangle = 1$ for any divisor D

4. *Verdier duality*: The perfect pairing realizes

$$\mathbb{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\mathcal{A})) \simeq (\mathcal{A})_{\infty}^!$$

as factorization algebras on $\text{Ran}(X)$; on the Koszul locus, Theorem A identifies $(\mathcal{A})_{\infty}^! \simeq \mathcal{A}^!$

Proof. Step 1: Well-definedness of the pairing

Logarithmic forms on $\bar{C}_n(X)$ restrict to distributional forms on $C_n(X)$. Explicitly, near a divisor $D = \{z_i = z_j\}$ with local coordinate $\epsilon = z_i - z_j$:

Logarithmic form: $\omega = \frac{d\epsilon}{\epsilon} \wedge (\text{smooth forms})$

Restriction to $C_n(X)$: $\iota^*\omega$ has a pole at $\epsilon = 0$, hence is a distribution on $C_n(X) = \bar{C}_n(X) \setminus D$.

The pairing integrates this distribution against the corresponding distributional representative on the Verdier-dual side:

$$\langle \omega, K \rangle = \int_{\bar{C}_n(X)} \omega \wedge K$$

This is well-defined by the theory of currents (de Rham's theorem on distributions).

Step 2: Differential compatibility

We verify:

$$\langle d_{\text{bar}}\omega, K \rangle = -\langle \omega, d_{\text{cobar}}K \rangle$$

At the level of $\mathcal{D}$ -modules on $\bar{C}_n(X)$, the bar differential and its Verdier-transported differential on the post-Verdier factorization-algebra side are flat connections (the bar complex is a complex of holonomic $\mathcal{D}$ -modules by Lemma 7.0.12). Verdier duality is an exact contravariant involution on $D_{\text{hol}}^b(\mathcal{D}_{\bar{C}_n(X)})$ that sends a flat connection ∇ to the adjoint connection $\nabla^\dagger$ (see [250], Chapter 4).

We make the adjoint identity explicit. For a holonomic $\mathcal{D}$ -module $\mathcal{M}$ on a smooth variety Y of dimension d , the Verdier dual is $\mathbb{D}\mathcal{M} = R\mathcal{H}om_{\mathcal{D}_Y}(\mathcal{M}, \mathcal{D}_Y \otimes \Omega_Y^{-1})[d]$. When $\mathcal{M}$ carries a flat connection $\nabla: \mathcal{M} \rightarrow \mathcal{M} \otimes \Omega_Y^1$, sections $m^* \in \mathbb{D}\mathcal{M}$ inherit the adjoint connection $\nabla^\dagger$ defined by

$$\langle \nabla^\dagger m^*, m \rangle = -\langle m^*, \nabla m \rangle$$

for all local sections $m \in \mathcal{M}$, where $\langle -, - \rangle$ is the canonical pairing $\mathbb{D}\mathcal{M} \otimes \mathcal{M} \rightarrow \omega_Y$. This is the unique connection on $\mathbb{D}\mathcal{M}$ making the pairing flat, i.e., satisfying $d\langle m^*, m \rangle = \langle \nabla^\dagger m^*, m \rangle + \langle m^*, \nabla m \rangle = 0$.

Applying this to $Y = \bar{C}_n(X)$, $\mathcal{M} = \bar{B}_n^{\text{ch}}(\mathcal{A})$ with $\nabla = d_{\text{bar}}$, and the post-Verdier factorization-algebra side identified with $\mathbb{D}\mathcal{M}$ by the pairing constructed in Steps 3–4, one obtains $d_{\text{cobar}} = d_{\text{bar}}^\dagger$ as the Verdier-adjoint connection. The differential compatibility

$$\langle d_{\text{bar}}\omega, K \rangle = -\langle \omega, d_{\text{cobar}}K \rangle$$

therefore holds by the flatness of the canonical pairing on holonomic $\mathcal{D}$ -modules, without requiring a component-by-component Stokes argument.

Step 3: Residue-distribution pairing

The fundamental pairing:

$$\langle \eta_{ij}, \delta(z_i - z_j) \rangle = \int \frac{dz_i - dz_j}{z_i - z_j} \wedge \delta(z_i - z_j) = 1$$

where $\eta_{ij} = \frac{dz_i - dz_j}{z_i - z_j}$ is the logarithmic 1-form along D_{ij} .

Proof of identity. Regularize the delta function:

$$\delta_\epsilon(z) = \frac{1}{\pi\epsilon^2} e^{-|z|^2/\epsilon^2}$$

Then:

$$\begin{aligned} \langle \eta_{ij}, \delta_\epsilon \rangle &= \int \frac{dz_i - dz_j}{z_i - z_j} \wedge \delta_\epsilon(z_i - z_j) \\ &= \int_{|w| < \infty} \frac{dw}{w} \wedge \delta_\epsilon(w) \\ &= \lim_{\epsilon \rightarrow 0} \int_{|w| < \infty} \frac{dw}{w} \wedge \frac{1}{\pi\epsilon^2} e^{-|w|^2/\epsilon^2} \end{aligned}$$

Change variables $u = w/\epsilon$:

$$\begin{aligned} &= \lim_{\epsilon \rightarrow 0} \int \frac{d(\epsilon u)}{\epsilon u} \wedge \frac{1}{\pi} e^{-|u|^2} \\ &= \int \frac{du}{u} \wedge \frac{1}{\pi} e^{-|u|^2} \\ &= \frac{1}{2\pi i} \oint_{|u|=1} \frac{du}{u} \quad (\text{by residue theorem}) \\ &= 1 \end{aligned}$$

The pairing between residues and delta functions is therefore exact.

Step 4: Verdier duality realization

The pairing establishes an isomorphism of factorization algebras on $\text{Ran}(X)$:

$$\mathbf{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\mathcal{A})) \xrightarrow{\sim} (\mathcal{A})_\infty^!$$

where $(\mathcal{A})_\infty^!$ denotes the homotopy Koszul dual factorization algebra of Theorem A; on the Koszul locus this is the same post-Verdier factorization algebra that Theorem A identifies with $\mathcal{A}^!$.

Non-degeneracy. At bar degree $n = 1$, Step 3 establishes the fundamental pairing $\langle \eta_{ij}, \delta(z_i - z_j) \rangle = 1$. For $n > 1$, non-degeneracy follows by induction using the coalgebra structure: the comultiplication on $\bar{B}^n$ decomposes an n -point integrand into products of lower-point integrands via the Künneth formula on the FM boundary strata $\partial \bar{C}_n(X) \cong \coprod_{|S|=k} \bar{C}_k(X) \times \bar{C}_{n-k+1}(X)$. The induced pairing at degree n is the tensor product of pairings at degrees k and $n-k+1$, which are non-degenerate by the induction hypothesis. Therefore the map is an isomorphism at each bar degree.

Geometric meaning.

- Bar = logarithmic-form realization of the pre-Verdier bar coalgebra
- Verdier-dual side = distributional realization of the post-Verdier factorization algebra
- Pairing = Poincaré–Verdier duality between these two realizations

This completes the proof. □

COROLLARY 7.0.37 (*Bar-cobar mutual inverses*;). Let $\mathcal{A}$ be an augmented chiral algebra on a smooth curve X , valued in holonomic $\mathcal{D}$ -modules (Convention 1.10.1), and let C be a coaugmented chiral coalgebra. *Algebra side.* If

- (A1) $\mathcal{A}$ is *chiral Koszul*: the bar complex $\bar{B}^{\text{ch}}(\mathcal{A})$ has cohomology concentrated in a single degree (Definition 11.1.15);
- (A2) *Conilpotence or completion*: either $\bar{B}^{\text{ch}}(\mathcal{A})$ is conilpotent, or $\mathcal{A}$ is complete with respect to its augmentation ideal (§8.1.2),

then the counit of the adjunction is a quasi-isomorphism:

$$\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}.$$

Coalgebra side. If, dually,

- (C1) C is *coKoszul*: the cobar complex $\Omega^{\text{ch}}(C)$ has cohomology concentrated in a single degree;
- (C2) C is conilpotent (Definition 7.0.8),

then the unit of the adjunction is a quasi-isomorphism:

$$C \xrightarrow{\sim} \bar{B}^{\text{ch}}(\Omega^{\text{ch}}(C)).$$

Both quasi-isomorphisms are induced by the Verdier pairing (Theorem 7.0.36). When $(\mathcal{A}, C)$ form a chiral Koszul pair (Definition 11.1.15) with $C \simeq \bar{B}^{\text{ch}}(\mathcal{A})$, the two sides combine to exhibit the bar and cobar functors as mutually quasi-inverse.

Proof. Algebra side. Consider the coradical filtration $F_{\bullet}$ on $\bar{B}^{\text{ch}}(\mathcal{A})$, where F_n is spanned by elements of tensor degree $\leq n$. The associated spectral sequence has $E_1^{p,q} = H^{p+q}(\text{gr}_p \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})))$.

Under hypothesis (A1), the Koszulity condition ensures that E_2 collapses: the only nonzero column is $p = 0$, where it gives $\mathcal{A}$.

Convergence of the spectral sequence is guaranteed by hypothesis (A2): conilpotence ensures the filtration is exhaustive with finite-length iterated coproducts, so the cobar differential involves only finite sums. In the completed regime, convergence follows from the strong filtration axiom (Definition 8.1.25): on each quotient $\mathcal{A}_{\leq N}$, the degree cutoff (Lemma 8.1.26) ensures only μ_r for $r \leq N$ contributes, so the completed cobar differential is quotientwise finite and the spectral sequence converges on each quotient. Passing to the inverse limit by the complete filtered comparison lemma gives convergence on $\text{CompCl}(F_{\text{ft}})$.

The counit $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$ is induced by the Verdier pairing (Theorem 7.0.36) and is a quasi-isomorphism by the spectral sequence argument.

Coalgebra side. Dually, filter $\Omega^{\text{ch}}(C)$ by word length in the free chiral algebra. Conilpotence (C2) makes the filtration exhaustive; coKoszulity (C1) collapses the spectral sequence to a single column. The unit $C \rightarrow \bar{B}^{\text{ch}}(\Omega^{\text{ch}}(C))$ is a quasi-isomorphism by the same spectral sequence argument, applied with the roles of algebra and coalgebra interchanged. $\square$

PROPOSITION 7.0.38 (*Explicit cobar-bar augmentation*;). Let $\mathcal{A}$ be an augmented chiral algebra satisfying the algebra-side hypotheses (A1)–(A2) of Corollary 7.0.37. The *augmentation map* $\varepsilon: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$ is constructed as follows.

On generators. By Theorem 7.0.50, $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) = \text{Free}_{\text{ch}}(s^{-1}\bar{B})$ where $\bar{B} = \bigoplus_{n \geq 1} \bar{B}_n^{\text{ch}}(\mathcal{A})$ is the coaugmentation coideal of the bar coalgebra. Define ε on generators $s^{-1}\bar{B}$ as the composite

$$s^{-1}\bar{B} \xrightarrow{s^{-1}\pi_1} s^{-1}\bar{B}_1^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \bar{\mathcal{A}} \hookrightarrow \mathcal{A}, \quad (7.1)$$

where π_1 projects to bar degree 1 and $s^{-1}\bar{B}_1^{\text{ch}}(\mathcal{A}) \cong \bar{\mathcal{A}}$ uses the suspension identification $\bar{B}_1^{\text{ch}} = s\bar{\mathcal{A}}$. In particular, ε kills all generators from bar degree ≥ 2 .

Extension. By the universal property of the free chiral algebra (Theorem 7.0.50), the restriction (7.1) extends uniquely to a chiral algebra morphism $\varepsilon: \text{Free}_{\text{ch}}(s^{-1}\bar{B}) \rightarrow \mathcal{A}$.

Low-degree formulas. On generators:

$$\begin{aligned} \varepsilon(s^{-1}[s\bar{a}]) &= \bar{a} && \text{(inclusion of the augmentation ideal),} \\ \varepsilon(s^{-1}[s\bar{a}_1 \mid s\bar{a}_2]) &= 0 && \text{(projection kills bar degree } \geq 2). \end{aligned}$$

On products of generators (by the algebra map property):

$$\varepsilon(s^{-1}[s\bar{a}_1] \cdot s^{-1}[s\bar{a}_2]) = \bar{a}_1 \bar{a}_2 \quad (\text{the zeroth chiral product}).$$

Here $s^{-1}[s\bar{a}_1 \mid s\bar{a}_2]$ is a *single generator* from bar degree 2 (which ε kills), while $s^{-1}[s\bar{a}_1] \cdot s^{-1}[s\bar{a}_2]$ is a *product* of two generators from bar degree 1 (which ε evaluates via the chiral multiplication $\bar{a}_1 \bar{a}_2$).

Proof. Step 1: Chain map property. We verify $\varepsilon \circ d_\Omega = 0$ (the target differential vanishes since $\mathcal{A}$ is a strict chiral algebra). Since ε is an algebra morphism and d_Ω is a derivation (Theorem 7.0.50), it suffices to check on generators $s^{-1}b$ for $b \in \bar{B}_n^{\text{ch}}(\mathcal{A})$.

The cobar differential on generators decomposes as (Theorem 7.0.20):

$$d_\Omega(s^{-1}b) = \pm s^{-1}(d_{\text{bar}} b) + \sum \pm s^{-1}b' \cdot s^{-1}b''$$

where d_{bar} is the bar differential and $\bar{\Delta}(b) = \sum b' \otimes b''$ is the reduced coproduct (signs determined by the Koszul rule for desuspension).

Bar degree $n = 1$: $b = [s\bar{a}] \in \bar{B}_1^{\text{ch}}$. Then $d_{\text{bar}} b = 0$ (bar degree 1 elements are primitives annihilated by the differential) and $\bar{\Delta}(b) = 0$ (no non-trivial decomposition). Hence $d_\Omega(s^{-1}[s\bar{a}]) = 0$ and $\varepsilon(0) = 0$.

Bar degree $n = 2$: $b = [s\bar{a}_1 \mid s\bar{a}_2] \in \bar{B}_2^{\text{ch}}$. The bar differential yields $d_{\text{bar}} b = \pm [s(\bar{a}_1 \bar{a}_2)] \in \bar{B}_1^{\text{ch}}$ (residue extraction of the OPE), while the coproduct gives $\bar{\Delta}(b) = [s\bar{a}_1] \otimes [s\bar{a}_2]$ (deconcatenation). Applying ε :

$$\begin{aligned} \varepsilon(d_\Omega(s^{-1}b)) &= \pm \varepsilon(s^{-1}[s(\bar{a}_1 \bar{a}_2)]) + \pm \varepsilon(s^{-1}[s\bar{a}_1] \cdot s^{-1}[s\bar{a}_2]) \\ &= \pm \bar{a}_1 \bar{a}_2 \pm \bar{a}_1 \bar{a}_2 = 0, \end{aligned}$$

where the two signs are opposite by the Maurer–Cartan equation for the universal twisting morphism $\tau = \varepsilon|_{s^{-1}\bar{B}}: \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ ([299, §2.2, Proposition 2.2.6]).

Bar degree $n \geq 3$: $d_{\text{bar}} b$ lies in bar degree $n-1 \geq 2$, which ε kills. Each summand $s^{-1}b' \cdot s^{-1}b''$ in the coproduct decomposition has at least one factor of bar degree ≥ 2 , so ε kills it. Hence $\varepsilon(d_\Omega(s^{-1}b)) = 0$.

Step 2: Quasi-isomorphism. Filter $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}))$ by word length in the free algebra:

$$F_p = \bigoplus_{k \leq p} \text{Free}_{\text{ch}}^{(k)}(s^{-1}\bar{B}),$$

where $\text{Free}_{\text{ch}}^{(k)}$ is the component of word length k . On the associated graded, the differential reduces to the *linearized* part $d_{\text{lin}} = s^{-1}d_{\text{bar}}s$, acting within each copy of $s^{-1}\bar{B}$. The E_1 page is:

$$E_1^{p,q} = \text{Free}_{\text{ch}}^{(p)}(s^{-1}H^q(\bar{B}^{\text{ch}}(\mathcal{A}))).$$

The Koszul hypothesis forces the bar coalgebra cohomology $H^*(\bar{B}^{\text{ch}}(\mathcal{A}))$ to be concentrated in a single cohomological degree (Convention 6.0.2). Therefore $E_1^{p,q} = 0$ for $q \neq 0$, so $d_1 = 0$ and $E_2 = E_1 = E_\infty$.

The augmentation ε induces on E_∞ :

$$\varepsilon_*: E_\infty^{1,0} = s^{-1}H^0(\bar{B}_1^{\text{ch}}) = \bar{\mathcal{A}} \xrightarrow{\sim} \mathcal{A}, \quad \varepsilon_*|_{E_\infty^{p,0}} = 0 \text{ for } p \geq 2.$$

Convergence of the spectral sequence (by conilpotence or completeness, as in Corollary 7.0.37) yields $H^*(\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}))) \cong \mathcal{A}$, and ε realizes this isomorphism at the cochain level. $\square$

Remark 7.0.39 (The chiral bar-cobar adjunction via twisting morphisms). The projection $\pi = \varepsilon|_{s^{-1}\bar{B}}: \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ is the chiral universal twisting morphism (Proposition 3.1.21(i), Definition 11.1.1). By the two universal properties (Proposition 3.1.21(i)–(ii)), the *chiral bar-cobar adjunction* is:

$$\text{Hom}_{\text{dg CoAlg}}(C, \bar{B}^{\text{ch}}(\mathcal{A})) \cong \text{Tw}^{\text{ch}}(C, \mathcal{A}) \cong \text{Hom}_{\text{dg Alg}}(\Omega^{\text{ch}}(C), \mathcal{A}).$$

On the Koszul locus, $\bar{B}^{\text{ch}}(\mathcal{A}) \otimes_\pi \mathcal{A} \simeq \mathbb{k}$ (Theorem 11.1.9): unit and counit are quasi-isomorphisms.

Example 7.0.40 (Augmentation for $\widehat{\mathfrak{sl}}_2$). For the affine Kac–Moody algebra $\mathcal{A} = V_k(\mathfrak{sl}_2)$ with basis $\{J^+, J^0, J^-\}$ and OPE $J^a(z)J^b(w) \sim f_c^{ab}J^c(w)/(z-w) + k\kappa(J^a, J^b)/(z-w)^2$, the augmentation acts as:

$$\begin{aligned} \varepsilon(s^{-1}[sJ^a]) &= J^a && \text{(recovery of generators),} \\ \varepsilon(s^{-1}[sJ^a] \cdot s^{-1}[sJ^b]) &= J_{(0)}^a J^b = f_c^{ab}J^c && \text{(recovery of structure constants).} \end{aligned}$$

Thus $\varepsilon(s^{-1}[sJ^+] \cdot s^{-1}[sJ^-]) = J^0$ ($= [J^+, J^-] = H$), confirming that the augmentation recovers the $\mathfrak{sl}_2$ Lie bracket from the cobar-bar resolution.

Example 7.0.41 (Explicit pairing: two-point function). Consider $n = 2$. The bar element is:

$$\omega_{\text{bar}} = a_1(z_1) \otimes a_2(z_2) \otimes \frac{dz_1 - dz_2}{z_1 - z_2}$$

The cobar element is:

$$K_{\text{cobar}} = c_1(z_1) \otimes c_2(z_2) \otimes \delta(z_1 - z_2)$$

The pairing:

$$\begin{aligned} \langle \omega_{\text{bar}}, K_{\text{cobar}} \rangle &= \int_{\bar{C}_2(X)} (a_1 \otimes a_2) \cdot (c_1 \otimes c_2) \wedge \frac{dz_1 - dz_2}{z_1 - z_2} \wedge \delta(z_1 - z_2) \\ &= \int_X (a_1 \otimes a_2)(z, z) \cdot (c_1 \otimes c_2)(z, z) \wedge dz \wedge d\bar{z} \end{aligned}$$

By the residue-distribution identity:

$$\int \frac{dz_1 - dz_2}{z_1 - z_2} \wedge \delta(z_1 - z_2) = 1$$

Therefore:

$$\langle \omega_{\text{bar}}, K_{\text{cobar}} \rangle = \int_X \langle a_1, c_1 \rangle \cdot \langle a_2, c_2 \rangle dz \wedge d\bar{z}$$

This is the two-point correlation function in CFT.

7.0.9 KONTSEVICH FORMALITY AND CHIRAL BAR CONSTRUCTION

THEOREM 7.0.42 (*Kontsevich formality (1997) [275];*). For any smooth manifold M , there exists an L_∞ quasi-isomorphism:

$$\mathcal{U} : T_{\text{poly}}(M) \xrightarrow{\sim} D_{\text{poly}}(M)$$

from polyvector fields to polydifferential operators, given by configuration space integrals:

$$\mathcal{U}_n(\gamma_1, \dots, \gamma_n) = \sum_{\Gamma \in G_n} w_\Gamma \int_{\overline{C}_{n,m}(\mathbb{H})} \omega_\Gamma$$

where G_n = admissible graphs, w_Γ = combinatorial weights, and ω_Γ involves propagators $d \log(z_i - z_j)$ and angle forms $d\theta_i$.

Remark 7.0.43 (Relation to chiral bar construction). Kontsevich's formality is the prototype for our construction: replace $\mathbb{R}^d$ with a Riemann surface X , polyvector fields with $\mathcal{A}$, $\overline{C}_n(\mathbb{H})$ with $\overline{C}_n(X)$, and L_∞ with curved A_∞ . Both realize a duality (deformation quantization resp. Koszul duality) via configuration space integrals.

Remark 7.0.44 (Costello–Gwilliam factorization algebras). Our construction extends [92]: Vol. 1 develops factorization homology on manifolds, Vol. 2 treats quantum corrections and curved A_∞ in QFT. We specialize to complex curves (essential for chiral structure) and use configuration geometry rather than the BV formalism.

Remark 7.0.45 (Cobar summary). The geometric cobar is Verdier-dual to the bar (Section 6.1.5): the three-component differential, nine-term $d^2 = 0$ verification, and Arnold relations all mirror their bar counterparts.

PROPOSITION 7.0.46 (*Cobar as modular shadow carrier*). The cobar complex $\Omega(\overline{B}(\mathcal{A}))$, viewed as an FCom-algebra (Theorem 8.2.12), carries the full shadow obstruction tower: for each $r \geq 2$, the degree- r operadic structure map of $\Omega(\overline{B}(\mathcal{A}))$ encodes $\Theta_{\mathcal{A}}^{\leq r}$.

Proof. The bar-intrinsic MC element $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ (Theorem 13.21.69) lives in the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, and the cobar complex reconstructs $\mathcal{A}$ from $\overline{B}(\mathcal{A})$ by the bar-cobar adjunction (Theorem 11.1.84). The degree- r component of the FCom-algebra structure on $\Omega(\overline{B}(\mathcal{A}))$ is the graph sum $\sum_{|\Gamma|=r} |\text{Aut}(\Gamma)|^{-1} \ell_\Gamma$, which is precisely the degree- r projection $\Theta_{\mathcal{A}}^{\leq r}$ of the universal MC element (Corollary 13.21.74). $\square$

7.0.10 ČECH-ALEXANDER COMPLEX REALIZATION

THEOREM 7.0.47 (*Cobar as Čech complex;*). The geometric cobar complex is quasi-isomorphic to a Čech-type complex:

$$\Omega^{\text{ch}}(C) \simeq \check{C}^\bullet(\mathfrak{U}, \mathcal{F}_C)$$

where $\mathfrak{U} = \{U_\sigma\}$ is the open cover of $\overline{C}_n(X)$ by coordinate charts and $\mathcal{F}_C$ is the factorization algebra associated to C .

Proof. The factorization algebra $\mathcal{F}_C$ on X is defined by the assignment $U \mapsto \mathcal{F}_C(U) = \Omega(C|_U)$, with factorization structure maps $\mathcal{F}_C(U_1) \otimes \mathcal{F}_C(U_2) \rightarrow \mathcal{F}_C(U_1 \sqcup U_2)$ for disjoint opens, given by the cobar product. This is a cosheaf on the Ran space $\text{Ran}(X)$, hence in particular a precosheaf on X .

Step 1: Cover and nerve. Choose a cover $\mathfrak{U} = \{U_\sigma\}_{\sigma \in S}$ of X by coordinate discs. The configuration space $C_n(X)$ inherits an open cover $\mathfrak{U}^{(n)} = \{U_{\sigma_1} \times \cdots \times U_{\sigma_n} \cap C_n(X)\}$. The FM compactification $\overline{C}_n(X)$ is covered by the closures $\overline{U_{\sigma_1} \times \cdots \times U_{\sigma_n}}$ together with boundary coordinate charts at collision strata. The nerve of this cover computes the Čech complex $\check{C}^\bullet(\mathfrak{U}, \mathcal{F}_C)$.

Step 2: Čech-de Rham comparison. On each chart U_σ , the factorization algebra $\mathcal{F}_C|_{U_\sigma}$ is computed by the cobar complex with local coordinates. The cobar differential d_Ω on U_σ uses the coproduct $\bar{\Delta}$ of C together with the local propagator $\eta_{ij} = d \log(z_i - z_j)$. On overlaps $U_\sigma \cap U_\tau$, the transition data is encoded by the change-of-coordinate forms, which are $\bar{\partial}$ -exact on the holomorphic curve X .

The cobar complex $\Omega^{\text{ch}}(C)$ computes global sections of $\mathcal{F}_C$ via integration of local cobar elements against logarithmic forms on $\overline{C}_n(X)$. This is the Čech-de Rham double complex: the Čech direction glues local cobar data across charts, while the de Rham direction is the cobar differential.

Step 3: Quasi-isomorphism. Since X is a smooth algebraic curve, the FM compactification $\overline{C}_n(X)$ is a smooth variety with normal crossings boundary (Theorem 5.1.12). The cover $\mathfrak{U}^{(n)}$ can be chosen to be a Leray cover: each finite intersection $U_{\sigma_1} \cap \cdots \cap U_{\sigma_k}$ is either empty or contractible (being an intersection of coordinate discs in $C_n(X)$). For a Leray cover of a smooth variety, the Čech-to-derived-functor spectral sequence degenerates at E_1 , giving:

$$\check{H}^p(\mathfrak{U}, \mathcal{F}_C) \cong H^p(X^n, \mathcal{F}_C).$$

The right-hand side is the factorization homology $\int_X \mathcal{F}_C$, which by the Costello–Gwilliam equivalence (cf. [92]) agrees with the cobar cohomology $H^*(\Omega^{\text{ch}}(C))$. $\square$

7.0.II INTEGRATION KERNELS AND COBAR OPERATIONS

Definition 7.0.48 (Cobar integration kernel). Elements of the cobar complex can be represented by integration kernels:

$$K_{p+1}(z_0, \dots, z_p; w_0, \dots, w_p) \in \Gamma\left(C_{p+1}(X) \times C_{p+1}(X), \text{Hom}(C^{\otimes(p+1)}, \mathbb{C}) \otimes \Omega^*\right)$$

acting on sections of C by:

$$(\Phi_K \cdot c)(z_0, \dots, z_p) = \int_{C_{p+1}(X)} K_{p+1}(z_0, \dots, z_p; w_0, \dots, w_p) \wedge c(w_0) \otimes \cdots \otimes c(w_p)$$

Example 7.0.49 (Fundamental cobar element). For the trivial chiral coalgebra $C = \omega_X$, the fundamental cobar element is:

$$K_2(z_1, z_2; w_1, w_2) = \frac{1}{(z_1 - w_1)(z_2 - w_2) - (z_1 - w_2)(z_2 - w_1)}$$

This kernel reconstructs the chiral multiplication from the coalgebra data.

THEOREM 7.0.50 (Cobar as free chiral algebra;). As a graded chiral algebra (forgetting the differential), the cobar construction $\Omega^{\text{ch}}(C)$ is the free chiral algebra generated by $s^{-1}\bar{C}$, where $\bar{C} = \ker(\epsilon: C \rightarrow \omega_X)$. The differential d_Ω is the unique derivation extending the reduced comultiplication $\bar{\Delta}: \bar{C} \rightarrow \bar{C} \otimes \bar{C}$ (this is essential data: $\Omega^{\text{ch}}(C)$ is a DG chiral algebra, not merely a free algebra).

Proof. By construction (Definition 13.2.14), the underlying graded chiral algebra of $\Omega^{\text{ch}}(C)$ is $\text{Free}_{\text{ch}}(s^{-1}\bar{C})$, the free chiral algebra generated by $s^{-1}\bar{C}$ as a $\mathcal{D}_X$ -module. The universal property of free

algebras then gives: for any chiral algebra $\mathcal{A}$ and graded $\mathcal{D}_X$ -module morphism $f: s^{-1}\bar{C} \rightarrow \mathcal{A}$, there exists a unique chiral algebra morphism $\tilde{f}: \text{Free}_{\text{ch}}(s^{-1}\bar{C}) \rightarrow \mathcal{A}$ extending f .

It remains to verify that d_Ω is a derivation. Since Free_{ch} is left adjoint to the forgetful functor, a derivation on a free algebra is determined by its restriction to generators. The restriction $d_\Omega|_{s^{-1}\bar{C}}$ equals the desuspended reduced comultiplication $s^{-1}\bar{\Delta}: s^{-1}\bar{C} \rightarrow (s^{-1}\bar{C})^{\otimes 2} \hookrightarrow \text{Free}_{\text{ch}}(s^{-1}\bar{C})$, which is a well-defined map of $\mathcal{D}_X$ -modules. The Leibniz extension to all of $\Omega^{\text{ch}}(C)$ is unique, giving d_Ω as the unique derivation extending $\bar{\Delta}$. $\square$

7.0.12 GEOMETRIC BAR-COBAR COMPOSITION

THEOREM 7.0.51 (*Geometric unit of adjunction*;). The unit of the bar-cobar adjunction $\eta: \mathcal{A} \rightarrow \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}))$ is geometrically realized by:

$$\eta(\phi)(z) = \sum_{n \geq 0} \int_{\bar{C}_{n+1}(X)} \phi(z) \wedge \text{ev}_0^*(\bar{B}_n^{\text{ch}}(\mathcal{A})) \wedge \omega_n$$

where:

- $\text{ev}_0: \bar{C}_{n+1}(X) \rightarrow X$ evaluates at the 0-th point
- ω_n is the Poincaré dual of the small diagonal
- The sum converges due to nilpotency/completeness conditions

Geometric proof. The unit $\eta_{\mathcal{A}}: \mathcal{A} \rightarrow \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}))$ is constructed as follows. The tautological inclusion $s^{-1}\bar{C} \hookrightarrow T^a(s^{-1}\bar{C})$ (where $C = \bar{B}^{\text{ch}}(\mathcal{A})$) into the degree-1 component of the tensor algebra, composed with the canonical projection from the tensor algebra to the cobar construction, gives a map of graded $\mathcal{D}_X$ -modules from $\mathcal{A}$ to $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}))$ (identifying $\mathcal{A}$ with $s^{-1}s\bar{\mathcal{A}} \subset s^{-1}\bar{C}$ at bar degree 1). At higher tensor degrees, the formula in the theorem statement extends this inclusion via configuration space integrals over the Fulton–MacPherson compactifications $\bar{C}_{n+1}(X)$.

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\text{bar}} & \bar{B}^{\text{ch}}(\mathcal{A}) \\ & \searrow \eta & \downarrow \text{cobar} \\ & & \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \end{array}$$

That $\eta_{\mathcal{A}}$ is a quasi-isomorphism follows from the spectral sequence associated to the bar filtration $F^p = \bigoplus_{n \geq p} \bar{B}^n$. At the E_1 page, the unit reduces to the classical Koszul resolution of $\mathcal{A}$ by $\Omega(\bar{B}(\mathcal{A}))$, which is acyclic by the Koszul hypothesis (Remark 7.3.1). The spectral sequence converges to $H^*(\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})))$ by the completeness of the filtration (Theorem 8.1.7), so E_1 -acyclicity implies $\eta_{\mathcal{A}}$ is a quasi-isomorphism.

At the geometric level, the spectral sequence collapse rests on the identity

$$\int_{\partial \bar{C}_n} \text{Res}_{D_{ij}}[\cdots] = \int_{\bar{C}_n} d[\cdots] = \int_{C_n} \delta_{D_{ij}} \wedge [\cdots]$$

which shows that residue extraction (bar) and distributional integration (cobar) are inverse operations up to exact terms, so their composition is homotopic to the identity. $\square$

Definition 7.0.52 (Categorical logarithm and exponential). The bar functor $\bar{B}^{\text{ch}}$ and the cobar functor Ω^{ch} are the *categorical logarithm* and *categorical exponential* of chiral algebras on X . Four properties justify the terminology.

(i) *Additivity* (log sends products to sums):

$$\bar{B}^{\text{ch}}(\mathcal{A} \otimes \mathcal{A}') \simeq \bar{B}^{\text{ch}}(\mathcal{A}) \oplus \bar{B}^{\text{ch}}(\mathcal{A}').$$

This holds because the logarithmic forms $\eta_{ij} = d \log(z_i - z_j)$ on $\text{Conf}_n(X)$ are additive under the product of chiral brackets: $\eta_{ij}^{\mathcal{A} \otimes \mathcal{A}'} = \eta_{ij}^{\mathcal{A}} + \eta_{ij}^{\mathcal{A}'}$.

(ii) *Integral kernel*: the bar differential is the integral operator with kernel $\eta_{ij} = d \log(z_i - z_j) \in \Omega_{\log}^1(\text{Conf}_2(X))$. The Fourier modes of η_{ij} are the OPE residues $a_{(n)}b$ at all pole orders.

(iii) *Cocycle condition* ($d \log$ is closed): the Arnold relation

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$$

implies $d_B^2 = 0$. The three terms correspond to the three boundary faces of $\overline{\text{FM}}_3(X)$; the Arnold relation is their signed cancellation.

(iv) *Inversion* ($\exp \circ \log = \text{id}$): $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ on the Koszul locus (Theorem 8.6.1). The cobar functor reconstructs the algebra from its bar coalgebra.

7.1 PRECISE DISTRIBUTION SPACES

Definition 7.1.1 (Distribution space). The space $\text{Dist}(C_n(X), C^{\boxtimes n})$ consists of distributional sections with:

- Prescribed singularities along diagonals
- Growth conditions at infinity
- Appropriate transformation under $\mathfrak{S}_n$

THEOREM 7.1.2 (Topology;). The distribution space $\text{Dist}(C_n(X), C^{\boxtimes n})$ is a complete locally convex topological vector space under the weak-* topology defined by the pairing:

$$\langle K, \phi \rangle = \int_{C_n(X)} K \cdot \phi$$

for test functions $\phi \in C_c^\infty(C_n(X))$. The cobar differential d_Ω is continuous in this topology.

Proof. Step 1: Topological structure. The test function space $C_c^\infty(C_n(X), (C^{\boxtimes n})^*)$ carries the standard inductive limit topology (over compacta). The distribution space $\text{Dist}(C_n(X), C^{\boxtimes n})$ is its continuous dual, equipped with the weak-* topology: a net $K_\alpha \rightarrow K$ iff $\langle K_\alpha, \phi \rangle \rightarrow \langle K, \phi \rangle$ for all test functions ϕ . By the Banach-Alaoglu theorem, bounded subsets of the distribution space are weak-* precompact. Completeness follows from the completeness of $\mathbb{C}$ and the fact that C_c^∞ is a nuclear LF-space (a strict inductive limit of nuclear Fréchet spaces C_K^∞ indexed by compact exhaustions K), so its dual is complete in the weak-* topology by Grothendieck's completeness theorem.

Step 2: Prescribed singularities. The distributions $K \in \text{Dist}(C_n(X), C^{\boxtimes n})$ have singularities supported on the diagonals $\Delta_{ij} = \{z_i = z_j\}$, of the form $K \sim c_{ij}^{(k)} / (z_i - z_j)^k$ for finitely many k (determined by the OPE orders of C). This regularity condition defines a closed subspace of the full distribution space, hence inherits completeness.

Step 3: Continuity of d_Ω . The cobar differential $d_\Omega(K) = \sum_{i < j} \delta_{\Delta_{ij}} * K_{\text{coproduct}}$ involves convolution with delta functions supported on diagonals. For each test function ϕ , $\langle d_\Omega(K), \phi \rangle = \langle K, d_\Omega^*(\phi) \rangle$ where d_Ω^* is the formal adjoint (restriction to diagonals followed by the coalgebra coproduct). Since d_Ω^* maps $C_c^\infty \rightarrow C_c^\infty$ continuously (restriction to a submanifold is continuous in the C^∞ topology), d_Ω is weak-* continuous. $\square$

Remark 7.1.3 (Regularization methods). When distributional products arising in the cobar differential require regularization, three standard methods are available:

1. *Dimensional regularization:* analytic continuation in dimension $d = d_0 - \epsilon$;
2. *Principal value prescription:* $\text{P.V.} \int f(z)/z \, dz$;
3. *Hadamard finite parts:* extracting the finite part of a divergent integral.

For the cobar construction in the chiral setting, no regularization is needed at genus 0 because the distributional products are convolutions with delta functions supported on smooth submanifolds (the diagonals $\Delta_{ij} \subset C_n(X)$), and such convolutions are well-defined by the calculus of wavefront sets [221]: the conormal bundles $N^*\Delta_{ij}$ do not intersect the wavefront set of the coalgebra coproduct, which is supported along the diagonals themselves. At higher genus, the propagator acquires distributional corrections requiring the regularization methods listed above; see the genus- g analysis in Theorem 13.18.4.

Example 7.1.4 (Cobar via integration kernels). The cobar construction uses distributional integration kernels. For a chiral coalgebra C with coproduct $\Delta : C \rightarrow C \boxtimes C$, elements of $\Omega^{\text{ch}}(C)$ are:

$$\sum_{n \geq 0} \int_{C_n(X)} K_n(z_1, \dots, z_n) \cdot c_1(z_1) \cdots c_n(z_n) \, dz_1 \cdots dz_n$$

where:

- K_n are distributions on $C_n(X)$ (typically with poles on diagonals)
- $c_i \in C$ are coalgebra elements
- Integration is regularized via analytic continuation or principal values

The cobar differential acts by:

$$d_{\text{cobar}} = \sum_{i < j} \Delta_{ij} \cdot \delta(z_i - z_j)$$

inserting Dirac distributions that “pull apart” colliding points.

This realizes the cobar complex as the linear dual to the bar complex under the pairing:

$$\langle \omega_{\text{bar}}, K_{\text{cobar}} \rangle = \int_{\overline{C}_n(X)} \omega_{\text{bar}} \wedge \iota^* K_{\text{cobar}}$$

where $\iota : C_n(X) \hookrightarrow \overline{C}_n(X)$ is the inclusion.

Physical interpretation. In quantum field theory:

- Bar elements = algebraic shadow data for off-shell states with infrared cutoffs
- Cobar elements = algebraic shadow data for on-shell propagators with UV regularization
- The pairing = conjectural algebraic shadow of S-matrix elements

7.1.1 POINCARÉ–VERDIER DUALITY REALIZATION

THEOREM 7.1.5 (*Bar-cobar Verdier pairing*;). The bar and cobar constructions are related by the Verdier intertwining of Theorem II.1.84:

$$\mathbb{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\mathcal{A})) \simeq (\mathcal{A})_{\infty}^!,$$

where $\mathbb{D}_{\text{Ran}}$ denotes Verdier duality on $\text{Ran}(X)$ and $(\mathcal{A})_{\infty}^!$ is the homotopy Koszul dual factorization algebra. On the Koszul locus, Theorem II.1.84 identifies $(\mathcal{A})_{\infty}^! \simeq \mathcal{A}^!$. The cobar construction Ω^{ch} is the *inverse*, not the dual: $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \simeq \mathcal{A}$ on the Koszul locus (Theorem B). The Verdier pairing between bar forms and cobar distributions is the configuration-space incarnation of this intertwining. (The seven-face identification of $r(z)$ is the subject of Chapter ??.)

Geometric realization. The duality is realized through the perfect pairing:

$$\langle \omega_{\text{bar}}, \omega_{\text{cobar}} \rangle = \int_{\bar{C}_n(X)} \omega_{\text{bar}} \wedge \iota^* \omega_{\text{cobar}}$$

where $\iota : C_n(X) \hookrightarrow \bar{C}_n(X)$ is the inclusion.

The duality has the following structure:

- Logarithmic forms on $\bar{C}_n(X)$ (bar) are dual to distributions on $C_n(X)$ (cobar)
- Residues at divisors (bar) are dual to principal value integrals (cobar)
- Collision divisors (bar) correspond to extension loci (cobar)
- The duality exchanges extraction (analysis) with reconstruction (synthesis)

□

7.1.2 EXPLICIT COBAR COMPUTATIONS

Example 7.1.6 (*Cobar of exterior coalgebra*). Let $\mathcal{E} = \Lambda_{\text{ch}}^*(V)$ be the chiral exterior coalgebra on generators V . Then:

$$\Omega^{\text{ch}}(\mathcal{E}) \cong S_{\text{ch}}(s^{-1}V)$$

the chiral symmetric algebra on the desuspension of V .

Geometrically, this duality is realized by:

- Fermionic fields $\psi \in V$ with antisymmetric OPE become bosonic fields $\phi \in s^{-1}V$ with symmetric OPE
- The cobar differential vanishes since the reduced comultiplication $\bar{\Delta}(\psi) = 0$
- Configuration space integrals enforce bosonic statistics through symmetric integration domains

This is the chiral analogue of the classical Koszul duality between exterior and symmetric algebras.

Example 7.1.7 (Cobar of bar of free fermions). For the free fermion algebra $\mathcal{F}$, bar-cobar inversion gives:

$$\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{F})) \xrightarrow{\sim} \mathcal{F}$$

recovering the free fermion algebra itself (not the $\beta\gamma$ system). The Koszul dual $\mathcal{F}^! \cong \beta\gamma$ is obtained instead by linear duality of the bar coalgebra: $\mathcal{F}^! = \bar{B}^{\text{ch}}(\mathcal{F})^\vee$ (see Example 7.0.28 and Theorem 7.0.29). This distinction is the chiral analog of the classical fact that $\Omega(\bar{B}(\Lambda(V))) \simeq \Lambda(V)$ (bar-cobar inversion), while $\Lambda(V)^! = \text{Sym}(V^*)$ (Koszul dual algebra via linear duality).

7.1.3 COBAR A_∞ STRUCTURE

THEOREM 7.1.8 (*A_∞ structure on cobar [299];*). The cobar construction $\Omega^{\text{ch}}(C)$ carries a canonical A_∞ structure with operations:

$$m_k : \Omega^{\text{ch}}(C)^{\otimes k} \rightarrow \Omega^{\text{ch}}(C)[2 - k]$$

geometrically realized by:

$$m_k(\alpha_1, \dots, \alpha_k) = \int_{\partial \bar{M}_{0,k+1}} \alpha_1 \wedge \dots \wedge \alpha_k \wedge \omega_{0,k+1}$$

where $\bar{M}_{0,k+1}$ is the moduli space of stable curves with $k + 1$ marked points.

Proof. By [299, Theorem 9.2.8], A_∞ structures arise from operadic bar-cobar resolutions. The boundary stratification of the Deligne–Mumford compactification gives:

$$\partial \bar{M}_{0,k+1} = \bigcup_{\substack{I \sqcup J = [k+1] \\ |I|, |J| \geq 2}} \bar{M}_{0,|I|+1} \times \bar{M}_{0,|J|+1}$$

Each boundary stratum $\bar{M}_{0,|I|+1} \times \bar{M}_{0,|J|+1}$ contributes a composition $m_{|I|} \circ m_{|J|}$ to the boundary of m_k . The topological identity $\partial^2 = 0$ on the chain complex $C_*(\bar{M}_{0,k+1})$ then gives $\sum_{i+j=k+1} m_i \circ m_j = 0$, which is the A_∞ relation. Signs are determined by the orientation of the boundary strata, matching the Koszul sign convention in [299, §10.3]. $\square$

7.1.4 GEOMETRIC COBAR FOR CURVED COALGEBRAS

Definition 7.1.9 (Curved cobar). For a curved chiral coalgebra (C, κ_C) with curvature element $\kappa_C \in C^{\otimes 2}[2]$, the cobar complex has modified differential:

$$d_{\text{curved}} = d_{\text{cobar}} + m_0$$

where $m_0 \in \Omega^{\text{ch}}(C)[2]$ is the curvature term geometrically realized by:

$$m_0 = \int_{S^1 \times X} \kappa_C(z, w) \wedge K_{\text{prop}}(z, w)$$

with K_{prop} the propagator kernel encoding quantum corrections.

THEOREM 7.1.10 (*Curved Maurer–Cartan equation;*). [Regime: curved-central (Convention 1.10.2).]
Elements $\alpha \in \Omega^{\text{ch}}(C)[-1]$ satisfying the curved Maurer–Cartan equation:

$$d_{\text{curved}}\alpha + \frac{1}{2}m_2(\alpha, \alpha) + m_0 = 0$$

correspond geometrically to:

- Deformations of the chiral structure that do not preserve the grading
- Quantum anomalies in the conformal field theory
- Central extensions and their geometric representatives

Proof. By the general theory of curved A_∞ algebras (Positselski [350], Loday–Vallette [299] §10.1), the curved Maurer–Cartan equation $d\alpha + \frac{1}{2}[\alpha, \alpha] + m_0 = 0$ parametrizes gauge equivalence classes of curved deformations (gauge equivalence in the L_∞ sense). In the chiral setting, $m_0 \in \Omega^{\text{ch}}(C)$ is the curvature element. The three geometric correspondences are: (i) A solution α defines a twisted differential $d_\alpha = d + [\alpha, -]$ satisfying $d_\alpha^2 = 0$, which deforms the chiral structure. (ii) The curvature m_0 is the genus-0 obstruction to $d^2 = 0$; for a chiral algebra with central charge c , $m_0 \propto c$ (Proposition 7.1.11), which is the conformal anomaly. (iii) At genus 1, solutions α with $m_0 = 0$ classify central extensions of the chiral algebra by $\mathbb{C}$, as established in Section 7.2. $\square$

PROPOSITION 7.1.11 (*Curvature of the affine bar complex;*). For the affine Kac–Moody chiral algebra $\widehat{\mathfrak{g}}_k$ at level k , the bar complex $\bar{B}^{\text{ch}}(\widehat{\mathfrak{g}}_k)$ has curvature

$$m_0 = \frac{k + h^\vee}{2h^\vee} \cdot \Omega$$

where $h^\vee$ is the dual Coxeter number and $\Omega = \sum_a J^a \otimes J_a$ is the Casimir element (we write Ω rather than κ for the Casimir to avoid confusion with the modular characteristic $\kappa(\mathcal{A})$). In particular:

- (i) $m_1^2 = 0$ (i.e., $d^2 = 0$ on the internal differential) if and only if $k = -h^\vee$ (critical level);
- (ii) The total bar differential $d_{\bar{B}}$ always satisfies $d_{\bar{B}}^2 = 0$, regardless of the level.

Proof. The bar differential on degree-1 elements $J^a \boxtimes J^b \cdot \eta_{12}$ extracts the OPE:

$$d(J^a \boxtimes J^b \cdot \eta_{12}) = k \cdot (J^a, J^b) \cdot |0\rangle + f^{ab}{}_c J^c,$$

where the first term comes from the double-pole $k(J^a, J^b)/(z-w)^2$. Applying m_1 twice and using the Jacobi identity gives

$$m_1^2(J^a \boxtimes J^b \cdot \eta_{12}) = (k + h^\vee) \cdot (\text{adjoint Casimir}),$$

since the Killing form contraction $\sum_{c,d} f^{ac}{}_d f^{bc}{}_d = 2h^\vee \cdot \delta^{ab}$ (with long roots normalized to length 2). The factor $h^\vee$ is the eigenvalue of the adjoint Casimir; the total coefficient $k + h^\vee$ vanishes precisely at critical level.

For $\mathfrak{g} = \mathfrak{sl}_2$ with $h^\vee = 2$, the explicit computation: $m_1(e \boxtimes f \cdot \eta_{12}) = k \cdot \mathbf{1} + h$ (from $e_{(0)}f = h$ and $e_{(1)}f = k$). Applying m_1 again: $m_1(h) = 0$ (since h is primitive) and $m_1(\mathbf{1}) = 0$, but the composite m_1^2 on degree-2 elements picks up the adjoint action: $m_1^2(e \boxtimes f \cdot \eta_{12}) = [h, k \cdot \mathbf{1} + h]_{\text{bar}} = k \cdot (\text{ad-action of Casimir}) + 2h = (k + 2) \cdot \partial h$. $\square$

Remark 7.1.12 (Feigin–Frenkel center at critical level). At the critical level $k = -h^\vee$, Proposition 7.1.11(i) gives $m_1^2 = 0$, so the bar complex is *uncurved*. A foundational result of Feigin–Frenkel [160] shows that the center of $\widehat{\mathfrak{g}}_{-h^\vee}$ is then isomorphic to the algebra of functions on $\mathfrak{g}^\vee$ -opers:

$$Z(\widehat{\mathfrak{g}}_{-h^\vee}) \cong \text{Fun}(\text{Op}_{\mathfrak{g}}(X)).$$

The critical level is the fixed point of the level-shifting involution $k \mapsto -k - 2h^\vee$, and the uncurved bar complex recovers $\widehat{\mathfrak{g}}_{-h^\vee}$ via cobar. See Part II for the detailed treatment.

COROLLARY 7.1.13 (*Level-shifting via Verdier duality*;). For any simple Lie algebra $\mathfrak{g}$ and level $k \neq -h^\vee$, the post-Verdier factorization-algebra identification (Theorem 11.1.84, Convention 6.0.2) applied to the curved bar coalgebra of Proposition 7.1.11 gives

$$\mathbb{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\widehat{\mathfrak{g}}_k)) \simeq (\widehat{\mathfrak{g}}_k)_\infty^\dagger \simeq \widehat{\mathfrak{g}}_{k'}, \quad k' = -k - 2h^\vee.$$

Bar-cobar *inversion* recovers the original algebra: $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\widehat{\mathfrak{g}}_k)) \simeq \widehat{\mathfrak{g}}_k$ on the Koszul locus (Theorem B). The level-shifted algebra $\widehat{\mathfrak{g}}_{k'}$ is the *Koszul dual*, obtained by Verdier duality on $\text{Ran}(X)$, not by the cobar functor.

The dual level $k' = -k - 2h^\vee$ satisfies:

- (i) $k + k' = -2h^\vee$;
- (ii) the central charges satisfy $c(\widehat{\mathfrak{g}}_k) + c(\widehat{\mathfrak{g}}_{k'}) = 2 \dim \mathfrak{g}$ (Theorem 1.3.8);
- (iii) the curvatures are opposite: $m_0(k') = -m_0(k)$.

Proof. The Verdier intertwining on the factorization-algebra side (Theorem 11.1.84, Convention 6.0.2) identifies $\mathbb{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\mathcal{A})) \simeq (\mathcal{A})_\infty^\dagger$ for any chiral algebra $\mathcal{A}$, and on the Koszul locus $(\mathcal{A})_\infty^\dagger \simeq \mathcal{A}^\dagger$. For $\mathcal{A} = \widehat{\mathfrak{g}}_k$, the Koszul dual is $\mathcal{A}^\dagger = \widehat{\mathfrak{g}}_{k'}$ with $k' = -k - 2h^\vee$: Verdier duality on Ran negates the curvature element, sending $m_0 = (k + h^\vee)\Omega/(2h^\vee)$ (Proposition 7.1.11) to $m'_0 = -(k + h^\vee)\Omega/(2h^\vee) = (k' + h^\vee)\Omega/(2h^\vee)$ where Ω is the Casimir element. Since the simple-pole data f^{ab}_c (the Lie bracket) is preserved by Verdier duality and the double-pole coefficient is determined by the curvature, the dual algebra has OPE

$$J'^a(z)J'^b(w) \sim \frac{k' (J^a, J^b)}{(z-w)^2} + \frac{f^{ab}_c J'^c(w)}{z-w}$$

with $k' = -k - 2h^\vee$. Parts (i)–(iii) follow by direct substitution. $\square$

7.1.5 COMPUTATIONAL ALGORITHMS FOR COBAR

Remark 7.1.14 (Cobar complex computation). Given a chiral coalgebra C with basis $\{e_i\}$, structure constants $\Delta(e_i) = \sum_{j,k} c^i_{jk} e_j \otimes e_k$, and counit ϵ , the cobar complex $(\Omega^{\text{ch}}(C), d_{\text{cobar}})$ is constructed as follows.

1. Initialize $\Omega^0 = \text{Free}_{\text{ch}}(s^{-1}\bar{C})$ where $\bar{C} = \ker(\epsilon)$.
2. For each generator $s^{-1}e_i$ with $\epsilon(e_i) = 0$, compute $d(s^{-1}e_i) = -\sum_{j,k} c^i_{jk} s^{-1}e_j \otimes s^{-1}e_k$.
3. Extend to products by the Leibniz rule: $d(xy) = d(x)y + (-1)^{|x|}xd(y)$.
4. For each n -fold product, tensor with $\Omega^*(C_{n+1}(X))$.
5. Impose Arnold–Orlik–Solomon relations among logarithmic forms and factorization constraints from the chiral structure.

7.2 GENUS 1 CONTRIBUTIONS: CENTRAL EXTENSIONS IN THE BAR-COBAR COMPLEX

Everything constructed so far lives on a *fixed* curve X . The bar differential is a residue on $\overline{C}_n(X)$; the cobar differential inserts delta functions on $C_n(X)$; Verdier duality exchanges the two. None of this involves the moduli of curves.

Now let the curve vary. Replace X by a family $\pi: \mathcal{X} \rightarrow S$ over a base S , and ask: how does the bar complex change as X moves in $\overline{\mathcal{M}}_g$? At genus 0 the answer is: it does not; there are no moduli. At genus 1, the propagator $K^{(1)} = \theta'_1/\theta_1$ depends on the modular parameter τ , and the bar differential acquires a correction. This correction is the central extension: curvature $m_0 = \kappa(\mathcal{A})$ emerges because the trace of the OPE around the A -cycle of the torus is nonzero. The central charge, invisible at genus 0, is the first shadow of the shadow obstruction tower (Definition 13.22.46): the scalar level $\Theta_{\mathcal{A}}^{\leq 2} = \kappa(\mathcal{A})$.

Remark 7.2.1 (Central extension as tower level). The hierarchy of what becomes visible at each genus mirrors the tower levels:

- Genus 0: $\Theta|_{h=0}$, the strict bar-cobar adjunction (Theorem A).
- Genus 1: $\Theta_{\mathcal{A}}^{\leq 2} = \kappa(\mathcal{A})$, the central extension / modular characteristic (Theorem D).
- Higher genus: the cubic and quartic shadows $\mathfrak{C}$, $\mathfrak{Q}$ contribute to the $g \geq 2$ bar differential via the shadow obstruction tower (Definition 13.22.46).

7.2.1 CENTRAL EXTENSIONS AT GENUS 1: INTUITION

7.2.1.1 Physical picture

Consider the Heisenberg vertex algebra with generators $a(z)$, $a^*(z)$ satisfying:

$$[a(z), a^*(w)] \sim \frac{\kappa}{(z-w)^2}$$

where κ is the level (= modular characteristic for Heisenberg).

The double pole $1/(z-w)^2$ in the OPE produces different behavior at each genus: at genus 0, residues at $z = w$ give derivatives of delta functions that integrate to zero over the sphere; at genus 1, the *trace* $\text{Tr}(a \otimes a^*)$ around the S^1 cycle picks up the κ coefficient as a non-vanishing residue.

This is the first manifestation of the principle that central extensions are intrinsically one-loop phenomena.

7.2.1.2 Absence at genus 0

Consider the genus 0 bar differential on $\mathcal{A} \otimes \mathcal{A}$:

$$d^{(0)}(a \otimes b) = \mu(a \otimes b) - a \otimes 1 - 1 \otimes b$$

where μ is the OPE product.

For central terms: $\mu(a \otimes a^*) \sim \kappa \cdot 1$

But $d^{(0)}(\kappa \cdot 1) = \kappa \cdot 1 - \kappa \cdot 1 - \kappa \cdot 1 = -\kappa \cdot 1$

So the cocycle $a \otimes a^* - \kappa \cdot 1$ satisfying $d^{(0)}(\dots) = 0$ would require $\kappa = 0$. The central charge cannot appear at genus 0.

7.2.2 THE GEOMETRIC CONSTRUCTION: CONFIGURATION SPACES ON THE TORUS

7.2.2.1 Setup: the genus 1 configuration space

Let $\mathbb{T}^2 = \mathbb{C}/\Lambda$ be a torus with period lattice Λ . Define:

$$\text{Conf}_n(\mathbb{T}^2) = \{(z_1, \dots, z_n) \in (\mathbb{T}^2)^n \mid z_i \neq z_j\}$$

The genus 1 bar complex is:

$$C_\bullet^{(1)}(\mathcal{A}) = C_\bullet(\text{Conf}_\bullet(\mathbb{T}^2), \mathcal{A}^{\boxtimes \bullet})$$

chains on configuration space with coefficients in $\mathcal{A}$.

7.2.2.2 The trace element

The key new element at genus 1 is the *trace operation*. For $a \in \mathcal{A}$, define:

$$\text{Tr}(a) = \int_{S^1 \subset \mathbb{T}^2} \text{ev}^*(a) \in C_0^{(1)}(\mathcal{A})$$

where $\text{ev} : \mathbb{T}^2 \rightarrow X$ is the constant map to the base curve.

More explicitly, using the uniformization $\mathbb{T}^2 = \mathbb{C}/\mathbb{Z} \oplus \tau\mathbb{Z}$:

$$\text{Tr}(a) = \oint_{|z|=1} \rho_{\mathbb{T}^2}(a(z)) \frac{dz}{2\pi i z}$$

where $\rho_{\mathbb{T}^2}$ is the regularized insertion on the torus.

7.2.2.3 Explicit formula for central charge cocycle

For the Heisenberg algebra, consider:

$$c_1 = \text{Tr}(a \otimes a^*) - \kappa \cdot 1 \in C_1^{(1)}(\mathcal{A}) \otimes C_1^{(1)}(\mathcal{A})$$

THEOREM 7.2.2 (*Central charge cocycle*;). [Regime: curved-central (Convention 1.10.2).]

The element c_1 satisfies:

$$d^{(1)}c_1 = 0$$

and represents the central extension in $H_1^{(1)}(\mathcal{A})$.

The class $[c_1]$ is:

- Non-trivial: $[c_1] \neq 0$ in homology
- Universal: independent of the choice of cycle on $\mathbb{T}^2$
- Generates: all genus 1 central phenomena factor through $[c_1]$

Proof. The differential $d^{(1)}$ at genus 1 includes:

1. Standard bar differential (as at genus 0)
2. *New term:* Contraction around the S^1 cycle

Computing:

$$\begin{aligned} d^{(1)}[\text{Tr}(a \otimes a^*)] &= \text{Tr}[\mu(a \otimes a^*)] - \text{Tr}(a) \otimes \text{Tr}(a^*) \\ &= \text{Tr}[\kappa \cdot \mathbb{1}] - 0 \quad (\text{Tr}(a) = \text{Tr}(a^*) = 0 \text{ for non-vacuum modes}) \\ &= \kappa \cdot \mathbb{1} \quad (\text{normalized trace: } \text{Tr}(\mathbb{1}) = 1) \end{aligned}$$

Therefore: $d^{(1)}[\text{Tr}(a \otimes a^*) - \kappa \cdot \mathbb{1}] = 0$. □

7.2.3 FORMAL CALCULATIONS: DEGREE-BY-DEGREE ANALYSIS

7.2.3.1 Degree 0: the vacuum

$C_0^{(1)} = \mathbb{C} \cdot \mathbb{1}$, the vacuum state.

7.2.3.2 Degree 1: trace insertions

$$C_1^{(1)} = \text{span}\{\text{Tr}(a_n), \text{Tr}(a_n^*) \mid n \in \mathbb{Z}\}$$

The differential $d^{(1)} : C_1^{(1)} \rightarrow C_0^{(1)}$ maps:

$$\begin{aligned} d^{(1)}[\text{Tr}(a_n)] &= 0 \quad \text{for } n \neq 0 \\ d^{(1)}[\text{Tr}(a_0)] &= 0 \quad (\text{but } a_0 = 0 \text{ in Heisenberg}) \end{aligned}$$

Homology. $H_1^{(1)} = \text{span}\{[\text{Tr}(a_n)], [\text{Tr}(a_n^*)] \mid n \neq 0\}$

7.2.3.3 Degree 2: the central charge emerges

$$C_2^{(1)} = \text{span}\{\text{Tr}(a_m \otimes a_n^*), \text{Tr}(a_m \otimes a_n), \text{Tr}(a_m^* \otimes a_n^*)\}$$

The computation.

$$\begin{aligned} d^{(1)}[\text{Tr}(a_m \otimes a_n^*)] &= \text{Tr}[\text{OPE}(a_m, a_n^*)] \\ &= \text{Tr}\left[\sum_{k \geq 0} \binom{m}{k} a_{m+n+k}^* \cdot a_{-k} + \kappa m \delta_{m+n,0} \cdot \mathbb{1}\right] \\ &= \kappa m \delta_{m+n,0} \cdot \mathbb{1} \end{aligned}$$

Here we used $\text{Tr}(a_i^* \cdot a_j) = 0$ always (no tadpoles).

The modular characteristic κ appears only in the $m + n = 0$ term, corresponding to modes that go around the S^1 cycle exactly once: geometrically, κ measures the obstruction to extending the Heisenberg algebra to the loop algebra.

7.2.3.4 Degrees 3–5: modular corrections

At degree 3, we have triple traces:

$$\mathrm{Tr}(a_{m_1} \otimes a_{m_2} \otimes a_n^*)$$

The differential now includes pairwise OPE contractions (three terms) and tadpole corrections from κ (when indices sum to zero).

Degree 3 cocycle example:

$$c_3 = \mathrm{Tr}(a_1 \otimes a_1 \otimes a_{-2}^*) - \kappa \cdot \mathrm{Tr}(a_1) + (\text{boundary terms})$$

At degrees 4 and 5, we see:

- Multiple κ insertions
- Modular dependence on the torus parameter τ
- Connection to Eisenstein series $E_2(\tau)$ at weight 2

7.2.4 THE COBAR RESOLUTION: RECOVERING CENTRAL EXTENSIONS

The cobar construction $\Omega C_\bullet^{(1)}(\mathcal{A})$ recovers the centrally extended algebra $\widehat{\mathcal{A}}$.

THEOREM 7.2.3 (*Genus-1 cobar-bar duality*;). [Regime: curved-central, genus-1 (Convention 1.10.2).]

Let $\mathcal{A}$ be a vertex algebra with modular characteristic κ . Then:

$$H^0(\Omega C_\bullet^{(1)}(\mathcal{A})) \cong \widehat{\mathcal{A}}$$

where $\widehat{\mathcal{A}}$ is the universal central extension of $\mathcal{A}$.

The central extension is encoded by the genus-1 cocycle:

$$\omega_\kappa = \mathrm{Tr}(a \otimes a^*) - \kappa \cdot \mathbb{1}$$

Proof. The genus-1 bar complex $C_\bullet^{(1)}(\mathcal{A})$ is built on configuration spaces over the elliptic curve E_τ . We compute the cobar $\Omega C_\bullet^{(1)}$ and show its zeroth cohomology is the universal central extension.

Step 1: Genus-1 bar complex in low degrees. At degree 0, $C_0^{(1)} = \mathbb{C}$. At degree 1, $C_1^{(1)} = \Gamma(\overline{C}_2(E_\tau), \mathcal{A} \boxtimes \mathcal{A} \otimes \Omega_{\log}^1)$, where the logarithmic form is the elliptic propagator $\eta_{12}^{(1)} = d \log \theta_1(z_{12}|\tau)$. At degree 2, $C_2^{(1)}$ involves triple products with genus-1 logarithmic 2-forms.

Step 2: The genus-1 cocycle. The bar differential $d : C_1^{(1)} \rightarrow C_0^{(1)}$ maps

$$d(a \otimes b \cdot \eta_{12}^{(1)}) = \mathrm{Res}_{z_1=z_2} [a(z_1)b(z_2) \cdot \eta_{12}^{(1)}] + \int_{E_\tau} a \otimes b \cdot d\eta_{12}^{(1)}.$$

The first term is the genus-0 collision residue. The second term is new at genus-1: the propagator $\eta_{12}^{(1)} = d \log \theta_1(z_{12}|\tau)$ is a closed meromorphic 1-form on E_τ (away from poles), but its B -cycle monodromy is non-trivial: $\oint_B \eta_{12}^{(1)} = 2\pi i$. This monodromy defect, which we write formally as $\int_{E_\tau} \delta_B \eta_{12}^{(1)} = 2\pi i \omega_\tau$ (where ω_τ is the normalized holomorphic 1-form on E_τ), gives

$$\int_{E_\tau} a \otimes b \cdot 2\pi i \omega_\tau = 2\pi i \cdot \mathrm{Tr}(a \otimes b)$$

where $\text{Tr}(a \otimes b) = \oint a(z)b(z) dz$ is the trace pairing on $\mathcal{A}$.

Step 3: Cobar complex computation. The cobar $\Omega C_\bullet^{(1)}$ has generators dual to $C_1^{(1)}$ and differential encoded by the structure maps of the coalgebra $C_\bullet^{(1)}$. The zeroth cohomology $H^0(\Omega C_\bullet^{(1)})$ is the algebra generated by the dual generators modulo the relations imposed by d_Ω .

The genus-1 contribution to d_Ω produces the central extension relation: for generators J^a of $\mathcal{A}$,

$$[J^a, J^b]_{\widehat{\mathcal{A}}} = [J^a, J^b]_{\mathcal{A}} + \kappa \cdot \text{Tr}(J^a \otimes J^b) \cdot \mathbf{K}$$

where $\mathbf{K}$ is the central element and κ is the central charge. This is the relation defining the universal central extension $\widehat{\mathcal{A}}$.

Step 4: Universality. The resulting central extension is universal because any 2-cocycle $\omega : \mathcal{A} \otimes \mathcal{A} \rightarrow \mathbb{C}$ that defines a central extension of $\mathcal{A}$ factors through the genus-1 trace pairing. Indeed, the Hochschild 2-cocycle condition requires ω to be $\mathcal{A}$ -bilinear and invariant, which forces $\omega = c \cdot \text{Tr}$ for some constant c . The genus-1 construction produces exactly this with $c = \kappa$. $\square$

Remark 7.2.4 (Central extension as genus-1 component of Θ). The central extension cocycle $\omega_\kappa = \kappa \cdot \text{Tr}$ is exactly the genus-1 component θ_1 of the universal MC class (Theorem 13.21.80): $\theta_1 = \kappa(\mathcal{A}) \cdot \mu \otimes \lambda_1$, where $\mu = [-, -]$ is the Lie bracket and λ_1 is the Hodge class. The universality of the central extension is a shadow of the universality of $\Theta_{\mathcal{A}}$: there is only one direction for genus-1 deformations because $H_{\text{cyc}}^2(\mathfrak{g}, \mathfrak{g}) \cong \mathbb{C}$.

7.2.5 COMPARISON WITH PHYSICAL LITERATURE

Our construction recovers known results from physics:

- *Kac–Moody algebras:* For the affine vertex algebra $V_k(\mathfrak{g})$ at level k , the modular characteristic is $\kappa(V_k(\mathfrak{g})) = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee)$, recovering the Sugawara central charge. The Heisenberg algebra is a separate family with $\kappa(\mathcal{H}_k) = k$ (Census C1); it is *not* a specialization of the Kac–Moody formula (the abelian limit $\dim(\mathfrak{g}) = 1$ does not admit a dual Coxeter number).
- *Virasoro central charge:* For the Virasoro vertex algebra, the central charge c appears as $\text{Tr}(L_m \otimes L_n)$ with $m + n = 0$
- *W-algebras:* For W -algebras (following Arakawa), higher-weight central charges appear at genus 1 in traces of higher-weight operators

7.2.6 GENUS 1 SUMMARY

<i>Algebra</i>	Physics	Bar-Cobar
Central extension	One-loop correction	Genus 1 cocycle
Modular characteristic κ	Genus-1 curvature scalar	Trace coefficient
Level of Kac–Moody	UV divergence	$H_2^{(1)}$ class
Virasoro c	Conformal anomaly	$\text{Tr}(T \otimes T)$

Remark 7.2.5 (Functoriality). The entire construction is functorial: a morphism $\mathcal{A} \rightarrow \mathcal{B}$ of vertex algebras preserving central charge induces:

$$C_\bullet^{(1)}(\mathcal{A}) \rightarrow C_\bullet^{(1)}(\mathcal{B})$$

respecting the central extension cocycles. This is the Grothendieck perspective: genus 1 phenomena are determined by functoriality from genus 0 data plus the choice of torus.

7.2.7 EXTENSION THEORY: FROM GENUS 0 TO HIGHER GENUS

7.2.7.1 The obstruction complex

Not every genus 0 chiral algebra extends to higher genus. The obstructions live in specific cohomology groups:

THEOREM 7.2.6 (*Extension obstruction* [40];). Let $\mathcal{A}$ be a chiral algebra on $\mathbb{CP}^1$. The obstruction to extending $\mathcal{A}$ to genus g lies in:

$$\text{Obs}_g(\mathcal{A}) \in H^2(\overline{\mathcal{M}}_g, \mathcal{E}nd(\mathcal{A})_0)$$

where $\mathcal{E}nd(\mathcal{A})_0$ is the sheaf of traceless endomorphisms.

Proof. By the deformation theory of chiral algebras on families of curves (Theorem 13.12.6), there is a long exact sequence:

$$0 \rightarrow H^1(\Sigma_g, \mathcal{A}) \rightarrow \text{Ext}_{\Sigma_g}(\mathcal{A}) \rightarrow H^2(\mathcal{M}_g, \mathbb{C}) \rightarrow \text{Obs}_g(\mathcal{A}) \rightarrow 0$$

The obstruction lives in $H^2(\mathcal{M}_g, \mathcal{E}nd(\mathcal{A})_0)$ with local system coefficients. For specific classes:

1. For the matter-ghost BRST system, the obstruction vanishes when $c_{\text{matter}} = 26$ (cancellation with $c_{\text{ghost}} = -26$).
2. For a general chiral algebra $\mathcal{A}$, the obstruction depends on $[\omega_g] \in H^2(\mathcal{M}_g, Z(\mathcal{A}))$, where $Z(\mathcal{A})$ is the center.
3. Free theories (Heisenberg at any level, free fermions with spin structure) extend to all genera without central charge restrictions, as the curvature m_0 is central and the obstruction class is scalar (Proposition 7.1.11).

□

Example 7.2.7 (Free fermion extension). The free fermion extends to all genera with spin structure:

For genus 1: The extension depends on the choice of spin structure (periodic/antiperiodic boundary conditions):

$$\mathcal{F}_{E_\tau}^{\text{NS}} = \bigoplus_{n \in \mathbb{Z}} \mathcal{F}_n \quad (\text{Neveu-Schwarz})$$

$$\mathcal{F}_{E_\tau}^{\text{R}} = \bigoplus_{n \in \mathbb{Z} + 1/2} \mathcal{F}_n \quad (\text{Ramond})$$

The partition function encodes the obstruction:

$$Z_{\text{ferm}}(\tau) = \frac{\theta_3(0|\tau)}{\eta(\tau)} \quad (\text{NS sector})$$

7.2.7.2 The tower of extensions

THEOREM 7.2.8 (*Universal extension tower*;). There exists a tower of extensions:

$$\mathcal{A}_0 \rightarrow \mathcal{A}_1 \rightarrow \mathcal{A}_2 \rightarrow \cdots \rightarrow \mathcal{A}_\infty$$

where:

- $\mathcal{A}_0$: Original genus 0 algebra
- $\mathcal{A}_g$: Extension to genus $\leq g$
- $\mathcal{A}_\infty$: Universal extension to all genera

The connecting maps are given by:

$$\mathcal{A}_g \rightarrow \mathcal{A}_{g+1} : \quad a \mapsto a + \sum_{\gamma \in H_1(\Sigma_{g+1})} \oint_{\gamma} a \cdot [\gamma]$$

Proof. The tower is constructed from the genus filtration on the bar complex. By the modular operad decomposition (Theorem 15.12.26), $\bar{B}(\mathcal{A}) = \bigoplus_{g \geq 0} \bar{B}^{(g)}(\mathcal{A})$. Define $\mathcal{A}_g = \Omega(\bigoplus_{h \leq g} \bar{B}^{(h)}(\mathcal{A}))$: the cobar construction applied to the genus- $\leq g$ truncation. The inclusion $\bigoplus_{h \leq g} \bar{B}^{(h)} \hookrightarrow \bigoplus_{h \leq g+1} \bar{B}^{(h)}$ induces $\mathcal{A}_g \rightarrow \mathcal{A}_{g+1}$. The connecting map adds the genus- $(g+1)$ correction: the new bar complex component $\bar{B}^{(g+1)}$ involves integration over $\overline{\mathcal{M}}_{g+1,n}$, and the correction term $\sum_{\gamma} \oint_{\gamma} a \cdot [\gamma]$ arises from the new homology cycles $\gamma \in H_1(\Sigma_{g+1})$ not present at lower genus. The tower stabilizes for rational chiral algebras (finitely many modules, hence finite-dimensional conformal blocks at each genus) and converges to $\mathcal{A}_\infty = \Omega(\bar{B}(\mathcal{A}))$. $\square$

7.2.8 SPECTRAL SEQUENCE CONVERGENCE

THEOREM 7.2.9 (*Bar complex spectral sequence*;). There exists a spectral sequence:

$$E_2^{p,q} = H^p(\bar{C}_*(X), H^q(\mathcal{A}^{\boxtimes*})) \Rightarrow H^{p+q}(\bar{B}(\mathcal{A}))$$

which converges under the following conditions:

1. $\mathcal{A}$ is bounded below: $\mathcal{A}_i = 0$ for $i < i_0$
2. The configuration spaces have finite cohomological dimension
3. The chiral algebra has finite homological dimension

Proof. We filter the bar complex by *configuration degree* (= bar degree):

$$F_p \bar{B}(\mathcal{A}) = \bigoplus_{n \leq p} \bar{B}^n(\mathcal{A}), \quad p \geq 0,$$

and set $F_{-1} = 0$. The bar differential decomposes as $d = d_{\text{int}} + d_{\text{fact}}$, where d_{int} preserves configuration degree and d_{fact} raises it by one. Both respect the filtration, so $d(F_p) \subset F_{p+1}$ and the filtration is compatible with the differential.

Step 1 (associated graded and E_1 page). The successive quotients are

$$\mathrm{Gr}_p = F_p / F_{p-1} \cong \Omega^*(\overline{C}_{p+1}(X)) \otimes \mathcal{A}^{\boxtimes(p+1)},$$

and the induced differential on Gr_p is d_{int} (the internal differential on each factor). The E_1 page is therefore:

$$E_1^{p,q} = H^q(\mathrm{Gr}_p) = H^q(\Omega^*(\overline{C}_{p+1}(X)) \otimes \mathcal{A}^{\boxtimes(p+1)}).$$

The d_1 differential $d_1: E_1^{p,q} \rightarrow E_1^{p+1,q}$ is the map induced by d_{fact} on the E_1 page. Taking cohomology yields the E_2 page:

$$E_2^{p,q} = H^p(\overline{C}_*(X), H^q(\mathcal{A}^{\boxtimes*})).$$

Step 2 (bounded-below and exhaustive). The filtration satisfies two structural properties:

1. *Bounded below:* $F_{-1} = 0$, so configuration degree is ≥ 0 . In particular, $E_r^{p,q} = 0$ for $p < 0$ at every page $r \geq 0$.
2. *Exhaustive:* Every element of $\bar{\mathbf{B}}(\mathcal{A})$ has finite bar degree (it is a finite linear combination of terms, each lying in some $\bar{\mathbf{B}}^n(\mathcal{A})$), so $\bar{\mathbf{B}}(\mathcal{A}) = \bigcup_{p \geq 0} F_p \bar{\mathbf{B}}(\mathcal{A})$.

The bounded-below hypothesis $\mathcal{A}_i = 0$ for $i < i_0$ ensures that $E_1^{p,q} = 0$ for $q < (p+1) \cdot i_0$, so the spectral sequence is concentrated in a half-plane. For each fixed total degree $n = p + q$, only finitely many pairs (p, q) with $p \geq 0$ and $q \geq (p+1) \cdot i_0$ satisfy $p + q = n$; hence only finitely many terms contribute in each total degree.

Step 3 (convergence). We verify the hypotheses of the classical convergence theorem for filtered complexes ([395], Theorem 5.5.1; see also Boardman [56], Theorem 7.1):

- (a) *Bounded below:* $F_{-1} = 0$, i.e., the filtration starts at $p = 0$. Therefore $E_r^{p,q} = 0$ for all $p < 0$ and all $r \geq 0$.
- (b) *Exhaustive:* $\bar{\mathbf{B}}(\mathcal{A}) = \bigcup_{p \geq 0} F_p \bar{\mathbf{B}}(\mathcal{A})$, established in Step 2.

The bounded-below condition implies that for each fixed bidegree (p, q) , the incoming differentials $d_r: E_r^{p-r, q+r-1} \rightarrow E_r^{p,q}$ eventually have source in the vanishing region $p-r < 0$, so $\ker(d_r)$ stabilizes at $E_r^{p,q}$ for $r > p$. Similarly, the outgoing differentials $d_r: E_r^{p,q} \rightarrow E_r^{p+r, q-r+1}$ stabilize because the half-plane concentration from Step 2 forces the target to vanish for r sufficiently large. Therefore $E_\infty^{p,q} = E_{p+1}^{p,q}$ exists for every (p, q) , and the convergence

$$E_\infty^{p,q} \cong \mathrm{Gr}_p H^{p+q}(\bar{\mathbf{B}}(\mathcal{A}))$$

holds: the E_∞ page computes the associated graded of the induced filtration on cohomology. The finite cohomological dimension of configuration spaces ensures $E_2^{p,q} = 0$ for p exceeding $\dim_{\mathrm{coh}}(\overline{C}_*(X))$ in each total degree. This makes the filtration on $H^n(\bar{\mathbf{B}}(\mathcal{A}))$ finite in each degree, so the convergence is *strong*: there is no $\varprojlim^1$ obstruction to recovering H^n from $\mathrm{Gr}_\bullet H^n$, and the short exact sequences $0 \rightarrow F_{p-1} H^n \rightarrow F_p H^n \rightarrow E_\infty^{p, n-p} \rightarrow 0$ split (by induction on the finite filtration length).

Step 4 (Koszul degeneration). On the Koszul locus (Definition 11.1.15), the E_2 page is concentrated: $H^q(\mathcal{A}^{\boxtimes(p+1)})$ is nonzero only for $q = p$ (diagonal concentration from bar cohomology purity). This forces all higher differentials $d_r = 0$ for $r \geq 2$ by bidegree considerations, so the spectral sequence degenerates at E_2 (Corollary 7.2.10). $\square$

COROLLARY 7.2.10 (*Degeneration [41];*). If $\mathcal{A}$ is Koszul (Definition 11.1.15), the spectral sequence degenerates at E_2 :

$$E_2^{p,q} = E_\infty^{p,q}$$

This gives:

$$H^n(\bar{\mathbf{B}}(\mathcal{A})) = \bigoplus_{p+q=n} H^p(\bar{C}_*(X)) \otimes H^q(\mathcal{A}^\dagger)$$

where $\mathcal{A}^\dagger$ is the Koszul dual.

7.2.9 ESSENTIAL IMAGE OF THE BAR FUNCTOR

THEOREM 7.2.11 (*Complete essential image characterization;*). The essential image of the bar functor

$$\bar{\mathbf{B}}: \text{ChiralAlg}_X \rightarrow \text{Coalg}_{\text{conilp}}^{\text{ch}}$$

consists precisely of those conilpotent chiral coalgebras C satisfying:

1. *Logarithmic structure*: The coderivation $\delta : C \rightarrow C^{\otimes 2}$ has logarithmic singularities
2. *Support condition*: $\text{supp}(\delta) \subset \bigcup_{i < j} D_{ij}$
3. *Residue formula*: At D_{ij} :

$$\text{Res}_{D_{ij}}[\delta(c)] = \mu_{ij}^* \otimes c$$

where μ_{ij}^* is dual to chiral multiplication

4. *Arnold relations*: The logarithmic coefficients satisfy the Arnold–Orlik–Solomon relations

Proof. Necessity: Let $C = \bar{\mathbf{B}}(\mathcal{A})$ for some chiral algebra $\mathcal{A}$.

(1) The coderivation is:

$$\delta = (d_{\text{fact}})^* : \bar{\mathbf{B}}^n(\mathcal{A}) \rightarrow \bar{\mathbf{B}}^{n+1}(\mathcal{A})$$

This is given by residues at collision divisors, hence has logarithmic singularities.

(2) The support is exactly $\bigcup_{i < j} D_{ij}$ by construction.

(3) The residue formula follows from the definition of d_{fact} .

(4) The Arnold relations are satisfied by logarithmic forms on configuration spaces.

Sufficiency: Given C satisfying (1)–(4), we reconstruct $\mathcal{A}$.

Define $\mathcal{A} = \Omega^{\text{ch}}(C)$ (cobar construction). We need to show:

$$C \cong \bar{\mathbf{B}}(\Omega^{\text{ch}}(C))$$

The isomorphism is constructed by reading each axiom as a construction step: logarithmic structure determines integration kernels, the support condition ensures locality, the residue formula recovers the OPE, and the Arnold relations ensure associativity.

If C satisfies (1)–(4), then $\Omega^{\text{ch}}(C)$ is a chiral algebra with:

$$\phi_i(z)\phi_j(w) = \text{Res}_{D_{ij}}[\delta(\phi_i \otimes \phi_j)]$$

The reconstruction map:

$$\Phi : C \rightarrow \bar{\mathbf{B}}(\Omega^{\text{ch}}(C))$$

is given by:

$$\Phi(c) = \int_{\overline{C}_n(X)} c \wedge K_n$$

where K_n is the universal kernel determined by the logarithmic structure.

This is an isomorphism by:

1. Injectivity: The logarithmic structure uniquely determines c
2. Surjectivity: Every bar element arises from some $c \in C$
3. Preserves coalgebra structure: By compatibility of residues

□

COROLLARY 7.2.12 (*Recognition principle*;). A chiral coalgebra C is in the essential image of $\bar{\mathbf{B}}$ if and only if its cobar $\Omega^{\text{ch}}(C)$ is a chiral algebra (not just A_∞).

Proof. The bar-cobar adjunction (Theorem 7.0.51) provides unit and counit maps for any augmented chiral algebra and any conilpotent coalgebra. On the Koszul locus (Definition 11.1.15), the counit $\bar{B}(\Omega(C)) \rightarrow C$ is a quasi-isomorphism (Theorem 11.1.84), which identifies C as the bar of its cobar. This holds precisely when $\Omega(C)$ has strict (not homotopy) chiral algebra structure. □

7.2.10 BRST COHOMOLOGY AND STRING THEORY CONNECTION

Conjecture 7.2.13 (*Heuristic BRST/bar comparison*;). There should exist a comparison map from an appropriate BRST complex of the corresponding string theory to the geometric bar complex,

$$\Phi_{\text{BRST}} : (C_{\text{BRST}}^\bullet(\mathcal{A}), Q_{\text{BRST}}) \longrightarrow (\bar{\mathbf{B}}(\mathcal{A}), d_{\text{bar}}),$$

whose cohomological effect models the BRST/bar dictionary after choosing the correct matter–ghost system and anomaly prescription. On the anomaly-free genus-0 total matter+ghost locus, this comparison is realized algebraically by Theorem R.3.1; beyond that setting it remains heuristic.

The expected correspondences are:

$$Q_{\text{BRST}} \leftrightarrow d_{\text{bar}} = d_{\text{int}} + d_{\text{fact}} + d_{\text{config}}$$

$$\text{Ghost number} \leftrightarrow \text{Homological degree}$$

$$\text{BRST classes} \leftrightarrow \text{Bar cohomology classes}$$

Remark 7.2.14 (*Physical motivation: string field theory*). The correspondence is heuristically motivated by the following parallel:

Step 1: String Field Theory. The string field Ψ satisfies the BRST equation:

$$Q_{\text{BRST}} \Psi + \Psi \star \Psi = 0$$

where $\star$ is the string product.

Step 2: Chiral Algebra Correspondence. The string field decomposes as:

$$\Psi = \sum_{n=0}^{\infty} \Psi^{(n)} \otimes \omega^{(n)}$$

where $\Psi^{(n)} \in \mathcal{A}^{\otimes n}$ and $\omega^{(n)} \in \Omega^n(\bar{C}_n(X))$.

Step 3: BRST Action. The BRST operator acts as:

$$\begin{aligned} Q_{\text{BRST}}(\Psi^{(n)} \otimes \omega^{(n)}) &= \sum_{i=1}^n Q_i(\Psi^{(n)}) \otimes \omega^{(n)} \\ &\quad + \sum_{i < j} \mu_{ij}(\Psi^{(n)}) \otimes \text{Res}_{D_{ij}}[\omega^{(n)}] \\ &\quad + \Psi^{(n)} \otimes d_{\text{config}}\omega^{(n)} \end{aligned}$$

This heuristically matches the bar differential $d = d_{\text{int}} + d_{\text{fact}} + d_{\text{config}}$.

Step 4: Cohomology. BRST classes are represented by BRST-closed states modulo exact states, and the conjectural comparison predicts

$$H_{\text{BRST}}^* = \text{Ker}(Q_{\text{BRST}})/\text{Im}(Q_{\text{BRST}}) \cong H^*(\bar{\mathbf{B}}(\mathcal{A})).$$

Example 7.2.15 (Bosonic string theory). For the bosonic string with central charge $c = 26$:

Ghost System. The (b, c) ghost system has OPE:

$$b(z)c(w) \sim \frac{1}{z-w}$$

BRST charge.

$$Q_{\text{BRST}} = \oint dz \left[c(z)T(z) + \frac{1}{2} : c(z)\partial c(z)b(z) : \right]$$

Bar complex. The string field theory complex is classified by the geometric bar complex:

$$\bar{\mathbf{B}}(\text{Vir}_{26} \otimes \text{ghosts}) \cong \text{String field theory}$$

Cohomology. Physical states correspond to bar cohomology classes of weight $(1, 1)$.

Example 7.2.16 (Superstring theory). For the superstring with central charge $c = 15$:

Superghost system. The (β, γ) system has OPE:

$$\beta(z)\gamma(w) \sim \frac{1}{z-w}$$

BRST charge.

$$Q_{\text{BRST}} = \oint dz \left[\gamma(z)G(z) + \frac{1}{2} : \gamma(z)\partial\gamma(z)\beta(z) : \right]$$

Bar complex. The geometric bar complex includes both NS and R sectors:

$$\bar{\mathbf{B}}(\mathcal{A}_{\text{NS}} \oplus \mathcal{A}_{\text{R}}) \cong \text{Superstring field theory}$$

GSO Projection. The bar complex automatically implements the GSO projection through the fermionic constraints.

Conjecture 7.2.17 (Anomaly cancellation for matter-ghost systems;). For the *coupled matter-ghost BRST system* in string theory, anomaly cancellation admits a geometric interpretation via the bar complex:

1. *Central Charge Constraint:* The BRST differential of the combined matter-ghost system satisfies $d_{\text{BRST}}^2 = 0$ if and only if $c_{\text{matter}} = 26$ (bosonic) or $c_{\text{matter}} = 15$ (superstring).
2. *Modular Invariance:* The bar complex of the total system transforms covariantly under $\text{SL}_2(\mathbb{Z})$ if and only if the anomaly polynomial vanishes.
3. *Geometric interpretation.* The anomaly corresponds to the obstruction to extending the bar complex of the total system to higher genus.

Remark 7.2.18 (Individual vs. total nilpotence). This is *not* in contradiction with the fact that the bar differential $d_{\text{bar}}^2 = 0$ for any individual chiral algebra (Theorem 6.1.21). The bar differential of each chiral algebra squares to zero by the Arnold relations. The BRST anomaly arises when one couples a matter chiral algebra to a ghost system and requires the *total* BRST charge to be nilpotent; this imposes $c_{\text{total}} = c_{\text{matter}} + c_{\text{ghost}} = 0$.

Remark 7.2.19 (Physical motivation: configuration space geometry). The anomaly arises from the failure of the *total BRST differential* (not the individual bar differential) to square to zero on the compactified configuration space.

Step 1: Individual Nilpotency. On any chiral algebra, the bar differential satisfies $d_{\text{bar}}^2 = 0$ by Theorem 6.1.21.

Step 2: BRST Coupling. The total BRST differential $d_{\text{BRST}} = d_{\text{matter}} + d_{\text{ghost}} + d_{\text{coupling}}$ includes a coupling term from the matter-ghost interaction. The cross-terms yield:

$$d_{\text{BRST}}^2 = \frac{c_{\text{matter}} + c_{\text{ghost}}}{24} \cdot \chi(\overline{C}_n(X))$$

where χ is the Euler characteristic.

Step 3: Cancellation. The anomaly vanishes precisely when $c_{\text{matter}} + c_{\text{ghost}} = 0$. Since $c_{\text{ghost}} = -26$ (bosonic) or $c_{\text{ghost}} = -15$ (superstring), this forces $c_{\text{matter}} = 26$ or $c_{\text{matter}} = 15$ respectively.

Remark 7.2.20. The geometric bar complex connects BRST cohomology (string theory), OPEs as residues on configuration spaces (conformal field theory), geometric constraints on the central charge (anomaly cancellation), and compatibility with genus-one geometry (modular invariance).

7.3 RELATIONSHIP BETWEEN BAR-COBAR AND KOSZUL DUALITY

For a chiral Koszul pair $(\mathcal{A}_1, \mathcal{A}_2)$, the bar of one is the Koszul dual coalgebra of the other, and Verdier duality on $\text{Ran}(X)$ provides the equivalence. The Koszul property (diagonal Ext vanishing in the (bar degree, weight) bigrading) is the condition under which this equivalence descends from the coderived category to the ordinary derived category.

7.3.1 PRECISE FORMULATION OF THE RELATIONSHIP

Remark 7.3.1 (Criteria for chiral Koszul pairs: updated recollection). Recall from Definition 11.1.15 that a chiral Koszul pair is specified by antecedent recognition data: a chiral twisting datum, a Koszul twisting morphism, compatible filtrations, and Verdier-compatible dual coalgebras. The bar/cobar quasi-isomorphisms are then proved consequences (Theorem 11.1.9 and Theorem 11.1.84), not part of the definition.

Remark 7.3.2 (Bar-cobar vs. Koszul: the fundamental distinction). Always true (for any augmented chiral algebra $\mathcal{A}$):

- $\bar{B} : \mathcal{A} \rightarrow \bar{B}(\mathcal{A})$ exists and $d^2 = 0$ (Theorem 6.1.21)
- $\Omega : \bar{B}(\mathcal{A}) \rightarrow \Omega(\bar{B}(\mathcal{A}))$ exists and $d^2 = 0$ (Theorem 7.0.21)

These are *constructions*: they work for any augmented algebra.

On the Koszul locus only (chiral Koszul pairs, Definition 11.1.15):

- The counit $\Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ is a quasi-isomorphism (Theorem 11.1.84).
- $\bar{B}(\mathcal{A}_1) \simeq (\mathcal{A}_2^!)^\vee$ as chiral coalgebras (equivalently $\bar{B}(\mathcal{A}_1)^\vee \simeq \mathcal{A}_2^!$ as chiral algebras) (Theorem 11.1.25). The Koszul dual algebra $\mathcal{A}_2^!$ and the Koszul dual coalgebra $\bar{B}(\mathcal{A}_1)$ live in different categories and are related by linear duality; conflating them violates the distinction of Remark 7.0.1.

Off the Koszul locus, $\Omega(\bar{B}(\mathcal{A}))$ still exists but the counit need not be a quasi-isomorphism; the bar-cobar object represents $\mathcal{A}$ in the completed coderived category $D^{\text{co}}(-\text{CoMod})$ of Positselski (Theorem 13.18.4(b)).

THEOREM 7.3.3 (Necessary conditions for chiral Koszul duality [167];). For $(\mathcal{A}_1, \mathcal{A}_2)$ to form a chiral Koszul pair, the following must hold:

1. Both algebras are finitely generated over $\mathcal{D}_X$
2. The bar complexes have finite-dimensional cohomology in each degree
3. There exists a non-degenerate pairing $\langle -, - \rangle : \bar{B}(\mathcal{A}_1) \otimes \bar{B}(\mathcal{A}_2) \rightarrow \omega_X$

7.3.2 DIAGRAM OF RELATIONSHIPS

The relationship between bar, cobar, and Koszul duality can be summarized. The diagram below respects the category distinction of Remark 7.0.1: the bar functor lands in coalgebras, the Koszul dual lives in algebras, and linear duality $(-)^\vee$ mediates between them.

$$\begin{array}{ccccccc}
 \mathcal{A}_1 & \xrightarrow{\bar{B}} & \bar{B}(\mathcal{A}_1) & \xrightarrow{(-)^\vee} & \bar{B}(\mathcal{A}_1)^\vee & \xrightarrow{\simeq} & \mathcal{A}_2^! \\
 \uparrow \text{duality} & & & \searrow \Omega & \uparrow \Omega & & \\
 \mathcal{A}_2 & \xrightarrow{\bar{B}} & \bar{B}(\mathcal{A}_2) & \xrightarrow{(-)^\vee} & \bar{B}(\mathcal{A}_2)^\vee & \xrightarrow{\simeq} & \mathcal{A}_1^!
 \end{array}$$

Reading the diagram.

- Horizontal arrow $\bar{B}$: always exists; sends chiral algebra to factorization coalgebra.
- Horizontal arrow $(-)^\vee$: linear duality (coalgebra to algebra).
- Horizontal equivalence $\simeq$: the Koszul condition identifies $\bar{B}(\mathcal{A}_i)^\vee$ with the Koszul dual algebra $\mathcal{A}_{3-i}^!$. The left and right columns live in different categories (algebras vs. coalgebras); conflating $\bar{B}(\mathcal{A}_1)$ with $\mathcal{A}_2^!$ violates the distinction of Remark 7.0.1.
- Vertical double arrow: Koszul duality as an operation on algebras (exists only for Koszul pairs).
- Diagonal arrow Ω : cobar reconstruction; the inversion $\Omega(\bar{B}(\mathcal{A}_i)) \simeq \mathcal{A}_i$ (Corollary 7.0.37). This is the round-trip, not a map to $\mathcal{A}_{3-i}^!$.

7.3.3 EXAMPLES ILLUSTRATING THE DISTINCTION

Example 7.3.4 (Heisenberg: level shift required). Bar-cobar inversion gives $\Omega(\bar{B}(\mathcal{H}_k)) \simeq \mathcal{H}_k$ automatically, while Koszul duality yields $\mathcal{H}_k^! \simeq \text{Sym}^{\text{ch}}(V^*)$ with curvature $m_0 = -k \omega$ (cf. §E.4). These are distinct statements: bar-cobar inverts $\mathcal{H}_k$, but the Koszul dual is a different type of algebra (commutative vs. Lie). See Part II.

7.4 CURVED KOSZUL DUALITY AND QUANTUM OBSTRUCTIONS

THEOREM 7.4.1 (*Quantum deformation-obstruction complementarity*;). [Regime: curved-central on the Koszul locus; all genera (Convention 1.10.2).]

For a chiral algebra $\mathcal{A}$ on a curve X , the genus- g quantum corrections satisfy:

$$Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!) \simeq H^*(\mathcal{M}_g, Z(\mathcal{A}))$$

where:

- $Q_g(\mathcal{A})$ = space of genus- g obstructions to Koszul duality
- $Q_g(\mathcal{A}^!)$ = space of genus- g deformations of the dual algebra
- $Z(\mathcal{A})$ = center of $\mathcal{A}$
- $H^*(\mathcal{M}_g, Z(\mathcal{A}))$ = cohomology of moduli space with coefficients in center

Proof (outline; full proof in §13.15). The complete proof, synthesizing five lemmas via the Verdier involution σ and the genus spectral sequence, is given in Theorem 13.15.14.

Foundation: Curved A_∞ Structures

Following Gui–Li–Zeng [213], a curved chiral algebra $\mathcal{A}$ has:

1. Multiplication: $\mu_2 : \mathcal{A}^{\otimes 2} \rightarrow \mathcal{A}$
2. Higher operations: $\mu_n : \mathcal{A}^{\otimes n} \rightarrow \mathcal{A}$ for $n \geq 3$
3. Curvature: $\mu_0 : \mathbb{C} \rightarrow \mathcal{A}$

satisfying the curved A_∞ relations:

$$\sum_{\substack{r+s+t=n \\ r,t \geq 0, s \geq 0}} (-1)^{rs+t} \mu_{r+1+t}(\text{id}^{\otimes r} \otimes \mu_s \otimes \text{id}^{\otimes t}) = 0$$

For $n = 0$: $\mu_1(\mu_0) = 0$ (the curvature element is a μ_1 -cycle).

For $n = 1$: $\mu_1^2 = [\mu_0, -]_{\mu_2}$, so μ_1 is a differential only modulo curvature.

Step 1: Genus Stratification of Obstructions

Notation. The differential d_{fib} denotes the *fiberwise* bar differential at genus g : the collision-residue differential on a fixed curve Σ_g . It is generically *curved* ($d_{\text{fib}}^2 \neq 0$). The total corrected differential D_g , which incorporates period corrections to restore strict nilpotence ($D_g^2 = 0$), is introduced in Convention 13.0.2.

The failure of the fiberwise bar differential to square to zero is measured by:

$$d_{\text{fib}}^2 : \bar{B}_g^n(\mathcal{A}) \rightarrow \bar{B}_g^{n+2}(\mathcal{A})$$

LEMMA 7.4.2 (*Obstruction operator [350];*). The composition d_{fib}^2 is the chain-level curvature operator

$$d_{\text{fib}}^2 = m_0^{(g)} * (-)$$

with $m_0^{(g)} \in Z(\mathcal{A})$. It vanishes if and only if the genus- g fiberwise bar differential is square-zero on the nose.

Proof. In the CDG framework (Definition 8.5.2), the genus- g bar complex carries curvature $h = m_0^{(g)}$ satisfying $d_{\text{fib}}^2 = h * (-)$. Explicitly, $m_0^{(g)}$ is the genus- g contribution to the bar curvature, constructed as a fiber integral:

$$m_0^{(g)} = \int_{\Sigma_g} \omega_g \in \bar{B}_g^0(\mathcal{A}),$$

where ω_g is the volume form of the genus- g propagator (cf. Definition 13.7.1).

Centrality. The element $m_0^{(g)}$ lies in the center $Z(\mathcal{A})$ by the following chain-level argument. For any generator $a \in \mathcal{A}$, the OPE $m_0^{(g)}(n)a$ for $n \geq 0$ vanishes because $m_0^{(g)}$ has conformal weight 0 (it is a scalar on each conformal-weight space), and the Borchers identity forces the iterated residue $[\text{Res}_{D_{ij}}, \text{Res}_{D_{kl}}]$ to act trivially on generators when $D_{ij} \cap D_{kl} = \emptyset$ (factorization axiom), while nested collisions contribute only scalar multiples (OPE associativity).

Cocycle condition. The curved A_∞ relation at $n = 0$ (Definition 8.1.1) gives $\mu_1(m_0^{(g)}) = 0$, so $m_0^{(g)}$ is closed. Hence $d_{\text{fib}}^2 = m_0^{(g)} * (-)$ is the chain-level obstruction to lifting the genus-0 square-zero differential (where $m_0^{(0)} = 0$) to genus g . It vanishes exactly when the fiberwise genus- g differential is already square-zero. Otherwise one must pass either to the strict flat comparison differential or to the coderived framework; ordinary cohomology of the curved fiber complex is not the correct invariant. $\square$

Step 2: Moduli space interpretation.

The genus- g corrections are parametrized by $H^*(\mathcal{M}_g, \mathcal{Z}(\mathcal{A}))$ (cohomology with coefficients in the center). The connection comes from period integrals:

LEMMA 7.4.3 (*Period integral formula [159];*). For $\omega \in \Omega^1(\bar{\mathcal{M}}_g)$, the genus- g obstruction is:

$$\text{Obs}_g(\omega) = \int_{C_g} \omega \wedge \left(\sum_{\text{cycles}} \text{Res}_{D_i} \wedge \text{Res}_{D_j} \right)$$

where the integral is over the universal curve $C_g \rightarrow \bar{\mathcal{M}}_g$.

Proof. The fiberwise bar differential at genus g is $d_{\text{fib}} = \sum_{D \subset \partial \bar{C}_n(\Sigma_g)} \text{Res}_D$, constructed from logarithmic propagators $\eta_{ij} = d \log(z_i - z_j)$ on configuration spaces (Definition 6.1.15). We compute d_{fib}^2 at the cochain level.

Step 1: Double residue as fiber 2-form. For $\phi \in \bar{B}_g^n(\mathcal{A})$, the composition $d_{\text{fib}}^2(\phi)$ is a sum of double residues $\text{Res}_{D_i} \circ \text{Res}_{D_j}$ over pairs of boundary divisors. When $D_i \cap D_j = \emptyset$ (disjoint collisions), the residues commute and cancel pairwise (cf. the anticommutator $\{d_{\text{fact}}, d_{\text{config}}\} = 0$ of Theorem 14.2.2). The surviving terms come from nested collisions $D_i \subset D_j$, producing a 2-form kernel $K_{ij}^{(g)}$ on $\bar{C}_n(\Sigma_g)$. By Lemma 7.4.2, this kernel takes values in $Z(\mathcal{A})$.

Step 2: Fiber integration. Consider the universal family $\pi: \overline{C}_n(C_g) \rightarrow \overline{M}_g$. The pushforward $\pi_*(K_{ij}^{(g)})$ is a section of $\mathcal{Z}(\mathcal{A})$ on $\overline{M}_g$, the fiber integral of the double-residue kernel. Evaluating against $\omega \in \Omega^1(\overline{M}_g)$ gives:

$$\text{Obs}_g(\omega) = \int_{\overline{M}_g} \omega \wedge \pi_* \left(\sum_{i < j} K_{ij}^{(g)} \right) = \int_{C_g} \omega \wedge \sum_{\text{cycles}} \text{Res}_{D_i} \wedge \text{Res}_{D_j},$$

where the second equality is the projection formula.

Step 3: Boundary vanishing. The boundary contributions from $\partial \overline{C}_n(\Sigma_g)$ vanish fiberwise: on each fiber $\overline{C}_n(\Sigma_g)$, the Arnold relations (Theorem 6.1.31) ensure $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$, which forces the boundary integral to cancel term by term. The detailed bookkeeping across all boundary strata is carried out in the proof of Theorem 13.15.14, Steps 3–4. $\square$

Step 3: Dual Deformations

Now consider the Koszul dual $\mathcal{A}^!$. Its genus- g structure is given by the cobar construction:

$$\Omega_g(\mathcal{A}^!) = \text{Sym}(\mathcal{A}^![1])$$

with differential induced from the coproduct $\Delta: \mathcal{A}^! \rightarrow \mathcal{A}^! \otimes \mathcal{A}^!$.

LEMMA 7.4.4 (*Deformation space*;). The genus- g deformations of $\mathcal{A}^!$ are parametrized by a summand of the cohomology with coefficients in the center:

$$\text{Def}_g(\mathcal{A}^!) \hookrightarrow H^*(\overline{M}_g, \mathcal{Z}(\mathcal{A}))$$

Proof. A genus- g deformation of $\mathcal{A}^!$ is a flat family $\tilde{\mathcal{A}}^! \rightarrow \overline{M}_g$ with fiber at a basepoint equal to $\mathcal{A}^!$. Infinitesimally, such deformations are classified by $H^1(\overline{M}_g, \underline{\text{End}}(\mathcal{A}^!))$, where $\underline{\text{End}}(\mathcal{A}^!)$ is the local system of endomorphisms.

Chain-level identification. By the bar-cobar adjunction (Proposition 7.0.38), the endomorphism complex of $\mathcal{A}^!$ is quasi-isomorphic to the CDG Hom-complex (Proposition 8.5.17):

$$\underline{\text{End}}(\mathcal{A}^!) \simeq \underline{\text{Hom}}_C^{\text{ch}}(\mathcal{A}^!, \mathcal{A}^!).$$

The degree-0 cohomology of this complex is $HH^0(\mathcal{A}^!) = Z(\mathcal{A}^!)$. By Koszul duality (Theorem 11.3.7), the center local system satisfies $Z(\mathcal{A}^!) \cong Z(\mathcal{A})$ (the bar-cobar involution preserves centers). Hence:

$$\text{Def}_g(\mathcal{A}^!) = H^1(\overline{M}_g, Z(\mathcal{A}^!)) \hookrightarrow H^*(\overline{M}_g, Z(\mathcal{A})).$$

(Note: One must use the local system $Z(\mathcal{A})$, not the trivial local system. By Harer's theorem, $H^1(M_g, \mathbb{Q}) = 0$ for $g \geq 2$, so the deformation space would be trivially zero with trivial coefficients.) $\square$

Step 4: Perfect Pairing

LEMMA 7.4.5 (*Obstruction-deformation pairing*;). There is a perfect pairing:

$$\langle -, - \rangle: \mathcal{Q}_g(\mathcal{A}) \otimes \mathcal{Q}_g(\mathcal{A}^!) \rightarrow H^{3g-3}(\overline{M}_g, \mathbb{C})$$

given by the trace:

$$\langle \text{Obs}, \text{Def} \rangle = \text{Tr}(\text{Obs} \circ \text{Def}).$$

Proof. Step 1: Cochain-level pairing. At the cochain level, the Verdier duality involution σ on the center local system $\mathcal{Z}(\mathcal{A})$ (Theorem 7.0.36) induces an involution σ^* on $C^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$. Define the pairing on cochains by:

$$\langle \alpha, \beta \rangle_\sigma := \int_{\overline{\mathcal{M}}_g} \text{Tr}_{\mathcal{Z}(\mathcal{A})}(\alpha \wedge \sigma(\beta)),$$

where $\text{Tr}_{\mathcal{Z}(\mathcal{A})}$ is the trace on the center. This is well-defined because σ is an isometry for the Killing form on $\mathcal{Z}(\mathcal{A})$ and the integral converges on the compact orbifold $\overline{\mathcal{M}}_g$.

Step 2: Eigenspace decomposition. By Theorem 13.15.14(ii), the Verdier involution satisfies $\sigma^2 = \text{id}$, so $H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$ decomposes into ± 1 -eigenspaces: $\mathcal{Q}_g(\mathcal{A}) = \ker(\sigma - \text{id})$ and $\mathcal{Q}_g(\mathcal{A}^!) = \ker(\sigma + \text{id})$. The pairing $\langle -, - \rangle_\sigma$ restricts to zero on each eigenspace (since $\sigma(\beta) = \pm \beta$ and the antisymmetry $\langle \alpha, \sigma\beta \rangle = -\langle \sigma\alpha, \beta \rangle$ forces vanishing on equal eigenvalues).

Step 3: Non-degeneracy. On the cross-terms $\mathcal{Q}_g(\mathcal{A}) \otimes \mathcal{Q}_g(\mathcal{A}^!)$, the pairing reduces to Serre duality on $\overline{\mathcal{M}}_g$ with coefficients in $\mathcal{Z}(\mathcal{A})$. Serre duality is non-degenerate on the compact orbifold $\overline{\mathcal{M}}_g$, so the pairing is perfect. $\square$

Step 5: Center Cohomology

LEMMA 7.4.6 (*Center as obstruction-deformation space*;). The direct sum $\mathcal{Q}_g(\mathcal{A}) \oplus \mathcal{Q}_g(\mathcal{A}^!)$ naturally identifies with:

$$H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$$

Proof. The Verdier involution σ on the center local system $\mathcal{Z}(\mathcal{A})$ is an involution ($\sigma^2 = \text{id}$) that acts on cohomology. Since we work over $\mathbb{C}$, the eigenvalues of σ^* on $H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$ are ± 1 , giving a direct sum decomposition:

$$H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A})) = \ker(\sigma^* - \text{id}) \oplus \ker(\sigma^* + \text{id}).$$

It remains to identify the two summands.

The +1-eigenspace is $\mathcal{Q}_g(\mathcal{A})$. By Lemma 7.4.2, the chain-level obstruction is governed by the central coefficient $m_0^{(g)}$. Its flat-side comparison class lies in the σ -invariant part of $H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$, because $\sigma(m_0^{(g)}) = m_0^{(g)}$ (the curvature is Verdier-self-dual: it is constructed from the volume form ω_g , which is a canonical section of K_{Σ_g} , and Verdier duality acts as the identity on canonical sections). The full +1-eigenspace is generated by such obstruction classes as g varies, giving $\mathcal{Q}_g(\mathcal{A}) = \ker(\sigma^* - \text{id})$.

The -1-eigenspace is $\mathcal{Q}_g(\mathcal{A}^!)$. By Lemma 7.4.4, $\text{Def}_g(\mathcal{A}^!)$ embeds in $H^*(\overline{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$. Since Koszul duality negates the Verdier involution ($\sigma_{\mathcal{A}^!} = -\sigma_{\mathcal{A}}$ on centers, by Theorem 7.0.36), deformation classes lie in the -1-eigenspace:

$$\mathcal{Q}_g(\mathcal{A}^!) = \ker(\sigma^* + \text{id}).$$

Exhaustion. Since $\ker(\sigma^* - \text{id}) \oplus \ker(\sigma^* + \text{id})$ is the full space (over $\mathbb{C}$, any involution is diagonalizable), the decomposition is exhaustive. $\square$

Step 6: Conclusion

Combining Lemmas 7.4.2, 7.4.3, 7.4.4, 7.4.5, and 7.4.6, we conclude:

$$\mathcal{Q}_g(\mathcal{A}) \oplus \mathcal{Q}_g(\mathcal{A}^!) \simeq H^*(\mathcal{M}_g, \mathcal{Z}(\mathcal{A}))$$

as claimed. $\square$

Remark 7.4.7 (Explicit formulas for low genus). Genus 0. $\mathcal{M}_0 = \text{pt}$, so $H^*(\mathcal{M}_0, \mathcal{Z}(\mathcal{A})) = \mathcal{Z}(\mathcal{A})$. There are no quantum corrections.

Genus 1. The moduli space $\mathcal{M}_1$ has $H^1(\mathcal{M}_1, \mathbb{Q}) = 0$ (as for all $\mathcal{M}_g$), but $\dim \mathcal{M}_1 = 1$. Quantum corrections enter through the *partition function*, which depends on the modulus $\tau \in \mathfrak{h}/\text{SL}_2(\mathbb{Z})$:

$$Q_1(\mathcal{H}_k) = \mathbb{C} \cdot k$$

where k is the level of the Heisenberg algebra. Here Q_1 is computed from the center $\mathcal{Z}(\mathcal{A})$ evaluated over $\mathcal{M}_1$, not from H^1 .

The dual deformation:

$$Q_1(\text{Sym}(V^*)) = \mathbb{C} \cdot [V^* \wedge V^*]$$

measures how the symmetric algebra deforms from genus 0 to genus 1.

Genus 2. $\dim \mathcal{M}_2 = 3$ and $H^2(\mathcal{M}_2, \mathbb{Q}) = \mathbb{Q} \cdot \lambda_1$ (generated by the Hodge class). For $\widehat{\mathfrak{sl}}_2$ at critical level, the obstructions are:

$$Q_2(\widehat{\mathfrak{sl}}_2) = \mathbb{C} \cdot \lambda_1 \oplus \mathbb{C} \cdot [\alpha, \alpha]$$

where $\lambda_1 \in H^2(\mathcal{M}_2)$ is the first Hodge class and $[\alpha, \alpha]$ is the self-commutator of the simple root.

COROLLARY 7.4.8 (*Curved differential formula*). For a curved chiral algebra $\mathcal{A}$ with curvature μ_0 , the fiberwise genus- g bar differential is schematically of the form

$$d_{\text{fib}} = d_0 + \mu_0 \otimes \omega_g$$

where $\omega_g \in H^*(\mathcal{M}_g, \mathcal{Z}(\mathcal{A}))$ is the quantum correction class (living in the cohomology of $\mathcal{M}_g$ with coefficients in the center $\mathcal{Z}(\mathcal{A})$).

Its square is the chain-level obstruction operator

$$d_{\text{fib}}^2 = [\mu_0, -] \otimes \omega_g^2,$$

whose cohomological shadow appears only after passage to the flat comparison differential or the corresponding Chern–Weil class.

Proof. The genus- g bar differential receives quantum corrections from the period matrix of the curve (Theorem 13.16.13). When $\mathcal{A}$ has nonzero curvature $m_0 = \mu_0(1) \in \mathcal{A}^2$, the correction class ω_g lives in $H^*(\mathcal{M}_g, \mathcal{Z}(\mathcal{A}))$ by Theorem 13.15.14. Write $d_{\text{fib}} = d_0 + m_0 \otimes \omega_g$, where the second term acts via the inner derivation $[m_0, -]_{m_2}$ tensored with the modular class. Squaring:

$$d_{\text{fib}}^2 = \underbrace{d_0^2}_{=0} + d_0(m_0 \otimes \omega_g) + (m_0 \otimes \omega_g)d_0 + (m_0 \otimes \omega_g)^2.$$

The cross terms vanish: $d_0(m_0) = m_1(m_0) = 0$ by the curved A_∞ relation at $n = 0$ (Theorem 8.1.5(1)), and $(m_0 \otimes \omega_g) \circ d_0$ vanishes on cocycles by the same centrality. The surviving term $(m_0 \otimes \omega_g)^2 = [m_0, -]_{m_2} \otimes \omega_g^2$ uses the $n = 1$ curved A_∞ relation $m_1^2 = [m_0, -]_{m_2}$ (Theorem 8.1.5(2)). $\square$

Chapter 8

Bar-cobar adjunction and curved Koszul duality

The bar-cobar adjunction $\Omega^{\text{ch}} \dashv \bar{B}^{\text{ch}}$ represents the space of twisting morphisms $\text{Tw}(C, \mathcal{A}) = \text{MC}(\text{Conv}(C, \mathcal{A}))$ by a pair of functors between chiral algebras and conilpotent chiral coalgebras on $\text{Ran}(X)$ (Theorem 7.0.51). The universal twisting morphism $\tau_{\mathcal{A}} \in \text{MC}(\text{Conv}(\bar{B}^{\text{ch}}(\mathcal{A}), \mathcal{A}))$ is the genus-0 binary component of the MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$; the degree-2 projection of $\Theta_{\mathcal{A}}$ is the modular characteristic $\kappa(\mathcal{A})$. Theorem B (Theorem 8.6.1) says that $\tau_{\mathcal{A}}$ is *acyclic*: the twisted tensor product $\mathcal{A} \otimes_{\tau_{\mathcal{A}}} \bar{B}^{\text{ch}}(\mathcal{A})$ has trivial cohomology, so the counit $\psi: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ is a quasi-isomorphism on the Koszul locus. The two theorems are a single statement: every algebraic identity in chiral Koszul duality is a component of the MC equation $\partial(\tau_{\mathcal{A}}) + \tau_{\mathcal{A}} \star \tau_{\mathcal{A}} = 0$ in the convolution algebra, and inversion is the acyclicity of this MC element.

Not every chiral algebra is quadratic: Virasoro, $\mathcal{W}_N$, and $\mathcal{W}_{\infty}$ all require curved or filtered presentations in which $\mu_0 \neq 0$ and $\mu_1^2 = [\mu_0, -]_{\mu_2}$. On this extended locus the adjunction survives in the language of curved A_{∞} algebras, I -adic completions, and coderived categories. The strict convolution dg Lie algebra $\text{Conv}_{\text{str}}(\bar{B}^{\text{ch}}(\mathcal{A}), \mathcal{A})$ is replaced by its homotopy-invariant envelope $\text{Conv}_{\infty}(\bar{B}^{\text{ch}}(\mathcal{A}), \mathcal{A})$, and the twisting morphism mediating the adjunction becomes a Maurer–Cartan element in this larger algebra. Bar-cobar preserves quasi-isomorphisms because it is a quantum L_{∞} functor whose Maurer–Cartan moduli are invariant under gauge equivalence.

The precise content of Theorem A (Theorem 7.0.51) is this: there is an adjunction of functors $\Omega^{\text{ch}} \dashv \bar{B}^{\text{ch}}$ between chiral algebras and conilpotent chiral coalgebras on $\text{Ran}(X)$, with the unit $\eta: C \rightarrow \bar{B}^{\text{ch}}(\Omega^{\text{ch}}(C))$ and counit $\psi: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$ both compatible with Verdier intertwining: $\mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!$ (factorization *algebra*, not coalgebra). The adjunction is mediated by the canonical twisting morphism $\tau: \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$, which is a Maurer–Cartan element in the strict convolution dg Lie algebra $\text{Conv}_{\text{str}}(\bar{B}^{\text{ch}}(\mathcal{A}), \mathcal{A})$ (Definition 3.1.13); at the homotopy level, τ is an MC element in Conv_{∞} and therefore invariant under quasi-isomorphic replacement (Theorem 3.1.24). On the strict quadratic locus the adjunction is classical; off it, the curvature $\mu_0 \in A^2$ forces $\mu_1^2(a) = \mu_2(\mu_0, a) - \mu_2(a, \mu_0) = [\mu_0, a]_{\mu_2}$ (Theorem 8.1.5), so the bar differential no longer squares to zero internally; the total bar differential $d_B^2 = 0$ is preserved, but the internal differential μ_1 is obstructed by the curvature commutator. The four-regime hierarchy organizes the successively stronger completions needed:

- (i) *Quadratic* ($d_0^2 = 0$): strict $d_{\text{bar}}^2 = 0$, no completion needed (Heisenberg, free fields, lattice VOAs);
- (ii) *Curved-central* ($d_0^2 \neq 0, \mu_0 \in Z(A)$): completed bar-cobar, geometric curvature $d_{\text{fib}}^2 = \kappa \cdot \omega_g$

(affine algebras, Virasoro);

(iii) *Filtered-complete* (non-quadratic OPE): I -adic completion required, work in coderived category ($\mathcal{W}_N$ at finite N);

(iv) *Programmatic* (infinite generators): MC4 completion (proved; Theorem 8.1.27).

This hierarchy is codified in Convention 1.10.2 and governs every theorem statement in this chapter and the next.

The chapter has two movements. The first (§8.1–§8.3) develops curved A_∞ structures, I -adic completion, and the regime hierarchy (quadratic, curved-central, filtered-complete, programmatic) that determines which completions are needed. The second (§8.4–§8.10) proves inversion, establishes the categorical logarithm reading of bar-cobar ($\bar{B}^{\text{ch}} = \log, \Omega^{\text{ch}} = \exp$), and lifts the whole story to the Ran-space via the Čech resolution. Once the adjunction and its inversion are established, the genus-0 bar complex is a functor, and the passage to higher genus (Chapter 13) amounts to deforming the differential by curvature. The curved extension provides the framework in which $\kappa(\mathcal{A}) \cdot \omega_g$ and the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ operate.

Remark 8.0.1 (The ordered bar as primitive). The bar complex $\bar{B}^{\text{ch}}(\mathcal{A})$ presented in this chapter is the *symmetric* bar: it lives on $(s^{-1}\bar{\mathcal{A}})_{\Sigma_n}^{\otimes n}$ with the coshuffle coproduct, a cocommutative coalgebra on unordered configurations. The natural primitive is the *ordered* bar complex $\bar{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$ of Chapter 22, the cofree conilpotent coalgebra with deconcatenation coproduct. The two are related by a surjective map

$$\bar{B}^{\text{ord}}(\mathcal{A}) \xrightarrow{\text{av}} \bar{B}^{\text{ch}}(\mathcal{A}), \quad \text{av}(a_1 \otimes \cdots \otimes a_n) = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} a_{\sigma(1)} \otimes \cdots \otimes a_{\sigma(n)},$$

which is the Σ_n -coinvariant projection at each degree. This map is a quasi-isomorphism of chain complexes in characteristic 0, but it is *not* an isomorphism of coalgebras: the deconcatenation coproduct on $\bar{B}^{\text{ord}}$ is coassociative but not cocommutative, while the coshuffle coproduct on $\bar{B}^{\text{ch}}$ is cocommutative. Passing to coinvariants destroys the ordered coproduct and with it three layers of structure:

- (i) *The R -matrix.* The genus-0, degree-2 component of the ordered MC element $\Theta_{\mathcal{A}}^{\text{E}_1}$ is the classical r -matrix $r(z) \in \text{End}(V^{\otimes 2}) \otimes \mathcal{O}(*\Delta)$, a matrix-valued meromorphic function satisfying the classical Yang–Baxter equation. Its Σ_2 -coinvariant is the scalar $\kappa(\mathcal{A}) = \text{av}(r(z))$ (equation (1.5)): the full spectral data collapses to a single number.
- (ii) *The braided monoidal category.* The deconcatenation coproduct on $\bar{B}^{\text{ord}}(\mathcal{A})$ controls the tensor product on the category of ordered factorization modules $\text{Fact}_{\text{E}_1}^{\text{ord}}(\mathcal{A})$. The R -matrix provides the braiding. After coinvariants, only the symmetric monoidal shadow survives.
- (iii) *The Swiss-cheese directionality.* The $\text{SC}^{\text{ch}, \text{top}}$ picture couples holomorphic collision data on $\text{FM}_k(\mathbb{C})$ with topological interval splitting on $C_k(\mathbb{R})$. On the ordered bar these appear as the bar differential and the deconcatenation coproduct, but they do *not* make $\bar{B}^{\text{ord}}(\mathcal{A})$ itself an $\text{SC}^{\text{ch}, \text{top}}$ object: the ordered bar remains a single-coloured E_1 -chiral coalgebra, and the actual Swiss-cheese datum emerges only on the derived center pair $(C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A})$.

The five main theorems A–H are invariants of the symmetric bar and therefore survive averaging. The Yangian R -matrix, the Drinfeld–Kohno comparison, and the full braided monoidal category of line operators live in the ordered bar and are invisible to the symmetric theory. The reader should regard this

chapter as developing the av-image of the ordered theory: every construction here has a richer ordered ancestor in Chapter 22, and the passage from ordered to symmetric is the unique source of information loss (Theorem 1.4.1).

8.1 CURVED KOSZUL DUALITY AND I-ADIC COMPLETION

The Virasoro algebra cannot be quadratic: the Virasoro OPE $T(z)T(w) \sim (c/2)/(z-w)^4 + 2T(w)/(z-w)^2 + \partial T(w)/(z-w)$ involves a fourth-order pole, and the stress tensor T appears on both sides of the relation, so no finite-dimensional generating space and quadratic relation space suffice. The bar complex $\overline{B}(\text{Vir}_c)$ is curved: its differential squares not to zero but to the commutator $\mu_1^2(a) = [\mu_0, a]$, where $\mu_0 = \kappa \cdot \omega$ is the curvature element encoding the central extension. The failure of $d^2 = 0$ is the algebraic trace of the genus-1 boundary $\delta_0 \in \partial \overline{\mathcal{M}}_{1,1}$: nodal degeneration introduces curvature into every genus tower.

The same phenomenon intensifies for $\mathcal{W}_N$ (composite fields, higher-order poles) and becomes qualitatively new for $\mathcal{W}_\infty$ (infinitely many generators, no finite presentation). In each case, the categorical logarithm $\overline{B}$ still produces a well-defined object, but recovering the original algebra by exponentiation $\Omega \circ \overline{B} \xrightarrow{\sim} \mathcal{A}$ requires increasingly refined completions. Three regimes emerge:

- *Curved structures*: $\mu_0 \neq 0$, the differential satisfies $\mu_1^2 = [\mu_0, -]$ (commutator, with minus sign).
- *I-adic completion*: the bar complex must be completed against the augmentation ideal to ensure convergence of infinite sums.
- *Filtered structures*: more general than curved; the filtration controls the infinite-dimensional hierarchy of generators (Gui–Li–Zeng [213]).

8.1.1 CURVED A_∞ ALGEBRAS: DEFINITIONS

Definition 8.1.1 (Curved A_∞ algebra). A curved A_∞ algebra is a graded vector space A with operations:

$$\{\mu_n : A^{\otimes n} \rightarrow A\}_{n \geq 0}$$

of degree $2 - n$, satisfying the curved A_∞ relations:

$$\sum_{\substack{r+s+t=n \\ r,t \geq 0, s \geq 0}} (-1)^{r^{s+t}} \mu_{r+1+t}(\text{id}^{\otimes r} \otimes \mu_s \otimes \text{id}^{\otimes t}) = 0 \quad (8.1)$$

The summation begins at $n = 0$: the operation $\mu_0 : \mathbb{C} \rightarrow A$ is the *curvature*.

Remark 8.1.2 (Consequences of the curved relations at low n). Setting $n = 1$ in (8.1) gives $\mu_1^2 = [\mu_0, -]_{\mu_2}$, so μ_1 is a differential only when μ_0 is central with respect to μ_2 . For $n \geq 2$ the relations coincide with those of an ordinary A_∞ algebra.

Remark 8.1.3 (Curvature, backreaction, and d^2). (i) The *curvature* is $m_0 := \mu_0(1) \in A^2$.

(ii) $\mu_1^2(a) = \mu_2(m_0, a) - \mu_2(a, m_0)$: the total bar differential always satisfies $d_{\text{bar}}^2 = 0$; curvature manifests in the *internal* A_∞ structure.

(iii) In physics, *backreaction* is the same phenomenon: the BRST operator $Q = \mu_1$ satisfies $Q^2 \neq 0$, with the obstruction measured by m_0 .

- (iv) A curved A_∞ algebra is *strictifiable* iff m_0 is central (Theorem 8.1.5) and the curvature class is gauge-trivial in the completed filtration.

Remark 8.1.4 (Gravity dictionary for curved A_∞). For genus $g \geq 1$, the curved fiberwise bar model carries the scalar curvature element

$$m_0^{(g)} = \kappa(\mathcal{A}) \cdot \omega_g \cdot \mathbf{1}, \quad \omega_g = c_1(\lambda) \in H^2(\overline{\mathcal{M}}_g),$$

where $\lambda = \det \mathbb{E}$ is the Hodge line bundle on the moduli space. The fiberwise differential satisfies

$$d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g,$$

while the total bar differential still satisfies $d_{\text{bar}}^2 = 0$. This gives the gravity dictionary:

- (i) $m_0^{(g)} \neq 0$ if and only if $\kappa(\mathcal{A}) \neq 0$, equivalently if and only if $d_{\text{fib}}^2 \neq 0$. This is the precise sense in which gravity is turned on. The scalar curvature term $m_0^{(g)}$ is the cosmological-constant term of the genus- g curved A_∞ model. This statement is fiberwise. For the standard families $m_0^{(g)}$ is central, so the internal commutator formula $m_1^2 = [m_0, -]$ may vanish even when $d_{\text{fib}}^2 \neq 0$.
- (ii) $\kappa(\mathcal{A})$ is the coefficient of the Hodge class in d_{fib}^2 , hence the strength of the genus- g gravitational backreaction. In that dictionary, $\kappa(\mathcal{A})$ is the Newton coupling. It is family-specific: $\kappa(\widehat{\mathfrak{g}}_k) = (k + h^\vee) \dim \mathfrak{g} / (2h^\vee)$ for affine Kac–Moody, $\kappa(\text{Vir}_c) = c/2$ for Virasoro, and $\kappa(\mathcal{B}^k) = c/6$ for Bershadsky–Polyakov.
- (iii) The critical gravitational coupling is the fixed point of the duality involution on the scalar lane. When the scalar complementarity constant is written as $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) = K_\kappa(\mathcal{A})$, the fixed point is $\kappa_{\text{crit}} = K_\kappa(\mathcal{A})/2$. This constant is family-specific. For affine Kac–Moody, Heisenberg, and free-field families one has $K_\kappa = 0$, so $\kappa_{\text{crit}} = 0$. For Virasoro one has $K_\kappa = 13$, so $\kappa_{\text{crit}} = 13/2$, equivalently $c = 13$. For the Bershadsky–Polyakov family the manuscript uses $\kappa(\mathcal{B}^k) = c/6$ together with the central-charge conductor $c(\mathcal{B}^k) + c((\mathcal{B}^k)^\dagger) = 196$; hence the self-dual central charge is $c = 98$, and the induced scalar critical coupling is $\kappa_{\text{crit}} = 49/3$.

THEOREM 8.1.5 (*Curvature as μ_1 -cycle*). For a curved A_∞ algebra $(A, \mu_0, \mu_1, \mu_2, \dots)$, the curvature element satisfies:

1. $\mu_1(\mu_0) = 0$ (the curvature is a μ_1 -cycle);
2. $\mu_1^2 = [\mu_0, -]_{\mu_2}$, where $[\mu_0, a]_{\mu_2} := \mu_2(\mu_0, a) - \mu_2(a, \mu_0)$ is the inner derivation.

In particular, μ_1 fails to be a differential precisely when μ_0 is *not* central with respect to μ_2 . For chiral algebras (which are graded-commutative), $[\mu_0, -]_{\mu_2} = 0$ automatically, so the curvature enters through higher operations $(\mu_3, \mu_4, \dots)$ or via the completed tensor product.

Proof. The curved A_∞ relations $\sum_{r+s+t=n} (-1)^{r+s+t} \mu_{r+1+t}(\text{id}^{\otimes r} \otimes \mu_s \otimes \text{id}^{\otimes t}) = 0$ give, at each level:

- $n = 0$: $\mu_1(\mu_0) = 0$ (the curvature is a μ_1 -cycle).
- $n = 1$: $\mu_1^2(a) - \mu_2(\mu_0, a) + \mu_2(a, \mu_0) = 0$ for all a (failure of $\mu_1^2 = 0$).

Rearranging the $n = 1$ relation: $\mu_1^2(a) = \mu_2(\mu_0, a) - \mu_2(a, \mu_0) = [\mu_0, a]_{\mu_2}$.

The $n = 2$ relation (Leibniz rule for μ_1 acting on μ_2) applied using $\mu_1(\mu_0) = 0$ from $n = 0$ gives:

$$\mu_1(\mu_2(\mu_0, a)) = \mu_2(\mu_0, \mu_1(a))$$

confirming that the inner derivation $[\mu_0, -]_{\mu_2}$ commutes with μ_1 , as required for the self-consistency of the curved structure. $\square$

8.1.2 I-ADIC COMPLETION: TOPOLOGY AND CONVERGENCE

Definition 8.1.6 (I-adic topology). Let A be a curved A_∞ algebra with augmentation ideal $I = \ker(\varepsilon : A \rightarrow \mathbb{C})$.

The *I-adic completion* of A is:

$$\begin{aligned} \hat{A} &:= \varprojlim_n A/I^n \\ &= \{a \in \prod_{n \geq 0} A/I^n : \text{compatible}\}. \end{aligned}$$

An element $a \in \hat{A}$ can be written as a formal series:

$$a = a_0 + a_1 + a_2 + \cdots \quad \text{where } a_n \in I^n/I^{n+1}$$

THEOREM 8.1.7 (*When completion is necessary [350, 213];*). Completion $A \rightarrow \hat{A}$ is necessary when:

1. *Infinite sums*: Operations μ_n produce infinite sums not convergent in A
2. *Non-nilpotent*: Bar complex $\bar{B}(A)$ is not conilpotent
3. *Non-quadratic*: Relations involve infinitely many generators

For example, the Virasoro algebra and W_∞ need completion, while Heisenberg and Kac–Moody (conilpotent) do not.

The key question is not *whether* to complete, but *how*: what structure on the filtration guarantees that the completed bar-cobar round-trip remains a quasi-isomorphism? The answer is the strong filtration axiom $\mu_r(F^{i_1}, \dots, F^{i_r}) \subset F^{i_1 + \dots + i_r}$ (Definition 8.1.25), which ensures that the bar differential on each finite quotient $\mathcal{A}_{\leq N}$ is a *finite* sum (Lemma 8.1.26). Virasoro admits a completed same-family shadow used throughout Parts II–III; W_∞ is handled by the strong completion-tower theorem (Theorem 8.1.27), which upgrades the former MC4 conjecture to a theorem with sharp hypotheses.

Illustration: Virasoro (condition (1)). The Virasoro algebra has generators $\{L_n\}_{n \in \mathbb{Z}}$ with:

$$[L_m, L_n] = (m - n)L_{m+n} + \frac{c}{12}m(m^2 - 1)\delta_{m+n,0}$$

Consider the bar complex element $\omega = L_{-2} \otimes L_2 \in \bar{B}^2(\text{Vir})$. Applying the bar differential involves the bracket:

$$d(\omega) = [L_{-2}, L_2] = -4L_0 - \frac{c}{2}.$$

More generally, a bar element $L_m \otimes L_n$ with $m + n = 0$ contributes central terms $\frac{c}{12}m(m^2 - 1)$; these accumulate as $|m| \rightarrow \infty$. Already at bar length 3, terms like $\sum_k L_{-k} \otimes L_k \otimes L_0$ involve infinitely many

summands. This sum is *infinite* and does not converge in the discrete topology. We need completion with respect to the conformal-weight filtration to make sense of it.

In $\hat{\text{Vir}}$, the sum converges because the conformal-weight grading ensures that at any given total weight, only finitely many mode combinations contribute. Formally, the state space of Vir_c is graded by conformal weight with finite-dimensional weight spaces, so the completed bar differential is a well-defined continuous map in the inverse-limit topology. $\square$

Remark 8.1.8 (Scope of the proof). The Virasoro example above establishes necessity for condition (1). Condition (2) is demonstrated by the $\beta\gamma$ -system, whose bar complex is not conilpotent due to the infinite-rank coproduct on the symmetric coalgebra (see §K.7.1 in Chapter K.7.1). Condition (3) is illustrated by affine $\widehat{\mathfrak{sl}}_2$ at non-integral level, where the Serre-type relations involve infinitely many generators (see §K.7.1 in Chapter K.7.1).

PROPOSITION 8.1.9 (Acyclicity of curved bar complexes;). Let $\mathcal{A}$ be a Koszul chiral algebra with nonzero obstruction coefficient $\kappa(\mathcal{A}) \neq 0$. At genus $g \geq 1$, the curved bar complex $\bar{B}^{(g)}(\mathcal{A})$ has *acyclic* underlying cochain complex: $H^*(\bar{B}^{(g)}(\mathcal{A}), d_{\text{total}}) = 0$.

Proof. At genus $g \geq 1$, the bar differential satisfies $d_{\text{fb}}^2 = m_0^{(g)} \cdot \text{id}$ where $m_0^{(g)} = \kappa(\mathcal{A}) \cdot \lambda_g \neq 0$ (Theorem 13.13.16; Convention 13.0.2). The fiberwise differential d_{fb} is curved, but the total corrected differential D_g satisfies $D_g^2 = 0$. The internal A_∞ operation m_1 fails nilpotence: $m_1^2 = [m_0, -]_{m_2} \neq 0$ (Corollary 13.13.31).

The standard Positselski argument [350, Remark 3.6] applies: for a CDG-coalgebra (C, d, h) with $h \neq 0$, the bar construction is acyclic. Here $C = \bar{B}^{(g)}(\mathcal{A})$ with curvature $h = m_0^{(g)} \neq 0$. $\square$

Remark 8.1.10 (Necessity of exotic derived categories at higher genus). At genus $g \geq 1$ with $\kappa \neq 0$, acyclicity of $\bar{B}^{(g)}(\mathcal{A})$ removes ordinary cohomological information from the bar object itself. The correct framework for the associated comodule homological algebra is Positselski's coderived category $D^{\text{co}}(\bar{B}^{(g)}\text{-CoMod})$ [350, §§3–4], which is why Theorem 12.10.3 requires the coderived/contraderived setting.

Remark 8.1.11 (Derived-coderived reduction for chiral CDG-coalgebras). The chiral bar complex $C = \bar{B}^{\text{ch}}(\mathcal{A})$ is a CDG-coalgebra with curvature $h = m_0^{(g)}$. Three hypotheses govern the relationship between its coderived and ordinary derived categories:

- (H1) *Conilpotency:* C is conilpotent, i.e., the coaugmentation filtration is exhaustive. This holds by Theorem 10.4.3(4): the conformal weight grading on $\bar{B}^{\text{ch}}(\mathcal{A})$ provides an exhaustive $\mathbb{N}$ -filtration with $C = \bigcup_n F^n C$.
- (H2) *Finite-type weight spaces:* each graded piece of C is finite-dimensional. This holds because $\mathcal{A}$ is finitely generated with finite-dimensional conformal weight spaces (the positive-energy axiom), so $\bar{B}^n(\mathcal{A})$ in each weight is a finite-dimensional vector space.
- (H3) *Compact generation:* (H1) and (H2) together imply that the coderived category $D^{\text{co}}(C\text{-comod}^{\text{ch}})$ is compactly generated by finite-dimensional comodules.

Genus 0 ($h = 0$). By the conilpotent reduction theorem of Positselski [350, Corollary 4.4] (cf. Remark 8.5.14), (H1) and $h = 0$ imply that every acyclic CDG-comodule is coacyclic, so

$$D^{\text{co}}(C\text{-comod}^{\text{ch}}) \simeq D(C\text{-comod}^{\text{ch}}).$$

The coderived category reduces to the ordinary derived category. This is the regime of Theorem B (bar-cobar inversion on the Koszul locus).

Genus $g \geq 1$ with $\kappa(\mathcal{A}) \neq 0$ ($h \neq 0$). Ordinary bar-complex cohomology collapses on the higher-genus bar-object surface (Proposition 8.1.9), but the coderived–contraderived equivalence (Theorem 8.5.23) is non-trivial. The Positselski equivalence $D^{\text{co}}(\overline{B}^{\text{ch}}(\mathcal{A})\text{-comod}) \simeq D^{\text{ctr}}(\overline{B}^{\text{ch}}(\mathcal{A})\text{-contra})$ of Theorem 8.5.23 provides the correct framework. Its proof uses (H1)–(H3) at three points: conilpotency for cofree resolutions, finite-type for the duality between contramodules and complete modules over the graded dual bar-dual algebra, and compact generation for the triangulated comparison functor. See Remark 8.8.3 for the connection to bar-cobar duality and §8.5.4 for the chiral coderived and contraderived categories.

Summary. The bar complex of every positive-energy Koszul chiral algebra satisfies (H1)–(H3). At genus 0, this yields $D^{\text{co}} \simeq D$ (ordinary derived category). At genus $g \geq 1$, it yields $D^{\text{co}} \simeq D^{\text{ctr}}$ (comodule–contramodule correspondence). The three models of the genus- g bar complex (flat associated graded in D ; corrected holomorphic in D ; curved geometric in D^{co}) are linked by these identifications.

8.1.3 FILTERED VERSUS CURVED STRUCTURES

THEOREM 8.1.12 (*Filtered cooperads (Gui–Li–Zeng [213]);*). A filtered cooperad C is more general than a curved cooperad:

$$C = \bigcup_{n=0}^{\infty} F^n C$$

where $F^n C \subset F^{n+1} C$ is an increasing filtration, with:

1. Comultiplication: $\Delta(F^n) \subset \bigoplus_{i+j=n} F^i \otimes F^j$
2. Counit: $\varepsilon(F^{>0}) = 0$

The filtered structure does not reduce to a single curvature element.

Remark 8.1.13 (Provenance and citation). This theorem is imported and treated as . The filtered-cooperad framework used here is sourced from [213]; subsequent internal reductions in this manuscript are organized by Theorem 8.1.15 and Theorem 8.4.1.

Example 8.1.14 ($\mathcal{W}$ -algebras: filtered but not simply curved). For the $\mathcal{W}_3$ algebra, the filtration is by conformal weight:

$$F^n \mathcal{W}_3 = \text{span}\{T, W, \partial T, TT, \partial W, \dots \text{ up to weight } n\}$$

This does not come from a single curvature element μ_0 . Instead, there are curvature contributions at each weight:

$$\begin{aligned} \mu_0^{(2)} &= T \quad (\text{weight } 2) \\ \mu_0^{(3)} &= W \quad (\text{weight } 3) \\ \mu_0^{(4)} &= TT + \text{regular} \quad (\text{weight } 4) \\ &\vdots \end{aligned}$$

The full structure requires the complete filtered cooperad, not just a curved one.

THEOREM 8.1.15 (*When filtered reduces to curved;*). Let C be a filtered chiral cooperad with exhaustive, separated, complete filtration $F_\bullet C$. Assume:

1. $\dim(F_n C / F_{n-1} C) < \infty$ for every n ;
2. $\text{gr}(C)$ is generated in degree 1 with quadratic relations;
3. higher relation classes differ from quadratic consequences by central filtration- ≥ 2 corrections.

Then there exists a curved cooperad C_{curv} with curvature $\mu_0 \in F_2 C_{\text{curv}}$ and a filtered quasi-isomorphism

$$C_{\text{curv}} \xrightarrow{\simeq_f} C.$$

If $\text{gr}(C)$ has infinitely many nonzero graded pieces, this curved description is only defined after completion.

Proof. Set $\mathcal{A} := C^\vee$ (continuous dual with respect to $F_\bullet$). By assumption (1), filtration pieces are finite-dimensional, so duality exchanges filtered cooperads and filtered chiral algebras without loss of filtration data.

Assumptions (2)–(3) are exactly the hypotheses of Proposition 16.9.13 for $\mathcal{A}$. Hence there is a curved model $\mathcal{A}_{\text{curv}}$ with curvature $\mu_0 \in F_2 \mathcal{A}_{\text{curv}}$ and a filtered quasi-isomorphism $\mathcal{A}_{\text{curv}} \rightarrow \mathcal{A}$.

Dualizing back gives a curved cooperad $C_{\text{curv}} := \mathcal{A}_{\text{curv}}^\vee$ and a filtered quasi-isomorphism $C_{\text{curv}} \rightarrow C$. The curved identity $d^2 = [\mu_0, -]$ is preserved under this dualization because all filtration quotients are finite-dimensional.

If $\text{gr}(C)$ has infinitely many nonzero graded pieces, the curvature decomposes into infinitely many filtration components. Then the bar/cobar operations are no longer finite strict and convergence requires completion, as in Theorem 8.1.18 and Theorem 8.4.1. $\square$

Remark 8.1.16 (Dependencies). This proof uses:

- (D1) the filtered algebra-side reduction in Proposition 16.9.13;
- (D2) finite-type filtered duality between filtered algebras and cooperads;
- (D3) convergence control from Theorem 8.1.18 and Theorem 8.4.1.

8.1.4 CONILPOTENCY AND CONVERGENCE WITHOUT COMPLETION

DEFINITION 8.1.17 (*Conilpotent coalgebra*). A coalgebra C is *conilpotent* if for each $c \in C$, there exists N such that:

$$\Delta^{(N)}(c) = 0$$

where $\Delta^{(N)}$ is the N -fold iterated comultiplication.

THEOREM 8.1.18 (*Conilpotency ensures convergence;*). If $\bar{B}(A)$ is conilpotent, then:

1. The bar-cobar composition $\Omega \circ \bar{B}(A) \rightarrow A$ converges without completion
2. All infinite sums in the cobar differential terminate after finitely many steps
3. The Koszul duality $A \leftrightarrow A^\dagger$ is well-defined without taking $\hat{A}$

Proof. Write $C = \bar{B}(A)$ and $\bar{C} = \ker(\varepsilon)$ for the augmentation ideal. The cobar construction is the tensor algebra $\Omega(C) = T(s^{-1}\bar{C}) = \bigoplus_{k \geq 0} (s^{-1}\bar{C})^{\otimes k}$ equipped with the differential d_Ω determined on generators by the reduced comultiplication $\bar{\Delta}: \bar{C} \rightarrow \bar{C} \otimes \bar{C}$:

$$d_\Omega(s^{-1}c) = - \sum (-1)^{|c'|} s^{-1}c' \otimes s^{-1}c'' \quad (8.2)$$

where $\bar{\Delta}(c) = \sum c' \otimes c''$ (Sweedler notation), extended to all of $T(s^{-1}\bar{C})$ as a derivation:

$$d_\Omega(s^{-1}c_1 \otimes \cdots \otimes s^{-1}c_k) = \sum_{i=1}^k (-1)^{\epsilon_i} s^{-1}c_1 \otimes \cdots \otimes d_\Omega(s^{-1}c_i) \otimes \cdots \otimes s^{-1}c_k \quad (8.3)$$

with signs $\epsilon_i = |s^{-1}c_1| + \cdots + |s^{-1}c_{i-1}|$.

Step 1 (conilpotent case). Suppose C is conilpotent (Definition 8.1.17): for each $c \in \bar{C}$, there exists $N = N(c)$ such that the iterated reduced comultiplication $\bar{\Delta}^{(N)}(c) = 0$. Then $\bar{\Delta}(c)$ is a *finite* sum in $\bar{C} \otimes \bar{C}$, so (8.2) is a finite sum. On a general element $\xi = s^{-1}c_1 \otimes \cdots \otimes s^{-1}c_k$, the derivation rule (8.3) applies the comultiplication to each factor c_i individually; conilpotency of each c_i ensures each summand is finite. The outer sum has exactly k terms. Therefore $d_\Omega(\xi)$ is a finite sum in $T(s^{-1}\bar{C})$, and no completion or topology is needed.

Step 2 ($d_\Omega^2 = 0$). Since d_Ω is a derivation of the free algebra $T(s^{-1}\bar{C})$, the Leibniz rule gives $d_\Omega^2(x \otimes y) = d_\Omega^2(x) \otimes y + x \otimes d_\Omega^2(y)$, so it suffices to verify $d_\Omega^2 = 0$ on generators $s^{-1}c$. Write $\bar{\Delta}(c) = \sum c' \otimes c''$ in Sweedler notation. Then by (8.2):

$$\begin{aligned} d_\Omega^2(s^{-1}c) &= d_\Omega\left(- \sum (-1)^{|c'|} s^{-1}c' \otimes s^{-1}c''\right) \\ &= - \sum (-1)^{|c'|} (d_\Omega(s^{-1}c') \otimes s^{-1}c'' + (-1)^{|s^{-1}c'|} s^{-1}c' \otimes d_\Omega(s^{-1}c'')). \end{aligned}$$

The first group of terms applies $\bar{\Delta}$ to the left tensorand: writing $\bar{\Delta}(c') = \sum c'_{(1)} \otimes c'_{(2)}$, it produces $+ \sum \pm s^{-1}c'_{(1)} \otimes s^{-1}c'_{(2)} \otimes s^{-1}c''$. The second group applies $\bar{\Delta}$ to the right tensorand: writing $\bar{\Delta}(c'') = \sum c''_{(1)} \otimes c''_{(2)}$, it produces $+ \sum \pm s^{-1}c' \otimes s^{-1}c''_{(1)} \otimes s^{-1}c''_{(2)}$. Coassociativity of $\bar{\Delta}$ states $(\bar{\Delta} \otimes \text{id}) \circ \bar{\Delta} = (\text{id} \otimes \bar{\Delta}) \circ \bar{\Delta}$, so these two sums are identical up to sign. Tracking the Koszul signs from the desuspension (each s^{-1} shifts degree by -1), the two contributions cancel exactly: the sign discrepancy between applying $\bar{\Delta}$ on the left versus the right factor is $(-1)^{|s^{-1}c'|} = (-1)^{|c'|-1}$, and this combines with the outer sign $(-1)^{|c'|}$ to produce opposite signs on the two coassociativity terms. Therefore $d_\Omega^2(s^{-1}c) = 0$. All sums involved are finite by Step 1 (cf. also [299], §2.2).

Step 3 (bar-cobar composition). The bar-cobar composition $\Omega(\bar{B}(A)) = T(s^{-1}\overline{\bar{B}(A)})$ inherits conilpotency from $\bar{B}(A)$: every element of $\bar{B}^n(A)$ lies in the tensor algebra on A , and the comultiplication is the deconcatenation coproduct, which satisfies $\bar{\Delta}^{(n)}(\omega) = 0$ for $\omega \in \bar{B}^n(A)$. All cobar operations therefore terminate after finitely many steps, and the counit $\varepsilon: \Omega(\bar{B}(A)) \rightarrow A$ is well-defined without completion.

Step 4 (completed case). If C is not conilpotent but is *cocomplete* (pro-conilpotent), i.e., the natural map $C \xrightarrow{\sim} \varprojlim C/F_N C$ is an isomorphism, where $F_N C = \ker(\bar{\Delta}^{(N)})$ is the coradical filtration, then elements of C are coherent sequences $(c_N)_{N \geq 0}$ with $c_N \in C/F_N C$ and the canonical projections $\pi_{N+1, N}: C/F_{N+1} C \rightarrow C/F_N C$ satisfying $\pi_{N+1, N}(c_{N+1}) = c_N$. The completed cobar construction is $\bar{\Omega}(C) = \varprojlim_N \Omega(C/F_N C)$. Each quotient $C/F_N C$ is conilpotent by construction ($\bar{\Delta}^{(N)} = 0$ on $C/F_N C$), so the cobar differential d_Ω is well-defined on each $\Omega(C/F_N C)$ by Steps 1–2. Since d_Ω respects the coradical filtration: if $c \in F_N C$, then $\bar{\Delta}(c) \in \sum_{i+j=N} F_i C \otimes F_j C$ (since the

coradical filtration is a coalgebra filtration), so the differentials on $\Omega(C/F_N C)$ form a compatible system; the projection $\pi_{N+1,N}$ intertwines d_Ω at level $N + 1$ with d_Ω at level N . The completed differential $d_{\hat{\Omega}}$ is therefore well-defined on the inverse limit: for an element $(c_N)_{N \geq 0} \in \hat{\Omega}(C)$, the image $d_{\hat{\Omega}}((c_N)) = (d_\Omega(c_N))_{N \geq 0}$ is a coherent sequence because each $d_\Omega(c_N)$ is well-defined (Step 1) and the compatibility $\pi_{N+1,N}(d_\Omega(c_{N+1})) = d_\Omega(\pi_{N+1,N}(c_{N+1})) = d_\Omega(c_N)$ holds. The identity $d_{\hat{\Omega}}^2 = 0$ follows from $d_\Omega^2 = 0$ at each finite level (Step 2), since a compatible system of zeros has zero inverse limit.

This proves all three conclusions: the cobar differential terminates (1–2), the bar-cobar composition converges without completion in the conilpotent case (3), and Koszul duality $A \leftrightarrow A^\dagger$ is well-defined via the direct (uncompleted) bar-cobar adjunction. $\square$

Example 8.1.19 (Heisenberg: conilpotent). The Heisenberg algebra $\mathcal{H}_\kappa$ has bar complex:

$$\bar{B}^n(\mathcal{H}_\kappa) = \mathcal{H}_\kappa^{\otimes n} \otimes \Omega^n$$

For $\omega = a_{n_1} \otimes \cdots \otimes a_{n_k} \otimes \eta_{ij}$, the comultiplication is:

$$\Delta(\omega) = \sum_{\text{splittings}} \omega_L \otimes \omega_R$$

After k iterations, $\Delta^{(k)}(\omega) = 0$ because we run out of tensor factors. Thus $\bar{B}(\mathcal{H}_\kappa)$ is conilpotent, and no completion is needed.

Example 8.1.20 (Virasoro: not conilpotent). The Virasoro algebra has infinitely many generators L_n . Consider:

$$\omega = L_0 \in \bar{B}^1(\text{Vir})$$

The comultiplication gives:

$$\Delta(\omega) = \sum_{k \in \mathbb{Z}} (\text{terms with } L_k \otimes L_{-k})$$

This sum is infinite and does not converge in the discrete topology on $\bar{B}(\text{Vir})$, so $\Delta^{(N)}(\omega) \neq 0$ for all N . Thus $\bar{B}(\text{Vir})$ is not conilpotent; completion is required.

8.1.5 EXAMPLES: COMPUTING KOSZUL DUALS WITH COMPLETION

Example 8.1.21 (Virasoro Koszul dual). Since $\bar{B}(\text{Vir})$ is not conilpotent (Example 8.1.20), one forms the completed bar complex and takes continuous linear dual. Writing $\text{Vir}_c = \mathcal{W}^k(\mathfrak{sl}_2)$ with $h^\vee = 2$, level-shifting duality (Corollary 7.1.13) gives $k' = -k - 2h^\vee = -k - 4$, so

$$\text{Vir}_c^\dagger \cong \text{Vir}_{26-c},$$

since $c(k) + c(k') = 2 \text{rank}(\mathfrak{sl}_2) + 4h^\vee \dim \mathfrak{sl}_2 = 2 + 24 = 26$ by Theorem 1.3.8(b) (the $\mathcal{W}$ -algebra central-charge sum; this is the Virasoro-family formula, not the affine KM formula $c + c' = 2 \dim \mathfrak{g}$). Physically, matter–ghost duality pairs a matter system at central charge c with ghosts at $c_{\text{ghost}} = 26 - c$. In particular, $\text{Vir}_{26}^\dagger \cong \text{Vir}_0$, consistent with bosonic string BRST cohomology at ghost number zero.

At the M/S level, the completed dual has infinitely many primitive cumulants $(\Delta_{\text{Vir}}(t) = t^3 + 2t^5 + \cdots; \text{Definition 11.1.79})$. The MC4 structural framework is proved (Theorem 8.1.27); the residual H-level target identification is the subject of Example 8.1.24.

The infinite primitive-cumulant tail in Example 8.1.21 is the genus-0 shadow of a more concrete analytic object: the spectral R-matrix of Vir_c acting on a primary state. On a rank-1 primary line the path-ordered exponential of the collision residue closes into an elementary function.

COMPUTATION 8.1.22 (*Virasoro spectral R-matrix on primary states*;). For the Virasoro algebra at central charge c acting on a primary state of conformal weight h , the spectral R-matrix admits the closed form

$$R(z) = z^{2h} \exp\left(-\frac{c}{4z^2}\right) = z^{2h} \sum_{k=0}^{\infty} \frac{(-c/4)^k}{k! z^{2k}}. \quad (8.4)$$

The first four series coefficients are

$$R_0 = z^{2h}, \quad R_2 = -\frac{c}{4}, \quad R_4 = \frac{c^2}{32}, \quad R_6 = -\frac{c^3}{384}.$$

Only even powers of $1/z$ appear, reflecting bosonic parity. The non-terminating character of this series is the genus-0 signature of class M (infinite shadow depth): unlike Heisenberg ($R(z) = z^k$, terminating after the leading power) or affine Kac–Moody ($R(z) = z^{\Omega/(k+h^\vee)}$, terminating), the Virasoro R-matrix has infinitely many corrections in $1/z^2$.

Proof. The Virasoro OPE is

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}.$$

By the d log absorption principle, the collision residue has poles one order lower than the OPE:

$$r^{\text{coll}}(z) = \frac{c/2}{z^3} + \frac{2T}{z}.$$

On a primary state $|h\rangle$ the modes act as $T_{(1)}|h\rangle = h|h\rangle$ (by $L_0|h\rangle = h|h\rangle$), while $T_{(3)}$ acts as the central scalar $c/2$. The path-ordered exponential

$$R(z) = \mathcal{P} \exp\left(\oint \sum_{n \geq 0} r_n z^{-n-1} dz\right)$$

on the primary sector is a scalar path-ordered exponential of commuting generators ($\mathbb{1}$ and L_0), hence reduces to the ordinary exponential

$$R(z)|h\rangle = \exp\left(2h \log z - \frac{c/2}{2z^2}\right)|h\rangle = z^{2h} \exp\left(-\frac{c}{4z^2}\right)|h\rangle.$$

The z^{2h} factor comes from integrating $2h/z$ along the contour; the exponential of the central term produces $\exp(-c/(4z^2))$. Expanding the exponential yields (8.4). $\square$

Remark 8.1.23 (*Multi-path verification*). The closed form $R(z) = z^{2h} \exp(-c/(4z^2))$ is verified by 91 tests in `compute/lib/theorem_virasoro_spectral_r_matrix_engine.py`, including:

- direct OPE mode computation;
- path-ordered exponential numerical integration;

- series coefficient verification at $c = 1, 13, 25, 26$;
- comparison with the BPZ connection on conformal blocks;
- bosonic parity (only even $1/z$ powers).

The $R_2 = -c/4$ first correction is the genus-0 non-formality witness: it is the coefficient from which the infinite primitive-cumulant series $\Delta_{\text{Vir}}(t) = t^3 + 2t^5 + \dots$ of Example 8.1.21 descends via the shadow obstruction tower.

The Virasoro example exposes the shape of the general completion problem: finite-type truncations W_N lie in the proved Koszul regime, and the challenge is to assemble these finite-stage quasi-isomorphisms into a completed quasi-isomorphism for the full infinite-type algebra. The obstacle is purely analytic (convergence of the inverse system), and it admits a clean algebraic resolution once the correct filtration axiom is identified.

Example 8.1.24 (W_∞ : MC4 completion (proved)). The tower $W_\infty = \varprojlim_N W_N$ is the archetype of the programmatic regime: each finite stage W_N is principal finite type with proved bar-cobar quasi-isomorphism, but infinitely many generators prevent a direct application of the finite-stage theorem. The strong completion-tower theorem (Theorem 8.1.27) resolves this: the strong filtration axiom $\mu_r(F^{i_1}, \dots, F^{i_r}) \subset F^{i_1+\dots+i_r}$ makes the inverse-limit differential continuous and the Mittag-Leffler condition automatic, so the completed bar-cobar round-trip is a quasi-isomorphism.

The remaining example-specific tasks are:

1. identify the separated complete H-level/factorization target whose finite quotients recover W_N ;
2. verify the exact residue identities of Proposition 8.1.59;
3. close finite detection on I_N , after which Corollary 8.1.39 makes the comparison formal.

At each finite stage N , the bar-cobar adjunction (Theorem 11.1.84) is mediated by the universal twisting morphism $\tau_N: \bar{B}^{\text{ch}}(\mathcal{A}_{\leq N}) \rightarrow \mathcal{A}_{\leq N}$, which is a Maurer–Cartan element in the convolution algebra $\text{Conv}(\bar{B}^{\text{ch}}(\mathcal{A}_{\leq N}), \mathcal{A}_{\leq N})$ (Definition 3.1.19). The MC4 completion problem asks: *when do these finite-stage MC elements assemble to an MC element $\hat{\tau} \in MC(\widehat{\text{Conv}}(\widehat{B}^{\text{ch}}(\mathcal{A}), \mathcal{A}))$ in the completed convolution algebra?* The answer is that a single axiom on the filtration (that the A_∞ operations respect the additive weight) makes the MC equation $\partial(\hat{\tau}) + \hat{\tau} \star \hat{\tau} = 0$ converge in the inverse limit. Each component of this equation involves only finitely many terms (Lemma 8.1.26), so the passage to the completion is automatic.

Definition 8.1.25 (Strong completion tower). An augmented curved chiral A_∞ -algebra $\mathcal{A}$ on a curve X is a *strong completion tower* if it carries a descending filtration

$$\mathcal{A} = F^0 \mathcal{A} \supset F^1 \mathcal{A} \supset F^2 \mathcal{A} \supset \dots, \quad \bigcap_{N \geq 0} F^{N+1} \mathcal{A} = 0,$$

such that:

1. $\mathcal{A}$ is separated and complete: $\mathcal{A} \cong \varprojlim_N \mathcal{A}_{\leq N}$, where $\mathcal{A}_{\leq N} := \mathcal{A}/F^{N+1} \mathcal{A}$;
2. every quotient $\mathcal{A}_{\leq N}$ is finite type and lies in the proved bar-cobar regime;
3. $\bar{\mathcal{A}} = F^1 \mathcal{A}$ (the augmentation ideal is the first filtration piece); and
4. all chiral A_∞ -operations are filtration-nondecreasing:

$$\mu_r(F^{i_1} \mathcal{A}, \dots, F^{i_r} \mathcal{A}) \subset F^{i_1+\dots+i_r} \mathcal{A}. \quad (8.5)$$

In particular, each projection $p_N: \mathcal{A}_{\leq N+1} \rightarrow \mathcal{A}_{\leq N}$ is a strict morphism of curved chiral A_∞ -algebras, and the finite-stage bar constructions are compatible with the tower.

LEMMA 8.1.26 (*Degree cutoff: finite MC equation at each stage;*). For a strong completion tower, the MC equation $\partial(\tau_N) + \tau_N \star \tau_N = 0$ in $\text{Conv}(\bar{B}^{\text{ch}}(\mathcal{A}_{\leq N}), \mathcal{A}_{\leq N})$ involves only degrees $r \leq N$: the bar differential on $\mathcal{A}_{\leq N}$ is a finite sum.

Proof. If all inputs lie in $\bar{\mathcal{A}} = F^1 \mathcal{A}$, then $\mu_r(\bar{\mathcal{A}}^{\otimes r}) \subset F^r \mathcal{A}$ by (8.5). Modulo $F^{N+1} \mathcal{A}$, any term with $r \geq N+1$ vanishes. So on $\mathcal{A}_{\leq N}$ the bar differential is the finite sum $b_1 + \cdots + b_N$ of coderivations. $\square$

THEOREM 8.1.27 (*MC element lifts to the completed convolution algebra;*). Let $\mathcal{A}$ be a strong completion tower (Definition 8.1.25). Write $\tau_N \in \text{MC}(\text{Conv}(\bar{B}^{\text{ch}}(\mathcal{A}_{\leq N}), \mathcal{A}_{\leq N}))$ for the universal twisting morphism at stage N . Then:

1. *Completed coalgebra.* The completed bar construction $\widehat{B}^{\text{ch}}(\mathcal{A}) := \varprojlim_N \bar{B}^{\text{ch}}(\mathcal{A}_{\leq N})$ exists as a separated complete pronilpotent curved dg chiral coalgebra with continuous differential. It is the codomain of the completed twisting morphism $\widehat{\tau}: \widehat{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$. At each stage, $\widehat{B}^{\text{ch}}(\mathcal{A})/F^{N+1} \cong \bar{B}^{\text{ch}}(\mathcal{A}_{\leq N})$.
2. *Completed algebra.* The completed cobar object $\widehat{\Omega}^{\text{ch}}(\widehat{B}^{\text{ch}}(\mathcal{A})) := \varprojlim_N \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}_{\leq N}))$ is the twisted tensor product $\mathcal{A} \otimes_{\widehat{\tau}} \widehat{B}^{\text{ch}}(\mathcal{A})$: a separated complete curved dg chiral algebra.
3. *MC element is acyclic.* The completed twisting morphism $\widehat{\tau}$ is acyclic: the counit

$$\widehat{\epsilon}: \widehat{\Omega}^{\text{ch}}(\widehat{B}^{\text{ch}}(\mathcal{A})) \longrightarrow \mathcal{A}$$

is a quasi-isomorphism. At each quotient this is the finite-stage acyclicity of τ_N ; the passage to the limit uses the Milnor exact sequence with the Mittag–Leffler condition guaranteed by the strong filtration axiom.

4. *Dual acyclicity.* If $C = \varprojlim_N C_{\leq N}$ is a separated complete pronilpotent curved dg chiral coalgebra with every finite quotient in the theorematic regime, then the completed unit $\widehat{\eta}: C \rightarrow \widehat{B}^{\text{ch}}(\widehat{\Omega}^{\text{ch}}(C))$ is a quasi-isomorphism.
5. *Completed Koszul duality.* Completed bar and completed cobar are quasi-inverse equivalences on the full subcategory of strong completion towers whose finite quotients lie in the theorematic regime. The completed twisting morphism $\widehat{\tau} = \varprojlim_N \tau_N$ is a Maurer–Cartan element in the completed convolution algebra $\widehat{\text{Conv}} := \varprojlim_N \text{Conv}(\bar{B}^{\text{ch}}(\mathcal{A}_{\leq N}), \mathcal{A}_{\leq N})$, and this MC element represents the Koszul duality equivalence by twisting representability (Theorem 8.1.49).

This resolves the MC4 completion problem for strong completion towers. When the strong-filtration axiom holds, the degree cutoff (Lemma 8.1.26) makes each component of the MC equation a finite sum. For towers that do not satisfy the strong-filtration axiom (e.g. W_∞ with its spin-truncation tower), the same conclusion holds by a different route: the weight-cutoff criterion (Proposition 8.1.32) together with inverse-limit continuity (Proposition 8.1.36) supplies the Mittag–Leffler and convergence inputs needed by the reduction principle (Proposition 8.1.29).

Proof. Step 1: the completed coalgebra (codomain of $\widehat{\tau}$). Each quotient map $p_N : \mathcal{A}_{\leq N+1} \twoheadrightarrow \mathcal{A}_{\leq N}$ induces a morphism of finite-stage bar coalgebras $q_N : \widehat{B}^{\text{ch}}(\mathcal{A}_{\leq N+1}) \rightarrow \widehat{B}^{\text{ch}}(\mathcal{A}_{\leq N})$ that commutes with the bar differential, coproduct, coaugmentation, and curvature (by functoriality of the finite-stage bar construction and strictness of p_N). So the inverse limit $\widehat{B}^{\text{ch}}(\mathcal{A})$ exists in the dg category of chiral coalgebras with structure maps defined componentwise: $b = \varprojlim_N b_N$, $\Delta = \varprojlim_N \Delta_N$, $h = \varprojlim_N h_N$. The curved coalgebra identities hold quotientwise and hence on the limit. The completed twisting morphism $\widehat{\tau} := \varprojlim_N \tau_N$ is well-defined as a degree-+1 map $\widehat{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$.

Continuity: the MC equation converges. By Lemma 8.1.26, modulo F^{N+1} only degrees $\leq N$ contribute to the convolution product $\widehat{\tau} \star \widehat{\tau}$. The MC equation $\partial(\widehat{\tau}) + \widehat{\tau} \star \widehat{\tau} = 0$ therefore holds modulo F^{N+1} (where it reduces to the finite-stage equation for τ_N), hence on the completed coalgebra. The bar differential $\widehat{b}$ is continuous because the inverse-limit topology is initial for the projections.

Pronilpotence. The reduced coproduct on bar-length- $\leq m$ elements is nilpotent on each finite quotient (since bar length is bounded). Passing to the inverse limit gives topological pronilpotence.

Step 2: the completed cobar object. Each $\Omega^{\text{ch}}(\widehat{B}^{\text{ch}}(\mathcal{A}_{\leq N}))$ is a curved dg algebra, and the transition maps are compatible, so the inverse limit is again a complete curved dg algebra. The inverse-limit description ensures continuity automatically: everything is defined quotientwise.

Step 3: counit is a quasi-isomorphism. The quotient of $\widehat{\epsilon}$ modulo F^{N+1} is exactly the finite-stage counit $\epsilon_N : \Omega^{\text{ch}}(\widehat{B}^{\text{ch}}(\mathcal{A}_{\leq N})) \xrightarrow{\sim} \mathcal{A}_{\leq N}$, which is a quasi-isomorphism by the finite-stage theorem. Now apply the complete filtered comparison lemma (Lemma 8.6.24; Milnor exact sequence + surjective quotient tower):

$$0 \rightarrow \varprojlim_N^1 H^{m-1}(\text{Cone}(\epsilon_N)) \rightarrow H^m(\text{Cone}(\widehat{\epsilon})) \rightarrow \varprojlim_N H^m(\text{Cone}(\epsilon_N)) \rightarrow 0.$$

The right term vanishes because each ϵ_N is a quasi-isomorphism. The left term vanishes because the surjective quotient tower is Mittag-Leffler. Hence $\widehat{\epsilon}$ is a quasi-isomorphism.

Step 4: unit on the coalgebra side. By the same quotientwise argument: the quotient of $\widehat{\eta}$ modulo F^{N+1} is the finite-stage unit, which is a quasi-isomorphism. Lemma 8.6.24 applies identically. $\square$

PROPOSITION 8.1.28 (*Standard weight truncations and the induced bar filtration;*). Let $\mathcal{A}$ be one of the following chiral algebras:

- (a) $V_k(\mathfrak{g})$ for any simple $\mathfrak{g}$ and $k \neq -h^\vee$;
- (b) Vir_c for any c ;
- (c) $\mathcal{W}^k(\mathfrak{g}, f_{\text{prin}})$ for any simple $\mathfrak{g}$, principal nilpotent f , and non-critical k ;
- (d) V_Λ for any positive-definite even lattice Λ .

Write

$$\mathcal{A} = \bigoplus_{h \geq 0} \mathcal{A}_h, \quad \mathcal{A}_{\leq N} := \bigoplus_{0 \leq h \leq N} \mathcal{A}_h, \quad \widehat{\mathcal{A}}^{\text{wt}} := \prod_{h \geq 0} \mathcal{A}_h.$$

Then:

- (i) the inverse limit of the finite weight truncations is the weight completion,

$$\varprojlim_N \mathcal{A}_{\leq N} \cong \widehat{\mathcal{A}}^{\text{wt}},$$

and the direct sum $\mathcal{A}$ embeds into $\widehat{\mathcal{A}}^{\text{wt}}$ as a dense subspace; in particular, the direct-sum algebra $\mathcal{A}$ is not identified with this inverse limit unless it is already weight-complete;

(ii) the finite truncations $\{\mathcal{A}_{\leq N}\}_{N \geq 0}$ form an inverse system of finite-type curved chiral A_∞ -algebras;

(iii) for the reduced bar complexes

$$C_N := \bar{B}(\mathcal{A}_{\leq N}),$$

the total conformal-weight filtration

$$F_{\leq w} C_N := \text{span} \left\{ s^{-1}a_1 | \cdots | s^{-1}a_r \left| \sum_{j=1}^r \text{wt}(a_j) \leq w \right. \right\}$$

is an exhaustive increasing filtration preserved by the bar differential;

(iv) for each weight bound w and each $N \geq w$, the transition map $C_{N+1} \rightarrow C_N$ restricts to an isomorphism

$$F_{\leq w} C_{N+1} \xrightarrow{\sim} F_{\leq w} C_N.$$

Consequently these standard families supply the bar-level hypotheses of Proposition 8.1.32. What they do not supply is the strong-filtration axiom (8.5) on $\mathcal{A}$ itself for the descending conformal-weight filtration.

Proof. Each family carries the standard nonnegative conformal-weight decomposition

$$\mathcal{A} = \bigoplus_{h \geq 0} \mathcal{A}_h$$

with finite-dimensional weight spaces. For affine Kac–Moody, Virasoro, and principal $\mathcal{W}$ -algebras this is the usual L_0 -grading by conformal weight; for a positive-definite even lattice vertex algebra, finite-dimensionality of each $\mathcal{A}_h$ follows because only finitely many lattice vectors have a given norm.

The finite truncation $\mathcal{A}_{\leq N}$ is therefore finite-dimensional. The transition map $\mathcal{A}_{\leq N+1} \twoheadrightarrow \mathcal{A}_{\leq N}$ is the quotient by the weight- $(N+1)$ summand, so the inverse system $\{\mathcal{A}_{\leq N}\}_N$ is well defined. Its inverse limit is the product

$$\varprojlim_N \mathcal{A}_{\leq N} \cong \prod_{h \geq 0} \mathcal{A}_h = \widehat{\mathcal{A}}^{\text{wt}},$$

whereas the original chiral algebra is the direct sum $\bigoplus_{h \geq 0} \mathcal{A}_h$. This is the completion issue in the finding: bounded-below grading gives an inverse limit only after passing to the weight completion.

Now let $C_N = \bar{B}(\mathcal{A}_{\leq N})$. The weight decomposition on $\mathcal{A}_{\leq N}$ induces the total conformal weight on bar words by

$$\text{wt}(s^{-1}a_1 | \cdots | s^{-1}a_r) := \sum_{j=1}^r \text{wt}(a_j).$$

Desuspension changes cohomological degree, not conformal weight. A summand of the bar differential applies one of the chiral operations μ_r to a consecutive block of homogeneous inputs $a_1, \dots, a_r$ and extracts singular modes. For a single OPE step,

$$\text{wt}(a_{(n)}b) = \text{wt}(a) + \text{wt}(b) - n - 1 \leq \text{wt}(a) + \text{wt}(b) \quad (n \geq 0),$$

so residue extraction never increases conformal weight. Iterating this estimate through the A_∞ terms shows that every summand of the bar differential weakly decreases total conformal weight. Equivalently,

$$d_{\text{bar}}(F_{\leq w} C_N) \subset F_{\leq w} C_N.$$

This is the correct bar-level statement corresponding to the OPE weight formula. It does *not* imply the strong-filtration axiom (8.5) on $\mathcal{A}$ itself; for instance, for affine currents one has $\text{wt}(J_{(0)}^a J^b) = 1 < 2$.

Finally, if a homogeneous bar word has total conformal weight at most w , then each letter occurring in it has weight at most w . Hence for $N \geq w$ every such word already lies in $\bar{B}(\mathcal{A}_{\leq N})$, and the transition map $C_{N+1} \rightarrow C_N$ is an isomorphism on $F_{\leq w}$. This proves (iv), and the conclusion about Proposition 8.1.32 is immediate. $\square$

PROPOSITION 8.1.29 (*Reduction of MC4 to finite-stage compatibility;*). Let $\{C_N\}_{N \geq 0}$ be the inverse system of finite-stage bar complexes

$$C_N := \bar{B}(\mathcal{A}_{\leq N}), \quad \widehat{C} := \varprojlim_N C_N,$$

for a tower whose finite stages $\mathcal{A}_{\leq N}$ lie in the proved bar-cobar regime. Assume:

1. each transition map $C_{N+1} \rightarrow C_N$ is a morphism of complexes;
2. for every cohomological degree m , the inverse system $\{H^m(C_N)\}_N$ satisfies the Mittag-Leffler condition; and
3. the finite-stage bar-cobar quasi-isomorphisms $\epsilon_N : \Omega(C_N) \xrightarrow{\sim} \mathcal{A}_{\leq N}$ are compatible with the tower maps.

Then:

1. the completed cohomology is computed by the limit of the finite-stage cohomologies,

$$H^m(\widehat{C}) \cong \varprojlim_N H^m(C_N);$$

2. the induced map

$$\widehat{\epsilon} : \Omega(\widehat{C}) \longrightarrow \varprojlim_N \mathcal{A}_{\leq N}$$

is a quasi-isomorphism whenever the completed cobar differential is continuous.

Consequently, the remaining content of MC4 for a concrete tower is to verify continuity, pro-nilpotence, and the Mittag-Leffler/convergence conditions; no new formal obstruction remains once these are checked.

Proof. For any inverse system of cochain complexes there is a Milnor exact sequence

$$0 \rightarrow \varprojlim_N^1 H^{m-1}(C_N) \rightarrow H^m(\widehat{C}) \rightarrow \varprojlim_N H^m(C_N) \rightarrow 0.$$

Assumption (2) kills the derived limit term $\varprojlim_N^1$, so the first claim follows.

For the second claim, the maps ϵ_N assemble by Assumption (3) into a morphism of inverse systems. Passing to limits therefore gives a map $\widehat{\epsilon} : \Omega(\widehat{C}) \rightarrow \varprojlim_N \mathcal{A}_{\leq N}$. The finite-stage maps are quasi-isomorphisms, so after applying the first part to the bar complexes and the same Milnor argument to the compatible cobar tower, $\widehat{\epsilon}$ induces an isomorphism on cohomology. The continuity hypothesis ensures that the completed cobar differential is well defined, so $\widehat{\epsilon}$ is a quasi-isomorphism. $\square$

COROLLARY 8.1.30 (*Degree-wise stabilization criterion for MC₄*). In the setting of Proposition 8.1.29, assume in addition that for every cohomological degree m there exists $N(m)$ such that the transition maps

$$H^m(C_{N+1}) \longrightarrow H^m(C_N)$$

are isomorphisms for all $N \geq N(m)$. Then:

1. the inverse system $\{H^m(C_N)\}_N$ is Mittag–Leffler;
2. the completed cohomology stabilizes at the finite stage,

$$H^m(\widehat{C}) \cong H^m(C_{N(m)});$$

3. every compatible system of finite-stage bar-cobar quasi-isomorphisms induces a completed quasi-isomorphism

$$\Omega(\widehat{C}) \xrightarrow{\sim} \varprojlim_N \mathcal{A}_{\leq N},$$

provided the completed cobar differential is continuous.

Thus eventual stabilization of the finite-stage bar cohomology is a sufficient MC₄ input.

Proof. Eventual constancy implies the Mittag–Leffler condition, so Proposition 8.1.29 applies. Since the transition maps are isomorphisms for $N \geq N(m)$, the inverse limit $\varprojlim_N H^m(C_N)$ identifies with the stable value $H^m(C_{N(m)})$. The second and third claims are then exactly the conclusions of Proposition 8.1.29. $\square$

COROLLARY 8.1.31 (*Finite-dimensional surjectivity criterion for MC₄*). In the setting of Proposition 8.1.29, assume in addition that for every cohomological degree m :

1. each $H^m(C_N)$ is finite-dimensional; and
2. there exists $N_{\text{surj}}(m)$ such that the transition maps

$$H^m(C_{N+1}) \longrightarrow H^m(C_N)$$

are surjective for all $N \geq N_{\text{surj}}(m)$.

Then the inverse system $\{H^m(C_N)\}_N$ is Mittag–Leffler, and every compatible system of finite-stage bar-cobar quasi-isomorphisms induces a completed quasi-isomorphism

$$\Omega(\widehat{C}) \xrightarrow{\sim} \varprojlim_N \mathcal{A}_{\leq N},$$

provided the completed cobar differential is continuous. Thus MC₄ can be verified by eventual surjectivity on finite-dimensional weight slices; one does not need a priori eventual constancy of the full cohomology tower.

Proof. Fix m . For $N \geq N_{\text{surj}}(m)$ and every $r \geq 0$, the image of the composite map

$$H^m(C_{N+r}) \longrightarrow H^m(C_N)$$

is all of $H^m(C_N)$. Hence the descending image filtration in $H^m(C_N)$ stabilizes immediately, so the inverse system is Mittag–Leffler. Proposition 8.1.29 then gives the completed cohomology comparison and the completed bar-cobar quasi-isomorphism. $\square$

PROPOSITION 8.1.32 (*Weight-cutoff criterion for MC_4* ;). In the setting of Proposition 8.1.29, assume in addition that each finite-stage bar complex C_N carries an exhaustive increasing auxiliary-weight filtration

$$F_{\leq 0}C_N \subset F_{\leq 1}C_N \subset \cdots \subset C_N$$

such that:

1. the differential and the transition maps preserve the filtration;
2. for each weight bound w , the filtered piece $F_{\leq w}C_N$ is finite-dimensional in every cohomological degree; and
3. for each w and every $N \geq w$, the transition map induces an isomorphism of filtered subcomplexes

$$F_{\leq w}C_{N+1} \xrightarrow{\sim} F_{\leq w}C_N.$$

Then for every cohomological degree m , weight bound w , and $N \geq w$, the induced map

$$H^m(F_{\leq w}C_{N+1}) \xrightarrow{\sim} H^m(F_{\leq w}C_N)$$

is an isomorphism. Consequently the associated graded weight slices of cohomology stabilize, and if the cohomology splits as a direct sum of finite-dimensional weight slices, then the maps

$$H^m(C_{N+1})_w \xrightarrow{\sim} H^m(C_N)_w$$

are isomorphisms for all $N \geq w$. Hence the eventual-surjectivity input of Corollary 8.1.31 is automatic once the tower is defined by genuine weight truncations.

Proof. Assumption (3) identifies the filtered subcomplexes $F_{\leq w}C_{N+1}$ and $F_{\leq w}C_N$ for every $N \geq w$, so their cohomology groups are canonically isomorphic. Passing to successive quotients gives stabilization of the associated graded weight pieces. If the cohomology splits by weight, the direct-summand description of the weight slices identifies $H^m(C_N)_w$ with the corresponding graded piece, so the same stabilization holds on the nose. In particular the transition maps are eventually surjective on each finite-dimensional weight slice, and Corollary 8.1.31 applies. $\square$

PROPOSITION 8.1.33 (*W_∞ criterion from principal finite-type stages*;). Let

$$W_\infty = \varprojlim_N W_N$$

be a separated complete infinite-generator $\mathcal{W}$ -tower whose finite stages W_N lie in the proved principal finite-type $\mathcal{W}$ regime. Assume:

1. the transition maps $W_{N+1} \rightarrow W_N$ are compatible with the finite-stage bar complexes and bar-cobar quasi-isomorphisms;
2. for every cohomological degree m , the inverse system $\{H^m(\bar{B}(W_N))\}_N$ is eventually constant; and
3. the transition maps define an inverse system of curved dg coalgebras on the finite-stage bar complexes.

Then the completed bar object

$$\widehat{\bar{B}}(W_\infty) := \varprojlim_N \bar{B}(W_N)$$

is a separated complete pro-nilpotent curved dg coalgebra, and the canonical comparison map

$$\Omega(\widehat{\bar{B}}(W_\infty)) \xrightarrow{\sim} W_\infty$$

is a quasi-isomorphism. Thus the M-level completed bar-cobar package for W_∞ reduces to compatible inverse-system dg structure and stabilization of the principal finite-type tower. The stronger H-level realization problem belongs to MC₄; any physics-facing identification built on top of that realization is downstream at MC₅. By Corollary 8.1.31, the eventual-constancy hypothesis may be replaced by eventual surjectivity on finite-dimensional weight slices, and Proposition 8.1.32 shows that this surjectivity is formal for the standard principal-stage tower.

Proof. The principal finite-type stages supply the finite-stage bar-cobar quasi-isomorphisms required by Proposition 8.1.29. Assumption (2) is exactly the degreewise stabilization hypothesis of Corollary 8.1.30, and Assumption (3) lets one apply Proposition 8.1.36 to the inverse-limit bar and cobar differentials. Applying Corollary 8.1.30 to the tower $\{\bar{B}(W_N)\}_N$ yields the stated completed quasi-isomorphism. $\square$

COROLLARY 8.1.34 (*Standard principal-stage cutoff for W_∞*). Let W_N be the standard principal finite-type stage of W_∞ , so that W_N retains exactly the generators of conformal weights $2, 3, \dots, N$ and the transition map $W_{N+1} \rightarrow W_N$ forgets the generator of weight $N + 1$. Then the tower of bar complexes $\{\bar{B}(W_N)\}_N$ satisfies the hypotheses of Proposition 8.1.32 for the total conformal-weight filtration. In particular, for every cohomological degree m and conformal weight w , the map

$$H^m(\bar{B}(W_{N+1}))_w \xrightarrow{\sim} H^m(\bar{B}(W_N))_w$$

is an isomorphism for all $N \geq w$.

Therefore the standard principal-stage tower already supplies the surjectivity/stabilization part of MC₄. Together with Proposition 8.1.36, this reduces the standard W_∞ tower to the standard-tower completed M-level package of Corollary 8.1.37.

Proof. A bar chain of total conformal weight w can involve only generators whose conformal weights are at most w . Once $N \geq w$, all such generators already occur in W_N , so the filtered bar subcomplex of weights $\leq w$ is identical in every later stage. The bar differential preserves the total conformal-weight filtration used throughout the W -algebra computations, so Proposition 8.1.32 applies. $\square$

Remark 8.1.35 (*MC₄ splitting: positive vs. resonant*). Proposition 8.1.32 and Corollary 8.1.34 show that positive towers (those carrying an honest positive weight grading preserved by the bar differential) are *unconditionally solved*: the weight- w summand stabilizes at finite stage w . This resolves the “MC₄⁺” subproblem for $\mathcal{W}_{1+\infty}$, affine Yangians, and positive RTT towers.

The residual “MC₄⁰” subproblem concerns algebras with weight-zero resonance: a finite-dimensional piece $R_{\mathcal{A}}$ on which higher operations can preserve filtration degree 0 (Definition K.7.1). The resonance rank $\rho(\mathcal{A}) := \dim H^*(R_{\mathcal{A}}, m_1^{R_{\mathcal{A}}})$ classifies the completion difficulty: $\rho = 0$ (positive, solved), $0 < \rho < \infty$ (finite resonance, tractable via Theorem K.7.1), or $\rho = \infty$ (wild).

For Virasoro and non-quadratic $\mathcal{W}_N$ -algebras, the proved regime is $0 < \rho < \infty$ (Theorem K.7.1). The same-family shadow Vir_{26-c} is the depth-zero resonance shadow; the genuine $\mathcal{W}_\infty$ -type dual requires the full resonance-filtered completion. See Appendix K.7.1, §K.7.1 for the complete development.

PROPOSITION 8.1.36 (*Continuity of inverse-limit bar and cobar differentials;*). Let $\{C_N, d_N, \Delta_N\}_{N \geq 0}$ be an inverse system of finite-stage curved dg coalgebras with transition maps $\pi_{N+1, N} : C_{N+1} \rightarrow C_N$ commuting with the differentials and coproducts. Endow

$$\widehat{C} := \varprojlim_N C_N$$

with the inverse-limit topology, and let

$$\Omega(\widehat{C}) := \prod_{m \geq 0} (s^{-1}\widehat{C})^{\widehat{\otimes} m}$$

carry the completed tensor-product topology. Then:

1. the componentwise differential $\widehat{d}((x_N)_N) := (d_N x_N)_N$ on $\widehat{C}$ is well defined and continuous;
2. the inverse-limit coproduct $\widehat{\Delta}$ is continuous; and
3. the completed cobar differential on $\Omega(\widehat{C})$ induced by $\widehat{d}$ and $\widehat{\Delta}$ is continuous.

Consequently, once an MC₄ tower is realized as a genuine inverse system of finite-stage curved dg coalgebras, continuity is formal for the inverse-limit topology.

Proof. Let $p_N : \widehat{C} \rightarrow C_N$ be the projection. Because the transition maps commute with the differentials,

$$p_N \circ \widehat{d} = d_N \circ p_N$$

for every N , so the componentwise formula defines a map $\widehat{d} : \widehat{C} \rightarrow \widehat{C}$. The inverse-limit topology on $\widehat{C}$ is initial with respect to the projections p_N , hence $\widehat{d}$ is continuous as soon as each composite $p_N \circ \widehat{d}$ is continuous. This holds because each C_N is given the finite-stage topology and d_N is a morphism of complexes.

The same argument applies to the coproduct. Writing $p_N^{\otimes 2} : \widehat{C} \widehat{\otimes} \widehat{C} \rightarrow C_N \otimes C_N$ for the induced projection, one has

$$p_N^{\otimes 2} \circ \widehat{\Delta} = \Delta_N \circ p_N,$$

so $\widehat{\Delta}$ is well defined and continuous.

The completed cobar differential on $\Omega(\widehat{C})$ is the sum of the internal part coming from $\widehat{d}$ and the bar part coming from $\widehat{\Delta}$. On each tensor-length summand $(s^{-1}\widehat{C})^{\widehat{\otimes} m}$, each contribution is a finite sum of maps obtained by inserting either $\widehat{d}$ or $\widehat{\Delta}$ in one slot. Completed tensor products preserve continuity of continuous multilinear maps, and finite sums of continuous maps remain continuous. The product topology on $\Omega(\widehat{C})$ is defined componentwise by the tensor-length summands, so the total cobar differential is continuous. $\square$

COROLLARY 8.1.37 (*Standard principal-stage W_∞ tower satisfies the M -level MC₄ package;*). For the standard principal finite-type stages W_N of W_∞ , the completed bar object

$$\widehat{B}(W_\infty) := \varprojlim_N \bar{B}(W_N)$$

has continuous bar and cobar differentials, and the canonical comparison map

$$\Omega(\widehat{B}(W_\infty)) \xrightarrow{\sim} W_\infty$$

is a quasi-isomorphism. Thus the standard principal-stage tower realizes the full standard-tower M-level completed bar-cobar package for W_∞ ; the remaining problem is the H-level comparison with stronger factorization-theoretic or physical realizations.

Proof. The finite-stage bar complexes form an inverse system of curved dg coalgebras by Proposition 8.1.33, Assumption (3), so Proposition 8.1.36 gives the continuity of the completed bar and cobar differentials. The finite-stage bar-cobar quasi-isomorphisms are provided by the proved principal finite-type regime, and Corollary 8.1.34 supplies the Mittag–Leffler/stabilization input. Since $W_\infty = \varprojlim_N W_N$ by definition, applying Proposition 8.1.29 to the standard tower gives the stated quasi-isomorphism. $\square$

PROPOSITION 8.1.38 (*Comparison with a completed target by compatible finite quotients;*). Let $\{\mathcal{A}_{\leq N}\}_{N \geq 0}$ be an inverse system of dg algebras with surjective transition maps and completed limit

$$\widehat{\mathcal{A}} := \varprojlim_N \mathcal{A}_{\leq N}.$$

Let $\mathcal{B}$ be a separated complete dg algebra with descending filtration by closed dg ideals

$$F^1\mathcal{B} \supset F^2\mathcal{B} \supset \cdots.$$

Assume:

1. the canonical map

$$\mathcal{B} \xrightarrow{\sim} \varprojlim_N \mathcal{B}/F^{N+1}\mathcal{B}$$

is an isomorphism of dg algebras;

2. for each N there is a dg algebra quasi-isomorphism

$$f_N: \mathcal{B}/F^{N+1}\mathcal{B} \xrightarrow{\sim} \mathcal{A}_{\leq N};$$

3. the maps f_N commute with the quotient and transition maps; and
4. for every cohomological degree m , the inverse systems $\{H^m(\mathcal{B}/F^{N+1}\mathcal{B})\}_N$ and $\{H^m(\mathcal{A}_{\leq N})\}_N$ satisfy the Mittag–Leffler condition.

Then the induced map

$$\widehat{f}: \mathcal{B} \longrightarrow \widehat{\mathcal{A}}$$

is a quasi-isomorphism.

If, in addition, the quotient tower $\{\mathcal{B}/F^{N+1}\mathcal{B}\}_N$ carries bar-cobar comparison maps compatible with the tower $\{\mathcal{A}_{\leq N}\}_N$ and the completed bar and cobar differentials on $\mathcal{B}$ are continuous, then $\mathcal{B}$ and $\widehat{\mathcal{A}}$ define quasi-isomorphic completed M-level bar-cobar objects.

Proof. Assumption (1) identifies $\mathcal{B}$ with the inverse limit of its finite quotients. By Assumptions (2) and (3), the maps f_N assemble into a morphism of inverse systems and hence into a map

$$\widehat{f}: \mathcal{B} \cong \varprojlim_N \mathcal{B}/F^{N+1}\mathcal{B} \longrightarrow \varprojlim_N \mathcal{A}_{\leq N} = \widehat{\mathcal{A}}.$$

Apply the Milnor exact sequence to the quotient tower of $\mathcal{B}$ and to the tower $\{\mathcal{A}_{\leq N}\}_N$. Assumption (4) kills the derived-limit terms, so for every cohomological degree m one has

$$H^m(\mathcal{B}) \cong \varprojlim_N H^m(\mathcal{B}/F^{N+1}\mathcal{B}), \quad H^m(\widehat{\mathcal{A}}) \cong \varprojlim_N H^m(\mathcal{A}_{\leq N}).$$

Since each f_N is a quasi-isomorphism, the maps $H^m(f_N): H^m(\mathcal{B}/F^{N+1}\mathcal{B}) \xrightarrow{\sim} H^m(\mathcal{A}_{\leq N})$ are isomorphisms compatible with the inverse systems. Passing to inverse limits shows that $H^m(\widehat{f})$ is an isomorphism for every m , so $\widehat{f}$ is a quasi-isomorphism.

For the final claim, apply the same inverse-limit comparison to the compatible bar towers. Continuity of the completed bar and cobar differentials makes the completed bar objects well defined, and Proposition 8.1.29 identifies both completed bar-cobar packages with the same inverse-limit finite-stage data. Hence the resulting completed M-level bar-cobar objects are quasi-isomorphic. $\square$

COROLLARY 8.1.39 (*H-level comparison criterion for W_∞ ; .*). Let $\mathcal{W}^{\text{ht}}$ be a separated complete dg model for a factorization-theoretic or physical completion of W_∞ , equipped with a descending conformal-weight filtration by closed dg ideals. Assume:

1. $\mathcal{W}^{\text{ht}}$ is the inverse limit of its finite quotients;
2. each finite quotient $\mathcal{W}^{\text{ht}}/F^{N+1}\mathcal{W}^{\text{ht}}$ is dg quasi-isomorphic to the principal finite-type stage W_N , compatibly with the truncation tower; and
3. the quotient tower inherits the same finite-stage bar-cobar data and continuity hypotheses as in Corollary 8.1.37.

Then the induced comparison map

$$\mathcal{W}^{\text{ht}} \xrightarrow{\sim} W_\infty$$

is a quasi-isomorphism, and $\mathcal{W}^{\text{ht}}$ carries the same completed M-level bar-cobar object as the standard principal-stage completion. Thus the remaining $\mathcal{W}_\infty$ problem is to construct such a filtered H-level target and identify its finite quotients by the exact residue identities $C_{s,t;u;m,n}^{\text{res}}(N) = C_{s,t;u;m,n}^{\text{DS}}(N)$, discharged on the finite-detection packet $\mathcal{I}_N$, whose first live higher-spin stages are already reduced on the theorem surface to the stage-3 fifteen-coefficient packet and the exact stage-4 six-entry identity packet on $\mathcal{I}_4$, organized as three local OPE blocks and splitting into four higher-spin channels together with two theoremic principal Virasoro-target values $C_{4,4;2;0,6}^{\text{DS}} = 2$ and $C_{3,4;2;0,5}^{\text{DS}} = 0$, with the corresponding residue-side contraction supplied only under the normalized two-point package of Corollary 8.1.88, not another stabilization theorem.

Proof. Apply Proposition 8.1.38 with $\mathcal{A}_{\leq N} = W_N$. The Mittag-Leffler input is supplied by the same weight-cutoff argument as in Corollary 8.1.34, and the final statement follows from the bar-cobar comparison part of Proposition 8.1.38. $\square$

Definition 8.1.40 (Principal-stage compatible W_∞ target). A separated complete dg algebra $\mathcal{W}^{\text{ht}}$ is called a *principal-stage compatible W_∞ target* if it is equipped with a descending conformal-weight filtration by closed dg ideals such that:

1. $\mathcal{W}^{\text{ht}} \cong \varprojlim_N \mathcal{W}^{\text{ht}} / F^{N+1} \mathcal{W}^{\text{ht}}$;
2. each finite quotient $\mathcal{W}^{\text{ht}} / F^{N+1} \mathcal{W}^{\text{ht}}$ is dg quasi-isomorphic to the principal finite-type stage W_N ;
3. the quotient maps intertwine the principal-stage truncation tower; and
4. the quotient tower carries bar-cobar comparison maps compatible with the finite-type W_N bar complexes.

This is the H-level input singled out by Corollary 8.1.39.

Definition 8.1.41 (Principal-stage quotient system for a factorization W_∞ completion). Let $\mathcal{W}_\infty^{\text{fact}}$ be a separated complete factorization-theoretic completion of the principal W -tower. A *principal-stage quotient system* on $\mathcal{W}_\infty^{\text{fact}}$ consists of dg quotient maps

$$q_N : \mathcal{W}_\infty^{\text{fact}} \longrightarrow \mathcal{W}_{\leq N}^{\text{fact}}$$

such that:

1. the kernels of the q_N define a descending separated complete conformal-weight filtration;
2. each quotient object $\mathcal{W}_{\leq N}^{\text{fact}}$ is dg quasi-isomorphic to the principal finite-type stage W_N ;
3. the transition maps between the quotients intertwine the principal-stage truncation tower; and
4. the induced bar complexes agree with the finite-type bar-cobar package already proved for W_N .

PROPOSITION 8.1.42 (*Formal descent criterion for the W_∞ factorization target;*). A separated complete factorization-theoretic completion equipped with a principal-stage quotient system (Definition 8.1.41) is a principal-stage compatible W_∞ target (Definition 8.1.40). Bar-cobar compatibility further implies Corollary 8.1.39.

Proof. The quotient-system data package precisely the inputs of Definition 8.1.40. □

PROPOSITION 8.1.43 (*Factorization-envelope criterion for principal stages;*). Let $\mathcal{F}_\infty$ be a separated complete factorization algebra on a curve with quotient maps $\mathcal{F}_\infty \twoheadrightarrow \mathcal{F}_{\leq N}$ whose kernels define a descending separated complete conformal-weight filtration. If each $\mathcal{F}_{\leq N}$ admits a BD chiral envelope quasi-isomorphic to W_N and the quotient maps intertwine the principal-stage tower, then the chiral envelope of $\mathcal{F}_\infty$ is a principal-stage compatible W_∞ target. Bar-data compatibility further implies Proposition 8.1.42 and Corollary 8.1.39.

Proof. The chiral-envelope functor produces compatible quotients recovering the principal stages; Proposition 8.1.42 applies. □

Definition 8.1.44 (Completion closure of the finite-type regime). Let F_{ft} denote the class of finite-type augmented curved chiral A_∞ -algebras for which the finite-stage bar-cobar theorem is proved. The *completion closure* $\text{CompCl}(F_{\text{ft}})$ is the class of strong completion towers $\mathcal{A} = \varprojlim_N \mathcal{A}_{\leq N}$ with every quotient $\mathcal{A}_{\leq N} \in F_{\text{ft}}$.

Dually, define $C_{\text{str}}^\wedge$ to be the class of separated complete pronilpotent curved dg chiral coalgebras $C = \varprojlim_N C_{\leq N}$ such that each $C_{\leq N}$ lies in the finite-stage essential image.

COROLLARY 8.1.45 (*Homotopy-categorical equivalence on the completion closure;*). If one localizes strong completion towers and objects in $C_{\text{str}}^\wedge$ by quotientwise quasi-isomorphisms, then

$$\widehat{B}^{\text{ch}} \dashv \widehat{\Omega}^{\text{ch}}$$

induces an equivalence of homotopy categories. That is, Theorem 8.1.27 gives quasi-inverse functors on the localized categories.

Proof. The counit and unit are quasi-isomorphisms by Theorem 8.1.27(3)–(4). Both pass to the localized categories. $\square$

Remark 8.1.46 (Adjunction direction convention). The canonical adjunction direction throughout this monograph is $\Omega^{\text{ch}} \dashv \bar{B}^{\text{ch}}$ (cobar left adjoint to bar), as stated in the chapter opening: the Hom-set identity is $\text{Hom}_{\text{Alg}}(\Omega^{\text{ch}}(C), \mathcal{A}) \cong \text{Tw}(C, \mathcal{A}) \cong \text{Hom}_{\text{Coalg}}(C, \bar{B}^{\text{ch}}(\mathcal{A}))$, following the Loday–Vallette convention [299]. The displayed formula above and occasional later passages write $\bar{B}^{\text{ch}} \dashv \Omega^{\text{ch}}$ or $B \dashv \Omega$; this denotes the same adjunction with the opposite notational convention (listing the right adjoint first). The mathematical content (unit $\eta: C \rightarrow \bar{B}^{\text{ch}}(\Omega^{\text{ch}}(C))$, counit $\psi: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$) is unambiguous and consistent throughout.

Definition 8.1.47 (Window-stability). For a tower $\{\mathcal{A}_{\leq N}\}_{N \geq 0}$ and each pair of bounds (m, q) (cohomological degree, total conformal weight), let

$$W_{m,q}(\mathcal{A}_{\leq N}) \subset \bar{B}^{\text{ch}}(\mathcal{A}_{\leq N})$$

be the finite-dimensional subcomplex spanned by bar chains of cohomological degree m and total conformal weight $\leq q$. The tower is *window-stable* if for every (m, q) there exists $N_0(m, q)$ such that for all $N \geq N_0(m, q)$ the transition maps identify $W_{m,q}(\mathcal{A}_{\leq N+1}) \cong W_{m,q}(\mathcal{A}_{\leq N})$ as subcomplexes (differentials agree under the identification).

THEOREM 8.1.48 (*Coefficient-stability criterion;*). Let $\{\mathcal{A}_{\leq N}\}_{N \geq 0}$ be a compatible tower of finite-type stages presented by generators and OPE/ A_∞ -structure constants. Suppose that for every finite generator set S , bar degree bound m , and total-weight bound q , the finitely many OPE/ A_∞ -coefficients entering the bar differential on the window $W_{m,q}(\mathcal{A}_{\leq N})$ are eventually independent of N . Then:

1. the tower is window-stable;
2. the inverse limit $\mathcal{A} = \varprojlim_N \mathcal{A}_{\leq N}$ carries a unique strong completion-tower structure; and
3. Theorem 8.1.27 applies.

Proof. Fix (m, q) . The window $W_{m,q}(\mathcal{A}_{\leq N})$ involves finitely many basis vectors. The bar differential on that finite-dimensional space is given by a finite matrix whose entries are universal polynomial expressions in finitely many OPE/ A_∞ -coefficients. By hypothesis, those coefficients stabilize for $N \gg 0$, so every matrix entry stabilizes. This gives window-stability.

Eventual constancy of the quotient structure tensors on every (m, q) -window provides a compatible inverse system of multilinear operations on all finite quotients. Passing to the inverse limit defines continuous A_∞ -operations on $\mathcal{A}$. The A_∞ identities are polynomial on each quotient and pass to the limit entrywise. Continuity of the completed bar differential follows because on each weight quotient only finitely many degrees survive and all matrices are stable. Theorem 8.1.27 then applies. $\square$

THEOREM 8.1.49 (*Completed twisting representability*;). For $\mathcal{A} \in \text{CompCl}(F_{\text{ft}})$ and $C \in \mathcal{C}_{\text{str}}^\wedge$, define $\text{Tw}_{\text{cts}}(C, \mathcal{A})$ to be the set of degree- (-1) continuous twisting morphisms from C to $\mathcal{A}$. Then

$$\text{Hom}_{\text{alg}}(\widehat{\Omega}^{\text{ch}} C, \mathcal{A}) \cong \text{Tw}_{\text{cts}}(C, \mathcal{A}) \cong \text{Hom}_{\text{coalg}}(C, \widehat{B}^{\text{ch}} \mathcal{A}).$$

Proof. A continuous map into or out of a complete object is equivalent to a compatible family of maps on finite quotients/windows. On each finite quotient, ordinary bar/cobar representability holds by the finite-stage regime. Passing to compatible inverse limits preserves the representing property because the windows are finite and stabilized. $\square$

THEOREM 8.1.50 (*MC-twisting closure of the completion closure*;). Let $\mathcal{A}$ be a strong completion tower and let $\alpha \in F^1 \mathcal{A}^1$ be a continuous Maurer–Cartan element. Then the twisted algebra $\mathcal{A}_\alpha$ is again a strong completion tower, and

$$\widehat{\Omega}^{\text{ch}}(\widehat{B}^{\text{ch}}(\mathcal{A}_\alpha)) \simeq \mathcal{A}_\alpha.$$

Proof. The twisted operations are

$$\mu_n^\alpha(a_1, \dots, a_n) = \sum_{k \geq 0} \mu_{n+k}(\alpha^{\otimes k}, a_1, \dots, a_n).$$

Since $\alpha \in F^1 \mathcal{A}$, each insertion raises filtration degree by at least one. Modulo F^{N+1} , only $k \leq N$ can contribute. So the twist is quotientwise finite and continuous, preserves the strong completion-tower axioms, and Theorem 8.1.27 applies. $\square$

THEOREM 8.1.51 (*Uniform PBW bridge from MC1 to MC4*;). Let $\mathcal{A} = \varprojlim_N \mathcal{A}_{\leq N}$ be a strong completion tower, and assume each finite stage carries a PBW filtration P . Suppose:

1. for each quotient level q , the associated-graded quotients $\text{gr}_P(\mathcal{A}_{\leq N}/F^{q+1})$ stabilize for $N \gg 0$; and
2. for each q , the bar spectral sequence of $\mathcal{A}_{\leq N}/F^{q+1}$ degenerates at a page $E^{r(q)}$ independent of sufficiently large N .

Then the quotient bar cohomology stabilizes for each q , and completed bar-cobar duality holds for $\mathcal{A}$.

Proof. For fixed q , the PBW filtration on the quotient bar complex is finite. Stabilization of the associated graded gives stabilization of the E^0 and E^1 pages for large N . Uniform degeneration at page $E^{r(q)}$ implies stabilization of E^∞ . Since the filtration is finite, stabilized E^∞ implies stabilized total cohomology of the quotient bar complex. Theorem 8.1.27 then applies quotientwise. $\square$

Remark 8.1.52 (Completion closure: the correct MC_4 envelope). Theorem 8.1.27 together with the coefficient-stability criterion (Theorem 8.1.48) and the uniform PBW bridge (Theorem 8.1.51) give the correct theorematic envelope for MC_4 . What was previously four abstract requirements (continuity, pro-nilpotence, Mittag–Leffler control, and inverse-limit identification) is now absorbed into a single structural axiom (strong completion tower) from which all formal properties follow automatically.

The genuine example-specific residue for $\mathcal{W}_\infty$ and Yangian towers is now reduced to: *verify coefficient stabilization on finite windows and identify the inverse-limit target*. For positive towers (weight-graded by an honest positive grading), the weight-cutoff criterion of Proposition 8.1.32 makes this automatic. For towers with weight-zero resonance, the finite-resonance criterion of Theorem K.7.1 applies once the resonance rank is shown to be finite.

PROPOSITION 8.1.53 (*Factorization realization package for W_∞ ; .*). There exists a principal-stage compatible W_∞ target $\mathcal{W}_\infty^{\text{fact}}$ in the sense of Definition 8.1.40, arising from a factorization-theoretic or physical completion of the principal W -tower. Equivalently:

1. $\mathcal{W}_\infty^{\text{fact}}$ carries a separated complete conformal-weight filtration;
2. its finite quotients recover the theorematic principal finite-type stages W_N ;
3. the induced bar-cobar data on those quotients agree with the standard finite-stage bar complexes; and
4. the resulting comparison map

$$\mathcal{W}_\infty^{\text{fact}} \xrightarrow{\sim} W_\infty$$

identifies the factorization-theoretic completion with the standard principal-stage completed M-level package.

This is resolved by Theorem H.26.28: the factorization target is constructed via E_∞ -sectorwise convergence at each finite stage, with the DS–KD intertwining (Theorem 15.10.1) providing the finite-stage identifications and the Mittag–Leffler property (Corollary 8.1.37) controlling the inverse limit.

Remark 8.1.54 (Attack route for the W_∞ factorization target). The reduction chain from Proposition 8.1.53 proceeds through higher-spin ideals (Proposition 8.1.55), spin-triangular OPE closure (Proposition 8.1.56), coefficient-level DS matching (Proposition 8.1.58), residue identity (Proposition 8.1.59), generator seeds (Proposition 8.1.60, Corollary 8.1.61), and the explicit stage-3 W_3 packet (Proposition 8.1.68). The first genuinely new higher-spin packet is stage 4.

PROPOSITION 8.1.55 (*Higher-spin ideal criterion for principal-stage W_∞ quotients; .*). Let $\mathcal{F}_\infty$ be a separated complete factorization algebra on a curve, topologically generated by fields $W^{(s)}$ of conformal weights $s \geq 2$. For each $N \geq 2$, let $I_{>N}\mathcal{F}_\infty$ denote the closed factorization ideal generated by the fields $W^{(s)}$ with $s > N$. Assume:

1. the differential, translation operator, and factorization products preserve each ideal $I_{>N}\mathcal{F}_\infty$;
2. modulo $I_{>N}\mathcal{F}_\infty$, the OPE of the generators $W^{(2)}, \dots, W^{(N)}$ closes among those same generators;
3. the quotient factorization algebra $\mathcal{F}_{\leq N} := \mathcal{F}_\infty / I_{>N}\mathcal{F}_\infty$ admits a chiral envelope or equivalent dg model quasi-isomorphic to the principal stage W_N ; and
4. the quotient maps $\mathcal{F}_{\leq N+1} \twoheadrightarrow \mathcal{F}_{\leq N}$ intertwine the principal-stage truncation tower.

Then the quotients $\{\mathcal{F}_{\leq N}\}_{N \geq 2}$ define a principal-stage quotient system in the sense of Definition 8.1.41. Consequently, Proposition 8.1.43, Proposition 8.1.42, and Corollary 8.1.39 apply.

In particular, the remaining $\mathcal{W}_\infty$ construction problem is to prove that the higher-spin generators above stage N define stable factorization ideals whose quotients recover the theoremtic principal stages.

Proof. Assumptions (1)–(4) supply closed factorization ideals, closed OPE, finite-stage identification with W_N , and compatibility with the principal-stage tower. This is exactly the data required by Definition 8.1.41. The stated comparison results then follow from Proposition 8.1.43, Proposition 8.1.42, and Corollary 8.1.39. $\square$

PROPOSITION 8.1.56 (*Spin-triangular OPE criterion for the W_∞ factorization ideals*;). Let $\mathcal{F}_\infty$ be a separated complete factorization algebra on a curve, topologically generated by fields $W^{(s)}$ of conformal weight $s \geq 2$. Assume:

1. for every pair of generators, the coefficient of the pole $(z - w)^{-n}$ in the local OPE $W^{(s)}(z)W^{(t)}(w)$ is a linear combination of derivatives of fields $W^{(u)}$ with $u \leq s + t - n$;
2. the translation operator and the residue/bar operations are obtained from these OPE coefficients by the standard factorization formulas, so no operation increases the maximal conformal weight appearing in an expression; and
3. for each N , after quotienting by the fields $W^{(s)}$ with $s > N$, the induced OPE formulas on $W^{(2)}, \dots, W^{(N)}$ agree with the principal finite-type stage W_N .

Then the closed factorization ideals

$$I_{>N}\mathcal{F}_\infty = \langle W^{(s)} \mid s > N \rangle_{\text{fact}}$$

form a compatible principal-stage quotient system. In particular, Proposition 8.1.55 applies, and the resulting quotients recover the principal finite-type stages.

Proof. Spin-triangularity (1) closes the quotient OPE on generators $\leq N$; (2) preserves the ideal under all operations; (3) identifies the quotient with W_N . Nesting of ideals gives compatibility for varying N . $\square$

PROPOSITION 8.1.57 (*Coefficient-level DS criterion for principal-stage W_∞ quotients*;). Fix $N \geq 2$ and let $\mathcal{F}_{\leq N} := \mathcal{F}_\infty / I_{>N}\mathcal{F}_\infty$ be a quotient from Proposition 8.1.56. If the quotient is strongly generated by $W^{(2)}, \dots, W^{(N)}$ with OPE coefficients matching the principal DS formulas for W_N , no additional local relations, and induced bar operations coinciding with the finite-stage package, then $\mathcal{F}_{\leq N}$ identifies with W_N and Proposition 8.1.55 applies.

Proof. The hypotheses supply the same generators, OPE, and bar data as W_N ; the reconstruction principle gives the identification. $\square$

PROPOSITION 8.1.58 (*Local-coefficient criterion for principal-stage W_∞ quotients*;). Fix $N \geq 2$ and let $\mathcal{F}_{\leq N} := \mathcal{F}_\infty / I_{>N}\mathcal{F}_\infty$ be as in Proposition 8.1.56. If the local OPE coefficients $C_{s,t}^{u;m,n}(N)$ agree with the principal DS data, translation descendants generate all local relations, and bar operations match, then Proposition 8.1.57 applies and the quotient identifies with W_N .

Proof. Immediate from Proposition 8.1.57. $\square$

PROPOSITION 8.1.59 (*Residue-coefficient identity criterion for principal-stage W_∞ quotients*;). Fix $N \geq 2$ and let $\mathcal{F}_{\leq N} := \mathcal{F}_\infty / I_{>N} \mathcal{F}_\infty$ be as in Proposition 8.1.56. If $C_{s,t;u;m,n}^{\text{res}}(N) = C_{s,t;u;m,n}^{\text{DS}}(N)$ for every admissible tuple and the quotient OPE and bar operations are entirely determined by these residue coefficients, then Proposition 8.1.58 applies and the quotient identifies with W_N .

Proof. Immediate from Proposition 8.1.58. $\square$

PROPOSITION 8.1.60 (*Generator-seed criterion for principal-stage W_∞ residue identities*;). Fix $N \geq 2$ and let

$$\mathcal{F}_{\leq N} := \mathcal{F}_\infty / I_{>N} \mathcal{F}_\infty$$

be as in Proposition 8.1.59. Assume:

1. $\mathcal{F}_{\leq N}$ is strongly generated by $W^{(2)}, \dots, W^{(N)}$;
2. for each pair of generators $W^{(s)}, W^{(t)}$ with $2 \leq s, t \leq N$, the primary residue coefficients

$$C_{s,t;u;0,n}^{\text{res}}(N)$$

agree with the principal Drinfeld–Sokolov coefficients $C_{s,t;u;0,n}^{\text{DS}}(N)$ for every visible pole order and target spin u ;

3. translation commutes with the residue extraction formulas, so all descendant coefficients are obtained from the primary ones by repeated application of ∂ ; and
4. the bar operations are generated from the same residue calculus and therefore are determined by those translated coefficient families.

Then the full mode-by-mode identities

$$C_{s,t;u;m,n}^{\text{res}}(N) = C_{s,t;u;m,n}^{\text{DS}}(N)$$

hold for all admissible indices. Consequently the hypotheses of Proposition 8.1.59 are satisfied.

Proof. Primary generator agreement propagates to all descendants by translation (assumption (3)), and strong generation (assumption (1)) plus bar recovery (assumption (4)) identify the full coefficient family, verifying Proposition 8.1.59. $\square$

COROLLARY 8.1.61 (*Finite primary seed set for principal-stage W_∞ comparison*;). Fix $N \geq 2$ and define the finite index set

$$\mathcal{I}_N := \left\{ (s, t, u, n) \left| \begin{array}{l} 2 \leq s \leq t \leq N, \\ 2 \leq u \leq \min(N, s + t - 1), \\ 1 \leq n \leq s + t - u \end{array} \right. \right\}.$$

Assume the hypotheses of Proposition 8.1.60. Then it is enough to check the primary identities

$$C_{s,t;u;0,n}^{\text{res}}(N) = C_{s,t;u;0,n}^{\text{DS}}(N) \quad \text{for all } (s, t, u, n) \in \mathcal{I}_N.$$

These finitely many checks imply the full residue/OPE identity package required by Proposition 8.1.59.

Proof. Spin-triangularity implies that for fixed $s, t \leq N$ only target spins $u \leq s + t - 1$ and pole orders $n \leq s + t - u$ can appear. Since the stage quotient discards spins $> N$, the admissible tuples are exactly those in $\mathcal{I}_N$, hence finite.

Proposition 8.1.60 shows that agreement on these primary generator coefficients propagates by translation to every descendant coefficient and therefore to the full residue/bar package. $\square$

COROLLARY 8.1.62 (*First principal-stage seed packets for W_∞ comparison;*). The finite seed sets of Corollary 8.1.61 begin as follows:

$$\mathcal{I}_2 = \{(2, 2, 2, 1), (2, 2, 2, 2)\},$$

and

$$\begin{aligned} \mathcal{I}_3 = & \{(2, 2, 2, 1), (2, 2, 2, 2), (2, 2, 3, 1)\} \\ & \sqcup \{(2, 3, 2, 1), (2, 3, 2, 2), (2, 3, 2, 3), (2, 3, 3, 1), (2, 3, 3, 2)\} \\ & \sqcup \{(3, 3, 2, 1), (3, 3, 2, 2), (3, 3, 2, 3), (3, 3, 2, 4), \\ & \quad (3, 3, 3, 1), (3, 3, 3, 2), (3, 3, 3, 3)\}. \end{aligned}$$

In particular, the first genuinely new infinite-generator stage beyond the theorematic Virasoro block is the stage-3 packet of fifteen primary coefficients: the two Virasoro coefficients, the single vanishing $W^{(2)}W^{(2)} \rightarrow W^{(3)}$ coefficient, five mixed $W^{(2)}/W^{(3)}$ coefficients, and seven $W^{(3)}$ self-coupling coefficients.

Proof. For $N = 2$, the defining inequalities for $\mathcal{I}_N$ force $s = t = u = 2$ and $1 \leq n \leq 2$, giving exactly the two displayed tuples. For $N = 3$, the admissible ordered pairs of generator spins are $(2, 2)$, $(2, 3)$, and $(3, 3)$. The inequalities

$$2 \leq u \leq \min(3, s + t - 1), \quad 1 \leq n \leq s + t - u$$

then give the displayed decomposition into the three corresponding blocks. The final sentence is simply a repackaging of those tuples by source pair and target spin. $\square$

PROPOSITION 8.1.63 (*Incremental interacting packet from stage N to stage $N+1$;*). Fix $N \geq 3$ and let $\mathcal{I}_N$ and $\mathcal{I}_{N+1}$ be the seed packets of Corollary 8.1.61. Write

$$\mathcal{I}_{N+1}^{\text{Vir,new}} := \mathcal{I}_{N+1}^{\text{Vir}} \setminus \mathcal{I}_N = \{(2, N+1, u, n) \in \mathcal{I}_{N+1}\},$$

and define the incremental interacting packet

$$\mathcal{J}_{N+1} := \mathcal{I}_{N+1} \setminus (\mathcal{I}_N \sqcup \mathcal{I}_{N+1}^{\text{Vir,new}}).$$

Assume the hypotheses of Proposition 8.1.60. Then:

1. the coefficients indexed by $\mathcal{I}_N$ are exactly the stage- N packet identities;
2. the coefficients indexed by $\mathcal{I}_{N+1}^{\text{Vir,new}}$ are determined by the exact stress-tensor action on the new generator $W^{(N+1)}$;

3. the genuinely new interacting stage- $(N + 1)$ packet is therefore exactly $\mathcal{J}_{N+1}$, and it decomposes as the disjoint union

$$\mathcal{J}_{N+1} = \mathcal{J}_{N+1}^{\text{tail}} \sqcup \mathcal{J}_{N+1}^{\text{mix}} \sqcup \mathcal{J}_{N+1}^{\text{self}},$$

where

$$\mathcal{J}_{N+1}^{\text{tail}} := \{(s, t, N+1, n) \in \mathcal{I}_{N+1} \mid 3 \leq s \leq t \leq N\},$$

$$\mathcal{J}_{N+1}^{\text{mix}} := \{(s, N+1, u, n) \in \mathcal{I}_{N+1} \mid 3 \leq s \leq N, 2 \leq u \leq N+1\},$$

$$\mathcal{J}_{N+1}^{\text{self}} := \{(N+1, N+1, u, n) \in \mathcal{I}_{N+1} \mid 2 \leq u \leq N+1\}.$$

Consequently, once the stage- N packet identities on $\mathcal{I}_N$ are known, the stage- $(N + 1)$ comparison is equivalent to matching the coefficients on the incremental interacting packet $\mathcal{J}_{N+1}$. For $N = 3$, this is exactly the stage-4 residual packet of Proposition 8.1.69.

Proof. Since $\mathcal{I}_N \subset \mathcal{I}_{N+1}$, new tuples have at least one index equal to $N+1$. Those with $s = 2$ form $\mathcal{I}_{N+1}^{\text{Vir, new}}$; the complement $\mathcal{J}_{N+1}$ (with $s \geq 3$) splits exhaustively into the three displayed blocks by whether the new index appears in u, t , or both. $\square$

COROLLARY 8.1.64 (*Top-pole/parity reduction of the incremental W_∞ stage-growth packet;*). Fix $N \geq 3$ and assume the hypotheses of Proposition 8.1.63, Proposition 8.1.66, and Proposition 8.1.67. Let

$$\mathcal{J}_{N+1}^{\text{top}} := \{(s, t, u, s + t - u) \in \mathcal{J}_{N+1}\},$$

and remove the odd self-OPE top-pole entries by setting

$$\mathcal{J}_{N+1}^{\text{red}} := \mathcal{J}_{N+1}^{\text{top}} \setminus \{(s, s, u, 2s - u) \in \mathcal{J}_{N+1}^{\text{top}} \mid 2s - u \text{ odd}\}.$$

Then, once the stage- N packet identities on $\mathcal{I}_N$ are known, the stage- $(N + 1)$ comparison closes as soon as the identities on the reduced incremental packet $\mathcal{J}_{N+1}^{\text{red}}$ are proved.

For $N = 3$, one has

$$\mathcal{J}_4^{\text{red}} = \mathcal{J}_4^{\text{par}},$$

so this is exactly the six-entry stage-4 block of Corollary 8.1.72. The additional contraction of that six-entry block to the four higher-spin channels is controlled by the stage-4 Ward-inheritance input.

Proof. Top-pole primaryity (Proposition 8.1.66) and odd self-OPE parity (Proposition 8.1.67) reduce $\mathcal{J}_{N+1}$ to $\mathcal{J}_{N+1}^{\text{red}}$. For $N = 3$ this recovers the stage-4 parity packet. $\square$

COROLLARY 8.1.65 (*First reduced incremental packet beyond $\mathcal{I}_4$;*). Assume the hypotheses of Corollary 8.1.64 with $N = 4$. Then the first reduced incremental packet beyond the stage-4 block is

$$\begin{aligned} \mathcal{J}_5^{\text{red}} = & \left\{ (3, 4; 5; 0, 2) \right\} \sqcup \left\{ (3, 5; 2; 0, 6), (3, 5; 3; 0, 5), (3, 5; 4; 0, 4), (3, 5; 5; 0, 3) \right\} \\ & \sqcup \left\{ (4, 5; 2; 0, 7), (4, 5; 3; 0, 6), (4, 5; 4; 0, 5), (4, 5; 5; 0, 4) \right\} \sqcup \left\{ (5, 5; 2; 0, 8), (5, 5; 4; 0, 6) \right\}. \end{aligned}$$

In particular,

$$|\mathcal{J}_5^{\text{red}}| = 11,$$

decomposed as one tail channel, two four-entry mixed blocks, and two self-coupling channels.

Proof. Enumerate the tail, mixed, and self blocks of $\mathcal{J}_5$ from Proposition 8.1.63; apply top-pole primaryity and odd self-OPE parity to each. The surviving entries are exactly the displayed eleven tuples. $\square$

PROPOSITION 8.1.66 (*Primary top-pole criterion for generator seed packets;*). Fix $N \geq 2$ and assume the hypotheses of Proposition 8.1.60. Assume that for each $2 \leq u \leq N$ the strong generator $W^{(u)}$ is primary of conformal weight u with respect to the Virasoro field $T := W^{(2)}$, and that the local OPE is decomposed into conformal families of these primary generators and their translation descendants.

Then for every visible triple (s, t, u) with

$$2 \leq s \leq t \leq N, \quad 2 \leq u \leq \min(N, s + t - 1),$$

the primary generator $W^{(u)}$ can appear only at the top pole order

$$n_{\max}(s, t; u) := s + t - u.$$

Equivalently,

$$C_{s,t;u;0,n}^{\text{res}}(N) = C_{s,t;u;0,n}^{\text{DS}}(N) = 0 \quad \text{for every } 1 \leq n < s + t - u.$$

Consequently the primary seed set of Corollary 8.1.61 reduces further to the top-pole subset

$$\mathcal{I}_N^{\text{top}} := \{(s, t, u, s + t - u) \in \mathcal{I}_N\}.$$

Proof. Because $W^{(s)}$, $W^{(t)}$, and $W^{(u)}$ are primary fields of weights s , t , and u , conformal covariance organizes the $W^{(u)}$ -family inside the OPE $W^{(s)}(z)W^{(t)}(w)$ as one primary coefficient multiplying $W^{(u)}(w)$ at pole order $s + t - u$, together with the translation descendants $\partial^m W^{(u)}(w)$ at the lower poles $s + t - u - m$. The undifferentiated primary field therefore occurs only at the top pole order $n = s + t - u$.

In the notation of Proposition 8.1.60, the coefficients

$$C_{s,t;u;0,n}^{\text{res}}(N), \quad C_{s,t;u;0,n}^{\text{DS}}(N)$$

record the coefficients of the undifferentiated primary generator $W^{(u)}$ itself. Hence those coefficients vanish for all lower pole orders $n < s + t - u$, both on the residue side and on the principal Drinfeld–Sokolov side. This proves the displayed vanishing and identifies the reduced top-pole seed set $\mathcal{I}_N^{\text{top}}$. $\square$

PROPOSITION 8.1.67 (*Odd top-pole vanishing for identical even generators;*). Fix $N \geq 2$ and assume the hypotheses of Proposition 8.1.66. Assume further that the strong generators $W^{(2)}, \dots, W^{(N)}$ are even fields. Then for every visible self-coupling triple (s, s, u) one has

$$C_{s,s;u;0,2s-u}^{\text{res}}(N) = C_{s,s;u;0,2s-u}^{\text{DS}}(N) = 0 \quad \text{whenever } 2s - u \text{ is odd.}$$

Equivalently, for identical even generators the top-pole primary coefficient can be nonzero only when the top pole order is even.

Proof. Let $A := W^{(s)}$ and set $m := 2s - u - 1$, so the top-pole primary coefficient of the target generator $W^{(u)}$ in the self-OPE $A(z)A(w)$ is the $A_{(m)}A$ term. Because A is even, the vertex-algebra skew-symmetry formula gives

$$A_{(m)}A = \sum_{j \geq 0} \frac{(-1)^{m+j+1}}{j!} \partial^j (A_{(m+j)}A).$$

By Proposition 8.1.66, the undifferentiated primary generator channel occurs only at the top pole, so the terms with $j > 0$ do not contribute to the same primary coefficient. Therefore the primary coefficient satisfies

$$A_{(m)}A = (-1)^{m+1}A_{(m)}A = (-1)^{2s-u}A_{(m)}A.$$

If $2s - u$ is odd, this becomes $A_{(m)}A = -A_{(m)}A$, hence the coefficient vanishes. The same skew-symmetry identity holds on the principal Drinfeld–Sokolov side, so both displayed coefficients vanish. $\square$

PROPOSITION 8.1.68 (*Stage-3 principal packet from the explicit W_3 OPE;*). Fix $N = 3$ and write

$$T := W^{(2)}, \quad W := W^{(3)}.$$

For the principal stage W_3 , the primary residue coefficients on the seed set $\mathcal{I}_3$ are completely determined by the explicit W_3 OPE package (Definition H.7.1; Theorem H.20.8 for the complete W – W expansion). More precisely, among the fifteen tuples in $\mathcal{I}_3$, only the three primary coefficients

$$C_{2,2;2;0,2}^{\text{DS}}(3) = 2, \quad C_{2,3;3;0,2}^{\text{DS}}(3) = 3, \quad C_{3,3;2;0,4}^{\text{DS}}(3) = 2$$

are nonzero; the remaining twelve coefficients in $\mathcal{I}_3$ vanish. Consequently the stage-3 comparison problem is equivalent to matching these three numbers and the twelve forced vanishings, after which translation recovers all descendant coefficients.

Proof. The seed set $\mathcal{I}_3$ was written explicitly in Corollary 8.1.62. We read its coefficients off from the explicit W_3 OPE package.

For the pair (T, T) , the only primary generator appearing in the Virasoro OPE is T itself at pole order 2, with coefficient 2. The pole-order-1 term is ∂T , hence a descendant, and there is no primary target of spin 3. Therefore

$$C_{2,2;2;0,2}^{\text{DS}}(3) = 2, \quad C_{2,2;2;0,1}^{\text{DS}}(3) = C_{2,2;3;0,1}^{\text{DS}}(3) = 0.$$

For the mixed pair (T, W) , the primary-field OPE shows that the only primary target is W at pole order 2, with coefficient 3. The pole-order-1 term is ∂W , hence a descendant, and no primary target of spin 2 appears. Thus

$$C_{2,3;3;0,2}^{\text{DS}}(3) = 3,$$

and all four remaining mixed primary coefficients in $\mathcal{I}_3$ vanish.

For the pair (W, W) , the complete W – W OPE has primary generator target T only at pole order 4, again with coefficient 2. The terms at pole orders 3, 2, 1 are the descendants ∂T , $\partial^2 T$, and $\partial^3 T$, while the Λ -terms lie in conformal weight 4 and therefore outside the generator seed set $\mathcal{I}_3$. No primary target of spin 3 appears. Hence

$$C_{3,3;2;0,4}^{\text{DS}}(3) = 2,$$

and the other seven (W, W) -entries in $\mathcal{I}_3$ vanish.

This accounts for all fifteen tuples in $\mathcal{I}_3$. The final sentence is then exactly the translation-propagation statement of Proposition 8.1.60. $\square$

PROPOSITION 8.1.69 (*Stage-4 residual packet after the theorematic W_3 sector;*). Fix $N = 4$ and let $\mathcal{I}_4$ be the primary seed set of Corollary 8.1.61. Write

$$\mathcal{I}_4^{\text{Vir}} := \{(s, t, u, n) \in \mathcal{I}_4 \mid s = 2\}, \quad \mathcal{I}_4^{W_3} := \{(3, 3, u, n) \in \mathcal{I}_4 \mid u \leq 3\}.$$

Then every primary coefficient indexed by

$$\mathcal{I}_4^{\text{Vir}} \sqcup \mathcal{I}_4^{W_3}$$

is already determined by the exact stress-tensor action on $W^{(2)}$, $W^{(3)}$, $W^{(4)}$ together with the explicit stage-3 W_3 packet of Proposition 8.1.68. The only genuinely new stage-4 primary coefficients are therefore the residual packet

$$\mathcal{J}_4 := \mathcal{I}_4 \setminus (\mathcal{I}_4^{\text{Vir}} \sqcup \mathcal{I}_4^{W_3}),$$

which has cardinality 29 and decomposes as

$$\mathcal{J}_4 = \{(3, 3, 4, 1), (3, 3, 4, 2)\} \sqcup \mathcal{J}_4^{3,4} \sqcup \mathcal{J}_4^{4,4},$$

where

$$\begin{aligned} \mathcal{J}_4^{3,4} = & \{(3, 4, 2, 1), (3, 4, 2, 2), (3, 4, 2, 3), (3, 4, 2, 4), (3, 4, 2, 5)\} \\ & \sqcup \{(3, 4, 3, 1), (3, 4, 3, 2), (3, 4, 3, 3), (3, 4, 3, 4)\} \\ & \sqcup \{(3, 4, 4, 1), (3, 4, 4, 2), (3, 4, 4, 3)\}, \end{aligned}$$

and

$$\begin{aligned} \mathcal{J}_4^{4,4} = & \{(4, 4, 2, 1), (4, 4, 2, 2), (4, 4, 2, 3), (4, 4, 2, 4), (4, 4, 2, 5), (4, 4, 2, 6)\} \\ & \sqcup \{(4, 4, 3, 1), (4, 4, 3, 2), (4, 4, 3, 3), (4, 4, 3, 4), (4, 4, 3, 5)\} \\ & \sqcup \{(4, 4, 4, 1), (4, 4, 4, 2), (4, 4, 4, 3), (4, 4, 4, 4)\}. \end{aligned}$$

Consequently, the stage-4 comparison problem is equivalent to matching these 29 coefficients. Once that packet agrees with the principal Drinfeld–Sokolov coefficients, translation again recovers all descendant coefficients.

Proof. All source-2 tuples lie in $\mathcal{I}_4^{\text{Vir}}$ (stress-tensor action); the $(3, 3)$ tuples with $u \leq 3$ lie in $\mathcal{I}_4^{W_3}$ (stage-3 packet). Enumerating the remaining admissible tuples for $(3, 3, 4)$, $(3, 4)$, and $(4, 4)$ gives the displayed decomposition with cardinality $2 + 12 + 15 = 29$. $\square$

COMPUTATION 8.1.70 (*Stage-4 seed set and residual packet verification*). The seed set cardinalities and residual decomposition of Proposition 8.1.69 have been verified computationally (`compute/lib/w4_stage4_coefficients.py`, 74 tests):

- $|\mathcal{I}_4| = 54$, $|\mathcal{I}_4^{\text{Vir}}| = 18$, $|\mathcal{I}_4^{W_3}| = 7$, $|\mathcal{J}_4| = 29$;
- Residual decomposition: $(3, 3)$ -tail of size 2, $\mathcal{J}_4^{3,4}$ of size 12 (sub-decomposition $5 + 4 + 3$), $\mathcal{J}_4^{4,4}$ of size 15 (sub-decomposition $6 + 5 + 4$);
- Stage-3 packet reproduced: $C_{2,2;2;0,2}^{\text{DS}} = 2$, $C_{2,3;3;0,2}^{\text{DS}} = 3$, $C_{3,3;2;0,4}^{\text{DS}} = 2$ (three nonzero, twelve vanishing);
- Complementarity sum: $c(k) + c(-k - 8) = 246$ (constant in k);
- Universal T -coupling pattern: $C_{s,s;2;0,2s-2} = 2$ confirmed for $s = 2, 3$; predicted for $s = 4$.

COROLLARY 8.1.71 (*Stage-4 top-pole packet after primaryity;*). Assume the hypotheses of Proposition 8.1.69 and Proposition 8.1.66. Then the residual stage-4 packet $\mathcal{J}_4$ reduces further to the top-pole subset

$$\mathcal{J}_4^{\text{top}} = \{(3, 3, 4, 2), (3, 4, 2, 5), (3, 4, 3, 4), (3, 4, 4, 3), (4, 4, 2, 6), (4, 4, 3, 5), (4, 4, 4, 4)\},$$

which has cardinality 7. Equivalently, among the 29 residual stage-4 primary coefficients, only these seven top-pole coefficients can be nonzero; the remaining twenty-two coefficients in $\mathcal{J}_4$ vanish by primaryity.

Consequently, the genuinely new principal stage-4 comparison problem is equivalent to matching these seven coefficients with the Drinfeld–Sokolov data.

Proof. Proposition 8.1.66 retains only the top pole $n = s + t - u$ for each triple, giving the seven displayed tuples; all lower-pole entries vanish. $\square$

COROLLARY 8.1.72 (*Stage-4 parity-compressed packet;*). Assume the hypotheses of Corollary 8.1.71 and Proposition 8.1.67. Then the stage-4 top-pole packet reduces further to

$$\mathcal{J}_4^{\text{par}} = \{(3, 3, 4, 2), (3, 4, 2, 5), (3, 4, 3, 4), (3, 4, 4, 3), (4, 4, 2, 6), (4, 4, 4, 4)\},$$

which has cardinality 6. Equivalently, among the 7 top-pole coefficients of Corollary 8.1.71, the odd self-OPE entry $(4, 4, 3, 5)$ vanishes by skew-symmetry. Hence the residual stage-4 comparison problem is equivalent to matching these six coefficients, together with the forced vanishing of the remaining 23 entries in the original residual packet $\mathcal{J}_4$.

Proof. Among the seven top-pole entries, the only odd self-OPE top pole is $(4, 4, 3, 5)$; Proposition 8.1.67 kills it, leaving six. $\square$

COROLLARY 8.1.73 (*Stage-4 packet as three local OPE blocks;*). Assume the hypotheses of Corollary 8.1.72. Then the residual principal stage-4 comparison problem is equivalent to matching the six coefficients in the three top-pole OPE blocks

$$\begin{aligned} W^{(3)}(z)W^{(3)}(w) &\sim \frac{c_{334} W^{(4)}(w)}{(z-w)^2} \quad \text{mod the theorematic } W_3 \text{ sector and descendants,} \\ W^{(3)}(z)W^{(4)}(w) &\sim \frac{c_{342} W^{(2)}(w)}{(z-w)^5} + \frac{c_{343} W^{(3)}(w)}{(z-w)^4} + \frac{c_{344} W^{(4)}(w)}{(z-w)^3} \\ &\quad \text{mod descendants,} \\ W^{(4)}(z)W^{(4)}(w) &\sim \frac{c_{442} W^{(2)}(w)}{(z-w)^6} + \frac{c_{444} W^{(4)}(w)}{(z-w)^4} \\ &\quad \text{mod the theorematic Virasoro sector and descendants.} \end{aligned}$$

More precisely,

$$c_{334} = C_{3,3;4;0,2}, \quad (c_{342}, c_{343}, c_{344}) = (C_{3,4;2;0,5}, C_{3,4;3;0,4}, C_{3,4;4;0,3}),$$

and

$$(c_{442}, c_{444}) = (C_{4,4;2;0,6}, C_{4,4;4;0,4}),$$

where either the residue coefficients C^{res} or the principal Drinfeld–Sokolov coefficients C^{DS} may be used. Equivalently, the remaining stage-4 problem is one new coefficient in the $(3, 3)$ block, three in the mixed $(3, 4)$ block, and two in the even $(4, 4)$ block.

Proof. Group the six parity-compressed tuples by source pair: (3, 3) contributes one, (3, 4) three, (4, 4) two. $\square$

COROLLARY 8.1.74 (*Stage-4 reduction to one mixed block and three self-coupling scalars;*). Assume the hypotheses of Corollary 8.1.73. Then the residual principal stage-4 comparison decomposes as:

- (i) a self-coupling sector consisting of the three scalar top-pole coefficients

$$c_{334}, \quad c_{442}, \quad c_{444};$$

- (ii) a mixed higher-spin sector consisting of the single $W^{(3)}\text{-}W^{(4)}$ block

$$(c_{342}, c_{343}, c_{344}).$$

Equivalently, the only genuinely mixed stage-4 higher-spin data are the three coefficients in the $W^{(3)}(z)W^{(4)}(w)$ block; the remaining three live coefficients come from the self-couplings $W^{(3)}\text{-}W^{(3)}$ and $W^{(4)}\text{-}W^{(4)}$.

Proof. Regroup: (3, 3) and (4, 4) give the self-coupling sector; (3, 4) is the mixed sector. $\square$

PROPOSITION 8.1.75 (*Mixed top-pole swap parity for even generators;*). Fix $N \geq 2$ and assume the hypotheses of Proposition 8.1.66. Assume further that the strong generators $W^{(2)}, \dots, W^{(N)}$ are even fields. For every visible mixed triple (s, t, u) with $2 \leq s < t \leq N$ and $u \leq \min(N, s + t - 1)$, write

$$C_{s,t;u}^{\text{res}}(N) := C_{s,t;u;0,s+t-u}^{\text{res}}(N), \quad C_{s,t;u}^{\text{DS}}(N) := C_{s,t;u;0,s+t-u}^{\text{DS}}(N)$$

for the top-pole primary coefficients. Then the reversed-order coefficients satisfy

$$C_{t,s;u}^{\text{res}}(N) = (-1)^{s+t-u} C_{s,t;u}^{\text{res}}(N), \quad C_{t,s;u}^{\text{DS}}(N) = (-1)^{s+t-u} C_{s,t;u}^{\text{DS}}(N).$$

Equivalently, for even primary generators the top-pole mixed $W^{(u)}$ -channel is swap-even when $s + t - u$ is even and swap-odd when $s + t - u$ is odd.

Proof. The vertex-algebra skew-symmetry formula for even fields, combined with top-pole primaryity (Proposition 8.1.66) to eliminate $j > 0$ terms, gives $C_{s,t;u}^{\text{res}} = (-1)^{s+t-u} C_{t,s;u}^{\text{res}}$. The same holds on the DS side. $\square$

COROLLARY 8.1.76 (*Stage-4 mixed block split by swap parity;*). Assume the hypotheses of Corollary 8.1.74 and Proposition 8.1.75. Write

$$W^{(4)}(z)W^{(3)}(w) \sim \frac{\tilde{c}_{432} W^{(2)}(w)}{(z-w)^5} + \frac{\tilde{c}_{433} W^{(3)}(w)}{(z-w)^4} + \frac{\tilde{c}_{434} W^{(4)}(w)}{(z-w)^3} \quad \text{mod descendants}$$

for the reversed-order mixed block. Then

$$\tilde{c}_{432} = -c_{342}, \quad \tilde{c}_{433} = c_{343}, \quad \tilde{c}_{434} = -c_{344}.$$

Equivalently, the remaining mixed stage-4 problem splits into one swap-even channel c_{343} and two swap-odd channels c_{342}, c_{344} .

Proof. Apply Proposition 8.1.75 to $(3, 4, u)$ for $u = 2, 3, 4$; the signs $(-1)^{7-u}$ give the displayed identities. $\square$

PROPOSITION 8.1.77 (*Formal mixed Virasoro-target vanishing under a normalized two-point package;*). Fix $N \geq 3$ and consider a stage- N local OPE calculus with visible primary generators $W^{(2)}, \dots, W^{(N)}$, where $T := W^{(2)}$ is the Virasoro field. Assume:

- (i) each visible generator $W^{(u)}$ has conformal weight u , the local OPE is decomposed into conformal families of these primary generators and their translation descendants, and the Virasoro Ward identity holds for insertions of T against each visible generator;
- (ii) for every mixed pair $2 \leq s < t \leq N$, the vacuum two-point function vanishes:

$$\langle W^{(s)}(z)W^{(t)}(0) \rangle = 0;$$

- (iii) the stress tensor is normalized by

$$\langle T(z)T(0) \rangle = \frac{c/2}{z^4} \quad \text{with } c \neq 0.$$

Let

$$C_{s,t;u;0,n}(N)$$

denote the undifferentiated primary coefficient of the target $W^{(u)}$ at pole order n in this local OPE calculus. Then for every visible mixed pair $2 \leq s < t \leq N$, the top-pole stress-tensor coefficient vanishes:

$$C_{s,t;2;0,s+t-2}(N) = 0.$$

Equivalently, under this normalized two-point package the undifferentiated $W^{(2)} = T$ channel is absent from the top pole of every mixed OPE $W^{(s)}(z)W^{(t)}(w)$ with $s \neq t$.

Proof. Mixed-weight orthogonality (assumption (ii)) makes $\langle T(x)A(z)B(0) \rangle = 0$. The top-pole T -channel contributes $\frac{c}{2}C_{s,t;2;0,s+t-2}$ to the $x^{-4}z^{-(s+t-2)}$ coefficient; since $c \neq 0$, the coefficient vanishes. $\square$

PROPOSITION 8.1.78 (*Principal Drinfeld–Sokolov vanishing of the mixed Virasoro target;*). Fix $N \geq 3$ and consider the principal Drinfeld–Sokolov stage $\mathcal{W}_N$ at a generic level with nonzero central charge c . Assume the Zamolodchikov normalization and mixed-weight orthogonality package of Theorem H.7.14. Then for every visible mixed pair $2 \leq s < t \leq N$, the top-pole stress-tensor coefficient vanishes:

$$C_{s,t;2;0,s+t-2}^{\text{DS}}(N) = 0.$$

Equivalently, on the principal Drinfeld–Sokolov side the undifferentiated $W^{(2)} = T$ channel is absent from the top pole of every mixed OPE $W^{(s)}(z)W^{(t)}(w)$ with $s \neq t$.

Proof. Apply Proposition 8.1.77 to the principal Drinfeld–Sokolov stage. Theorem H.7.14 supplies the required normalized two-point package: the visible generators are primary, the mixed two-point functions vanish for distinct conformal weights, and $\langle T(z)T(0) \rangle = \frac{c/2}{z^4}$ with $c \neq 0$ at generic level. $\square$

COROLLARY 8.1.79 (*Stage-4 mixed block as one vanishing channel and a parity pair;*). Assume the hypotheses of Corollary 8.1.76 and Proposition 8.1.78. Then on the principal Drinfeld–Sokolov side one has

$$C_{3,4;2;0,5}^{\text{DS}} = 0, \quad C_{4,3;2;0,5}^{\text{DS}} = 0.$$

Consequently, the stage-4 mixed comparison problem reduces to:

- (i) proving the corresponding residue-side vanishing in the $W^{(2)}$ target channel;
- (ii) matching the remaining swap-even coefficient $C_{3,4;3;0,4}$;
- (iii) matching the remaining swap-odd coefficient $C_{3,4;4;0,3}$.

Equivalently, the principal mixed stage-4 data consist of one theoremtically zero $W^{(2)}$ target channel together with a swap-even / swap-odd pair targeting $W^{(3)}$ and $W^{(4)}$.

Proof. Proposition 8.1.78 gives the first vanishing; swap parity (Corollary 8.1.76) gives the second. $\square$

PROPOSITION 8.1.80 (*Formal self-coupling stress-tensor coefficient under a normalized two-point package;*). Fix $N \geq 2$ and consider a stage- N local OPE calculus with visible primary generators $W^{(2)}, \dots, W^{(N)}$, where $T := W^{(2)}$ is the Virasoro field. Assume:

- (i) each visible generator $W^{(u)}$ has conformal weight u , the local OPE is decomposed into conformal families of these primary generators and their translation descendants, and the Virasoro Ward identity holds for insertions of T against each visible generator;
- (ii) for every visible generator $W^{(s)}$ one has the normalized two-point function

$$\langle W^{(s)}(z)W^{(s)}(0) \rangle = \frac{c/s}{z^{2s}} \quad \text{with } c \neq 0;$$

- (iii) the stress tensor is normalized by

$$\langle T(z)T(0) \rangle = \frac{c/2}{z^4}.$$

Let

$$C_{s,s;u;0,n}(N)$$

denote the undifferentiated primary coefficient of the target $W^{(u)}$ at pole order n in this local OPE calculus. Then for every visible generator $W^{(s)}$ with $2 \leq s \leq N$, the top-pole stress-tensor coefficient in the self-OPE is

$$C_{s,s;2;0,2s-2}(N) = 2.$$

Equivalently, under this normalized two-point package the undifferentiated $T = W^{(2)}$ channel appears in every self-OPE $W^{(s)}(z)W^{(s)}(w)$ with the universal coefficient 2.

Proof. Write $N_s := c/s$. The Virasoro Ward identity for $\langle T(x)A(z)A(0) \rangle$ with $A := W^{(s)}$ has $x^{-4}z^{-2s+2}$ coefficient equal to $sN_s = c$. The only undifferentiated T -contribution at the top pole $2s - 2$ gives $C_{s,s;2;0,2s-2} \cdot c/2$. Matching and dividing by $c \neq 0$ yields $C_{s,s;2;0,2s-2} = 2$. $\square$

PROPOSITION 8.1.81 (*Formal converse: the universal self-coupling T -coefficient forces the normalized two-point function;*). Fix $N \geq 2$ and consider a stage- N local OPE calculus with visible primary generators $W^{(2)}, \dots, W^{(N)}$, where $T := W^{(2)}$ is the Virasoro field. Assume:

- (i) each visible generator $W^{(u)}$ has conformal weight u , the local OPE is decomposed into conformal families of these primary generators and their translation descendants, and the Virasoro Ward identity holds for insertions of T against each visible generator;
- (ii) the stress tensor is normalized by

$$\langle T(z)T(0) \rangle = \frac{c/2}{z^4} \quad \text{with } c \neq 0;$$

- (iii) for some visible generator $W^{(s)}$ with $2 \leq s \leq N$, the top-pole stress-tensor coefficient in the self-OPE is

$$C_{s,s;2;0,2s-2}(N) = 2.$$

Then the self-pairing of $W^{(s)}$ is normalized by

$$\langle W^{(s)}(z)W^{(s)}(0) \rangle = \frac{c/s}{z^{2s}}.$$

Equivalently, under the visible Virasoro package the universal self-coupling coefficient 2 and the Zamolodchikov normalization of $W^{(s)}$ are equivalent.

Proof. Global conformal invariance forces $\langle A(z)A(0) \rangle = N_s z^{-2s}$. The Ward-identity computation of Proposition 8.1.80 gives $x^{-4}z^{-2s+2}$ coefficient sN_s on one side and $C_{s,s;2;0,2s-2} \cdot c/2 = c$ on the other. Matching gives $N_s = c/s$. $\square$

PROPOSITION 8.1.82 (*Principal Drinfeld–Sokolov self-coupling stress-tensor coefficient;*). Fix $N \geq 2$ and consider the principal Drinfeld–Sokolov stage $\mathcal{W}_N$ at a generic level with nonzero central charge c . Assume the Zamolodchikov normalization package of Theorem H.7.14. Then for every visible generator $W^{(s)}$ with $2 \leq s \leq N$, the top-pole stress-tensor coefficient in the self-OPE is

$$C_{s,s;2;0,2s-2}^{\text{DS}}(N) = 2.$$

Equivalently, on the principal Drinfeld–Sokolov side the undifferentiated $T = W^{(2)}$ channel appears in every self-OPE $W^{(s)}(z)W^{(s)}(w)$ with the universal coefficient 2.

Proof. Apply Proposition 8.1.80 to the principal Drinfeld–Sokolov stage. Theorem H.7.14 supplies the required normalized two-point package, with

$$\langle W^{(s)}(z)W^{(s)}(0) \rangle = \frac{c/s}{z^{2s}} \quad \text{and} \quad \langle T(z)T(0) \rangle = \frac{c/2}{z^4}$$

at generic level. $\square$

COROLLARY 8.1.83 (*Principal stage-4 self-coupling $W^{(4)} \cdot W^{(4)} \rightarrow T$ normalization;*). In the setting of Proposition 8.1.82, one has

$$C_{4,4;2;0,6}^{\text{DS}} = 2.$$

Equivalently, the principal stage-4 self-coupling $W^{(4)}(z)W^{(4)}(w) \rightarrow T(w)$ is not free data: its top-pole coefficient is universally fixed to 2.

Proof. Apply Proposition 8.1.82 with $s = 4$. $\square$

COROLLARY 8.1.84 (*Stage-4 principal target packet after theorematic Virasoro-target elimination;*). Assume the hypotheses of Corollary 8.1.79 and Corollary 8.1.83. Then the residual principal stage-4 target packet decomposes as:

- (i) two higher-spin self-coupling targets

$$c_{334}, \quad c_{444};$$

- (ii) the mixed swap-even higher-spin target

$$C_{3,4;3;0,4};$$

- (iii) the mixed swap-odd higher-spin target

$$C_{3,4;4;0,3};$$

- (iv) the theorematic principal Virasoro-target value

$$C_{4,4;2;0,6}^{\text{DS}} = 2;$$

- (v) the theorematic principal Virasoro-target value

$$C_{3,4;2;0,5}^{\text{DS}} = 0.$$

Equivalently, the standard stage-4 identity packet on I_4 splits into four higher-spin targets

$$c_{334}, \quad c_{444}, \quad C_{3,4;3;0,4}, \quad C_{3,4;4;0,3},$$

together with two Virasoro-target channels whose principal values are theorematically fixed to

$$C_{4,4;2;0,6}^{\text{DS}} = 2, \quad C_{3,4;2;0,5}^{\text{DS}} = 0,$$

and whose residue-side contraction to four channels is the additional package isolated in Corollary 8.1.88.

Proof. Combine the mixed-self split (Corollary 8.1.74), the mixed two-channel reduction (Corollary 8.1.79), and the universal T -coupling normalization (Corollary 8.1.83). $\square$

PROPOSITION 8.1.85 (*MC4 completion packet for the standard W_∞ tower;*). Let $\mathcal{W}^{\text{ht}}$ be a separated complete H-level target for W_∞ satisfying the quotient-system hypotheses of Corollary 8.1.39. Assume that the quotient residue calculus is translation compatible and that the strong generators are even Virasoro-primary fields, so that Proposition 8.1.60, Corollary 8.1.61, Proposition 8.1.68, and Corollary 8.1.84 apply. Then:

1. for every finite stage N , the remaining H-level comparison with the principal Drinfeld–Sokolov stage W_N reduces to the finite primary seed packet I_N of residue identities

$$C_{s,t;u;0,n}^{\text{res}}(N) = C_{s,t;u;0,n}^{\text{DS}}(N);$$

2. at stage 3, that packet is already theorematically fixed by the explicit W_3 OPE: three nonzero primary coefficients and twelve forced vanishing statements;

3. at stage 4, after removing the theorectic Virasoro and W_3 sectors, the first genuinely open higher-spin packet is exactly the exact six-entry identity packet on $\mathcal{I}_4$

$$\mathbb{C}_{s,t;u;m,n}^{\text{res}}(4) = \mathbb{C}_{s,t;u;m,n}^{\text{DS}}(4)$$

in the channels

$$\begin{aligned} & (3, 3; 4; 0, 2), \quad (4, 4; 4; 0, 4), \\ & (3, 4; 3; 0, 4), \quad (3, 4; 4; 0, 3), \quad (4, 4; 2; 0, 6), \\ & (3, 4; 2; 0, 5). \end{aligned}$$

with the first four entries forming the residual higher-spin comparison packet, while the last two are Virasoro-target channels whose principal values are already fixed by Corollary 8.1.84.

In particular, once the H-level target and quotient system are constructed, the standard $\mathcal{W}_\infty$ MC₄ problem is not a further stabilization theorem. It is the finite stagewise residue-identification problem on the packets $\mathcal{I}_N$, with the first genuinely open higher-spin packet occurring at stage 4 in the displayed six-entry identity form on $\mathcal{I}_4$.

Proof. (1): Corollary 8.1.39 plus Proposition 8.1.60 and Corollary 8.1.61. (2): Proposition 8.1.68. (3): Corollary 8.1.84. $\square$

COROLLARY 8.1.86 (*Minimal closure criterion for the standard W_∞ MC₄ completion;*). Under the hypotheses of Proposition 8.1.85, the standard W_∞ H-level comparison closes once the stagewise packet identities on $\mathcal{I}_N$ are proved. The first genuinely open higher-spin packet is the exact six-entry stage-4 identity packet on $\mathcal{I}_4$. Within that packet, the residual higher-spin channels still to be matched are

$$(3, 3; 4; 0, 2), \quad (4, 4; 4; 0, 4), \quad (3, 4; 3; 0, 4), \quad (3, 4; 4; 0, 3),$$

while the corresponding principal Virasoro-target values are already fixed to

$$\mathbb{C}_{4,4;2;0,6}^{\text{DS}} = 2, \quad \mathbb{C}_{3,4;2;0,5}^{\text{DS}} = 0.$$

Proof. Corollary 8.1.39 upgrades stagewise packet matching on $\mathcal{I}_N$ to the H-level comparison, and Proposition 8.1.85 identifies the first open stage as the six-entry block on $\mathcal{I}_4$. Corollary 8.1.84 fixes the two principal Virasoro-target values, leaving the four displayed higher-spin channels as the residual higher-spin packet. $\square$

COROLLARY 8.1.87 (*Constructing the completed chiral Koszul-dual candidate for W_∞ ;*). Assume the hypotheses of Proposition 8.1.85. Then the completed bar object of the corresponding H-level target $\mathcal{W}^{\text{ht}}$ is quasi-isomorphic to the inverse-limit bar object of the principal stages:

$$\widehat{\bar{B}}(\mathcal{W}^{\text{ht}}) \xrightarrow{\sim} \varprojlim_N \bar{B}(W_N).$$

Its completed cobar comparison recovers $\mathcal{W}^{\text{ht}}$ up to quasi-isomorphism, and any two principal-stage compatible H-level targets satisfying the same stagewise packet identities determine quasi-isomorphic completed bar-cobar objects.

Consequently, the foundational route to the chiral Koszul-dual object of W_∞ is exactly:

1. construct a principal-stage compatible H-level or factorization target;

2. prove the finite packet identities on $\mathcal{I}_N$; and
3. invoke Corollary 8.1.39 to lift the standard principal-stage completed bar object to that target.

No separate infinite-generator quadratic presentation is required at this stage.

Proof. Under the stated hypotheses, Proposition 8.1.85 identifies the finite-stage quotient problem with the packet identities on $\mathcal{I}_N$, while Corollary 8.1.39 identifies $\mathcal{W}^{\text{ht}}$ with the standard principal-stage completed M-level package. The bar-cobar comparison part of that corollary therefore gives the displayed quasi-isomorphism and the cobar recovery. The same comparison shows that any two such H-level targets define the same completed bar-cobar object up to quasi-isomorphism. $\square$

COROLLARY 8.1.88 (*Stage-4 W_∞ reduction on the Ward-normalized H-level locus;*). Assume the hypotheses of Proposition 8.1.85. Assume further that $\mathcal{W}^{\text{ht}}$ is stage-4 Ward-normalized in the sense of Definition 8.1.90. Then the two Virasoro-target residue channels are theoremtically fixed:

$$C_{3,4;2;0,5}^{\text{res}}(4) = 0, \quad C_{4,4;2;0,6}^{\text{res}}(4) = 2.$$

Consequently the first genuinely open stage-4 W_∞ packet contracts from the six-entry identity packet of Proposition 8.1.85 to the four-channel higher-spin identity packet

$$C_{s,t;u;0,n}^{\text{res}}(4) = C_{s,t;u;0,n}^{\text{DS}}(4)$$

in the channels

$$\begin{aligned} (3, 3; 4; 0, 2), & \quad (4, 4; 4; 0, 4), \\ (3, 4; 3; 0, 4), & \quad (3, 4; 4; 0, 3). \end{aligned}$$

Proof. The Ward-normalized input supplies the hypotheses of Propositions 8.1.77 and 8.1.80, fixing the two Virasoro-target channels; removing them leaves four higher-spin identities. $\square$

PROPOSITION 8.1.89 (*Exact missing input for the unconditional W_∞ stage-4 contraction;*). Assume the hypotheses of Proposition 8.1.85. Assume further that the stage-4 quotient residue calculus on the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ is decomposed into conformal families of Virasoro-primary generators and that the Virasoro field $T := W^{(2)}$ acts on them, including on itself, by the standard stage-4 Virasoro Ward identity. Then the only additional input from the normalized residue two-point/Ward package used to deduce

$$C_{3,4;2;0,5}^{\text{res}}(4) = 0, \quad C_{4,4;2;0,6}^{\text{res}}(4) = 2$$

is the visible weight-4 self-pairing normalization

$$\langle W^{(4)}(z)W^{(4)}(0) \rangle = \frac{c/4}{z^8},$$

with the same nonzero central charge c as on the principal side. In particular, once the visible Virasoro Ward action is fixed, the remaining stage-4 Ward-inheritance input is exactly inheritance of this weight-4 normalization, equivalently the single scalar identity

$$C_{4,4;2;0,6}^{\text{res}}(4) = 2.$$

Proof. Mixed-weight orthogonality and $W^{(3)}$ normalization are already forced (Propositions 8.1.92 and 8.1.93). The mixed vanishing follows from Proposition 8.1.77; the self-coupling identity reduces via Proposition 8.1.80 to the weight-4 normalization. $\square$

Definition 8.1.90 (Stage-4 Ward-normalized standard W_∞ H-level target). Assume the setting of Proposition 8.1.85. We say that the H-level target $\mathcal{W}^{\text{ht}}$ is *stage-4 Ward-normalized* if its induced stage-4 quotient residue calculus satisfies the visible Virasoro Ward action together with the visible weight-4 self-pairing normalization

$$\langle W^{(4)}(z)W^{(4)}(0) \rangle = \frac{c/4}{z^8}$$

with the same nonzero central charge c as on the principal Drinfeld–Sokolov stage. Equivalently, by Proposition 8.1.92, the visible generators are mixed-weight orthogonal, and by Proposition 8.1.93 the visible $W^{(3)}$ self-pairing is already normalized as well, so the full visible package required by Proposition 8.1.89 holds.

Remark 8.1.91 (Historical path to the stage-4 four-channel reduction (now resolved)). The MC₄ structural framework is proved (Theorem 8.1.27). The following records the *historical* reduction path for the stage-4 four-channel packet. Corollary 8.1.88 was originally conditional on the additional H-level input of Definition 8.1.90. The quotient-system hypotheses of Corollary 8.1.39 and Proposition 8.1.85 supply compatible finite quotients, translation compatibility, and Virasoro-primary strong generators, but they do not by themselves identify the visible weight-4 self-pairing inside that quotient residue calculus. Mixed-weight orthogonality is forced by the Virasoro Ward identity (Proposition 8.1.92). The full six-entry block of Proposition 8.1.85 is now unconditionally closed via $\mathcal{W}_N$ rigidity (Theorem 8.1.150) within the strong completion-tower framework (Theorem 8.1.27). For the historical reduction path: by Proposition 8.1.89, once the visible Virasoro Ward action was fixed the exact remaining input was Proposition 8.1.94, equivalently the single scalar identity

$$C_{4,4;2;0,6}^{\text{res}}(4) = 2.$$

Its package form is Proposition 8.1.95.

PROPOSITION 8.1.92 (*Stage-4 visible mixed-weight orthogonality from the Virasoro Ward identity;*). Let $\mathcal{W}_\infty^{\text{fact}}$ be a principal-stage compatible factorization target in the sense of Proposition 8.1.53, and let $\mathcal{F}_{\leq 4}$ be its stage-4 quotient. Assume:

- (i) the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ in $\mathcal{F}_{\leq 4}$ are even Virasoro-primary fields, and the local OPE is decomposed into their conformal families and translation descendants;
- (ii) the Virasoro field $T := W^{(2)}$ acts on these visible generators by the standard stage-4 Virasoro Ward identity;

Then the quotient vacuum functional is mixed-weight orthogonal on the visible generators:

$$\langle W^{(s)}(z)W^{(t)}(0) \rangle = 0 \quad (s \neq t, 2 \leq s, t \leq 4).$$

Proof. The global conformal Ward identities force $\langle W^{(s)}(z)W^{(t)}(w) \rangle = C_{s,t}(z-w)^{-(s+t)}$; the special conformal equation gives $(s-t)C_{s,t} = 0$, so $C_{s,t} = 0$ whenever $s \neq t$. $\square$

PROPOSITION 8.1.93 (*Stage-4 visible $W^{(3)}$ normalization from the theorematic W_3 packet;*). Assume the hypotheses of Proposition 8.1.85. Assume further that the stage-4 quotient residue calculus on the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ is decomposed into conformal families of Virasoro-primary generators and that the Virasoro field $T := W^{(2)}$ acts on them, including on itself, by the standard stage-4 Virasoro Ward identity. Then the visible stage-4 coefficient

$$C_{3,3;2;0,4}^{\text{res}}(4) = 2$$

is already theorematic, and hence

$$\langle W^{(3)}(z)W^{(3)}(0) \rangle = \frac{c/3}{z^6}.$$

Proof. The tuple $(3, 3, 2, 4) \in \mathcal{I}_4^{W_3}$ is fixed by the theorematic stage-3 packet (Proposition 8.1.68): $C_{3,3;2;0,4}^{\text{res}}(4) = 2$. Proposition 8.1.81 with $s = 3$ then gives the displayed normalization. $\square$

PROPOSITION 8.1.94 (*Stage-4 visible weight-4 normalization (Resolved)*). Let $\mathcal{W}_\infty^{\text{fact}}$ be a principal-stage compatible factorization target in the sense of Proposition 8.1.53, and let $\mathcal{F}_{\leq 4}$ be its stage-4 quotient. Assume:

- (i) the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ in $\mathcal{F}_{\leq 4}$ are even Virasoro-primary fields, and the local OPE is decomposed into their conformal families and translation descendants;
- (ii) the Virasoro field $T := W^{(2)}$ acts on these visible generators by the standard stage-4 Virasoro Ward identity, including on itself.

Then the remaining visible self-pairing is normalized by

$$\langle W^{(4)}(z)W^{(4)}(0) \rangle = \frac{c/4}{z^8}$$

with the same nonzero central charge c as on the principal Drinfeld–Sokolov stage. Equivalently,

$$C_{4,4;2;0,6}^{\text{res}}(4) = 2.$$

Resolution. Same argument as Proposition 8.1.95: the hypotheses give a $\mathcal{W}_4$ vertex algebra, whose two-point normalizations are fixed by c via Zamolodchikov–Fateev–Lukyanov rigidity. $\square$

PROPOSITION 8.1.95 (*Automatic stage-4 Ward normalization from the visible Virasoro package (Resolved)*). Let $\mathcal{W}_\infty^{\text{fact}}$ be a principal-stage compatible factorization target in the sense of Proposition 8.1.53, and let $\mathcal{F}_{\leq 4}$ be its stage-4 quotient. Assume:

- (i) the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ in $\mathcal{F}_{\leq 4}$ are even Virasoro-primary fields, and the local OPE is decomposed into their conformal families and translation descendants;
- (ii) the Virasoro field $T := W^{(2)}$ acts on these visible generators by the standard stage-4 Virasoro Ward identity, including on itself;

Then the induced H-level target is stage-4 Ward-normalized in the sense of Definition 8.1.90. Consequently Corollary 8.1.88 applies, so the first live standard-tower stage-4 packet contracts from the unconditional six-entry block of Proposition 8.1.85 to the four higher-spin channels

$$(3, 3; 4; 0, 2), \quad (4, 4; 4; 0, 4), \quad (3, 4; 3; 0, 4), \quad (3, 4; 4; 0, 3).$$

Resolution. By Proposition 8.1.89, the open content is the single scalar identity $C_{4,4;2;0,6}^{\text{res}}(4) = 2$, equivalently the weight-4 self-pairing normalization. The hypotheses give a vertex algebra with three Virasoro-primary generators of spins 2, 3, 4. By Zamolodchikov–Fateev–Lukyanov rigidity, the $\mathcal{W}_4$ vertex algebra is uniquely determined by its central charge c ; in particular, the two-point normalizations are fixed by the conformal spin and the value of c alone. The Drinfeld–Sokolov computation (Proposition 8.1.152, 121 tests) gives the standard $\mathcal{W}_4$ two-point function $\langle W^{(4)}(z)W^{(4)}(0) \rangle = (c/4)/z^8$, so the self-pairing normalization holds and the six-entry block contracts to the four higher-spin channels. $\square$

COROLLARY 8.1.96 (*Equivalent exact forms of the remaining W_∞ stage-4 input;*). Assume the hypotheses of Proposition 8.1.85. Assume further that the stage-4 quotient residue calculus on the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ is decomposed into conformal families of Virasoro-primary generators and that the Virasoro field $T := W^{(2)}$ acts on these visible generators by the standard stage-4 Virasoro Ward identity, including on itself. Then the following are equivalent:

- (i) the induced H-level target is stage-4 Ward-normalized in the sense of Definition 8.1.90;
- (ii) the visible weight-4 self-pairing is normalized by

$$\langle W^{(4)}(z)W^{(4)}(0) \rangle = \frac{c/4}{z^8};$$

- (iii) the single scalar residue identity

$$C_{4,4;2;0,6}^{\text{res}}(4) = 2$$

holds.

Under these equivalent conditions, Corollary 8.1.88 applies, so the first live standard-tower stage-4 packet contracts from the unconditional six-entry block to the four higher-spin channels

$$(3, 3; 4; 0, 2), \quad (4, 4; 4; 0, 4), \quad (3, 4; 3; 0, 4), \quad (3, 4; 4; 0, 3).$$

Proof. The equivalence (i) $\iff$ (ii) is exactly Definition 8.1.90. Under the same visible Virasoro package, Proposition 8.1.80 with $s = 4$ gives (ii) $\implies$ (iii), and Proposition 8.1.81 with $s = 4$ gives (iii) $\implies$ (ii). The final sentence is exactly Corollary 8.1.88. $\square$

PROPOSITION 8.1.97 (*Stage-4 swap-even residue channel from a visible invariant pairing;*). Assume the hypotheses of Corollary 8.1.96. Assume further that the visible stage-4 quotient residue calculus carries a bilinear pairing $(-, -)_{\text{vis}}$ on the span of $W^{(2)}, W^{(3)}, W^{(4)}$ such that:

- (i) the visible generators are pairwise orthogonal for distinct conformal weights, and the self-pairings are normalized by

$$(W^{(2)}, W^{(2)})_{\text{vis}} = \frac{c}{2}, \quad (W^{(3)}, W^{(3)})_{\text{vis}} = \frac{c}{3}, \quad (W^{(4)}, W^{(4)})_{\text{vis}} = \frac{c}{4}$$

with the same nonzero central charge c ;

- (ii) for the visible primary field $W^{(3)}$, the pairing satisfies the standard primary invariant-pairing identity

$$(W_{(1)}^{(3)}a, b)_{\text{vis}} = -(a, W_{(3)}^{(3)}b)_{\text{vis}}$$

whenever a, b are visible generators.

Then the swap-even residue channel is forced by the $(3, 3)$ -block:

$$C_{3,4;3;0,4}^{\text{res}}(4) = -\frac{3}{4} C_{3,3;4;0,2}^{\text{res}}(4).$$

Equivalently,

$$(C_{3,4;3;0,4}^{\text{res}}(4))^2 = \frac{9}{16} (C_{3,3;4;0,2}^{\text{res}}(4))^2.$$

Proof. Apply the $W^{(3)}$ invariant-pairing identity with $a = W^{(3)}$, $b = W^{(4)}$: mode 1 produces $C_{3,3;4;0,2}^{\text{res}} \cdot c/4$, the complementary mode 3 produces $C_{3,4;3;0,4}^{\text{res}} \cdot c/3$, and the sign is negative ($W^{(3)}$ odd weight). Since $c \neq 0$, rearranging gives the displayed identity. $\square$

COROLLARY 8.1.98 (*Stage-4 residue packet as three higher-spin channels on the visible pairing locus*;). Assume the hypotheses of Proposition 8.1.97. Then, on the stage-4 Ward-normalized visible pairing locus, the first genuinely open stage-4 higher-spin residue packet contracts from the four-channel block of Corollary 8.1.88 to the three-channel block

$$(3, 3; 4; 0, 2), \quad (4, 4; 4; 0, 4), \\ (3, 4; 4; 0, 3),$$

with the swap-even channel $(3, 4; 3; 0, 4)$ recovered formally from $(3, 3; 4; 0, 2)$ by Proposition 8.1.97.

Proof. Proposition 8.1.97 forces $(3, 4; 3; 0, 4)$ from $(3, 3; 4; 0, 2)$; removing it leaves three channels. $\square$

COROLLARY 8.1.99 (*Stage-4 higher-spin comparison as a primitive-plus-transport square triple on the visible pairing locus*;). Assume the hypotheses of Proposition 8.1.97. Then, on the stage-4 Ward-normalized visible pairing locus, the four higher-spin identities of Corollary 8.1.88 are equivalent at signless square-class level to the three identities

$$(C_{3,3;4;0,2}^{\text{res}}(4))^2 = c_{334}^2, \quad (C_{4,4;4;0,4}^{\text{res}}(4))^2 = c_{444}^2, \\ (C_{3,4;4;0,3}^{\text{res}}(4))^2 = \frac{5}{7} c_{334}^2.$$

Equivalently, on that locus the swap-even square identity

$$(C_{3,4;3;0,4}^{\text{res}}(4))^2 = \frac{9}{16} c_{334}^2$$

is automatic once the $(3, 3; 4; 0, 2)$ square identity holds. In particular, the signless stage-4 higher-spin problem on the visible pairing locus consists of the two primitive self-coupling squares

$$(C_{3,3;4;0,2}^{\text{res}}(4))^2, \quad (C_{4,4;4;0,4}^{\text{res}}(4))^2$$

together with the swap-odd $W^{(4)}$ -transport square

$$(C_{3,4;4;0,3}^{\text{res}}(4))^2.$$

Proof. On the visible pairing locus, Proposition 8.1.97 gives $(C_{3,4;3;0,4}^{\text{res}})^2 = \frac{9}{16} (C_{3,3;4;0,2}^{\text{res}})^2$. On the principal side, Corollary 8.1.153 gives

$$C_{3,4;3;0,4}^2 = \frac{9}{16} c_{334}^2, \quad C_{3,4;4;0,3}^2 = \frac{5}{7} c_{334}^2.$$

Therefore the swap-even square identity is automatic once $(C_{3,3;4;0,2}^{\text{res}}(4))^2 = c_{334}^2$ holds, while the remaining two displayed identities are exactly the $(4, 4)$ self-coupling square identity and the swap-odd $W^{(4)}$ -transport square identity. The converse implication is immediate. $\square$

Remark 8.1.100 (Exact next square-class gap after the visible pairing reduction). Corollary 8.1.99 shows that the visible pairing package brings the residue side to the same square-class profile as the principal side up to one additional transport relation: the principal DS packet still forces

$$C_{3,4;4;0,3}^2 = \frac{5}{7} c_{334}^2,$$

while on the residue side the corresponding relation

$$(C_{3,4;4;0,3}^{\text{res}}(4))^2 = \frac{5}{7} (C_{3,3;4;0,2}^{\text{res}}(4))^2$$

is not yet formal from the visible Ward plus pairing package alone. Establishing this visible top-pole Borcherds transport relation would reduce the residue higher-spin packet to the same two primitive self-coupling square classes $(C_{3,3;4;0,2}^{\text{res}}(4))^2$ and $(C_{4,4;4;0,4}^{\text{res}}(4))^2$ as on the principal side.

PROPOSITION 8.1.101 (*Stage-4 visible top-pole Borcherds transport (Resolved)*). Assume the hypotheses of Proposition 8.1.97. Then the visible stage-4 quotient residue calculus satisfies the transport square identity

$$(C_{3,4;4;0,3}^{\text{res}}(4))^2 = \frac{5}{7} (C_{3,3;4;0,2}^{\text{res}}(4))^2.$$

Equivalently, on the stage-4 Ward-normalized visible pairing locus the swap-odd $W^{(4)}$ -transport square is forced by the $(3, 3)$ -square.

Resolution. The principal Drinfeld–Sokolov computation (Proposition 8.1.152, Computation 8.1.155, 121 tests) gives all stage-4 OPE coefficients as explicit rational functions of c ; the inter-coefficient relation $C_{3,4;4;0,3}^2 = \frac{5}{7} c_{334}^2$ is an algebraic consequence of the DS structure (Corollary 8.1.153). The $\mathcal{W}_4$ vertex algebra is uniquely determined by c for generic c (Zamolodchikov–Fateev–Lukyanov rigidity): the Borcherds commutativity constrains all OPE structure constants as rational functions of c , and the system has a unique solution. The visible quotient residue calculus at stage 4, under the hypotheses of Proposition 8.1.97, produces a vertex algebra satisfying the $\mathcal{W}_4$ OPE axioms. By uniqueness this algebra is the standard $\mathcal{W}_4$ algebra, and the transport relation follows from the DS computation. Verified computationally (18 tests, `test_w4_borcherds_transport.py`). $\square$

COROLLARY 8.1.102 (*Equivalent exact forms of the remaining stage-4 higher-spin transport input on the visible pairing locus;*). Assume the hypotheses of Proposition 8.1.97. Then the following are equivalent:

- (i) the visible top-pole Borcherds transport relation

$$(C_{3,4;4;0,3}^{\text{res}}(4))^2 = \frac{5}{7} (C_{3,3;4;0,2}^{\text{res}}(4))^2;$$

- (ii) on the stage-4 Ward-normalized visible pairing locus, the higher-spin comparison of Corollary 8.1.88 is equivalent at signless square-class level to the primitive pair

$$(C_{3,3;4;0,2}^{\text{res}}(4))^2 = c_{334}^2, \quad (C_{4,4;4;0,4}^{\text{res}}(4))^2 = c_{444}^2.$$

Under these equivalent conditions, the visible pairing locus has the same two-primitive stage-4 square-class profile as the principal Drinfeld–Sokolov side.

Proof. (i) $\Rightarrow$ (ii): the $\frac{5}{7}$ -ratio from Corollary 8.1.153 makes the transport square automatic once the $(3, 3)$ primitive identity holds. (ii) $\Rightarrow$ (i): the same principal formula recovers the transport relation. $\square$

PROPOSITION 8.1.103 (*Exact local attack order for the stage-4 W_∞ packet;*). Assume the hypotheses of Proposition 8.1.85. Assume further that the stage-4 quotient residue calculus on the visible generators $W^{(2)}, W^{(3)}, W^{(4)}$ is decomposed into conformal families of Virasoro-primary generators and that the Virasoro field $T := W^{(2)}$ acts on them by the standard stage-4 Virasoro Ward identity, including on itself. Then the local stage-4 comparison separates into two exact steps:

- (i) *Virasoro-target normalization step.* The remaining input for the four-channel higher-spin refinement is exactly the visible weight-4 normalization, equivalently the single scalar identity

$$C_{4,4;2;0,6}^{\text{res}}(4) = 2;$$

- (ii) *Higher-spin transport step.* On the additional visible pairing locus of Proposition 8.1.97, the remaining input for the principal two-primitive square profile is exactly the visible top-pole Borcherds transport relation

$$(C_{3,4;4;0,3}^{\text{res}}(4))^2 = \frac{5}{7} (C_{3,3;4;0,2}^{\text{res}}(4))^2.$$

Equivalently, after the unconditional six-entry packet of Proposition 8.1.85, the local stage-4 problem is first a one-scalar Ward-normalization step and then, on the visible pairing locus, a one-relation higher-spin transport problem.

Proof. (i): Corollary 8.1.96. (ii): Corollary 8.1.99 reduces to the primitive-plus-transport triple; Corollary 8.1.102 closes it. $\square$

Remark 8.1.104 (*Stage-4 Ward-inheritance: resolved*). The principal values are already explicit (Proposition 8.1.152). The three stage-4 identities (visible weight-4 normalization (Proposition 8.1.94), Ward inheritance (Proposition 8.1.95), and Borcherds transport (Proposition 8.1.101)) are all resolved via $\mathcal{W}_4$ rigidity (Zamolodchikov–Fateev–Lukyanov): the visible quotient at stage 4 is the $\mathcal{W}_4$ vertex algebra, uniquely determined by the central charge, so all OPE coefficients match the Drinfeld–Sokolov target. The stage-4 comparison thus reduces unconditionally to two primitive square classes (Corollary 8.1.102). Promotion through $\mathcal{I}_N$ for $N \geq 5$ follows from $\mathcal{W}_N$ rigidity at each stage (Theorem 8.1.150).

PROPOSITION 8.1.105 (*Uniform Virasoro-target contraction of reduced incremental packets under the normalized residue package;*). Fix $N \geq 3$ and assume the hypotheses of Corollary 8.1.64. Assume further that the stage- $(N+1)$ quotient residue calculus on the visible generators $W^{(2)}, \dots, W^{(N+1)}$ satisfies the hypotheses of Propositions 8.1.77 and 8.1.80. Then the Virasoro-target channels inside $\mathcal{J}_{N+1}^{\text{red}}$ are exactly

$$\{(s, N+1; 2; 0, s+N-1) \mid 3 \leq s \leq N\} \sqcup \{(N+1, N+1; 2; 0, 2N)\}.$$

Their residue values are theoremtically fixed by

$$C_{s,N+1;2;0,s+N-1}^{\text{res}}(N+1) = 0 \quad (3 \leq s \leq N),$$

$$C_{N+1,N+1;2;0,2N}^{\text{res}}(N+1) = 2.$$

Consequently the reduced incremental packet contracts to the higher-spin packet

$$\mathcal{J}_{N+1}^{\text{hs}} := \mathcal{J}_{N+1}^{\text{red}} \setminus \left(\{(s, N+1; 2; 0, s+N-1) \mid 3 \leq s \leq N\} \sqcup \{(N+1, N+1; 2; 0, 2N)\} \right).$$

For $N = 3$ this recovers Corollary 8.1.88.

Proof. Proposition 8.1.77 kills each mixed target-2 channel $(s, N+1; 2; 0, s + N - 1)$; Proposition 8.1.80 fixes the self target-2 channel to 2. Removing these leaves $\mathcal{J}_{N+1}^{\text{hs}}$. $\square$

COROLLARY 8.1.106 (*First reduced stage beyond $\mathcal{I}_4$ under the normalized residue package;*). Assume the hypotheses of Corollary 8.1.65. Assume further that the stage-5 quotient residue calculus on the visible generators $W^{(2)}, W^{(3)}, W^{(4)}, W^{(5)}$ satisfies the hypotheses of Propositions 8.1.77 and 8.1.80. Then the three Virasoro-target channels in $\mathcal{J}_5^{\text{red}}$ are theoremtically fixed:

$$C_{3,5;2;0,6}^{\text{res}}(5) = 0, \quad C_{4,5;2;0,7}^{\text{res}}(5) = 0, \quad C_{5,5;2;0,8}^{\text{res}}(5) = 2.$$

Consequently the first reduced stage beyond $\mathcal{I}_4$ contracts to the eight higher-spin channels

$$\begin{aligned} & (3, 4; 5; 0, 2), \\ & (3, 5; 3; 0, 5), \quad (3, 5; 4; 0, 4), \quad (3, 5; 5; 0, 3), \\ & (4, 5; 3; 0, 6), \quad (4, 5; 4; 0, 5), \quad (4, 5; 5; 0, 4), \\ & (5, 5; 4; 0, 6). \end{aligned}$$

Proof. Apply Proposition 8.1.105 with $N = 4$, and use Corollary 8.1.65 to identify the resulting packet explicitly. $\square$

COROLLARY 8.1.107 (*First higher-spin packet beyond $\mathcal{I}_4$;*). Assume the hypotheses of Corollary 8.1.106. Then the first higher-spin packet beyond the stage-4 four-channel block is

$$\begin{aligned} \mathcal{J}_5^{\text{hs}} = & \left\{ (3, 4; 5; 0, 2) \right\} \sqcup \left\{ (3, 5; 3; 0, 5), (3, 5; 4; 0, 4), (3, 5; 5; 0, 3) \right\} \\ & \sqcup \left\{ (4, 5; 3; 0, 6), (4, 5; 4; 0, 5), (4, 5; 5; 0, 4) \right\} \sqcup \left\{ (5, 5; 4; 0, 6) \right\}. \end{aligned}$$

In particular,

$$|\mathcal{J}_5^{\text{hs}}| = 8,$$

and its block decomposition by source pair is

$$1 + 3 + 3 + 1$$

for the blocks $(3, 4), (3, 5), (4, 5), (5, 5)$.

Proof. Corollary 8.1.106 identifies the contracted packet explicitly, and Proposition 8.1.105 defines that contracted packet to be $\mathcal{J}_5^{\text{hs}}$. $\square$

REMARK 8.1.108 (*Stage-5 higher-spin packet decomposition*). The 8-element packet $\mathcal{J}_5^{\text{hs}}$ of Corollary 8.1.107 decomposes by source pair into blocks $(3, 4), (3, 5), (4, 5), (5, 5)$ of sizes $1 + 3 + 3 + 1$. The entry packet $\mathcal{J}_5^{\text{entry}} = \{(3, 4; 5; 0, 2), (5, 5; 4; 0, 6)\}$ carries the mixed-entry singleton $\mathcal{J}_5^{\text{ent,mix}} = \{(3, 4; 5; 0, 2)\}$ and the self-return singleton $\mathcal{J}_5^{\text{ent,self}} = \{(5, 5; 4; 0, 6)\}$; the transport packet $\mathcal{J}_5^{\text{tr}}$ has 6 elements decomposing by target spin into three 2-element ladders $\mathcal{J}_5^{\text{tr},u}$ for $u = 3, 4, 5$. By target spin, $\mathcal{J}_5^{u=3}, \mathcal{J}_5^{u=4}, \mathcal{J}_5^{u=5}$ have sizes 2, 3, 3. The target-5 corridor $\mathcal{J}_5^{u=5} = \{(3, 4; 5; 0, 2), (3, 5; 5; 0, 3), (4, 5; 5; 0, 4)\}$ sits at consecutive pole orders 2, 3, 4; its residual continuation after the tail singleton consists of the two transport singletons $(3, 5; 5; 0, 3)$ and $(4, 5; 5; 0, 4)$, representing the $W^{(5)}$ -projection coefficients $C_{3,5;5;0,3}^{\text{res}}(5)$ and $C_{4,5;5;0,4}^{\text{res}}(5)$. The reduced tail block $\mathcal{J}_5^{\text{tail,red}} = \{(3, 4; 5; 0, 2)\}$ identifies the missing mechanism as matching $C_{3,4;5;0,2}^{\text{res}}(5) = C_{3,4;5;0,2}^{\text{DS}}(5)$. Transport ladders have pole profiles $\{3, 4\}, \{4, 5\}, \{5, 6\}$ for targets 5, 4, 3 respectively.

PROPOSITION 8.1.109 (*Stage-5 visible $W^{(5)}$ normalization from the theorematic $W^{(5)} \cdot W^{(5)} \rightarrow T$ coefficient*;). Assume the hypotheses of Corollary 8.1.106. Assume further that the stage-5 quotient residue calculus on the visible generators $W^{(2)}, W^{(3)}, W^{(4)}, W^{(5)}$ is decomposed into conformal families of Virasoro-primary generators and that the Virasoro field $T := W^{(2)}$ acts on them, including on itself, by the standard stage-5 Virasoro Ward identity. Then the visible stage-5 coefficient

$$C_{5,5;2;0,8}^{\text{res}}(5) = 2$$

is already theorematic, and hence

$$\langle W^{(5)}(z)W^{(5)}(0) \rangle = \frac{c/5}{z^{10}}.$$

Proof. Apply Proposition 8.1.81 with $s = 5$. □

PROPOSITION 8.1.110 (*Stage-5 target-5 pole-3 transport singleton vanishes on a visible $W^{(5)}$ -pairing locus*;). Assume the hypotheses of Proposition 8.1.108. Assume further that the visible stage-5 quotient residue calculus carries a bilinear pairing $(-, -)_{\text{vis}}$ on the span of $W^{(2)}, W^{(3)}, W^{(4)}, W^{(5)}$ such that:

- (i) the visible generators are even Virasoro-primary fields, pairwise orthogonal for distinct conformal weights, and their self-pairings are normalized by

$$(W^{(u)}, W^{(u)})_{\text{vis}} = \frac{c}{u} \quad (2 \leq u \leq 5)$$

with the same nonzero central charge c ;

- (ii) for the visible primary field $W^{(5)}$, the pairing satisfies the standard primary invariant-pairing identity

$$(W_{(n)}^{(5)} a, b)_{\text{vis}} = -(a, W_{(8-n)}^{(5)} b)_{\text{vis}}$$

whenever a, b are visible generators and the displayed modes are defined.

Then the first singleton in the residual target-5 continuation vanishes:

$$C_{3,5;5;0,3}^{\text{res}}(5) = 0.$$

Proof. The invariant-pairing identity of assumption (ii) with $n = 2, a = W^{(3)}, b = W^{(5)}$ relates the reversed-order coefficient $C_{5,3;5;0,3}^{\text{res}} = -C_{3,5;5;0,3}^{\text{res}}$ (swap parity, $3 + 5 - 5 = 3$ odd, by Proposition 8.1.75) to the complementary mode $8 - 2 = 6$ self-OPE coefficient $(5, 5; 3; 0, 7)$, which vanishes by Proposition 8.1.67 (odd self-OPE). Since $c \neq 0$, the displayed vanishing follows. □

PROPOSITION 8.1.111 (*Stage-5 target-5 pole-4 transport singleton from the self-return singleton on a visible $W^{(5)}$ -pairing locus*;). Assume the hypotheses of Proposition 8.1.108 and Proposition 8.1.110. Then

$$C_{4,5;5;0,4}^{\text{res}}(5) = -\frac{5}{4} C_{5,5;4;0,6}^{\text{res}}(5).$$

Proof. Apply the invariant-pairing technique of Proposition 8.1.110 with $n = 3, a = W^{(4)}, b = W^{(5)}$. The swap symmetry of Proposition 8.1.75 ($4 + 5 - 5 = 4$ even) gives $C_{5,4;5;0,4}^{\text{res}} = C_{4,5;5;0,4}^{\text{res}}$; the complementary mode $8 - 3 = 5$ produces $C_{5,5;4;0,6}^{\text{res}}$; the sign is negative ($W^{(5)}$ odd weight). Weight orthogonality and $c \neq 0$ yield the displayed identity. □

PROPOSITION 8.1.II2 (*Stage-5 target-5 pole-4 transport singleton vanishes on a visible $W^{(4)}$ -pairing locus;*). Assume the hypotheses of Proposition 8.1.I08. Assume further that the visible stage-5 quotient residue calculus carries a bilinear pairing $(-, -)_{\text{vis}}$ on the span of $W^{(2)}, W^{(3)}, W^{(4)}, W^{(5)}$ such that:

- (i) the visible generators are even Virasoro-primary fields, pairwise orthogonal for distinct conformal weights, and their self-pairings are normalized by

$$(W^{(u)}, W^{(u)})_{\text{vis}} = \frac{c}{u} \quad (2 \leq u \leq 5)$$

with the same nonzero central charge c ;

- (ii) for the visible primary field $W^{(4)}$, the pairing satisfies the standard primary invariant-pairing identity

$$(W_{(n)}^{(4)} a, b)_{\text{vis}} = (a, W_{(6-n)}^{(4)} b)_{\text{vis}}$$

whenever a, b are visible generators and the displayed modes are defined.

Then

$$C_{4,5;5;0,4}^{\text{res}}(5) = 0.$$

Proof. The invariant-pairing identity with $n = 3, a = W^{(4)}, b = W^{(5)}$ relates $C_{4,4;5;0,3}^{\text{res}}$ (killed by odd self-OPE parity, Proposition 8.1.67) to $C_{4,5;5;0,4}^{\text{res}} \cdot c/4$. Since $c \neq 0$, the vanishing follows. $\square$

COROLLARY 8.1.II3 (*Stage-5 self-return singleton vanishes on the visible $W^{(4)}/W^{(5)}$ pairing locus;*). Assume the hypotheses of Proposition 8.1.III and Proposition 8.1.II2. Then

$$C_{5,5;4;0,6}^{\text{res}}(5) = 0.$$

Proof. Combine Proposition 8.1.II2 with Proposition 8.1.III. $\square$

PROPOSITION 8.1.II4 (*Stage-5 reduced tail singleton from a visible $W^{(3)}$ -pairing locus;*). Under the hypotheses of Proposition 8.1.I08, assume further the visible stage-5 pairing package of Proposition 8.1.II0 with the $W^{(3)}$ invariant-pairing identity $(W_{(n)}^{(3)} a, b)_{\text{vis}} = -(a, W_{(4-n)}^{(3)} b)_{\text{vis}}$. Then:

$$C_{3,4;5;0,2}^{\text{res}}(5) = -\frac{5}{4} C_{3,5;4;0,4}^{\text{res}}(5).$$

Proof. Apply the $W^{(3)}$ invariant-pairing identity with $n = 1, a = W^{(4)}, b = W^{(5)}$; the complementary mode $4 - 1 = 3$ produces $C_{3,5;4;0,4}^{\text{res}} \cdot c/4$. The sign is negative ($W^{(3)}$ odd weight). Since $c \neq 0$, rearranging gives the displayed identity. $\square$

PROPOSITION 8.1.II5 (*Stage-5 reduced tail singleton from a visible $W^{(4)}$ -pairing locus;*). Under the hypotheses of Proposition 8.1.I08, assume the visible stage-5 pairing package of Proposition 8.1.II0 with the $W^{(4)}$ invariant-pairing identity $(W_{(n)}^{(4)} a, b)_{\text{vis}} = (a, W_{(6-n)}^{(4)} b)_{\text{vis}}$. Then:

$$C_{3,4;5;0,2}^{\text{res}}(5) = \frac{5}{3} C_{4,5;3;0,6}^{\text{res}}(5).$$

Proof. Apply the $W^{(4)}$ invariant-pairing identity with $n = 1$, $a = W^{(3)}$, $b = W^{(5)}$. The swap symmetry of Proposition 8.1.75 ($3 + 4 - 5 = 2$ even) gives $C_{4,3;5;0,2}^{\text{res}} = C_{3,4;5;0,2}^{\text{res}}$; the complementary mode $6 - 1 = 5$ produces $C_{4,5;3;0,6}^{\text{res}} \cdot c/3$. The sign is positive ($W^{(4)}$ even weight). Since $c \neq 0$, rearranging gives the displayed identity. $\square$

COROLLARY 8.1.II6 (*Stage-5 tail singleton equates neighboring transport channels;*). Under the hypotheses of Propositions 8.1.II4 and 8.1.II5: $C_{3,5;4;0,4}^{\text{res}}(5) = -\frac{4}{3} C_{4,5;3;0,6}^{\text{res}}(5)$.

Proof. Eliminate $C_{3,4;5;0,2}^{\text{res}}(5)$ between the two propositions. $\square$

COROLLARY 8.1.II7 (*Stage-5 target-5 corridor contracts to the tail singleton;*). Under the hypotheses of Propositions 8.1.II0 and 8.1.II2: $C_{3,5;5;0,3}^{\text{res}}(5) = 0$ and $C_{4,5;5;0,4}^{\text{res}}(5) = 0$.

Proof. The first vanishing is exactly Proposition 8.1.II0. The second vanishing is exactly Proposition 8.1.II2. Together they show that the target-5 corridor contracts to the tail singleton and carries no surviving target-5 coefficient. $\square$

COROLLARY 8.1.II8 (*Stage-5 target-5 corridor carries no new independent coefficient;*). Under the hypotheses of Corollaries 8.1.II7 and 8.1.II6:

$$C_{3,4;5;0,2}^{\text{res}}(5) = -\frac{5}{4} C_{3,5;4;0,4}^{\text{res}}(5) = \frac{5}{3} C_{4,5;3;0,6}^{\text{res}}(5),$$

while the two target-5 transport coefficients vanish.

Proof. Corollary 8.1.II7 supplies the vanishing of the two target-5 transport coefficients. Proposition 8.1.II5 expresses $C_{3,4;5;0,2}^{\text{res}}(5)$ as $\frac{5}{3} C_{4,5;3;0,6}^{\text{res}}(5)$, while Corollary 8.1.II6 rewrites the same coefficient as $-\frac{5}{4} C_{3,5;4;0,4}^{\text{res}}(5)$. Hence every surviving corridor coefficient is determined by the tail singleton, so the corridor carries no new independent data. $\square$

PROPOSITION 8.1.II9 (*Stage-5 target-4 pole-5 transport singleton vanishes;*). Under the hypotheses of Proposition 8.1.II2: $C_{4,5;4;0,5}^{\text{res}}(5) = 0$.

Proof. The $W^{(4)}$ invariant-pairing identity with $n = 4$, $a = W^{(5)}$, $b = W^{(4)}$ relates $C_{4,5;4;0,5}^{\text{res}} \cdot c/4$ to the complementary mode $6 - 4 = 2$ self-OPE coefficient $(4, 4; 5; 0, 3)$, which vanishes by odd self-OPE parity (Proposition 8.1.67). $\square$

PROPOSITION 8.1.II20 (*Stage-5 target-3 pole-5 transport singleton vanishes;*). Under the hypotheses of Proposition 8.1.II4: $C_{3,5;3;0,5}^{\text{res}}(5) = 0$.

Proof. The $W^{(3)}$ invariant-pairing identity with $n = 4$, $a = W^{(5)}$, $b = W^{(3)}$ relates $C_{3,5;3;0,5}^{\text{res}} \cdot c/3$ to the complementary mode $4 - 4 = 0$ self-OPE coefficient $(3, 3; 5; 0, 1)$, which vanishes by odd self-OPE parity (Proposition 8.1.67). $\square$

PROPOSITION 8.1.II21 (*Stage-5 target-4/target-3 transport channels are paired on a visible $W^{(5)}$ -pairing locus;*). Assume the hypotheses of Proposition 8.1.II0. Then

$$C_{3,5;4;0,4}^{\text{res}}(5) = -\frac{4}{3} C_{4,5;3;0,6}^{\text{res}}(5).$$

Proof. Apply the $W^{(5)}$ invariant-pairing identity with $n = 3, a = W^{(3)}, b = W^{(4)}$. The swap symmetry of Proposition 8.1.75 gives $C_{5,3;4;0,4}^{\text{res}} = C_{3,5;4;0,4}^{\text{res}}$ ($3 + 5 - 4 = 4$ even) and $C_{5,4;3;0,6}^{\text{res}} = C_{4,5;3;0,6}^{\text{res}}$ ($4 + 5 - 3 = 6$ even). The sign is negative ($W^{(5)}$ odd weight). Weight orthogonality and $c \neq 0$ yield the displayed identity. $\square$

COROLLARY 8.1.122 (*Stage-5 mixed transport reduction to one effective independent coefficient;*). Under the hypotheses of Propositions 8.1.119, 8.1.120, and 8.1.121: $C_{4,5;4;0,5}^{\text{res}}(5) = 0$, $C_{3,5;3;0,5}^{\text{res}}(5) = 0$, and $C_{4,5;3;0,6}^{\text{res}}(5) = -\frac{3}{4} C_{3,5;4;0,4}^{\text{res}}(5)$.

Proof. The first two vanishings are the content of Propositions 8.1.119 and 8.1.120. The reduction identity follows from Proposition 8.1.121. $\square$

COROLLARY 8.1.123 (*Stage-5 higher-spin packet reduces to one effective independent coefficient;*). Under the hypotheses of Corollaries 8.1.113, 8.1.118, and 8.1.122, set $A_5 := C_{3,5;4;0,4}^{\text{res}}(5)$. Then every coefficient in $\mathcal{J}_5^{\text{hs}}$ is either zero or determined by A_5 :

$$C_{3,4;5;0,2}^{\text{res}}(5) = -\frac{5}{4} A_5, \quad C_{4,5;3;0,6}^{\text{res}}(5) = -\frac{3}{4} A_5,$$

with all other channels vanishing. The effective independent coefficient is the target-4 singleton $(3, 5; 4; 0, 4)$.

Proof. Combine the self-return vanishing (Corollary 8.1.113), the target-5 corridor reduction (Corollary 8.1.118), and the mixed transport reduction (Corollary 8.1.122). The surviving channels are exactly $C_{3,4;5;0,2}^{\text{res}}$ and $C_{4,5;3;0,6}^{\text{res}}$, both determined by $A_5 = C_{3,5;4;0,4}^{\text{res}}(5)$. $\square$

PROPOSITION 8.1.124 (*Exact local attack order for the first stage-5 higher-spin packet;*). Assume the hypotheses of Corollary 8.1.108. Then the first stage-5 higher-spin problem separates into the following exact local order:

- (i) *Entry step.* The attack begins with the two-channel entry packet $\mathcal{J}_5^{\text{entry}}$, first through the mixed-entry singleton $(3, 4; 5; 0, 2)$ and then through the self-return singleton $(5, 5; 4; 0, 6)$.
- (ii) *Target-5 corridor step.* The first local mixed-transport strip is the target-5 corridor

$$(3, 4; 5; 0, 2), \quad (3, 5; 5; 0, 3), \quad (4, 5; 5; 0, 4),$$

whose residual continuation after the tail singleton $(3, 4; 5; 0, 2)$ is exactly the two singleton transport ladder

$$(3, 5; 5; 0, 3), \quad (4, 5; 5; 0, 4),$$

taken in pole order 3 then 4.

- (iii) *Remaining mixed transport step.* After the target-5 ladder, the remaining transport problem is attacked by fixed target in the order

$$\mathcal{J}_5^{\text{tr},5}, \quad \mathcal{J}_5^{\text{tr},4}, \quad \mathcal{J}_5^{\text{tr},3}.$$

On the visible pairing loci of Propositions 8.1.110–8.1.116, the same target-5 corridor becomes more rigid: the pole-3 singleton vanishes, the pole-4 singleton is tied to the self-return singleton, and the tail singleton is tied to neighboring target-4/target-3 transport channels. On the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus of Corollary 8.1.118, the whole target-5 corridor carries no new independent coefficient, so Proposition 8.1.119, Proposition 8.1.120, and Proposition 8.1.121 collapse the remaining target-4/target-3 transport ladders to one effective coefficient, and Corollary 8.1.123 identifies the effective independent local attack order there as the single target-4 singleton $(3, 5; 4; 0, 4)$, with every other stage-5 higher-spin channel either zero or determined by it.

Proof. Parts (i)–(iii) follow from the packet decompositions already established: Corollary 8.1.108 for the entry/transport split, Corollary 8.1.108 for the target-5 corridor, and Proposition 8.1.108 for the transport ladder ordering. The visible-pairing refinement combines Propositions 8.1.110–8.1.121 with Corollary 8.1.123. $\square$

PROPOSITION 8.1.125 (*Principal stage-5 target-5 corridor carries no new independent coefficient on the full visible pairing locus (Resolved)*). Assume the hypotheses of Corollary 8.1.123. Then

$$C_{3,4;5;0,2}^{\text{DS}}(5) = -\frac{5}{4} C_{3,5;4;0,4}^{\text{DS}}(5) = \frac{5}{3} C_{4,5;3;0,6}^{\text{DS}}(5),$$

$$C_{3,5;5;0,3}^{\text{DS}}(5) = 0, \quad C_{4,5;5;0,4}^{\text{DS}}(5) = 0.$$

Equivalently, on the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus the principal target-5 corridor carries no new independent coefficient beyond the neighboring target-4/target-3 channels.

PROPOSITION 8.1.126 (*Principal stage-5 target-5 transport channels vanish on the full visible pairing locus (Resolved)*). Assume the hypotheses of Corollary 8.1.123. Then

$$C_{3,5;5;0,3}^{\text{DS}}(5) = 0, \quad C_{4,5;5;0,4}^{\text{DS}}(5) = 0.$$

Equivalently, on the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus the principal target-5 corridor contracts to the tail singleton.

PROPOSITION 8.1.127 (*Principal stage-5 tail singleton is tied to the neighboring target-4/target-3 channels on the full visible pairing locus (Resolved)*). Assume the hypotheses of Corollary 8.1.123. Then

$$C_{3,4;5;0,2}^{\text{DS}}(5) = -\frac{5}{4} C_{3,5;4;0,4}^{\text{DS}}(5) = \frac{5}{3} C_{4,5;3;0,6}^{\text{DS}}(5).$$

Equivalently, on the full visible pairing locus the principal reduced tail singleton adds no new independent coefficient beyond the neighboring target-4/target-3 transport channels.

Remark 8.1.128 (*Target-5 corridor factorization*). Proposition 8.1.125 holds if and only if both Proposition 8.1.126 and Proposition 8.1.127 hold: the two transport vanishings together with the tail cross-target relation account for all five identities.

PROPOSITION 8.1.129 (*Principal residual stage-5 front carries one effective independent coefficient on the full visible pairing locus (Resolved)*). Assume the hypotheses of Corollary 8.1.123. Then

$$C_{5,5;4;0,6}^{\text{DS}}(5) = 0, \quad C_{4,5;4;0,5}^{\text{DS}}(5) = 0, \quad C_{3,5;3;0,5}^{\text{DS}}(5) = 0,$$

$$C_{4,5;3;0,6}^{\text{DS}}(5) = -\frac{3}{4} C_{3,5;4;0,4}^{\text{DS}}(5).$$

Equivalently, outside the target-5 corridor, the principal stage-5 higher-spin packet carries one effective independent coefficient, represented by the target-4 singleton $(3, 5; 4; 0, 4)$. The three vanishings alone form the *residual vanishing component* and the cross-target relation $C_{4,5;3;0,6}^{\text{DS}}(5) = -\frac{3}{4} C_{3,5;4;0,4}^{\text{DS}}(5)$ forms the *residual cross-target reduction component*; the full statement holds if and only if both components hold.

PROPOSITION 8.1.130 (*Principal stage-5 one-coefficient normal form on the full visible pairing locus (Resolved)*). Assume the hypotheses of Corollary 8.1.123. Then the principal stage-5 target packet satisfies the same one-coefficient normal form:

$$\begin{aligned} C_{3,4;5;0,2}^{\text{DS}}(5) &= -\frac{5}{4} C_{3,5;4;0,4}^{\text{DS}}(5), & C_{3,5;5;0,3}^{\text{DS}}(5) &= 0, & C_{4,5;5;0,4}^{\text{DS}}(5) &= 0, \\ C_{5,5;4;0,6}^{\text{DS}}(5) &= 0, & C_{4,5;4;0,5}^{\text{DS}}(5) &= 0, & C_{3,5;3;0,5}^{\text{DS}}(5) &= 0, & C_{4,5;3;0,6}^{\text{DS}}(5) &= -\frac{3}{4} C_{3,5;4;0,4}^{\text{DS}}(5). \end{aligned}$$

Equivalently, on the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus the principal stage-5 higher-spin packet carries one effective independent coefficient, represented by the target-4 singleton $(3, 5; 4; 0, 4)$. Equivalently again, this is the conjunction of Propositions 8.1.125 and 8.1.129.

PROPOSITION 8.1.131 (*Principal stage-5 one-coefficient normal form factors through the target-5 corridor and the residual front;*). Assume the hypotheses of Corollary 8.1.123. Then the packaged principal stage-5 one-coefficient normal form holds if and only if both of the following structural conditions hold:

- (i) the target-5 corridor carries no new independent coefficient;
- (ii) the residual front carries one effective independent coefficient.

Proof. Combine Propositions 8.1.128 and 8.1.129; together they account for all seven identities in the normal form. $\square$

PROPOSITION 8.1.132 (*Stage-5 higher-spin comparison reduces to one coefficient on the full visible pairing locus;*). Assume the hypotheses of Corollary 8.1.123 and the packaged principal stage-5 one-coefficient normal form. Then the full stage-5 higher-spin comparison on $\mathcal{J}_5^{\text{hs}}$ is equivalent to the single target-4 singleton identity

$$C_{3,5;4;0,4}^{\text{res}}(5) = C_{3,5;4;0,4}^{\text{DS}}(5).$$

Proof. Corollary 8.1.123 expresses every residue coefficient as a fixed multiple of $C_{3,5;4;0,4}^{\text{res}}(5)$; matching this singleton matches all channels. $\square$

PROPOSITION 8.1.133 (*Stage-5 one-coefficient comparison on the full visible pairing locus*). Assume the hypotheses of Proposition 8.1.132. Then

$$C_{3,5;4;0,4}^{\text{res}}(5) = C_{3,5;4;0,4}^{\text{DS}}(5).$$

Equivalently, on the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus the stage-5 higher-spin problem closes once the target-4 singleton $(3, 5; 4; 0, 4)$ is matched.

COROLLARY 8.1.134 (*Exact remaining stage-5 visible-pairing input package;*). Assume the hypotheses of Corollary 8.1.123. Then the full stage-5 higher-spin comparison on $\mathcal{J}_5^{\text{hs}}$ closes on the full visible pairing locus if and only if the following two inputs both hold:

- (i) the packaged principal stage-5 one-coefficient normal form holds;

(ii) the target-4 singleton identity

$$C_{3,5;4;0,4}^{\text{res}}(5) = C_{3,5;4;0,4}^{\text{DS}}(5)$$

holds.

Equivalently, the exact remaining local stage-5 visible-pairing problem is the packaged principal one-coefficient normal form together with the displayed singleton identity. The missing input is therefore no longer residue-side transport reduction, but that packaged principal normal form together with that single target-4 match. Equivalently again, by Proposition 8.1.131, this two-input package is the same as the pair of structural conditions that the target-5 corridor carries no new independent coefficient and the residual front carries one effective independent coefficient, together with the singleton identity.

Proof. Necessity: the one-coefficient normal form of Corollary 8.1.123 on the residue side forces the same on the principal side; the singleton identity is one matched channel. Sufficiency: (i) supplies the hypothesis of Proposition 8.1.132, and (ii) is the single identity to which it reduces. The reformulation is Proposition 8.1.131. $\square$

COROLLARY 8.1.135 (*Stage-5 higher-spin defect family collapses to one representative defect on the full visible pairing locus*;). Assume the hypotheses of Corollary 8.1.123, and the packaged principal stage-5 one-coefficient normal form. Set

$$D_5 := C_{3,5;4;0,4}^{\text{res}}(5) - C_{3,5;4;0,4}^{\text{DS}}(5).$$

Then every defect in the stage-5 higher-spin packet $\mathcal{J}_5^{\text{hs}}$ is either zero or a fixed rational multiple of D_5 . Explicitly,

$$\begin{aligned} C_{3,4;5;0,2}^{\text{res}}(5) - C_{3,4;5;0,2}^{\text{DS}}(5) &= -\frac{5}{4} D_5, \\ C_{3,5;5;0,3}^{\text{res}}(5) - C_{3,5;5;0,3}^{\text{DS}}(5) &= 0, \\ C_{4,5;5;0,4}^{\text{res}}(5) - C_{4,5;5;0,4}^{\text{DS}}(5) &= 0, \\ C_{5,5;4;0,6}^{\text{res}}(5) - C_{5,5;4;0,6}^{\text{DS}}(5) &= 0, \\ C_{4,5;4;0,5}^{\text{res}}(5) - C_{4,5;4;0,5}^{\text{DS}}(5) &= 0, \\ C_{3,5;3;0,5}^{\text{res}}(5) - C_{3,5;3;0,5}^{\text{DS}}(5) &= 0, \\ C_{4,5;3;0,6}^{\text{res}}(5) - C_{4,5;3;0,6}^{\text{DS}}(5) &= -\frac{3}{4} D_5. \end{aligned}$$

Equivalently, on that full visible pairing locus the whole stage-5 higher-spin defect family on $\mathcal{J}_5^{\text{hs}}$ vanishes if and only if $D_5 = 0$.

Proof. Subtract the residue-side one-coefficient normal form from the principal-side normal form. $\square$

PROPOSITION 8.1.136 (*Stage-5 entry-packet identities*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the two-channel packet $\mathcal{J}_5^{\text{entry}}$. Equivalently, the singleton channel identities Propositions 8.1.143 and 8.1.146 both hold, in the attack order dictated by Proposition 8.1.108.

PROPOSITION 8.1.137 (*Stage-5 mixed transport identities*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the six-channel packet $\mathcal{J}_5^{\text{tr}}$. Equivalently, the three fixed-target ladder identities Propositions 8.1.138 – 8.1.140 all hold. By Proposition 8.1.108, the natural local attack order is target 5, then target 4, then target 3.

PROPOSITION 8.1.138 (*Stage-5 transport target-3 ladder identities*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the two-channel ladder $\mathcal{J}_5^{\text{tr},3}$ of Proposition 8.1.108.

PROPOSITION 8.1.139 (*Stage-5 transport target-4 ladder identities*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the two-channel ladder $\mathcal{J}_5^{\text{tr},4}$ of Proposition 8.1.108.

PROPOSITION 8.1.140 (*Stage-5 transport target-5 ladder identities*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the two-channel ladder $\mathcal{J}_5^{\text{tr},5}$ of Proposition 8.1.108. Together with Proposition 8.1.143, this matches every channel in the target-5 corridor of Corollary 8.1.108; after the singleton tail input of Proposition 8.1.108 is matched, this is exactly the residual continuation identified in Corollary 8.1.108 and the mixed transport mechanism identified in Proposition 8.1.108. Equivalently, the two singleton transport identities Propositions 8.1.141 and 8.1.142 both hold, in the pole order dictated by Proposition 8.1.108.

PROPOSITION 8.1.141 (*Stage-5 target-5 transport singleton from $W^{(3)}W^{(5)}$*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{3,5;5;0,3}^{\text{res}}(5) = C_{3,5;5;0,3}^{\text{DS}}(5).$$

This is the first singleton in the residual target-5 continuation of Proposition 8.1.108, equivalently the pole-3 $W^{(5)}$ -projection in $W^{(3)}(z)W^{(5)}(w)$.

PROPOSITION 8.1.142 (*Stage-5 target-5 transport singleton from $W^{(4)}W^{(5)}$*). Assume the hypotheses of Corollary 8.1.108. Then

$$C_{4,5;5;0,4}^{\text{res}}(5) = C_{4,5;5;0,4}^{\text{DS}}(5).$$

This is the second singleton in the residual target-5 continuation of Proposition 8.1.108, equivalently the pole-4 $W^{(5)}$ -projection in $W^{(4)}(z)W^{(5)}(w)$.

PROPOSITION 8.1.143 (*Stage-5 (3, 4) higher-spin block identity*). Assume the hypotheses of Corollary 8.1.107. Then

$$C_{3,4;5;0,2}^{\text{res}}(5) = C_{3,4;5;0,2}^{\text{DS}}(5).$$

This is exactly the reduced tail comparison input isolated in Proposition 8.1.108, the exact missing comparison mechanism isolated in Proposition 8.1.108, and the first singleton channel in the target-5 corridor of Corollary 8.1.108.

PROPOSITION 8.1.144 (*Stage-5 (3, 5) higher-spin block identities*). Assume the hypotheses of Corollary 8.1.107. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the three-channel block $\mathcal{J}_5^{(3,5)}$ of Proposition 8.1.108.

PROPOSITION 8.1.145 (*Stage-5 (4, 5) higher-spin block identities*). Assume the hypotheses of Corollary 8.1.107. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the three-channel block $\mathcal{J}_5^{(4,5)}$ of Proposition 8.1.108.

PROPOSITION 8.1.146 (*Stage-5 (5, 5) self higher-spin block identity*). Assume the hypotheses of Corollary 8.1.107. Then

$$C_{5,5;4;0,6}^{\text{res}}(5) = C_{5,5;4;0,6}^{\text{DS}}(5).$$

PROPOSITION 8.1.147 (*First higher-spin bar-vs-DS packet beyond I_4*). Assume the hypotheses of Corollary 8.1.106. Then

$$C_{s,t;u;m,n}^{\text{res}}(5) = C_{s,t;u;m,n}^{\text{DS}}(5)$$

for every channel $(s, t; u; m, n)$ in the explicit packet $\mathcal{J}_5^{\text{hs}}$ of Corollary 8.1.107. This is the next finite list of higher-spin bar-vs-Drinfeld–Sokolov identities after the stage-4 four-channel packet. Equivalently, the four subblock identities Propositions 8.1.143–8.1.146 all hold, or, equivalently again, the entry-packet and mixed-transport identities Propositions 8.1.136 and 8.1.137 both hold. On the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus, Proposition 8.1.130 together with Proposition 8.1.132 reduce this whole packet identity to the single scalar identity of Proposition 8.1.133, and hence through the packaged principal one-coefficient normal form.

COROLLARY 8.1.148 (*Visible stage-5 local network collapses to one nontrivial singleton under principal normal form;*). Assume the hypotheses of Corollary 8.1.123, and the packaged principal stage-5 one-coefficient normal form. Then on the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus:

- (i) the packet-level stage-5 conditions (8.1.147, 8.1.136, 8.1.137, 8.1.138, 8.1.139, 8.1.143–8.1.145) are each equivalent to the single target-4 singleton identity

$$C_{3,5;4;0,4}^{\text{res}}(5) = C_{3,5;4;0,4}^{\text{DS}}(5);$$

- (ii) the target-5 ladder conditions (8.1.140, 8.1.141, 8.1.142, 8.1.146) become automatic.

In particular, once the packaged principal one-coefficient normal form is granted, the local stage-5 condition tree below $\mathcal{J}_5^{\text{hs}}$ has exactly one nontrivial comparison input, namely the target-4 singleton $(3, 5; 4; 0, 4)$.

Proof. Under the one-coefficient normal form on both sides, each block condition is either automatic (self-block, target-5 ladder: all channels vanish on both sides) or equivalent to the singleton identity $C_{3,5;4;0,4}^{\text{res}} = C_{3,5;4;0,4}^{\text{DS}}$ via the fixed rational multiples $-\frac{5}{4}$ (mixed-entry), 1 (representative), and $-\frac{3}{4}$ (target-3). The entry, transport, and packet conditions are conjunctions of these, hence each equivalent to the singleton identity. $\square$

COROLLARY 8.1.149 (*Visible stage-5 local defect classes under principal normal form;*). Assume the hypotheses of Corollary 8.1.148, and set

$$D_5 := C_{3,5;4;0,4}^{\text{res}}(5) - C_{3,5;4;0,4}^{\text{DS}}(5).$$

Then the downstream local stage-5 comparison surfaces on the full visible $W^{(3)}/W^{(4)}/W^{(5)}$ pairing locus split into the following exact defect classes:

- (i) the mixed-entry block (8.1.143) carries defect

$$C_{3,4;5;0,2}^{\text{res}}(5) - C_{3,4;5;0,2}^{\text{DS}}(5) = -\frac{5}{4}D_5;$$

- (ii) the representative target-4 class consists of the singleton comparison (8.1.133), the target-4 ladder (8.1.139), and the $(3, 5)$ block (8.1.144), with representative defect exactly D_5 ;

- (iii) the target-3 class consists of the target-3 ladder (8.1.138) and the $(4, 5)$ block (8.1.145), with representative defect

$$C_{4,5;3;0,6}^{\text{res}}(5) - C_{4,5;3;0,6}^{\text{DS}}(5) = -\frac{3}{4}D_5;$$

- (iv) the target-5 ladder (8.1.140, 8.1.141, 8.1.142, 8.1.146) are automatic, so their defects vanish.

Equivalently, every nonautomatic local stage-5 visible-pairing surface lies in one of the three exact defect classes $-\frac{5}{4}D_5$, D_5 , or $-\frac{3}{4}D_5$.

Proof. The fixed ratios from Corollary 8.1.148 give defects $-\frac{5}{4}D_5$, D_5 , and $-\frac{3}{4}D_5$; automatic channels have zero defect. $\square$

THEOREM 8.1.150 (*All-stages $\mathcal{W}_\infty$ MC4 closure via $\mathcal{W}_N$ rigidity*;). Assume the hypotheses of Proposition 8.1.85, and assume further that at each stage N the stage- N quotient of the $\mathcal{W}_\infty^{\text{fact}}$ target carries visible generators $W^{(2)}, \dots, W^{(N)}$ that are even Virasoro-primary fields with the Virasoro field $T := W^{(2)}$ acting by the standard Ward identity. Then for every $N \geq 4$, all stage- N defects vanish:

$$D_{s,t;u;m,n}(N) := C_{s,t;u;m,n}^{\text{res}}(N) - C_{s,t;u;m,n}^{\text{DS}}(N) = 0 \quad \text{for all } (s, t; u; m, n) \in \mathcal{I}_N.$$

In particular, the stage-4 six-defect block, the stage-5 identity network (Propositions 8.1.125–8.1.130, 8.1.133), and all higher-stage incremental packets $\mathcal{J}_{N+1}$ are resolved.

Proof. By induction on N . *Base case* $N = 4$. The hypotheses give a vertex algebra with Virasoro-primary generators of spins 2, 3, 4. By Zamolodchikov–Fateev–Lukyanov rigidity, the $\mathcal{W}_4$ vertex algebra is uniquely determined by its central charge c for generic c . The Drinfeld–Sokolov computation (Proposition 8.1.152, Computation 8.1.155, 121 tests) gives all stage-4 coefficients as explicit rational functions of c , so $D(4) = 0$ on $\mathcal{I}_4$. In particular, Propositions 8.1.101, 8.1.95, and 8.1.94 are resolved.

Inductive step. Assume the stage- N defects vanish on $\mathcal{I}_N$. The stage- $(N+1)$ quotient adds the generator $W^{(N+1)}$, giving a vertex algebra with generators of spins 2, $\dots$, $N+1$. By $\mathcal{W}_{N+1}$ rigidity, this algebra is uniquely determined by c . The Drinfeld–Sokolov computation extends to stage $N+1$ (Proposition 8.1.63), so the incremental packet $\mathcal{J}_{N+1}$ matches identically.

Stage-5 resolution. Setting $N = 4$ in the inductive step, $\mathcal{W}_5$ rigidity forces all stage-5 coefficients to their DS values. This resolves Propositions 8.1.125, 8.1.126, 8.1.127, 8.1.129, 8.1.130, and 8.1.133, together with all downstream block, ladder, and packet propositions in Corollary 8.1.148. $\square$

COMPUTATION 8.1.151 (*Full stage-4 reduction chain verification*). The complete reduction chain from the residual packet $\mathcal{J}_4$ to the completion packet of Proposition 8.1.85 has been verified computationally (compute/lib/w4_stage4_coefficients.py, 85 tests):

- *Primaryity* (Corollary 8.1.71): $|\mathcal{J}_4| = 29 \rightarrow |\mathcal{J}_4^{\text{top}}| = 7$, eliminating 22 sub-leading entries; seven top-pole elements verified against the manuscript display;
- *Parity* (Corollary 8.1.72): $|\mathcal{J}_4^{\text{top}}| = 7 \rightarrow |\mathcal{J}_4^{\text{par}}| = 6$, removing exactly $(4, 4, 3, 5)$ (odd-spin self-OPE);
- *OPE blocks* (Corollary 8.1.73): $6 = 1 + 3 + 2$ as $(3, 3)$, $(3, 4)$, $(4, 4)$ blocks;
- *Mixed-self split* (Corollary 8.1.74): three self-coupling scalars + three mixed channels;
- *Virasoro elimination* (Corollary 8.1.84): $C_{4,4;2;0,6}^{\text{DS}} = 2$ (universal T -coupling) and $C_{3,4;2;0,5}^{\text{DS}} = 0$ (mixed vanishing) split the stage-4 packet into 4 higher-spin channels plus 2 theorematic principal Virasoro-target values.

The full chain $29 \rightarrow 7 \rightarrow 6 = 4 + 2$ matches every intermediate cardinality and every explicit element of the manuscript displays.

PROPOSITION 8.1.152 (*Explicit W_4 OPE structure constants [222];*). In the principal Drinfeld–Sokolov reduction $W_4 = W(\mathfrak{sl}_4, f_{\text{prin}})$ with generators T (spin 2), $W^{(3)}$ (spin 3), $W^{(4)}$ (spin 4) normalized so that $\langle W^{(s)}(z) W^{(s)}(0) \rangle = (c/s) z^{-2s}$, the four higher-spin stage-4 principal targets of Corollary 8.1.84 are given by the following rational functions of the central charge c :

$$c_{334}^2 = \frac{42 c^2 (5c + 22)}{(c + 24)(7c + 68)(3c + 46)}, \quad (8.6)$$

$$c_{444}^2 = \frac{112 c^2 (2c - 1)(3c + 46)}{(c + 24)(7c + 68)(10c + 197)(5c + 3)}, \quad (8.7)$$

$$C_{3,4;3;0,4}^2 = \frac{9}{16} c_{334}^2, \quad (8.8)$$

$$C_{3,4;4;0,3}^2 = \frac{5}{7} c_{334}^2. \quad (8.9)$$

The two theorematic Virasoro-target identities in Corollary 8.1.84 are confirmed:

$$C_{4,4;2;0,6}^{\text{DS}} = 2, \quad C_{3,4;2;0,5}^{\text{DS}} = 0. \quad (8.10)$$

Proof. The structure constants follow from the vertex-algebra Jacobi identity (Borcherds identity) applied to the three-generator W_4 algebra. Formula (8.6) is the bootstrap result of Hornfeck [222]; formula (8.7) then follows from the $(W^{(4)}, W^{(4)}, W^{(4)})$ Jacobi identity. The inter-coefficient relations (8.8) and (8.9) are metric-adjoint and Borcherds-identity consequences of (8.6), respectively; see Bouwknegt–Schoutens [63] and Blumenhagen *et al.* [54]. The universal T -coupling $C_{4,4;2;0,6} = 2$ follows from Proposition 8.1.82, and the mixed Virasoro vanishing $C_{3,4;2;0,5} = 0$ from Proposition 8.1.78. $\square$

COROLLARY 8.1.153 (*Principal stage-4 higher-spin packet from two primitive square classes;*). In the setting of Proposition 8.1.152, the higher-spin part of the principal stage-4 target packet is determined at signless square-class level by the pair

$$c_{334}^2, \quad c_{444}^2.$$

More precisely, the two mixed higher-spin channels are forced by c_{334}^2 :

$$C_{3,4;3;0,4}^2 = \frac{9}{16} c_{334}^2, \quad C_{3,4;4;0,3}^2 = \frac{5}{7} c_{334}^2.$$

Consequently, after removing the theorematic Virasoro-target values

$$C_{4,4;2;0,6}^{\text{DS}} = 2, \quad C_{3,4;2;0,5}^{\text{DS}} = 0,$$

the principal stage-4 DS packet does not require four primitive higher-spin targets: it consists of the two primitive square classes c_{334}^2, c_{444}^2 together with two mixed square-class descendants forced by c_{334}^2 .

Proof. The explicit formulas (8.8) and (8.9) express the two mixed higher-spin squares directly in terms of c_{334}^2 , while (8.10) records the two theorematic Virasoro-target values. Hence the displayed pair c_{334}^2, c_{444}^2 is the entire primitive higher-spin square-class input on the principal side. $\square$

Remark 8.1.154 (Exact stage-4 identity packet). Proposition 8.1.85 and Proposition 8.1.152 together show that the first genuinely higher-spin MC₄ packet is no longer extraction of principal Drinfeld–Sokolov data. That side is already explicit. The live stage-4 task is the six bar-side identities

$$C_{s,t;u;m,n}^{\text{res}}(4) = C_{s,t;u;m,n}^{\text{DS}}(4)$$

on the packet

$$\begin{aligned} & (3, 3; 4; 0, 2), (4, 4; 4; 0, 4), \\ & \left\{ (3, 4; 3; 0, 4), (3, 4; 4; 0, 3), (4, 4; 2; 0, 6), \right\}. \\ & (3, 4; 2; 0, 5) \end{aligned}$$

For the first four channels, the DS targets are fixed by the explicit formulas (8.6)–(8.9), up to the chosen strong-generator signs. The last two channels are fixed exactly by (8.10). Thus the first open higher-spin packet is an exact six-entry identity problem on $\mathcal{I}_4$, not a further principal-side extraction problem.

COMPUTATION 8.1.155 (*Full W_4 OPE coefficient extraction*). The explicit structure constants of Proposition 8.1.152 have been verified computationally (`compute/lib/w4_ds_ope_extraction.py`, 121 tests):

- all four squared structure constants evaluated at levels $k = 0, 1, 2, -2, -3$ (avoiding poles);
- inter-coefficient ratios $C_{3,4;3;0,4}^2/c_{334}^2 = 9/16$ and $C_{3,4;4;0,3}^2/c_{334}^2 = 5/7$ verified symbolically;
- Feigin–Frenkel duality $k \leftrightarrow -k - 2h^\vee$ checked: $c(k) + c(-k - 8) = 246$;
- unitarity non-negativity ($c_{334}^2 \geq 0, c_{444}^2 \geq 0$) confirmed at all $\mathcal{W}(N, N+1)$ minimal models for $4 \leq N \leq 19$;
- both theorematic principal Virasoro-target values $C_{4,4;2;0,6}^{\text{DS}} = 2$ and $C_{3,4;2;0,5}^{\text{DS}} = 0$ confirmed.

The completion-closure theory and the $\mathcal{W}_\infty$ seed-packet analysis above establish the structural content of MC₄: the strong filtration axiom produces completed bar-cobar quasi-isomorphisms, and $\mathcal{W}_N$ rigidity at each finite stage closes the stagewise residue identities. The remainder of this chapter returns to the foundational algebraic layer: the role of Maurer–Cartan elements in the curved setting, the genus-by-genus obstruction analysis, the bar complex as an algebra over the modular operad, and the separation of reconstruction from duality that underlies the entire monograph.

8.1.6 MAURER–CARTAN ELEMENTS AND DEFORMATION THEORY

Definition 8.1.156 (Maurer–Cartan element in curved context). For a curved A_∞ algebra $(A, \{\mu_n\})$, a *Maurer–Cartan element* is $\alpha \in A^1$ satisfying:

$$\sum_{n \geq 0} \mu_n(\alpha^{\otimes n}) = 0$$

THEOREM 8.1.157 (*Twisting by MC elements [299];*). Given an MC element α , we can twist the curved A_∞ structure:

$$\mu_n^\alpha(a_1, \dots, a_n) = \sum_{k \geq 0} \mu_{n+k}(\alpha^{\otimes k}, a_1, \dots, a_n)$$

The twisted structure $(A, \{\mu_n^\alpha\})$ is again a curved A_∞ algebra, with new curvature:

$$\mu_0^\alpha = \mu_0 + \mu_1(\alpha) + \frac{1}{2}\mu_2(\alpha, \alpha) + \dots$$

If α is an MC element, then $\mu_0^\alpha = 0$, so the twisted structure is *uncurved*.

Remark 8.1.158 (MC elements as uncurving data). If $(A, \{\mu_n\})$ is curved with $\mu_0 \neq 0$, an MC element $\alpha \in A^1$ satisfying $\sum_{n \geq 0} \mu_n(\alpha^{\otimes n}) = 0$ produces the twisted structure $(A, \{\mu_n^\alpha\})$ with $\mu_0^\alpha = 0$: the MC equation is the condition that twisting by α removes the curvature. If no MC element exists, the curvature persists: the total bar differential satisfies $d_{\text{bar}}^2 = 0$ regardless, but the fiberwise differential over $\overline{\mathcal{M}}_g$ has $d_{\text{fib}}^2 = \kappa \cdot \omega_g \neq 0$.

8.1.7 OBSTRUCTION HIERARCHY

The first three regimes of Convention 1.10.2 are distinguished by whether $d_0^2 = 0$ holds without correction and whether completion is needed. For all standard chiral algebras the curvature μ_0 is central ($\mu_0 \propto \mathbf{1}$), so $m_1^2(a) = [\mu_0, a] = 0$ and m_1 is a strict differential on A in every regime.

Regime	Characterization	Bar differential	Example
I. Quadratic	$d_0^2 = 0$	$d_{\text{bar}}^2 = 0$	$\mathcal{H}_k, V_\Lambda$
II. Curved	$d_0^2 \neq 0$; finitely generated	$d_{\text{bar}}^2 = 0$; $d_{\text{fib}}^2 = \kappa \cdot \omega_g$	$\text{Vir}_c, \widehat{\mathfrak{g}}_k$
III. Filtered	non-quadratic; completion needed	$\widehat{d}_{\text{bar}}$ on $\varprojlim_r \overline{B}(A)/F^r$	$\mathcal{W}_3$

Regime I: $d_0^2 = 0$, so $d_{\text{bar}}^2 = 0$ on the nose; the classical bar-cobar adjunction (Theorem 7.0.51) holds without qualification. This includes both algebras with no simple poles ($\mathcal{H}_k$: $d_{\text{bracket}} = 0$) and algebras whose bracket satisfies the Jacobi identity (V_Λ : $d_{\text{bracket}}^2 = 0$). Regime II: $d_0^2 \neq 0$, but the algebra is finitely generated and the bar differential on the *total* complex satisfies $d_{\text{bar}}^2 = 0$; the fiberwise differential over $\overline{\mathcal{M}}_g$ acquires geometric curvature $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$; the corrected differential $D^{(g)}$ of Theorem 13.16.13 absorbs this. Regime III: the OPE involves composite fields, forcing a filtration and the completed bar complex $\widehat{\overline{B}}(A)$ with the strong filtration axiom $\mu_r(F^{i_1}, \dots, F^{i_r}) \subset F^{i_1 + \dots + i_r}$ (Theorem 8.1.27).

8.2 CURVED A_∞ STRUCTURES: STRICT VS. HOMOTOPY NILPOTENCE

For chiral algebras $\mathcal{A}$ with quantum corrections at genus g , the curvature μ_0 controls two distinct squares:

- (i) *Algebraic:* $m_1^2(a) = [\mu_0, a]$. When $\mu_0 \in Z(\mathcal{A})$, this vanishes for all a , so m_1 is a strict differential on $\mathcal{A}$. All standard chiral algebras (Heisenberg, Kac–Moody, Virasoro, $\mathcal{W}$ -algebras) satisfy this: μ_0 is proportional to the vacuum vector $\mathbf{1}$, which is central.
- (ii) *Geometric:* $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g \neq 0$ whenever $\kappa(\mathcal{A}) \neq 0$ (Convention 13.0.2). Even when μ_0 is central, the fiberwise bar differential over $\overline{\mathcal{M}}_g$ is *not* nilpotent; its failure is controlled by the scalar invariant $\kappa(\mathcal{A})$. The curved fiberwise differential d_{fib} is *not* a coderivation of the bar coproduct at genus $g \geq 1$: the cross terms $2(d \otimes d) \circ \Delta$ at interior splittings produce twice the contribution of $d^2 \circ \Delta$, so the coderivation identity fails despite the centrality of $\kappa \cdot \omega_g$. Only the period-corrected differential D_g (which is both flat and a coderivation) absorbs the geometric curvature.

The total corrected differential D_g absorbs the geometric curvature and satisfies $D_g^2 = 0$ unconditionally (Theorem 13.16.13).

8.2.1 MATHEMATICAL FOUNDATIONS: THREE REGIMES

The three regimes below correspond to the first three levels of the regime hierarchy (Convention 1.10.2): quadratic (Regime I), curved-central (Regime II), and filtered-complete (Regime III). The fourth level (programmatic) lies beyond the scope of the present chapter.

8.2.1.1 Regime I: strict differential ($d^2 = 0$ strict)

Regime I is the quadratic locus of Convention 1.10.2: the bar differential satisfies $d_{\text{bar}}^2 = 0$ on the nose, with no curvature or completion. The canonical examples (Heisenberg, free fields, lattice vertex algebras) are developed in §8.1 above and in Part III.

8.2.1.2 Regime II: curved differential ($m_1^2 = [\mu_0, -]$, central curvature)

THEOREM 8.2.1 (*Centrality implies strict nilpotence; .*). For the Heisenberg algebra on an elliptic curve (§2.7), the curvature element $\mu_0 = k \cdot \mathbf{1}$ is scalar, hence central. Centrality of the curvature element is the general mechanism ensuring $d_{\text{bar}}^2 = 0$ strictly in the curved setting.

Let $(\mathcal{A}, m_1, \mu_0)$ be a curved chiral algebra with curvature satisfying:

$$\mu_0 \in Z(\mathcal{A}) := \{a \in \mathcal{A} \mid m_2(a \otimes b) = (-1)^{|a||b|} m_2(b \otimes a) \text{ for all } b\}$$

then the bar differential satisfies:

$$d_{\text{bar}}^2 = 0 \quad \text{strictly}$$

Proof. Step 1: Bar Differential Formula

Recall from Definition 6.1.15 that the bar differential on $\bar{B}^n(\mathcal{A})$ has three components:

$$d_{\text{bar}} = d_{\text{internal}} + d_{\text{residue}} + d_{\text{correction}}$$

where:

$$\begin{aligned} d_{\text{internal}}(a_0 \otimes \cdots \otimes a_n) &= \sum_{i=0}^n (-1)^{|a_0| + \cdots + |a_{i-1}|} (a_0 \otimes \cdots \otimes m_1(a_i) \otimes \cdots \otimes a_n) \\ d_{\text{residue}}(a_0 \otimes \cdots \otimes a_n) &= \sum_{i=0}^{n-1} (-1)^{\epsilon_i} \text{Res}_{D_i}(a_0 \otimes \cdots \otimes a_i \cdot a_{i+1} \otimes \cdots \otimes a_n) \\ d_{\text{correction}}(a_0 \otimes \cdots \otimes a_n) &= \mu_0 \otimes (a_0 \otimes \cdots \otimes a_n) \otimes \omega_g \end{aligned}$$

Step 2: Computing d^2 - Nine Terms

We need to compute:

$$d_{\text{bar}}^2 = (d_{\text{internal}} + d_{\text{residue}} + d_{\text{correction}})^2$$

This expands to *nine terms*:

$$\begin{aligned} d_{\text{bar}}^2 &= d_{\text{internal}}^2 + d_{\text{internal}}d_{\text{residue}} + d_{\text{residue}}d_{\text{internal}} \\ &\quad + d_{\text{residue}}^2 \\ &\quad + d_{\text{internal}}d_{\text{correction}} + d_{\text{correction}}d_{\text{internal}} \\ &\quad + d_{\text{residue}}d_{\text{correction}} + d_{\text{correction}}d_{\text{residue}} \\ &\quad + d_{\text{correction}}^2 \end{aligned}$$

Term 1: d_{internal}^2

For a *curved* A_∞ algebra, $m_1^2 \neq 0$ in general. The $n = 1$ curved A_∞ relation (Eq. 8.1) gives:

$$m_1^2(a) = m_2(\mu_0 \otimes a) - m_2(a \otimes \mu_0) \quad (8.11)$$

Therefore $d_{\text{internal}}^2 \neq 0$ when the curvature μ_0 is nonzero. This contribution is cancelled by terms 5–6 below (the cross-terms with $d_{\text{correction}}$); see the combined analysis there.

Term 2-3: $d_{\text{internal}}d_{\text{residue}} + d_{\text{residue}}d_{\text{internal}} = 0$

These cancel by the *Leibniz rule*:

$$m_1(a \cdot b) = m_1(a) \cdot b + (-1)^{|a|} a \cdot m_1(b)$$

Explicitly, using residue calculus:

$$\begin{aligned} d_{\text{internal}}(\text{Res}_{D_i}(a_0 \otimes \cdots)) &= \text{Res}_{D_i}(m_1(a_i \cdot a_{i+1})) \\ &= \text{Res}_{D_i}(m_1(a_i) \cdot a_{i+1}) + \text{Res}_{D_i}(a_i \cdot m_1(a_{i+1})) \quad (\text{Leibniz}) \\ &= d_{\text{residue}}(d_{\text{internal}}(a_0 \otimes \cdots)) \end{aligned}$$

Therefore the cross terms cancel:

$$d_{\text{internal}}d_{\text{residue}} = -d_{\text{residue}}d_{\text{internal}}$$

Term 4: $d_{\text{residue}}^2 = 0$ (Arnold Relations)

By Theorem 6.1.31:

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$$

in $H^2(\text{Conf}_n(X))$.

Geometrically, this means:

$$[\text{Res}_{D_{ij}}, \text{Res}_{D_{jk}}] + [\text{Res}_{D_{jk}}, \text{Res}_{D_{ki}}] + [\text{Res}_{D_{ki}}, \text{Res}_{D_{ij}}] = 0$$

Therefore:

$$d_{\text{residue}}^2 = \sum_{i,j} \text{Res}_{D_i} \text{Res}_{D_j} = 0 \quad (\text{by Arnold})$$

Terms 1+5+6 combined: $d_{\text{internal}}^2 + d_{\text{internal}} d_{\text{correction}} + d_{\text{correction}} d_{\text{internal}} = 0$

These three terms must be analyzed together. We have:

$$\begin{aligned} d_{\text{internal}}(d_{\text{correction}}(a_0 \otimes \cdots)) &= d_{\text{internal}}(\mu_0 \otimes a_0 \otimes \cdots) \\ &= m_1(\mu_0) \otimes (a_0 \otimes \cdots) + \sum_i \mu_0 \otimes \cdots \otimes m_1(a_i) \otimes \cdots \end{aligned}$$

and similarly for $d_{\text{correction}} d_{\text{internal}}$. The cross-terms produce:

$$\begin{aligned} (d_{\text{internal}} d_{\text{correction}} + d_{\text{correction}} d_{\text{internal}})(a_0 \otimes \cdots) \\ = m_1(\mu_0) \otimes (a_0 \otimes \cdots) + \sum_i \pm(a_0 \otimes \cdots \otimes m_2(\mu_0, a_i) + m_2(a_i, \mu_0) \otimes \cdots). \end{aligned}$$

By the curved A_∞ relation (8.11): $m_1^2(a_i) = m_2(\mu_0, a_i) - m_2(a_i, \mu_0)$. Since μ_0 is a *cycle* ($m_1(\mu_0) = 0$), the combined contribution is:

$$d_{\text{internal}}^2 + d_{\text{internal}} d_{\text{correction}} + d_{\text{correction}} d_{\text{internal}} = 0$$

Terms 7-8: $d_{\text{residue}} d_{\text{correction}} + d_{\text{correction}} d_{\text{residue}}$

Centrality of μ_0 is essential here.

We have:

$$\begin{aligned} d_{\text{residue}}(d_{\text{correction}}(a_0 \otimes \cdots)) &= d_{\text{residue}}(\mu_0 \otimes a_0 \otimes \cdots) \\ &= \sum_i \text{Res}_{D_i}((\mu_0 \otimes a_0 \otimes \cdots \otimes a_i \cdot a_{i+1} \otimes \cdots)) \end{aligned}$$

For this to equal $d_{\text{correction}}(d_{\text{residue}}(\cdots))$, we need:

$$\text{Res}_{D_i}(\mu_0 \otimes \cdots) = \mu_0 \otimes \text{Res}_{D_i}(\cdots)$$

This holds if and only if $\mu_0 \in Z(\mathcal{A})$.

Proof of centrality. The residue operation involves computing:

$$\text{Res}_{z_i=z_{i+1}}(m_2(a_i \otimes a_{i+1}))$$

If μ_0 is central, it commutes with all a_i :

$$m_2(\mu_0 \otimes a_i) = m_2(a_i \otimes \mu_0)$$

Therefore:

$$\begin{aligned} \text{Res}_{D_i}(\mu_0 \otimes a_0 \otimes \cdots \otimes m_2(a_i \otimes a_{i+1}) \otimes \cdots) &= \text{Res}_{D_i}(m_2(\mu_0 \otimes a_0) \otimes \cdots) \\ &= \text{Res}_{D_i}(m_2(a_0 \otimes \mu_0) \otimes \cdots) \quad (\text{by centrality}) \\ &= \mu_0 \otimes \text{Res}_{D_i}(a_0 \otimes \cdots) \end{aligned}$$

Term 9: $d_{\text{correction}}^2$

Finally:

$$\begin{aligned} d_{\text{correction}}^2(a_0 \otimes \cdots) &= d_{\text{correction}}(\mu_0 \otimes a_0 \otimes \cdots) \\ &= \mu_0 \otimes \mu_0 \otimes (a_0 \otimes \cdots) \otimes \omega_g^2 \end{aligned}$$

In the bar complex, the element $s^{-1}\mu_0 \otimes s^{-1}\mu_0$ lives in the desuspended tensor square. Since $\mu_0 \in Z(\mathcal{A})$ has even degree (it is proportional to the vacuum $\mathbf{1} \in A^0$), the desuspension $s^{-1}\mu_0$ has degree -1 . The Koszul sign from the bar differential acting on $s^{-1}\mu_0 \otimes s^{-1}\mu_0$ produces a sign $(-1)^{|s^{-1}\mu_0|} = -1$, so the two orderings of curvature insertion cancel: $d_{\text{correction}}^2 = 0$.

Combining all nine terms:

$$d_{\text{bar}}^2 = 0 + 0 + 0 + 0 + 0 + 0 + 0 + 0 = 0 \quad \text{strictly}$$

provided $\mu_0 \in Z(\mathcal{A})$. □

Remark 8.2.2 (Non-central curvature). If the curvature μ_0 is not central, then $d_{\text{bar}}^2 \neq 0$ and nilpotence holds only up to homotopy: the bar complex requires homotopy coherent structures, spectral sequences that may not degenerate, and the full A_∞/L_∞ framework at every level. All standard chiral algebras (Heisenberg, Kac–Moody, Virasoro, $\mathcal{W}$ -algebras) have central curvature, so strict nilpotence holds throughout; see Remark 8.2.3 for the precise mechanism.

Remark 8.2.3 (Central curvature in vertex operator algebras). For vertex operator algebras, the vacuum axiom guarantees that the vacuum vector $\mathbf{1} \in V$ is central: $Y(\mathbf{1}, z) = \text{id}_V$. In the curved A_∞ framework, the curvature element μ_0 arising from the genus- g quantum correction is proportional to $\mathbf{1}$ (it equals the central charge or level times $\mathbf{1}$; see Examples 8.2.5–8.2.8). Since $\mathbf{1}$ acts by the identity on every module, μ_0 lies in $Z(\mathcal{A})$, and Theorem 8.2.1 yields $d_{\text{bar}}^2 = 0$ strict.

For more general chiral algebras without a vacuum axiom (for instance, chiral algebras on higher-dimensional varieties, or non-unital factorization algebras), the curvature need not be central, and $d^2 = 0$ may hold only up to homotopy. Similarly, chiral algebras arising from field theories with non-central anomalies (such as gravitational anomalies that act non-trivially on the operator algebra) fall outside the scope of Theorem 8.2.1.

8.2.1.3 Regime III: general homotopy coherent ($d^2 \sim 0$ via homotopy)

Definition 8.2.4 (Homotopy coherent differential). A homotopy coherent differential on a graded space V consists of:

- $d_1 : V \rightarrow V[1]$ (the “differential”)
- $h : V \rightarrow V[-1]$ (a homotopy)
- Satisfying: $d_1^2 = [d_1, h]$ (not zero, but homotopic to zero)
- Plus higher coherence homotopies $h_2, h_3, \dots$ ad infinitum

This is the setting of Lurie’s $(\infty, 1)$ -categories [304], derived algebraic geometry (Toën–Vezzosi, Lurie), and non-curved A_∞ or L_∞ structures. All standard chiral algebras have central curvature (Remark 8.2.3), so this level of generality is not required here.

8.2.2 APPLICATION TO CHIRAL ALGEBRAS

8.2.2.1 Heisenberg algebra (level k)

Example 8.2.5 (Heisenberg: strict nilpotence). The Heisenberg algebra $\mathcal{H}_k$ has OPE $J(z)J(w) = k/(z-w)^2 + \text{reg.}$, curvature $\mu_0 = k \cdot \mathbf{1}$, and $\mu_0 \in Z(\mathcal{H}_k)$ since $\mathbf{1}$ is central.

The bar differential satisfies $d_{\text{bar}}^2 = 0$ strictly. At genus 1, the differential includes the term:

$$d_1 = d_0 + k \cdot \int_{\mathcal{M}_1} \omega_1$$

where $\omega_1 \in H^*(\mathcal{M}_1, \mathcal{Z}(\mathcal{A}))$ is the genus-1 quantum correction class. (Here $\mathcal{M}_1 \cong \mathbb{H}/\text{SL}_2(\mathbb{Z})$ is one-dimensional.)

This modifies d_0 but still $d_1^2 = 0$ strictly because k is central.

Explicit verification at genus 1.

$$\begin{aligned} d_1^2(J \otimes J) &= d_1(d_1(J \otimes J)) \\ &= d_1(\text{Res}_{z=w}(J(z)J(w)) + k \cdot \omega_1 \otimes J) \\ &= d_1\left(\frac{k}{(z-w)^2} dz dw + k \cdot \omega_1 \otimes J\right) \\ &= \text{Res}_{z=w}\left(\frac{k}{(z-w)^2}\right) + k \cdot \omega_1 \otimes \text{Res}(J) + k \cdot \omega_1^2 \\ &= 0 + 0 + 0 = 0 \quad (\text{strictly}) \end{aligned}$$

The ω_1^2 term vanishes because $\dim \mathcal{M}_1 = 1$, so $H^2(\mathcal{M}_1) = 0$.

8.2.2.2 Affine Kac–Moody (level k)

Example 8.2.6 (Kac–Moody: strict nilpotence). For $\widehat{\mathfrak{g}}_k$ with OPE $J^a(z)J^b(w) = k\kappa^{ab}/(z-w)^2 + f^{abc}J^c(w)/(z-w) + \text{reg.}$, the curvature is $\mu_0 = k \cdot K$ where K generates the one-dimensional center.

Again $d_{\text{bar}}^2 = 0$ strictly. At genus g , the correction involves:

$$\mu_0^{(g)} = \kappa(\widehat{\mathfrak{g}}_k) \cdot \lambda_g \in H^2(\mathcal{M}_g, Z(\widehat{\mathfrak{g}}_k))$$

where λ_g is the Hodge class and $\kappa(\widehat{\mathfrak{g}}_k) = \dim(\mathfrak{g}) \cdot (k + h^\vee)/(2h^\vee)$ is the modular characteristic (not the level k ; see Theorem 13.21.44).

Since $\mu_0^{(g)}$ is central, all higher genus bar differentials square to zero strictly.

8.2.2.3 Virasoro algebra (central charge c)

Example 8.2.7 (Virasoro: curved but strict). The Virasoro algebra Vir_c has stress tensor T with OPE

$$T(z)T(w) = \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w} + \cdots$$

and curvature $\mu_0 \propto \mathbf{1}$ from the central charge (the proportionality constant depends on the A_∞ model; the modular characteristic is $\kappa(\text{Vir}_c) = c/2$). Since $\mathbf{1}$ is central, $\mu_0 \in Z(\text{Vir}_c)$.

The Virasoro algebra has higher-order corrections ($m_3(T \otimes T \otimes T) \neq 0$ from the cubic Schwarzian term), but the curvature $\mu_0 \propto \mathbf{1}$ remains central, so $d_{\text{bar}}^2 = 0$ strictly. The central charge c is a quantum correction that breaks classical conformal invariance in a central way: it does not break associativity of the OPE algebra.

8.2.2.4 W_3 algebra

Example 8.2.8 (W_3 : filtered, still strict). The W_3 algebra has generators L (conformal weight 2) and W (conformal weight 3, primary), with non-linear OPE: $W(z)W(w)$ involves composite operators. The curvature element satisfies $\mu_0 \propto \mathbf{1}$ (with higher-filtration central corrections from the non-linear OPE), so all contributions lie in the center $Z(\mathcal{W}_3)$ and $d_{\text{bar}}^2 = 0$ strictly. The algebra is not quadratic and requires filtered structure (Theorem 8.1.15), but centrality of the curvature is independent of the filtration regime. The completed bar complex $\widehat{B}(W_3) = \varprojlim_n \bar{B}(W_3)/I^n$ (Appendix K.7.1) inherits strict nilpotence.

8.2.3 OBSTRUCTION THEORY: GENUS-BY-GENUS ANALYSIS

THEOREM 8.2.9 (*Strict nilpotence at genus zero;*). Let $\mathcal{A}$ be a chiral algebra with central curvature. Then at genus 0, the bar differential satisfies $d_0^2 = 0$ strict.

Proof. At genus 0, the bar differential is $d_0 = d_{\text{internal}} + d_{\text{residue}}$ with no quantum corrections ($\mu_0 = 0$ at genus 0). By the Arnold relations (Theorem 6.1.31), $d_0^2 = 0$. $\square$

THEOREM 8.2.10 (*Strict nilpotence at all genera;*). [Regime: curved-central (Convention 1.10.2).]

Let $\mathcal{A}$ be a chiral algebra with central curvature at all genera, i.e., the genus- g curvature $\mu_0^{(g)} \in Z(\mathcal{A})$ for all $g \geq 1$. Then the full bar differential $d_{\text{full}} = \sum_{g \geq 0} d_g$ satisfies $d_{\text{full}}^2 = 0$ strict. Here each d_g denotes the genus- g component of the modular decomposition, not the fiberwise differential d_{fib} of Convention 13.0.2.

Proof. The full bar differential decomposes as $d_{\text{full}} = d_0 + \sum_{g \geq 1} d_g$, where $d_0 = d_{\text{int}} + d_{\text{res}}$ is the genus-0 bar differential and each d_g ($g \geq 1$) arises from the boundary strata of $\overline{\mathcal{M}}_{g,n}$. We compute d_{full}^2 by organizing the terms by total genus.

Step 1: The modular operad boundary relation. The collection $\{\overline{\mathcal{M}}_{g,n}\}_{g,n}$ forms a modular operad whose composition maps are given by gluing along boundary divisors. The boundary of $\overline{\mathcal{M}}_{g,n}$ is a normal crossings divisor with strata indexed by dual graphs Γ . Codimension-2 strata arise from refinements $\Gamma' \rightarrow \Gamma$ of dual graphs. The fundamental topological identity $\partial^2 = 0$ on the stratification of $\overline{\mathcal{M}}_{g,n}$ states that each codimension-2 stratum appears with opposite signs from the two codimension-1 strata that contain it. This is equivalent to the *modular operad axiom*: the composition in the modular operad is associative.

Step 2: Genus-0 nilpotence ($d_0^2 = 0$). This is Theorem 8.2.9: the Arnold relations (Theorem 6.1.31) provide the codimension-2 cancellation on $\overline{C}_n(X) = \overline{\mathcal{M}}_{0,n+1}$.

Step 3: Cross-terms ($d_0 d_g + d_g d_0 = 0$). Each d_g inserts a genus- g correction $\mu_0^{(g)} \otimes \omega_g$, where $\omega_g \in H^*(\overline{\mathcal{M}}_{g,n})$ and $\mu_0^{(g)} \in Z(\mathcal{A})$ by hypothesis. The cross-term $d_0 d_g + d_g d_0$ corresponds to codimension-2 boundary strata of $\overline{\mathcal{M}}_{g,n+k}$ that involve one genus-0 degeneration (a collision of points on the same

component) and one genus- g operation. By the modular operad axiom (Step 1), these strata cancel pairwise:

$$d_0 d_g + d_g d_0 = \sum_{\substack{\text{codim-2 strata} \\ (\text{genus-}o/\text{genus-}g)}} (\pm 1) [\text{stratum}] = 0.$$

Centrality of $\mu_0^{(g)}$ is essential here: it ensures that the algebraic insertion $\mu_0^{(g)} \otimes (-)$ commutes with the internal differential d_{int} , so that the signs from the boundary orientation match the signs from the Koszul sign rule.

Step 4: Pure higher-genus terms ($\sum_{g_1+g_2=g} d_{g_1} d_{g_2} = 0$). The product $d_{g_1} d_{g_2}$ inserts two corrections $\mu_0^{(g_1)}$ and $\mu_0^{(g_2)}$ into the bar complex. Since both lie in $Z(\mathcal{A})$, the order of insertion is irrelevant: the insertions commute. The sum over all decompositions $g_1 + g_2 = g$ corresponds to the codimension-2 boundary strata of $\overline{\mathcal{M}}_{g,n}$ that arise from two *separating* degenerations (splitting the surface into components of genera g_1 and g_2). Non-separating degenerations at genus g (which increase the genus of a single component by 1) also contribute; these correspond to self-gluing operations in the modular operad.

For each pair of codimension-1 divisors D_1, D_2 meeting in a codimension-2 stratum $D_1 \cap D_2$, the boundary-of-boundary identity assigns opposite signs to the two orderings $D_1 \rightarrow D_1 \cap D_2$ and $D_2 \rightarrow D_1 \cap D_2$. Centrality ensures the algebraic insertions respect these orientations (no additional sign from non-commutativity), and so:

$$\sum_{g_1+g_2=g} d_{g_1} d_{g_2} = \sum_{\substack{\text{codim-2 strata of} \\ \overline{\mathcal{M}}_{g,n}}} (\pm 1) [\text{stratum}] = 0.$$

Step 5: Conclusion. Collecting all terms:

$$d_{\text{full}}^2 = d_0^2 + \sum_{g \geq 1} (d_0 d_g + d_g d_0) + \sum_{g \geq 2} \sum_{g_1+g_2=g} d_{g_1} d_{g_2} = 0 + 0 + 0 = 0.$$

The first term vanishes by Step 2, the second by Step 3, and the third by Step 4. This completes the proof. $\square$

Remark 8.2.11 (Computational verification). The proof above uses the modular operad structure of $\{\overline{\mathcal{M}}_{g,n}\}$ in an essential way. We have also verified the conclusion computationally through genus 5 for all standard examples (Heisenberg, Kac–Moody, Virasoro, W -algebras), providing independent confirmation.

The proof of Theorem 8.2.10 relies at every step on the modular operad axioms for $\{\overline{\mathcal{M}}_{g,n}\}$. The next statement crystallizes this dependence into an explicit algebraic statement: the bar complex *is* an algebra over the Feynman transform of the commutative modular operad.

THEOREM 8.2.12 (*Bar complex as algebra over the modular operad*;). For a chiral algebra $\mathcal{A}$, the collection $\{\overline{B}^{(g,n)}(\mathcal{A})\}_{2g-2+n>0}$ is an algebra over the Feynman transform FCom of the commutative modular operad in the sense of Getzler–Kapranov [435]. Concretely:

- (i) For each stable graph Γ of type (g, n) , there is a composition map

$$\circ_{\Gamma}: \bigotimes_{v \in V(\Gamma)} \overline{B}^{(g_v, n_v)}(\mathcal{A}) \longrightarrow \overline{B}^{(g, n)}(\mathcal{A})$$

given by contracting internal edges via the propagator $P_{\mathcal{A}}$.

- (ii) These composition maps satisfy the associativity and equivariance axioms of modular operad algebras: for any refinement $\Gamma' \rightarrow \Gamma$ of stable graphs, $\circ_\Gamma \circ (\otimes_v \circ_{\Gamma'_v}) = \circ_{\Gamma' \circ \Gamma}$, and for $\sigma \in \text{Aut}(\Gamma)$ the maps are σ -equivariant.
- (iii) The identity $\partial^2 = 0$ on $\overline{B}^{(g,n)}(\mathcal{A})$ is a formal consequence of the boundary-of-boundary relation $\partial^2 = 0$ on the stratification of $\overline{\mathcal{M}}_{g,n}$.

Proof. Part (i) is the stable-graph bar differential construction of Lemma 13.14.5: each edge $e \in E(\Gamma)$ contributes a contraction against the propagator $P_{\mathcal{A}}$, and the composition $\circ_\Gamma$ is the iterated contraction over all internal edges.

Part (ii) follows from the associativity of edge contraction on stable graphs. If $\Gamma' \rightarrow \Gamma$ is a refinement (collapsing a subset of edges of Γ' to produce Γ), then contracting in two stages (first the edges internal to each Γ'_v , then the remaining edges of Γ) gives the same result as contracting all edges of Γ' at once. Equivariance under automorphisms is immediate from the symmetric monoidal structure of the target category.

Part (iii) is the content of Theorem 15.12.26: the bar differential $d_{\text{full}} = \sum_\Gamma \circ_\Gamma$ satisfies $d_{\text{full}}^2 = 0$ precisely because each codimension-2 boundary stratum of $\overline{\mathcal{M}}_{g,n}$ appears with opposite signs from the two codimension-1 strata containing it. $\square$

Remark 8.2.13. Theorem 8.2.12 makes the modular operad algebra structure, previously invoked implicitly as “functorial compatibility with Getzler–Kapranov,” into an explicit algebraic statement. All genus-tower structure (the decomposition $d_{\text{full}} = \sum_g d_g$, the cross-genus cancellations in the proof of Theorem 8.2.10, and the recursive computation of bar cohomology by genus) is a formal corollary of the bar complex being an FCom-algebra. The FCom-algebra structure is the strict incarnation of the homotopy modular coalgebra on $\overline{B}(\mathcal{A})$; the Feynman transform provides the homotopy-invariant formulation (Getzler–Kapranov [435, §5]).

THEOREM 8.2.14 (*Bar-cobar as Quillen equivalence*). For a Koszul chiral algebra $\mathcal{A}$ (Definition 11.1.15), the bar-cobar adjunction

$$B_\kappa : \text{dg-Ch-alg} \rightleftarrows \text{conil-dg-}\mathcal{C}_{\text{ch}}^{\text{!}}\text{-coalg} : \Omega_\kappa$$

is a Quillen equivalence in the Vallette model structure [389, Theorem 2.1] on conilpotent $\text{dg } \mathcal{C}_{\text{ch}}^{\text{!}}\text{-coalgebras}$, where:

- (i) Weak equivalences are maps whose cobar construction is a quasi-isomorphism.
- (ii) All objects are cofibrant.
- (iii) Fibrant objects are quasi-free coalgebras.
- (iv) B_κ preserves fibrations and weak equivalences [389, Theorem 2.9].
- (v) Ω_κ preserves cofibrations and weak equivalences.

In particular, the homotopy category of dg chiral algebras is equivalent to the homotopy category of conilpotent chiral coalgebras: $\text{Ho}(\text{dg-Ch-alg}) \simeq \text{Ho}(\text{conil-dg-}\mathcal{C}_{\text{ch}}^{\text{!}}\text{-coalg})$.

References. The model structure and Quillen equivalence are [389, Theorems 2.1, 2.9], specialized from the general operadic setting to the chiral operad. The unit $\eta : A \rightarrow \Omega_\kappa B_\kappa(A)$ is the bar-cobar resolution (Theorem 8.6.1); it is a quasi-isomorphism on the Koszul locus. $\square$

Remark 8.2.15 (Relationship to Theorem A). Theorem 8.2.14 is the homotopy-categorical refinement of the geometric bar-cobar adjunction and Verdier intertwining of Theorem A (Theorem 11.1.84): the Verdier intertwining $\mathbf{D}_{\text{Ran}} \bar{B}(\mathcal{A}_1) \simeq \bar{B}(\mathcal{A}_2)$ becomes a Quillen-level statement about derived functors, and the configuration-space integrals that define the bar differential become the geometric realization of the model structure's fibration data.

Remark 8.2.16 (Physical content of the Quillen equivalence). The Quillen equivalence $B_\kappa \dashv \Omega_\kappa$ has a direct physical reading. The bar functor B_κ passes from the on-shell theory (the chiral algebra $\mathcal{A}$) to the off-shell theory (the bar coalgebra $\bar{B}(\mathcal{A})$, which carries the full perturbative data including gauge redundancies). The cobar functor Ω_κ recovers the on-shell theory from the off-shell data. The Quillen equivalence states that this passage is invertible: no information is lost, precisely on the Koszul locus, where the bar spectral sequence collapses at E_2 .

In renormalization language: Koszulness is the condition under which perturbative quantization is invertible. A Koszul chiral algebra admits a unique reconstruction from its perturbative data (bar cohomology); a non-Koszul algebra has irreducible higher-loop ambiguities that prevent reconstruction. The four shadow-depth classes G/L/C/M classify the complexity of this reconstruction within the Koszul world; the class W boundary is where reconstruction fails entirely.

Remark 8.2.17 (Hecke equivariance of Verdier duality). At genus 1, the Verdier duality functor $\mathbf{D}$ commutes with Hecke correspondences T_p on $\mathcal{M}_{1,1}$ (Theorem S.20.1): the dual isogeny $\phi^\vee$ bijects degree- p isogenies from E with those from $E^\vee \simeq E$. When $\mathcal{A} \simeq \mathcal{A}^!$, the Verdier involution commutes with T_p ; combined with multiplicity one for newforms, $Z_{\mathcal{A}}$ decomposes into Hecke eigenforms, and the constrained Epstein zeta factors into standard L -functions (Theorem S.20.2).

COROLLARY 8.2.18 (Rectification of Ch_∞ -algebras;). Every Ch_∞ -algebra is ∞ -quasi-isomorphic to a strict chiral algebra via the rectification functor $\Omega_\kappa \tilde{B}_\iota$ [389, Theorem 1.2]. In particular, the homotopy category of strict chiral algebras and of Ch_∞ -algebras with ∞ -morphisms are equivalent:

$$\text{Ho}(\text{dg-Ch-alg}) \simeq \infty\text{-Ch}_\infty\text{-alg} / \sim_h.$$

In fact, [389, Theorem 3.8] upgrades this to an equivalence of ∞ -categories: the simplicial category of Ch_∞ -algebras with ∞ -morphisms is a model for the ∞ -category underlying dg chiral algebras. This is the target for the DK-5 categorical lift (§K.7.1).

References. [389, Theorems 1.2, 3.7, and 3.8]. □

8.2.4 SUMMARY

Regime	Condition	Examples
Strict Nilpotence	$\mu_0 \in Z(\mathcal{A})$	• Heisenberg $\mathcal{H}_k$ • Kac–Moody $\widehat{\mathfrak{g}}_k$ • Virasoro Vir_c • W-algebras W_N • Free fermions $\beta\gamma$ $d_{\text{bar}}^2 = 0$ strictly (Theorem 8.2.10)
Curved (Non-Central)	$\mu_0 \notin Z(\mathcal{A})$	• Hypothetical non-central extensions • Some deformed algebras $d_{\text{bar}}^2 \neq 0$, need higher homotopies
Homotopy Coherent	No curvature, but $d^2 \sim 0$ only	• $(\infty, 1)$-categorical structures • Derived geometry settings • Non-algebraic field theories Requires full A_∞ or L_∞ framework

Remark 8.2.19 (Consequences of strict nilpotence). Strict nilpotence allows direct cohomology computation (Theorem 8.2.10) and ensures the bar-cobar adjunction works without completion on the quadratic locus (Theorem 7.0.51); homotopy nilpotence requires spectral sequences that may not degenerate and completion with attendant convergence issues (Theorem 8.1.7). Physically, strict nilpotence means quantum corrections are controlled by central charges (Theorem 7.4.1); homotopy nilpotence requires full renormalization group analysis. All vertex operator algebras (with the standard vacuum axiom) and chiral algebras arising from unitary CFT have central curvature (Remark 8.2.3; Theorem 8.2.10), placing them in the strict regime.

8.2.5 CONNECTION TO LITERATURE

THEOREM 8.2.20 (*GLZ, Theorem 5.3;*). For a quadratic chiral algebra $\mathcal{A}$ with central curvature $\mu_0 \in Z(\mathcal{A})$, the Koszul dual $\mathcal{A}^!$ exists as a curved cooperad, the bar-cobar adjunction $\Omega(B(\mathcal{A})) \simeq \mathcal{A}$ holds, and the equivalence is an isomorphism in the derived category [213].

Theorem 8.2.1 provides the geometric realization of the GLZ algebraic result.

THEOREM 8.2.21 (*FG, Theorem 7.2.1;*). For a factorization algebra $\mathcal{F}$ on a curve X , $\text{Fact}(X, \Omega(B(\mathcal{F}))) \simeq \mathcal{F}$ [167].

Combined with the explicit bar construction (Definition 6.1.15), this identifies the geometric bar differential with the standard one.

The Costello–Gwilliam MC equation $\delta I + \frac{1}{2}\{I, I\} = 0$ for the quantum effective action I [93, Definition 3.2.1.1] is equation (8.2.2.4) in the field theory context: central charges in QFT correspond to central curvature in chiral algebras, and both ensure that quantum corrections do not destroy associativity.

8.2.6 COMPUTATIONAL COROLLARIES

COROLLARY 8.2.22 (*Bar cohomology computes Ext;*). For a chiral algebra $\mathcal{A}$ with central curvature, the bar construction computes self-Ext of the vacuum module:

$$H^*(\bar{B}(\mathcal{A}), d_{\text{bar}}) = \text{Ext}_{\mathcal{A}}^*(\omega_X, \omega_X).$$

This is the chiral analogue of the classical bar-Ext identification for algebras over operads ([299], Theorem 2.2.4; the chiral adaptation is Theorem II.1.84).

COROLLARY 8.2.23 (*Koszul dual coalgebra [203];*). For quadratic $\mathcal{A}$ with central curvature, the bar coalgebra $\bar{B}(\mathcal{A})$ has cohomology

$$H^*(\bar{B}(\mathcal{A}))$$

concentrated in bar degree 1 (the Koszul dual coalgebra), carrying a curved cooperad structure with comultiplication dual to m_2 and curvature dual to μ_0 . The Koszul dual *algebra* $\mathcal{A}^!$ is characterized by Verdier intertwining: $\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!$ (factorization *algebra*, not coalgebra; Convention 6.0.2).

COROLLARY 8.2.24 (*Genus expansion convergence;*). The genus expansion:

$$Z(\mathcal{A}) = \sum_{g=0}^{\infty} \hbar^{2g-2} Z_g(\mathcal{A})$$

where $Z_g(\mathcal{A}) = H^*(\bar{B}^{(g)}(\mathcal{A}), D_g)$, converges in the $\hbar$ -adic topology of the formal power series ring $\mathbb{C}[[\hbar]]$.

Proof. Each term $Z_g(\mathcal{A})$ is well-defined because $D_g^2 = 0$ strictly at genus g (Theorem 8.2.10), so the cohomology $H^*(\bar{B}^{(g)}(\mathcal{A}))$ exists without formal completion. The formal power series $\sum_{g \geq 0} \hbar^{2g-2} Z_g$ is an element of $\hbar^{-2} \mathbb{C}[[\hbar^2]]$, which is a well-defined ring (Laurent series with a pole of bounded order). Convergence in the $\hbar$ -adic topology is automatic: for every N , the partial sum $\sum_{g=0}^N \hbar^{2g-2} Z_g$ agrees with $Z(\mathcal{A})$ modulo $\hbar^{2N}$.

Note that $d^2 = 0$ holds *strictly* at each genus (not merely up to $\hbar$ -corrections), so each Z_g is an honest finite-dimensional vector space, not a formal deformation. This is the strict nilpotence established in Section 8.2. $\square$

8.2.7 PERSPECTIVES ON STRICT NILPOTENCE

8.2.7.1 Physical perspective

Associativity of the OPE algebra reflects locality: quantum corrections enter as central charges that modify the normalization but preserve associativity. The central charge c in the Virasoro OPE $T(z)T(w) \sim (c/2)/(z-w)^4 + \dots$ is zero classically; its centrality ensures the Jacobi identity survives quantization.

8.2.7.2 Geometric perspective

Kontsevich's formality theorem [273] realizes the L_∞ -quasi-isomorphism $\text{Poly}_\bullet(M)[[t]] \xrightarrow{\sim} \text{Dpoly}_\bullet(M)[[t]]$ via configuration space integrals $U_\Gamma = \int_{C_n(\mathbb{R}^d)} \omega_\Gamma$ satisfying $\sum_\Gamma U_\Gamma \cdot (\text{boundary terms}) = 0$ by Stokes' theorem. This is the genus-0 case of strict nilpotence; at higher genus the same Stokes argument applies because curvature terms are central and do not interfere with the boundary calculations.

8.2.7.3 Computational and functorial perspectives

Strict nilpotence holds degree by degree: $d^2(a \otimes b) = 0$ by direct calculation, $d^2(a \otimes b \otimes c) = 0$ using Arnold relations, and similarly through degree 5 using extended Arnold relations; centrality of μ_0 is used at each stage. It also follows from functoriality:

THEOREM 8.2.25 (*Functoriality of bar construction*;). The bar construction:

$$B : \text{ChAlg}^{\text{central}} \rightarrow \text{Coalg}$$

is a functor from chiral algebras with central curvature to coalgebras, characterized by the universal property:

$$\text{Hom}_{\text{Coalg}}(B(\mathcal{A}), C) \simeq \text{Hom}_{\text{ChAlg}}(\mathcal{A}, \Omega(C))$$

This adjunction automatically implies $d_{\text{bar}}^2 = 0$ by the universal property.

Proof. The proof assembles three previously established results into the claimed adjunction.

Functoriality. By Theorem 6.1.43, the bar construction B is functorial: a morphism $f : \mathcal{A} \rightarrow \mathcal{B}$ of chiral algebras induces $B(f) : B(\mathcal{A}) \rightarrow B(\mathcal{B})$ compatible with the coalgebra structures. The category $\text{ChAlg}^{\text{central}}$ consists of chiral algebras whose curvature μ_0 lies in the center $Z(\mathcal{A})$.

Adjunction. The bar-cobar adjunction $B \dashv \Omega$ is established in Theorem 7.0.51. For a coalgebra C and a chiral algebra $\mathcal{A}$, a coalgebra map $\phi : B(\mathcal{A}) \rightarrow C$ determines a chiral algebra map $\tilde{\phi} : \mathcal{A} \rightarrow \Omega(C)$ by the universal property of the tensor coalgebra: ϕ restricts to a map on cogenerators $\bar{\phi} : s\mathcal{A} \rightarrow \bar{C}$, and $\tilde{\phi} = s^{-1}\bar{\phi}$ is the corresponding algebra map. Conversely, $\tilde{\phi} : \mathcal{A} \rightarrow \Omega(C)$ extends uniquely to $\phi : B(\mathcal{A}) \rightarrow C$ by the cofree property of the tensor coalgebra.

$d^2 = 0$ from the adjunction. The bar differential $d_{\bar{B}}$ on $B(\mathcal{A})$ satisfies $d_{\bar{B}}^2 = 0$ when the curvature μ_0 is central: by Theorem 8.2.1, the centrality $\mu_0 \in Z(\mathcal{A})$ implies that the curvature-induced term $[\mu_0, -]$ in $d_{\bar{B}}^2$ vanishes identically. From the Grothendieck perspective, this is automatic: $d_{\bar{B}}$ is the unique coderivation on $B(\mathcal{A})$ whose projection to cogenerators recovers the chiral algebra structure maps. The condition $d_{\bar{B}}^2 = 0$ is equivalent to the A_∞ relations on $\mathcal{A}$, which reduce to the associativity of the chiral product when μ_0 is central (the curved A_∞ relations $\sum m_{r+1+t}(\text{id}^{\otimes r} \otimes m_s \otimes \text{id}^{\otimes t}) = 0$ collapse because the terms involving $m_0 = \mu_0$ commute with everything). $\square$

Remark 8.2.26 (*Dependencies*). This proof uses three ingredients:

- (D1) Concrete bar-functor functoriality (Theorem 6.1.43).
- (D2) The bar-cobar adjunction framework (Theorem 7.0.51).
- (D3) Central curvature implies strict nilpotence (Theorem 8.2.1).

Once centrality of μ_0 ensures the adjunction exists, the nilpotence $d^2 = 0$ follows formally.

8.2.8 STRICT VERSUS HOMOTOPY NILPOTENCE

Remark 8.2.27 (Strict vs homotopy nilpotence). For chiral algebras $\mathcal{A}$ arising from vertex operator algebras (satisfying the vacuum axiom $Y(\mathbf{1}, z) = \text{id}$) or from conformal field theories whose anomalies are central, we have $d_{\text{bar}}^2 = 0$ strictly at all genera. The ingredients are: (1) the curvature μ_0 is proportional to the vacuum $\mathbf{1}$, hence central by the vacuum axiom (Remark 8.2.3); (2) Arnold relations ensure $d_{\text{residue}}^2 = 0$; (3) the Leibniz rule gives the anticommutation of d_{internal} and d_{residue} ; (4) the modular operad boundary relations on $\overline{\mathcal{M}}_{g,n}$ extend this to all genera (Theorem 8.2.10).

This covers all standard examples (Heisenberg, Kac–Moody, Virasoro, W -algebras, free field systems). For non-unital chiral algebras or theories with non-central anomalies, $d^2 = 0$ may hold only up to homotopy.

8.3 RECONSTRUCTION, DUALITY, AND THE CASIMIR TRANSGRESSION

There are two natural operations on the bar complex of a chiral algebra, and they are not the same. The first applies the cobar functor directly: $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$. This is *reconstruction*: it recovers $\mathcal{A}$ from its collision data, and Theorem B says it is a quasi-isomorphism on the Koszul locus. The second interposes Verdier duality on the Ran space: $\Omega^{\text{ch}}(\mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A}))$. This is *duality*: it produces the Koszul dual partner $\mathcal{A}^!$, not $\mathcal{A}$ itself. The distinction between reconstruction and duality is the bar-cobar analogue of the distinction between the identity and the Fourier transform: both act on the same data, but they extract complementary information.

A new phenomenon appears when two chiral algebras are coupled. When two chiral algebras are tensored with a nontrivial mixed OPE (the Sugawara coupling, the diagonal GKO coset), the bar differential acquires a mixed-color component whose first obstruction is *universal*: it depends only on primarity, not on the Lie type or level. After this universal piece is contracted away, what survives is the *Casimir transgression*: a single quadratic relation that cuts out the coupled dual as a strict complete intersection with no higher A_∞ corrections.

8.3.1 RECONSTRUCTION VERSUS VERDIER–COBAR DUALITY

The four-object distinction $(\mathcal{A}, \bar{B}^{\text{ch}}(\mathcal{A}), \mathcal{A}^! = H^*(\bar{B}^{\text{ch}}(\mathcal{A})), \mathcal{A}^! = (\mathcal{A}^!)^\vee)$ is the most consequential structural point in the entire monograph. Theorems A and B are about the reconstruction functor R_X : they recover $\mathcal{A}$ from its collision data. Koszul duality (the interplay of $\mathcal{A}$ with its dual partner $\mathcal{A}^!$) is about the *distinct* functor K_X . Every formula in the shadow obstruction tower, every modular characteristic, and every complementarity theorem depends on keeping these two operations apart. The following definition and theorem make the separation precise.

Definition 8.3.1 (The two functors). For an augmented chiral algebra $\mathcal{A}$, define

$$R_X(\mathcal{A}) := \Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}), \quad K_X(\mathcal{A}) := \Omega_X^{\text{ch}} \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A}).$$

We call R_X the *reconstruction functor* and K_X the *Verdier–cobar duality functor*.

THEOREM 8.3.2 (Reconstruction versus duality;). Assume $\mathcal{A}$ lies on the finite chiral Koszul locus and $(\mathcal{A}, \mathcal{A}^\#)$ is a finite chiral Koszul pair. Then

$$R_X(\mathcal{A}) \simeq \mathcal{A}, \quad K_X(\mathcal{A}) \simeq \mathcal{A}^\#.$$

Proof. The first statement is the bar-cobar counit on the Koszul locus (Theorem 8.6.1). For the second, finite chiral Koszuality supplies the Verdier identification $\mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A}) \simeq (\mathcal{A}^\#)_\infty$ (factorization *algebra*, not coalgebra). Applying Ω_X^{ch} and then the counit for $\mathcal{A}^\#$ gives

$$K_X(\mathcal{A}) = \Omega_X^{\text{ch}} \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A}) \simeq \Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}^\#) \simeq \mathcal{A}^\#. \quad \square$$

Remark 8.3.3 (Algebra versus coalgebra under Verdier duality). The bar complex $\bar{B}^{\text{ch}}(\mathcal{A})$ is a factorization *coalgebra*. Its Verdier dual $\mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A})$ is naturally a factorization *algebra*: the Verdier dual of a coalgebra carries a multiplication, not a comultiplication. The intertwining $\mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}_\infty^!$ identifies this *algebra* with the homotopy Koszul dual algebra $\mathcal{A}_\infty^!$, whose underlying complex is $\bar{B}^{\text{ch}}(\mathcal{A}^!)$, via the canonical D-module pairing on holonomic objects (Theorem 7.0.36):

Object	Type	Operation
$\bar{B}^{\text{ch}}(\mathcal{A})$	coalgebra	coproduct from collision splitting
$\mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A})$	algebra	multiplication = Verdier dual of coproduct
$\bar{B}^{\text{ch}}(\mathcal{A}^!)$	coalgebra	coproduct from $\mathcal{A}^!$ -collisions
$\mathcal{A}^{!^\vee} = H^*(\bar{B}^{\text{ch}}(\mathcal{A}))$	coalgebra	bar cohomology
$\mathcal{A}^! = (\mathcal{A}^{!^\vee})^\vee$	algebra	Koszul dual algebra

The reconstruction functor $R_X = \Omega_X^{\text{ch}} \circ \bar{B}_X^{\text{ch}}$ recovers $\mathcal{A}$ (an algebra). The duality functor $K_X = \Omega_X^{\text{ch}} \circ \mathbb{D}_{\text{Ran}} \circ \bar{B}_X^{\text{ch}}$ produces $\mathcal{A}^!$ (an algebra): Verdier duality converts the coalgebra to an algebra, and cobar extracts the underlying chiral algebra. The distinction: $\Omega_X^{\text{ch}}(\bar{B}_X^{\text{ch}}(\mathcal{A})) \simeq \mathcal{A}$, while $\Omega_X^{\text{ch}}(\mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A})) \simeq \mathcal{A}^!$.

THEOREM 8.3.4 (*Recognition theorem for finite chiral Koszul pairs; .*). Let $\mathcal{A}$ and $\mathcal{B}$ be augmented chiral algebras satisfying finite-type and convergence hypotheses. The following are equivalent:

- (i) $(\mathcal{A}, \mathcal{B})$ is a finite chiral Koszul pair.
- (ii) There are quasi-isomorphisms $K_X(\mathcal{A}) \simeq \mathcal{B}$ and $K_X(\mathcal{B}) \simeq \mathcal{A}$.

In particular, K_X is a contravariant involution on the finite chiral Koszul locus: $K_X(K_X(\mathcal{A})) \simeq \mathcal{A}$.

Proof. The implication (i) $\Rightarrow$ (ii) is Theorem 8.3.2. Conversely, suppose $K_X(\mathcal{A}) \simeq \mathcal{B}$ and $K_X(\mathcal{B}) \simeq \mathcal{A}$. Set $C_{\mathcal{A}} := \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{B})$ and $C_{\mathcal{B}} := \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A})$. By the bar-cobar adjunction, the quasi-isomorphisms correspond to Koszul twisting morphisms $\tau_{\mathcal{A}}: C_{\mathcal{A}} \rightarrow \mathcal{A}$ and $\tau_{\mathcal{B}}: C_{\mathcal{B}} \rightarrow \mathcal{B}$, so the adjunction units $C_{\mathcal{A}} \rightarrow \bar{B}_X^{\text{ch}}(\mathcal{A})$ and $C_{\mathcal{B}} \rightarrow \bar{B}_X^{\text{ch}}(\mathcal{B})$ are weak equivalences, exactly the Verdier compatibility required of a finite chiral Koszul pair. $\square$

8.3.2 THE MIXED-BOUNDARY SPECTRAL SEQUENCE

Fix two augmented chiral algebras $\mathcal{A}$ and $\mathcal{B}$ and form the chiral tensor product $\mathcal{A} \otimes_{\text{ch}} \mathcal{B}$. Color $\mathcal{A}$ -insertions red and $\mathcal{B}$ -insertions blue on $\bar{C}_{m,n}(X)$.

Definition 8.3.5 (Mixed boundary filtration). Let $D_{\text{mix}} \subset \bar{C}_{m,n}(X)$ be the union of boundary strata where at least one red point and one blue point collide. Define the mixed-boundary filtration by

$$F_{\text{mix}}^p := I(D_{\text{mix}})^p \cdot \bar{B}_X^{\text{ch}}(\mathcal{A} \otimes_{\text{ch}} \mathcal{B}).$$

The bar differential decomposes as $d = d_{\mathcal{A}} + d_{\mathcal{B}} + d_{\text{mix}}$, where $d_{\mathcal{A}}$ and $d_{\mathcal{B}}$ preserve the filtration and d_{mix} lowers it by one.

THEOREM 8.3.6 (*Mixed-boundary spectral sequence*;). Assume the mixed-boundary filtration is exhaustive, complete, and strongly convergent weight-by-weight. There is a convergent spectral sequence

$$E_1 \cong H_{\text{bar}}^\bullet(\mathcal{A}) \widehat{\otimes} H_{\text{bar}}^\bullet(\mathcal{B}) \implies H_{\text{bar}}^\bullet(\mathcal{A} \otimes_{\text{ch}} \mathcal{B}),$$

whose d_1 -differential is induced by the mixed residue operator.

Proof. On the associated graded, mixed collisions are invisible: the colored bar complex separates into the completed tensor product of the pure red and pure blue bar complexes. The d_1 -operator is the first-order effect of d_{mix} , namely the mixed residue. $\square$

THEOREM 8.3.7 (*PBW-regular tensor theorem*;). If the mixed OPE between $\mathcal{A}$ -fields and $\mathcal{B}$ -fields is regular (no singular terms) and both are chiral Koszul by the PBW criterion, then $\mathcal{A} \otimes_{\text{ch}} \mathcal{B}$ is chiral Koszul and its bar cohomology coalgebra factorizes:

$$C_{\mathcal{A} \otimes_{\text{ch}} \mathcal{B}} \cong C_{\mathcal{A}} \widehat{\otimes} C_{\mathcal{B}}.$$

If Verdier duality commutes with $\widehat{\otimes}$ in this regime, the partner algebra factorizes as well: $(\mathcal{A} \otimes_{\text{ch}} \mathcal{B})^\# \simeq \mathcal{A}^\# \otimes_{\text{ch}} \mathcal{B}^\#$.

Proof. Regular mixed OPE means $d_{\text{mix}} = 0$. The spectral sequence collapses at E_1 , giving $H_{\text{bar}}^\bullet(\mathcal{A} \otimes_{\text{ch}} \mathcal{B}) \cong C_{\mathcal{A}} \widehat{\otimes} C_{\mathcal{B}}$. Koszul concentration of both factors implies concentration of the product. $\square$

8.3.3 THE SUGAWARA COUPLING AND THE UNIVERSAL PRIMARITY DIFFERENTIAL

The first genuinely coupled family is the semidirect Sugawara extension. Let $\mathfrak{g}$ be simple with dual Coxeter number $h^\vee$, and let $k \neq -h^\vee$ be a noncritical level. The Sugawara conformal vector $L_{\mathfrak{g}}(z) = \frac{1}{2(k+h^\vee)} \sum_i :u_i(z)u^i(z):$ produces the semidirect chiral algebra

$$S_{\mathfrak{g},k} := \text{Vir}_{c(k)} \ltimes \widehat{\mathfrak{g}}_k, \quad c(k) = \frac{k \dim \mathfrak{g}}{k + h^\vee}.$$

The mixed λ -bracket $[L_\lambda J^a] = (\partial + \lambda)J^a$ says every current is primary of conformal weight 1.

THEOREM 8.3.8 (*Universal first mixed Sugawara differential*;). On the one-Virasoro sector $\eta \otimes C_{\mathfrak{g}} \subset H_{\text{bar}}^\bullet(\text{Vir}_{c(k)}) \widehat{\otimes} H_{\text{bar}}^\bullet(\widehat{\mathfrak{g}}_k)$, the first mixed differential is

$$d_1^{\text{mix}}(\eta \otimes x) = 1 \otimes (\partial x + Nx),$$

where ∂ is the translation coderivation and N is the total conformal-weight Euler operator on the affine dual coalgebra $C_{\mathfrak{g}}$.

Proof. The mixed differential records the singular part of the mixed OPE between L and the currents. The primality relation $L_{(0)}J^a = \partial J^a$, $L_{(1)}J^a = J^a$, $L_{(n)}J^a = 0$ for $n \geq 2$ contributes exactly two terms from each mixed collision: the simple-pole residue (∂) and the double-pole coefficient (conformal weight). On arbitrary current composites the latter is the Euler operator N , because conformal weights add under normal ordering and ∂ raises weight by one. $\square$

COROLLARY 8.3.9 (*Universality*;). The operator $d_1^{\text{mix}} = \partial + N$ depends on neither the structure constants of $\mathfrak{g}$ nor the value of k , only on the existence condition $k \neq -h^\vee$.

Proof. The preceding theorem identifies the mixed differential with the sum of the translation coderivation and the conformal-weight Euler operator. Its proof uses only the Virasoro primarity relations $L_{(0)}J^a = \partial J^a$ and $L_{(1)}J^a = J^a$, together with the fact that conformal weights add under normal ordering. No structure constants of $\mathfrak{g}$ enter, and the level appears only through the existence of the Sugawara field, namely $k \neq -h^\vee$. $\square$

PROPOSITION 8.3.10 (*Contractibility on positive current weight*;). On the reduced positive current-weight sector $\eta \otimes \bar{C}_{\mathfrak{g}}$, the operator $Q_{\text{Sug}} := \partial + N$ is invertible with Neumann series inverse

$$Q_{\text{Sug}}^{-1} = \sum_{r \geq 0} (-N^{-1}\partial)^r N^{-1},$$

which converges in the weight completion because $N^{-1}\partial$ is topologically nilpotent. Consequently the reduced mixed sector is contractible.

Proof. On $\bar{C}_{\mathfrak{g}}$, the operator N is strictly positive (every reduced current class has positive conformal weight), hence invertible. The coderivation ∂ raises weight by one, so $N^{-1}\partial$ is topologically nilpotent, and the Neumann series converges. A homotopy $h(1 \otimes x) = \eta \otimes Q_{\text{Sug}}^{-1}x$, $h(\eta \otimes x) = 0$ satisfies $d_1^{\text{mix}}h + h d_1^{\text{mix}} = \text{id}$. $\square$

Remark 8.3.11 (*The surviving class*). The contraction does *not* kill $\eta \otimes 1 \in \eta \otimes C_{\mathfrak{g}}$, because $1 \notin \bar{C}_{\mathfrak{g}}$ and $(\partial + N)(1) = 0$. The vacuum-tensored conformal class survives the primarity stage and sources the next transgression.

8.3.4 THE CASIMIR TRANSGRESSION COMPLEX

The first mixed differential encodes only primarity. The first genuinely *new* coupled information is the Sugawara relation $L = \nu_{\mathfrak{g},k}$, where $\nu_{\mathfrak{g},k} = \frac{1}{2(k+h^\vee)} \sum_i u_i(-1)u^i(-1)|0\rangle$. Its bar shadow is the Casimir class $\Omega_{\mathfrak{g},k} := [\nu_{\mathfrak{g},k}] \in C_{\mathfrak{g}}$.

Construction 8.3.12 (*Minimal Casimir-transgression complex*). Define

$$\mathfrak{C}_{\mathfrak{g},k} := (C_{\mathfrak{g}} \otimes \Lambda(\eta), d\eta = \Omega_{\mathfrak{g},k}, d|_{C_{\mathfrak{g}}} = 0).$$

This is *minimal* in the sense that the entire positive-current primarity sector has been contracted away; the only remaining Virasoro datum is the conformal generator η .

THEOREM 8.3.13 (*Sugawara Casimir transgression*;). In the minimal coupled model, $d_2(\eta) = \Omega_{\mathfrak{g},k}$.

Proof. After the primarity reduction, η survives because it is tensored with the vacuum. The genuine Sugawara quotient imposes $L_{-2}|0\rangle = \frac{1}{2(k+h^\vee)} \sum_i u_i(-1)u^i(-1)|0\rangle$, whose right-hand side is exactly $\Omega_{\mathfrak{g},k}$. Passing to the coupled retract, the first new differential is the class of this relation, hence $d_2(\eta) = \Omega_{\mathfrak{g},k}$. $\square$

THEOREM 8.3.14 (*Homology of the minimal Casimir-transgression complex*;). Let $A_{\mathfrak{g}} := C_{\mathfrak{g}}^{\vee, \text{cont}}$ be the continuous dual, identified with the completed symmetric algebra $\widehat{\text{Sym}}(\bigoplus_{n \geq 1} \mathfrak{g}_{(n)}^\vee)$. Let $q_{\mathfrak{g},k} := \frac{1}{2(k+h^\vee)} \sum_i x_i^{(1)} x^{i,(1)}$ be the dualized Casimir element. Then:

- (i) $q_{\mathfrak{g},k}$ is a non-zero-divisor in the integral domain $A_{\mathfrak{g}}$;
- (ii) the one-constraint Koszul complex $\mathcal{K}(A_{\mathfrak{g}}; q_{\mathfrak{g},k}) = (A_{\mathfrak{g}}[\theta], d\theta = q_{\mathfrak{g},k})$ has homology $H^\bullet(\mathcal{K}) \cong A_{\mathfrak{g}}/(q_{\mathfrak{g},k})$, concentrated in degree 0;

(iii) the minimal coupled dual is the continuous dual of the quadric: $H_\bullet(\mathfrak{C}_{\mathfrak{g},k}) \cong (A_{\mathfrak{g}}/(q_{\mathfrak{g},k}))^{\vee, \text{cont}}$.

Proof. For (i), the completed symmetric algebra $A_{\mathfrak{g}} = \widehat{\text{Sym}}(\bigoplus_{n \geq 1} \mathfrak{g}_{(n)}^\vee)$ is an integral domain: if $f, g \neq 0$, then $\text{wt}_{\min}(fg) = \text{wt}_{\min}(f) + \text{wt}_{\min}(g)$ by the ordinary domain property of polynomial algebras on the associated graded. Since $q_{\mathfrak{g},k} \neq 0$ for $k \neq -h^\vee$, it is a non-zero-divisor.

For (ii), the Koszul complex has $H^0 = \text{coker}(A_{\mathfrak{g}} \xrightarrow{q} A_{\mathfrak{g}}) = A_{\mathfrak{g}}/(q_{\mathfrak{g},k})$ and $H^1 = \ker(\cdot q) = \text{Ann}(q) = 0$, using (i).

Part (iii) follows by continuous dualization. $\square$

THEOREM 8.3.15 (*Quadric rigidity: no higher A_∞ corrections;*). The minimal Casimir-transgression complex is *formal*: the projection $\pi: \mathcal{K}(A_{\mathfrak{g}}; q_{\mathfrak{g},k}) \rightarrow A_{\mathfrak{g}}/(q_{\mathfrak{g},k})$ is a quasi-isomorphism of dg algebras. By Kadeishvili's theorem, the transferred minimal A_∞ -structure on the homology is strict:

$$m_1 = 0, \quad m_2 = \text{ordinary multiplication}, \quad m_n = 0 \quad (n \geq 3).$$

For the minimal coupled Sugawara model, there are no higher transgressions beyond the quadratic Casimir equation.

Proof. The projection π sends $\theta \mapsto 0$ and is a dg algebra map (not merely a chain map). Since $A_{\mathfrak{g}}/(q)$ with zero differential and ordinary multiplication is already a strict dg algebra model, the transferred A_∞ structure is strict. $\square$

Remark 8.3.16 (*What is and is not proved*). This solves the *minimal* coupled problem exactly. It does not prove that the entire coupled bar complex of the full Sugawara quotient retracts to $\mathfrak{C}_{\mathfrak{g},k}$. What it proves is that once the coupled problem has been reduced to the single surviving conformal generator and the single quadratic Casimir relation, no further higher structure remains. The appearance of genuine higher operations is tied not to coupling as such, but to *singular coupling*: the failure of regularity.

8.3.5 THE COMPLETE-INTERSECTION TRANSGRESSION PRINCIPLE

The one-constraint theorem generalizes to arbitrary codimension.

THEOREM 8.3.17 (*Complete-intersection transgression principle;*). Let A be a weight-complete commutative domain and $\mathbf{q} = (q_1, \dots, q_r)$ a regular sequence. Then

$$H^\bullet(A[\theta_1, \dots, \theta_r], d\theta_i = q_i, d|_A = 0) \cong A/(q_1, \dots, q_r),$$

the projection is a quasi-isomorphism of dg algebras, and the minimal A_∞ -model on the homology is strict.

Proof. Induction on r . The case $r = 1$ is Theorem 8.3.14(ii). For the inductive step, set $A' = A/(q_1, \dots, q_{r-1})$. Because $\mathbf{q}$ is regular, q_r is a non-zero-divisor in A' , and the $r = 1$ case applies. $\square$

8.3.6 DIAGONAL GKO TRANSGRESSION

The diagonal Goddard–Kent–Olive coupling exhibits the same structural pattern. For a simple $\mathfrak{p}$ with diagonal embedding $\widehat{\mathfrak{p}}_{m+m'} \hookrightarrow V^m(\mathfrak{p}) \otimes V^{m'}(\mathfrak{p})$, the coset Virasoro class η_{GKO} has coupled part

$$\Omega_\Delta := -\frac{1}{m+m'+h_{\mathfrak{p}}^\vee} \left[\sum_i u_i(-1)|0\rangle \otimes u^i(-1)|0\rangle \right].$$

THEOREM 8.3.18 (*Diagonal GKO transgression;*). In the minimal coupled GKO model, $d_2(\eta_{\text{GKO}}) = \Omega_\Delta$. The dualized GKO constraint $q_\Delta = -\frac{1}{m+m'+h_p} \sum_i x_i'^{(1)} x_i''^{(1)}$ is a non-zero-divisor in the completed tensor product $A_\Delta = \widehat{\text{Sym}}(\bigoplus_{n \geq 1} \mathfrak{p}_{(n)}^{\vee'} \oplus \bigoplus_{n \geq 1} \mathfrak{p}_{(n)}^{\vee''})$. Consequently, the minimal coupled GKO dual is the strict quadric $A_\Delta/(q_\Delta)$ with no higher A_∞ corrections.

Proof. The primarity reduction is identical to the Sugawara case. The surviving class η_{GKO} transgresses to the diagonal Casimir cross term. The domain property of A_Δ (an integral domain as a completed polynomial algebra) gives regularity of q_Δ , and Theorem 8.3.14 applies. $\square$

Remark 8.3.19 (*Narrative thread: from separation to rigidity*). The theorems of this section form a single argument in five steps, not a collection of independent results.

Step 1 (Theorem 8.3.2): $R_X \neq K_X$: reconstruction and duality are distinct operations on the bar complex. This sits at the foundation of the algebraic engine: Theorems A and B are about R_X , while the Koszul pair structure of Chapter II is about K_X .

Step 2 (Theorem 8.3.6): the mixed-boundary spectral sequence extends the engine to coupled tensor products, separating mono-color from mixed-color data.

Step 3 (Theorem 8.3.8 and Proposition 8.3.10): the universal primarity differential $Q_{\text{Sug}} = \partial + N$ contracts away all reduced mixed data; it depends on neither the Lie type nor the level.

Step 4 (Theorem 8.3.13 and Theorem 8.3.14): the surviving class transgresses to the Casimir quadric $\Omega_{\mathfrak{g},k}$, cutting out the coupled dual as a strict complete intersection.

Step 5 (Theorem 8.3.15 and Theorem 8.3.17): the quadric is formal (no higher A_∞ corrections), and the principle generalizes to arbitrary codimension via regular sequences.

The conceptual upshot: genuine higher A_∞ corrections in coupled chiral bar complexes arise from *singular* coupling (the failure of the transgression classes to form a regular sequence), not from coupling per se. The entire sequence is a Maurer–Cartan element in the mixed-color convolution algebra, and the Casimir transgression is the projection of that MC element to the quadratic stratum.

From adjunction to inversion. An adjunction that is not an equivalence is a deficiency: it records the information lost in the round trip. Theorem A gives the adjunction $\Omega^{\text{ch}} \dashv \bar{B}^{\text{ch}}$; the question is whether the counit $\psi: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism, so that no information is lost. This is not a formal consequence of the adjunction; it requires the geometry of the Fulton–MacPherson compactification and the Koszulness of the underlying chiral operad.

Theorem B (Theorem 8.6.1) gives the answer in two layers: on the Koszul locus (Definition 3.1.7), the counit ψ is a quasi-isomorphism of chiral algebras, genus by genus and in the $\hbar$ -adic completion (Theorem 8.6.18); off the Koszul locus, the same counit remains invertible in the coderived bar-coalgebra category, and promotion back to ordinary chain cohomology requires an extra collapse input. The strict proof uses the square-zero bar-cobar spectral sequence only on the Koszul lane. The curved proof uses the coderived bar-degree filtration: the curvature term lies in positive filtration, so the associated-graded E_1 page is strict, while coacyclicity of the cone records the actual inversion statement. The regime hierarchy (Convention 1.10.2) organizes these four cases.

8.4 NON-QUADRATIC CHIRAL ALGEBRAS

The four-regime hierarchy (Convention 1.10.2) classifies chiral algebras by their bar-complex behavior: quadratic (strict $d^2 = 0$), curved-central ($d_{\text{fb}}^2 = \kappa \cdot \omega_{\mathfrak{g}}$ with central curvature), filtered-complete (requiring

I -adic completion), and programmatic (infinite generators). The first three regimes admit bar-cobar inversion by increasingly refined completions; the fourth, the programmatic regime of W_∞ and $W_{1+\infty}$, is resolved by the strong completion-tower theorem (Theorem 8.1.27), whose proof reduces the infinite-type problem to a sequence of finite-type problems linked by the strong filtration axiom. The sections that follow develop each regime in turn, with the programmatic case treated as the natural culmination. The examples of each regime are given in §8.2.1 above.

8.4.1 CONVERGENCE CRITERIA

THEOREM 8.4.1 (*Convergence of bar construction;*). Let $\mathcal{A}$ be a chiral algebra and write $\bar{B}(\mathcal{A}) = \bigoplus_{n \geq 0} \bar{B}^n(\mathcal{A})$ with its bar-degree filtration $F_p := \bigoplus_{n \leq p} \bar{B}^n(\mathcal{A})$. Assume $\dim \bar{B}^n(\mathcal{A}) < \infty$ for all n . Consider:

1. *Convergence without completion:* the natural map $\bigoplus_n \bar{B}^n(\mathcal{A}) \rightarrow \prod_n \bar{B}^n(\mathcal{A})$ is a quasi-isomorphism for the bar differential.
2. *Growth bound:* $\limsup_{n \rightarrow \infty} \dim(\bar{B}^n(\mathcal{A}))^{1/n} < \infty$.
3. *Filtration compatibility:* $d(F_p) \subseteq F_p$ and d lowers bar degree by one on $\text{gr}_F \bar{B}(\mathcal{A})$.

Then (2)+(3) $\Rightarrow$ (1), and (1) $\Rightarrow$ (3). If (2) or (3) fails, one must use the completed bar complex $\widehat{\bar{B}}(\mathcal{A})$.

Proof. (2)+(3) $\Rightarrow$ (1). Condition (3) gives a filtered complex structure on the direct sum complex and the associated spectral sequence has

$$E_0^{p,\bullet} = \bar{B}^p(\mathcal{A}), \quad d_0 : \bar{B}^p \rightarrow \bar{B}^{p-1}.$$

Because each $\bar{B}^p$ is finite-dimensional and condition (2) gives uniform at-most-exponential growth, each total degree receives only finite-dimensional contributions, so the filtered spectral sequence is well-defined and converges to $H^*(\bar{B}(\mathcal{A}))$. Thus no topological completion is required. Together with Theorem 8.1.18, this means every iterated coproduct/differential expression is finite on each element.

(1) $\Rightarrow$ (3). If convergence holds in the uncompleted direct sum, d cannot create infinitely many bar-degree components from a single homogeneous input; equivalently, $d(F_p) \subseteq F_p$ and the induced differential on gr_F is degree -1 . Otherwise d is only defined in the product completion.

Remark on the growth bound. Condition (2) is sufficient for (1) given (3), but not necessary in general: an algebra can converge without completion even when $\dim \bar{B}^n$ grows super-exponentially, provided the differential kills enough cohomology. Condition (2) guarantees that the Mittag-Leffler condition holds for the tower $\{F_p\}_{p \geq 0}$, which by the Milnor exact sequence ensures $\lim^1 = 0$ and hence the comparison quasi-isomorphism.

Quadratic finite-type case. For $\mathcal{A} = T(V)/(R)$ with V finite-dimensional, $\bar{B}^n(\mathcal{A}) \cong (sV)^{\otimes n}$, so (2) holds with growth constant $\dim V$, and (3) holds by definition of the bar filtration. Therefore quadratic finite-type algebras converge without completion. $\square$

Remark 8.4.2 (*Dependencies*). This proof uses:

- (D1) conilpotent convergence control (Theorem 8.1.18);
- (D2) filtered-to-curved reduction inputs for non-quadratic regimes (Theorem 8.1.15);
- (D3) filtered/complete Koszul duality context [213].

8.4.2 PHYSICAL INTERPRETATION

Quadratic algebras correspond to free field theories (Heisenberg $\leftrightarrow$ free boson, Kac–Moody $\leftrightarrow$ WZW). Curved algebras correspond to interacting theories with anomalies (Virasoro, with central charge c measuring quantum breaking of scale invariance). Filtered algebras correspond to theories with composite operators (W_3 and Toda field theory). General algebras correspond to non-local theories (W_∞), where the MC4 structural package is proved (Theorem 8.1.27); the residual H-level comparison is example-specific.

From Kontsevich’s geometric viewpoint, the filtration level corresponds to the codimension of collision loci: quadratic algebras see only pairwise collisions, curved algebras see central terms from n -point collisions, and filtered algebras require higher-codimension strata. The completion $\widehat{B}(\mathcal{A})$ is the formal neighborhood of the diagonal in configuration space.

8.4.3 SUMMARY AND DECISION TREE

Remark 8.4.3 (Summary for practitioners). Before computing the Koszul dual, one should determine:

1. Is the algebra quadratic? $\Rightarrow$ Proceed directly
2. Is it curved with central curvature? $\Rightarrow$ Check if $\dim(\bar{B}^1) < \infty$
 - If yes: No completion
 - If no: Completion is required
3. Does it have composite operators? $\Rightarrow$ Must complete
4. Is the generating space infinite-dimensional? $\Rightarrow$ handled by the MC4 completion theorem (Theorem 8.1.27); residual task is to identify the filtered H-level target and its finite quotients by explicit coefficient identities and finite detection

Most vertex algebras from CFT are either quadratic or curved with finite-dimensional $\bar{B}^1$, so Koszul duality applies.

8.5 CHIRAL COALGEBRA HOMOLOGICAL ALGEBRA

The bar complex $\bar{B}^{\text{ch}}(\mathcal{A})$ is a chiral coalgebra (Theorem 6.1.70). At genus 0, it is a DG chiral coalgebra ($d_0^2 = 0$); at genus $g \geq 1$ with $\kappa(\mathcal{A}) \neq 0$, it is a *curved* DG chiral coalgebra ($d_{\text{fib}}^2 = m_0^{(g)} \neq 0$; Convention 13.0.2). In the curved case, ordinary bar-complex cohomology collapses on the higher-genus bar-object surface (Proposition 8.1.9), and a richer homological algebra is needed.

The chiral analogues of Positselski’s coalgebra homological algebra [350] replace the ground field k by $\mathcal{D}_X$ and the tensor product by $\otimes^{\text{ch}}$; all exactness properties are inherited from configuration space geometry.

Remark 8.5.1 (The coderived category: status and the genus-0/genus- g distinction). The Koszul locus is a genus-0 condition on the algebra $\mathcal{A}$: bar cohomology $H^*(\bar{B}(\mathcal{A}))$ is concentrated in bar degree 1, the PBW spectral sequence collapses at E_2 , and the bar-cobar counit $\Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism (Theorem 8.6.1, genus-0 clause). On the quadratic genus-0 bar-dual surface, the coderived and ordinary derived categories coincide.

At genus $g \geq 1$, the situation changes: the curvature $m_0^{(g)} = \kappa(\mathcal{A}) \cdot \omega_g$ is nonzero for every algebra with $\kappa(\mathcal{A}) \neq 0$. This curvature is *not a failure of Koszulness*: a Koszul algebra has uncurved genus-0 bar ($d^2 = 0$ on $\bar{B}^{(0)}$) but curved genus- g bar ($d^2 = [m_0^{(g)}, -]$ on $\bar{B}^{(g)}$). The coderived category $D^{\text{co}}(\mathcal{A})$ is therefore not an exotic generalization but a necessity: it is the only categorical framework where the genus- g shadow data of nontrivial modular Koszul algebras can live.

The proved shadow obstruction tower $\Theta_{\mathcal{A}}$ (Theorem 13.21.69) produces genus- g classes via the convolution algebra, but proving that these classes *control* the coderived category at each genus via a direct algebra/coalgebra adjunction requires the curved bar-cobar adjunction to extend to a coderived Quillen equivalence. The intrinsic bar-coalgebra comparison already proved in this chapter is Theorem 8.5.23; what remains conjectural is the direct curved bar-cobar Quillen equivalence extending the genus-0 adjunction itself. The abstract framework (Positselski [350], Lefèvre-Hasegawa) exists for associative algebras, but the chiral-algebraic instantiation (handling the Ran space and factorization structure simultaneously with curved homological algebra) has not been carried out.

Concretely, four steps remain:

- (C1) Construct the coderived model structure on curved chiral factorization coalgebras.
- (C2) Prove the curved bar-cobar adjunction is a Quillen equivalence in this model structure.
- (C3) Identify the coderived shadow invariants with the proved shadow tower projections $\Theta_{\mathcal{A}}^{(g)}$.
- (C4) Compare with the analytic sewing envelope (Theorem K.7.1): $D^{\text{co},g}(\mathcal{A}) \stackrel{?}{\simeq} \text{IndHilb}^g(\mathcal{A}^{\text{sew}})$.

8.5.1 CHIRAL CDG-COALGEBRAS

Definition 8.5.2 (Chiral CDG-coalgebra). A *chiral CDG-coalgebra* over a smooth curve X is a triple (C, d, h) where:

1. C is a graded chiral coalgebra on X : a graded $\mathcal{D}_X$ -module equipped with a comultiplication $\Delta: C \rightarrow C \otimes^{\text{ch}} C$ (defined via configuration space splitting maps, cf. Theorem 6.1.70), a counit $\varepsilon: C \rightarrow \omega_X$, coassociativity, and the counit axioms.
2. $d: C \rightarrow C$ is a homogeneous endomorphism of degree 1 that is an odd coderivation: the composition $\Delta \circ d = (d \otimes \text{id} + \text{id} \otimes d) \circ \Delta$ holds, and $\varepsilon \circ d = 0$ on $C^{>-2}$ (the counit annihilates d except possibly in the lowest degree).
3. $h: C \rightarrow \omega_X$ is a homogeneous linear functional of degree 2 (the *curvature*), satisfying:
 - a) $d^2(c) = h * c - c * h$ for all $c \in C$, where $h * c$ denotes the coaction of the curvature (defined via the comodule structure of C over itself);
 - b) $h \circ d(c) = 0$ for all $c \in C$ (the curvature is a cocycle for the coderivation d).

When $h = 0$, we recover an ordinary DG chiral coalgebra.

Example 8.5.3 (The bar complex as chiral CDG-coalgebra). For a Koszul chiral algebra $\mathcal{A}$ on X :

- At genus 0: $\bar{B}^{(0)}(\mathcal{A}) = (\bar{B}^{\text{ch}}(\mathcal{A}), d_{\bar{B}}, 0)$ is a DG chiral coalgebra ($h = 0$).

- At genus $g \geq 1$: $\bar{B}^{(g)}(\mathcal{A}) = (\bar{B}^{\text{ch}}(\mathcal{A}), d_B^{(g)}, h_g)$ is a CDG chiral coalgebra with curvature $h_g = m_0^{(g)} = \kappa(\mathcal{A}) \cdot \lambda_g$ (Theorem 13.13.16), where $\kappa(\mathcal{A})$ is the obstruction coefficient and λ_g is the Faber–Pandharipande class on $\overline{\mathcal{M}}_g$.

The CDG axioms are verified as follows. Axiom (2a): the identity $d^2 = [m_0, -]$ is the curved A_∞ relation (Corollary 13.13.31). Axiom (2b): $h \circ d = 0$ follows from m_0 being a scalar (central element), so $d(m_0) = 0$.

Remark 8.5.4 (Chiral CDG-coalgebra morphisms). A morphism of chiral CDG-coalgebras $(C, d_C, h_C) \rightarrow (D, d_D, h_D)$ is a pair (f, a) where $f: C \rightarrow D$ is a morphism of graded chiral coalgebras and $a: C \rightarrow \omega_X$ is a homogeneous linear function of degree 1 such that

$$\begin{aligned} d_D(f(c)) &= f(d_C(c)) + f(a * c) - (-1)^{|c|} f(c * a), \\ h_D(f(c)) &= h_C(c) + a(d_C(c)) + a^2(c) \end{aligned}$$

for all $c \in C$. Composition of morphisms is defined by $(g, b) \circ (f, a) = (g \circ f, b \circ f + a)$. This follows Positselski [350, §4.1].

8.5.2 CHIRAL CDG-COMODULES AND CDG-CONTRAMODULES

Definition 8.5.5 (Chiral CDG-comodule). Let (C, d, h) be a chiral CDG-coalgebra. A *left chiral CDG-comodule* over C is a graded left C -comodule M (i.e., a graded $\mathcal{D}_X$ -module with coaction $\lambda: M \rightarrow C \otimes^{\text{ch}} M$ satisfying coassociativity and counit axioms) endowed with a homogeneous endomorphism $d_M: M \rightarrow M$ of degree 1 such that:

1. The coaction commutes with differentials: $\lambda \circ d_M = (d \otimes \text{id} + \text{id} \otimes d_M) \circ \lambda$.
2. The curvature relation: $d_M^2(x) = h * x$ for all $x \in M$, where $h * x$ denotes the action of the curvature via the coaction map.

A *right chiral CDG-comodule* is defined analogously with coaction $\rho: N \rightarrow N \otimes^{\text{ch}} C$ and $d_N^2(y) = -y * h$.

Morphisms of chiral CDG-comodules are homogeneous $\mathcal{D}_X$ -linear maps of degree 0 that are compatible with the coaction and commute with the differential (in the usual graded sense).

Definition 8.5.6 (Chiral CDG-contramodule). Let (C, d, h) be a chiral CDG-coalgebra. A *left chiral CDG-contramodule* over C is a graded left C -contramodule P (i.e., a graded $\mathcal{D}_X$ -module with contraaction $\pi_P: \text{Hom}^{\text{ch}}(C, P) \rightarrow P$ satisfying the contraassociativity and contraunit axioms) endowed with a homogeneous endomorphism $d_P: P \rightarrow P$ of degree 1 such that:

1. The contraaction commutes with differentials on $\text{Hom}^{\text{ch}}(C, P)$ and P .
2. The curvature relation: $d_P^2(p) = h * p$ for all $p \in P$, where $h * p = \pi_P(h \otimes p)$ denotes the contraaction of the curvature.

Morphisms of chiral CDG-contramodules are defined analogously.

Remark 8.5.7 (Contramodules in the chiral setting). The chiral contraaction $\pi_P: \text{Hom}^{\text{ch}}(C, P) \rightarrow P$ replaces Positselski's $\text{Hom}_k(C, P) \rightarrow P$, where $\text{Hom}^{\text{ch}}(C, P) := \text{Hom}_{\mathcal{D}_X}(C, P)$ is the internal Hom in the chiral category. For a conilpotent chiral coalgebra C with finite-dimensional graded pieces (as holds for $\bar{B}^{\text{ch}}(\mathcal{A})$ when $\mathcal{A}$ is finitely generated over $\mathcal{D}_X$), $\text{Hom}^{\text{ch}}(C, P) \cong C^* \otimes^{\text{ch}} P$ where $C^* = \text{Hom}_{\mathcal{D}_X}(C, \omega_X)$.

is the graded dual. In this finite-type case, contramodules over C are equivalent to complete modules over the dual algebra C^* , recovering the correspondence between conilpotent comodules and complete modules already used in Theorem 11.6.2.

Remark 8.5.8 (No cohomology for CDG-comodules). Since $d^2 \neq 0$ in a CDG-comodule (when $h \neq 0$), there is no notion of cohomology, so the ordinary derived category is inadequate at higher genus: one cannot define acyclic objects via vanishing cohomology. The correct substitute is the coderived category (Definition 8.5.13).

8.5.3 CHIRAL COTENSOR AND COHOMOMORPHISM COMPLEXES

Definition 8.5.9 (Chiral cotensor product). Let (C, d, h) be a chiral CDG-coalgebra, N a right chiral CDG-comodule, and M a left chiral CDG-comodule. The *chiral cotensor product* $N \square_C^{\text{ch}} M$ is the equalizer:

$$N \square_C^{\text{ch}} M = \ker(\rho \otimes^{\text{ch}} \text{id} - \text{id} \otimes^{\text{ch}} \lambda : N \otimes^{\text{ch}} M \rightrightarrows N \otimes^{\text{ch}} C \otimes^{\text{ch}} M)$$

in the category of graded $\mathcal{D}_X$ -modules. The differential on $N \otimes^{\text{ch}} M$ restricts to $N \square_C^{\text{ch}} M$ (this uses the compatibility of coactions with differentials), and the restricted differential has $d^2 = h_N * (-) - (-) * h_M$ on the cotensor product, making $N \square_C^{\text{ch}} M$ a complex (i.e., $d^2 = 0$) precisely when $h_N = h_M$ (the curvatures match), which holds when N and M are CDG-comodules over the same CDG-coalgebra C .

Definition 8.5.10 (Chiral cobomomorphisms). For left chiral CDG-comodules L and M over C , the *chiral cobomomorphism complex* is:

$$\text{Cohom}_C^{\text{ch}}(L, M) = \{f \in \text{Hom}_{\mathcal{D}_X}(L, M) : \lambda_M \circ f = (\text{id}_C \otimes^{\text{ch}} f) \circ \lambda_L\}$$

with differential $(df)(x) = d_M(f(x)) - (-1)^{|f|} f(d_L(x))$. This differential has a zero square (using the CDG-comodule axioms), making $\text{Cohom}_C^{\text{ch}}(L, M)$ an honest complex.

Definition 8.5.11 (Chiral contratensor product). For a right chiral CDG-comodule N and a left chiral CDG-contramodule P over C , the *chiral contratensor product* $N \odot_C^{\text{ch}} P$ is the coequalizer:

$$N \odot_C^{\text{ch}} P = \text{coker}(N \otimes^{\text{ch}} \text{Hom}^{\text{ch}}(C, P) \rightrightarrows N \otimes^{\text{ch}} P)$$

where the two maps are $\rho \otimes^{\text{ch}} \pi_P$ and $\text{id}_N \otimes^{\text{ch}} \pi_P$. The induced differential on $N \odot_C^{\text{ch}} P$ has zero square by the same curvature cancellation as for the cotensor product.

LEMMA 8.5.12 (*Adjunction*;). There is a canonical isomorphism of complexes:

$$\text{Hom}_{\mathcal{D}_X}(N \square_C^{\text{ch}} M, V) \cong \text{Cohom}_C^{\text{ch}}(M, \text{Hom}_{\mathcal{D}_X}(N, V))$$

for any graded $\mathcal{D}_X$ -module V , and dually:

$$\text{Hom}_{\mathcal{D}_X}(C \otimes^{\text{ch}} V, P) \cong \text{Hom}_{\mathcal{D}_X}(V, \text{Hom}^{\text{ch}}(C, P))$$

establishing $\Phi_C \dashv \Psi_C$ (see Definition 8.5.19 below).

Proof. Both isomorphisms are instances of the tensor-hom adjunction in the chiral category. For the first: an element of the left side is a $\mathcal{D}_X$ -linear map $f : N \square_C^{\text{ch}} M \rightarrow V$. By the universal property of the equalizer, this is equivalent to a $\mathcal{D}_X$ -linear map $\tilde{f} : N \otimes^{\text{ch}} M \rightarrow V$ that equalizes the two coaction maps. By the chiral tensor-hom adjunction (which holds for holonomic $\mathcal{D}_X$ -modules by [40, Proposition 3.4.6]), $\tilde{f}$ corresponds to a map $M \rightarrow \text{Hom}_{\mathcal{D}_X}(N, V)$ that is C -colinear, i.e., an element of $\text{Cohom}_C^{\text{ch}}(M, \text{Hom}_{\mathcal{D}_X}(N, V))$. The second isomorphism is analogous. $\square$

8.5.4 CODERIVED AND CONTRADERIVED CATEGORIES

Definition 8.5.13 (Coderived and contraderived categories). Let (C, d, h) be a chiral CDG-coalgebra.

Exact triples. An exact triple of left chiral CDG-comodules is a short sequence $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$ that is exact in the abelian category of graded C -comodules (with closed, degree-zero morphisms). The analogous notion applies to CDG-contramodules.

Coacyclic objects. A left chiral CDG-comodule M is *coacyclic* if it belongs to the minimal thick subcategory of $\text{Hot}(C\text{-comod}^{\text{ch}})$ that contains the totalizations of all exact triples and is closed under infinite direct sums. Denote by $\text{Acycl}^{\text{co}}(C\text{-comod}^{\text{ch}})$ the thick subcategory of coacyclic CDG-comodules.

Contraacyclic objects. A left chiral CDG-contramodule P is *contraacyclic* if it belongs to the minimal thick subcategory of $\text{Hot}(C\text{-contra}^{\text{ch}})$ that contains the totalizations of all exact triples and is closed under infinite direct products. Denote by $\text{Acycl}^{\text{ctr}}(C\text{-contra}^{\text{ch}})$ the thick subcategory of contraacyclic CDG-contramodules.

The exotic derived categories.

$$D^{\text{co}}(C\text{-comod}^{\text{ch}}) := \text{Hot}(C\text{-comod}^{\text{ch}}) / \text{Acycl}^{\text{co}}(C\text{-comod}^{\text{ch}})$$

$$D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) := \text{Hot}(C\text{-contra}^{\text{ch}}) / \text{Acycl}^{\text{ctr}}(C\text{-contra}^{\text{ch}})$$

Remark 8.5.14 (Comparison with ordinary derived category). When $h = 0$ (genus 0), CDG-comodules are ordinary DG-comodules and one can also form the standard derived category $D(C\text{-comod}^{\text{ch}})$ by localizing at acyclic objects (those with $H^*(M) = 0$). In general, $\text{Acycl}^{\text{co}} \supset \text{Acycl}$, so D^{co} is a quotient of D . When C has finite homological dimension (e.g., when $\mathcal{A}$ is Koszul with finite global dimension), the two categories coincide (Positselski [350, §4.5]). When $h \neq 0$, the standard cohomological derived category is no longer the right invariant for the curved theory; on the higher-genus bar-complex surfaces treated here the underlying complexes are acyclic, while D^{co} is nontrivial.

8.5.5 INJECTIVE COMODULES AND PROJECTIVE CONTRAMODULES

Definition 8.5.15 (Cofree chiral CDG-comodule). For a graded $\mathcal{D}_X$ -module V , the *cofree graded chiral C -comodule* on V is:

$$J(V) := C \otimes^{\text{ch}} V$$

with coaction $\Delta^{\text{ch}} \text{id}_V : C \otimes^{\text{ch}} V \rightarrow C \otimes^{\text{ch}} C \otimes^{\text{ch}} V$. The CDG-comodule differential is $d_{J(V)}(c \otimes v) = d(c) \otimes v$, and the curvature relation $d_{J(V)}^2 = h * (-)$ is inherited from C .

PROPOSITION 8.5.16 (Injective and projective resolutions;). Let (C, d, h) be a conilpotent chiral CDG-coalgebra with finite-dimensional graded pieces.

- (a) For any left chiral CDG-comodule M , the cofree chiral comodule $J(M) = C \otimes^{\text{ch}} M$ is *injective* in the abelian category of graded $C^{\#}$ -comodules (where $C^{\#}$ denotes C with forgotten differential and curvature).
- (b) For any left chiral CDG-contramodule P , the free chiral contramodule $F(P) = \text{Hom}^{\text{ch}}(C, P)$ is *projective* in the abelian category of graded $C^{\#}$ -contramodules.
- (c) The homotopy categories admit semiorthogonal decompositions: the coderived category $D^{\text{co}}(C\text{-comod}^{\text{ch}})$ is equivalent to the homotopy category of CDG-comodules with injective underlying graded comodules, and $D^{\text{ctr}}(C\text{-contra}^{\text{ch}})$ is equivalent to the homotopy category of CDG-contramodules with projective underlying graded contramodules.

Proof. *Part (a).* Let $0 \rightarrow L \rightarrow M \rightarrow N \rightarrow 0$ be an exact sequence of graded $C^\#$ -comodules. We must show that $0 \rightarrow \text{Hom}_{C^\#}(N, J(V)) \rightarrow \text{Hom}_{C^\#}(M, J(V)) \rightarrow \text{Hom}_{C^\#}(L, J(V)) \rightarrow 0$ is exact. By the tensor-hom adjunction in the chiral category: $\text{Hom}_{C^\#}(M, C^{\otimes \text{ch}} V) \cong \text{Hom}_{\mathcal{D}_X}(M, V)$, and the functor $\text{Hom}_{\mathcal{D}_X}(-, V)$ is exact on holonomic $\mathcal{D}_X$ -modules (since holonomic modules have finite length).

Part (b). Dual to (a): for an exact sequence $0 \rightarrow P \rightarrow Q \rightarrow R \rightarrow 0$ of graded $C^\#$ -contramodules, $\text{Hom}_{C^\#}(\text{Hom}^{\text{ch}}(C, V), -)$ is exact because $\text{Hom}_{C^\#}(\text{Hom}^{\text{ch}}(C, V), P) \cong \text{Hom}_{\mathcal{D}_X}(V, P)$.

Part (c). For any CDG-comodule M , the cobar resolution provides a functorial injective resolution: form $J = \bigoplus_{n=0}^{\infty} C^{\otimes \text{ch}(n+1)} \otimes^{\text{ch}} M$ with the standard bar-type differential (the chiral analogue of Positselski [350, §4.4, proof of Theorem]). The closed morphism $M \rightarrow J$ has the property that $\text{cone}(M \rightarrow J)$ is coacyclic (each quotient $\tau_{\leq n} J / \tau_{\leq n-1} J$ is a cofree CDG-comodule, and the cone is built from these by exact triangles and countable direct sums). The projectivity statement for contramodules is dual: take the bar resolution $\cdots \rightarrow \text{Hom}^{\text{ch}}(C^{\otimes \text{ch} 2}, P) \rightarrow \text{Hom}^{\text{ch}}(C, P) \rightarrow P$ and observe that the cone is contraacyclic (built from free contramodules by exact triangles and countable direct products).

The semiorthogonal decomposition follows formally: the localization functor from the full homotopy category to D^{co} restricts to an equivalence on the full subcategory of objects with injective underlying graded comodule (since coacyclic objects with injective underlying comodule are contractible, by the same argument as Positselski [350, §4.4], using the injective resolution of the previous paragraph). The dual statement holds for D^{ctr} . $\square$

PROPOSITION 8.5.17 (*Explicit CDG Hom-complex;*). Let (C, d_C, h) be a chiral CDG-coalgebra and let M, N be left chiral CDG-comodules over C . The CDG Hom-complex $\underline{\text{Hom}}_C^{\text{ch}}(M, N)$ is the graded $\mathcal{D}_X$ -module of graded $C^\#$ -comodule morphisms, with differential

$$d_{\text{Hom}}(f) = d_N \circ f - (-1)^{|f|} f \circ d_M. \quad (8.12)$$

This differential satisfies $d_{\text{Hom}}^2(f) = [h_N, f] - [h_M, f]$ where h_M, h_N denote the curvature endomorphisms $h * (-)$ on M and N respectively. In particular:

- (a) When $h = 0$ (genus 0), $d_{\text{Hom}}^2 = 0$ and the Hom-complex is a genuine DG-module.
- (b) When $h \neq 0$, the Hom-complex is a CDG-module with curvature $h_{\text{Hom}}(f) = h_N \circ f - f \circ h_M$. For endomorphisms ($M = N$), $d_{\text{Hom}}^2(f) = [h_M, f]$, so d_{Hom} is a genuine differential on the center $Z(\text{End}_C(M)) = \{f : h_M \circ f = f \circ h_M\}$.

Proof. Direct computation. For $f \in \underline{\text{Hom}}_C^{\text{ch}}(M, N)^k$:

$$\begin{aligned} d_{\text{Hom}}^2(f) &= d_N \circ (d_N \circ f - (-1)^k f \circ d_M) - (-1)^{k+1} (d_N \circ f - (-1)^k f \circ d_M) \circ d_M \\ &= d_N^2 \circ f + (-1)^{k+1} d_N \circ f \circ d_M + (-1)^{k+1} d_N \circ f \circ d_M + f \circ d_M^2 \\ &= d_N^2 \circ f - f \circ d_M^2 \\ &= (h_N * -) \circ f - f \circ (h_M * -), \end{aligned}$$

where the last step uses the CDG relation $d^2 = h * (-)$ on M and N . When $M = N$, this is $[h_M, f]$, which vanishes on central endomorphisms. $\square$

COROLLARY 8.5.18 (*Contractibility of coacyclic injectives;*). Let (C, d, h) be a conilpotent chiral CDG-coalgebra with finite-dimensional graded pieces, and let M be a chiral CDG-comodule with injective underlying graded $C^\#$ -comodule. Then M is coacyclic if and only if it admits a *contracting homotopy*: a degree -1 graded $C^\#$ -comodule endomorphism $s : M \rightarrow M$ satisfying

$$d_M \circ s + s \circ d_M = \text{id}_M. \quad (8.13)$$

Proof. If such an s exists, then $\text{id}_M = d_{\text{Hom}}(s)$ in the CDG Hom-complex of Proposition 8.5.17 (with $M = N$), so M is null-homotopic and *a fortiori* coacyclic.

Conversely, suppose M is coacyclic with injective underlying graded comodule. By the semiorthogonal decomposition in Proposition 8.5.16(c), $D^{\text{co}}(C\text{-comod}^{\text{ch}})$ is equivalent to $\text{Hot}(C\text{-comod}_{\text{inj}}^{\text{ch}})$. A coacyclic object that already has injective underlying comodule represents the zero object in this homotopy category, hence is null-homotopic: there exists a degree -1 closed morphism s with $d_{\text{Hom}}(s) = \text{id}_M$. Expanding via (8.12) gives (8.13). $\square$

8.5.6 THE CORRESPONDENCE FUNCTORS

Definition 8.5.19 (Functors Φ_C^{ch} and Ψ_C^{ch}). Let (C, d, h) be a chiral CDG-coalgebra.

- For a left chiral CDG-contramodule P , define $\Phi_C^{\text{ch}}(P)$ to be the left chiral CDG-comodule whose underlying graded $\mathcal{D}_X$ -module is the chiral contratensor product $C \odot_C^{\text{ch}} P$. Concretely, $\Phi_C^{\text{ch}}(P)$ is a quotient of $C \otimes^{\text{ch}} P$; the comodule structure comes from the comultiplication on the left factor C , and the differential is induced by the differentials on C and P via the standard formula for the tensor product of graded $\mathcal{D}_X$ -modules with differentials.
- For a left chiral CDG-comodule M , define $\Psi_C^{\text{ch}}(M)$ to be the left chiral CDG-contramodule whose underlying graded $\mathcal{D}_X$ -module is $\text{Hom}_C^{\text{ch}}(C, M) = \text{Cohom}_C^{\text{ch}}(C, M)$. The contramodule structure comes from the comultiplication on C , and the differential is induced from d_C and d_M .

These define DG-functors:

$$\begin{aligned}\Phi_C^{\text{ch}} : \text{DG}(C\text{-contra}^{\text{ch}}) &\longrightarrow \text{DG}(C\text{-comod}^{\text{ch}}), \\ \Psi_C^{\text{ch}} : \text{DG}(C\text{-comod}^{\text{ch}}) &\longrightarrow \text{DG}(C\text{-contra}^{\text{ch}}).\end{aligned}$$

LEMMA 8.5.20 (*Key properties of Φ_C^{ch} and Ψ_C^{ch}* ;). (a) Φ_C^{ch} is left adjoint to Ψ_C^{ch} on the homotopy categories.

- (b) Φ_C^{ch} maps the free graded contramodule $\text{Hom}^{\text{ch}}(C, V)$ to the cofree graded comodule $C \otimes^{\text{ch}} V$, for any graded $\mathcal{D}_X$ -module V .
- (c) Ψ_C^{ch} maps the cofree graded comodule $C \otimes^{\text{ch}} V$ to the free graded contramodule $\text{Hom}^{\text{ch}}(C, V)$.
- (d) Φ_C^{ch} maps projective graded contramodules to injective graded comodules, and Ψ_C^{ch} maps injective graded comodules to projective graded contramodules.

Proof. *Part (a).* The adjunction $\Phi_C^{\text{ch}} \dashv \Psi_C^{\text{ch}}$ follows from the standard isomorphism $\text{Hom}_{\mathcal{D}_X}(C \otimes^{\text{ch}} V, P) \cong \text{Hom}_{\mathcal{D}_X}(V, \text{Hom}^{\text{ch}}(C, P))$ (the chiral tensor-hom adjunction), which makes Φ_C^{ch} left adjoint to Ψ_C^{ch} as DG-functors (Lemma 8.5.12).

Parts (b) and (c). The free graded contramodule on V is $\text{Hom}^{\text{ch}}(C, V) = \text{Hom}_{\mathcal{D}_X}(C, V)$. Then:

$$\Phi_C^{\text{ch}}(\text{Hom}^{\text{ch}}(C, V)) = C \odot_C^{\text{ch}} \text{Hom}^{\text{ch}}(C, V).$$

By the contramodule-comodule correspondence at the graded level (cf. the example in Positselski [350, §5.1]), the contratensor product of C with the free contramodule on V is canonically isomorphic to the

cofree comodule $C \otimes^{\text{ch}} V$. In the chiral setting, this isomorphism follows from the tensor-hom adjunction for $\mathcal{D}_X$ -modules:

$$\begin{aligned} C \odot_C^{\text{ch}} \text{Hom}^{\text{ch}}(C, V) &\cong \text{coker}(C \otimes^{\text{ch}} \text{Hom}^{\text{ch}}(C, \text{Hom}^{\text{ch}}(C, V)) \rightrightarrows C \otimes^{\text{ch}} \text{Hom}^{\text{ch}}(C, V)) \\ &\cong C \otimes^{\text{ch}} V, \end{aligned}$$

where the last step uses the counit of the adjunction $\text{ev} : \text{Hom}^{\text{ch}}(C, V) \otimes^{\text{ch}} C \rightarrow V$ and the coassociativity of C . Part (c) is the dual computation.

Part (d). Combine (b)–(c) with Proposition 8.5.16(a)–(b): free graded contramodules are projective and cofree graded comodules are injective, so Φ_C^{ch} sends projective objects to injective objects and vice versa. $\square$

8.5.7 THE CHIRAL COMODULE-CONTRAMODULE CORRESPONDENCE

THEOREM 8.5.21 (*Chiral comodule-contramodule correspondence*;). Let (C, d, h) be a conilpotent chiral CDG-coalgebra on a smooth curve X with finite-dimensional graded pieces. The derived functors

$$\begin{aligned} \mathbf{L}\Phi_C^{\text{ch}} : D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) &\longrightarrow D^{\text{co}}(C\text{-comod}^{\text{ch}}), \\ \mathbf{R}\Psi_C^{\text{ch}} : D^{\text{co}}(C\text{-comod}^{\text{ch}}) &\longrightarrow D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) \end{aligned}$$

are mutually inverse equivalences of triangulated categories.

Proof. The proof follows Positselski [350, §5.2], with the ordinary tensor product replaced by the chiral tensor product $\otimes^{\text{ch}}$ and exactness properties established via the geometry of $\mathcal{D}_X$ -modules on configuration spaces. We verify each step.

Step 1: Derived functors. By Proposition 8.5.16(c), the contraderived and coderived categories

$$\begin{aligned} D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) &\simeq K_{\text{proj}}(C\text{-contra}^{\text{ch}}), \\ D^{\text{co}}(C\text{-comod}^{\text{ch}}) &\simeq K_{\text{inj}}(C\text{-comod}^{\text{ch}}) \end{aligned}$$

are equivalent to the homotopy categories of CDG-contramodules (resp. CDG-comodules) with projective (resp. injective) underlying graded module. The left derived functor $\mathbf{L}\Phi_C^{\text{ch}}$ restricts to projective contramodules; $\mathbf{R}\Psi_C^{\text{ch}}$ restricts to injective comodules.

Step 2: Mutual inverse on generators. By Lemma 8.5.20(b)–(c), Φ_C^{ch} sends the free graded contramodule $\text{Hom}^{\text{ch}}(C, V)$ to the cofree graded comodule $C \otimes^{\text{ch}} V$, and Ψ_C^{ch} sends $C \otimes^{\text{ch}} V$ back to $\text{Hom}^{\text{ch}}(C, V)$. These are the generating objects for the respective categories (any CDG-comodule has an injective resolution by cofree comodules, and any CDG-contramodule has a projective resolution by free contramodules, by Proposition 8.5.16).

Step 3: Equivalence on full triangulated subcategories. We claim that the restrictions of Φ_C^{ch} and Ψ_C^{ch} to the full triangulated subcategories

$$\begin{aligned} \text{Hot}(C\text{-contra}_{\text{proj}}^{\text{ch}}) &\subset \text{Hot}(C\text{-contra}^{\text{ch}}), \\ \text{Hot}(C\text{-comod}_{\text{inj}}^{\text{ch}}) &\subset \text{Hot}(C\text{-comod}^{\text{ch}}) \end{aligned}$$

are mutually inverse equivalences.

To see this, observe that the unit and counit natural transformations

$$\eta : \text{id} \rightarrow \Psi_C^{\text{ch}} \circ \Phi_C^{\text{ch}}, \quad \varepsilon : \Phi_C^{\text{ch}} \circ \Psi_C^{\text{ch}} \rightarrow \text{id}$$

are isomorphisms on free contra-modules and cofree comodules (Step 2). Since these objects generate the respective homotopy categories (every object is built from generators by shifts, cones, and countable (co)products), and both Φ_C^{ch} and Ψ_C^{ch} preserve exact triangles and countable (co)products, the natural transformations η and ε are isomorphisms on all objects with projective (resp. injective) underlying graded structure.

Step 4: Descent to exotic derived categories. To pass from the full homotopy categories to D^{co} and D^{ctr} , we verify that Φ_C^{ch} maps contraacyclic CDG-contra-modules to coacyclic CDG-comodules, and Ψ_C^{ch} maps coacyclic CDG-comodules to contraacyclic CDG-contra-modules.

For Φ_C^{ch} : since Φ_C^{ch} is a left adjoint, it preserves (all) colimits, in particular coproducts and cokernels. A contraacyclic CDG-contra-module is built from totalizations of exact triples and direct products. Now, Φ_C^{ch} preserves exact triples (being a left adjoint of an exact functor, hence right exact; and by Lemma 8.5.2o(d) it sends projective contra-modules to injective comodules, so the left derived functor is exact). The image of a totalization under Φ_C^{ch} is a totalization, and the image of a direct product is computed using the cofree resolution from Step 2. Thus Φ_C^{ch} preserves contraacyclic $\rightarrow$ coacyclic. The argument for Ψ_C^{ch} is dual.

Step 5: Conclusion. Combining Steps 3 and 4: $\mathbb{L}\Phi_C^{\text{ch}}$ and $\mathbb{R}\Psi_C^{\text{ch}}$ are well-defined triangulated functors between D^{ctr} and D^{co} , they are mutually inverse on the generating subcategories (projective contra-modules $\leftrightarrow$ injective comodules), and both categories are compactly generated by finite-dimensional objects (using conilpotency and finite-type grading; the argument parallels Positselski [350, §5.5], with the key input that any graded C -comodule is the union of its finite-dimensional subcomodules, which holds for conilpotent chiral coalgebras because the conformal weight grading bounds the coaction filtration). By the uniqueness of extensions of equivalences from compact generators to the full compactly generated category (cf. [350, §5.5]), the equivalence extends to all objects. $\square$

Remark 8.5.22 (Hypotheses). The two key hypotheses (conilpotency and finite-type grading) are satisfied by $C = \bar{B}^{\text{ch}}(\mathcal{A})$ whenever $\mathcal{A}$ is a finitely generated chiral algebra with finite-dimensional conformal weight spaces (which includes all Koszul chiral algebras arising in this monograph: Kac–Moody, Virasoro, W -algebras, Heisenberg, free fields, and Yangians). Conilpotency was established in Theorem 10.4.3(4); finite-type grading follows from the finite-generation hypothesis on $\mathcal{A}$.

8.5.8 APPLICATION: THE POSITSIELSKI EQUIVALENCE ON THE CHIRAL BAR-COALGEBRA SURFACE

The chiral comodule-contra-module correspondence applies directly to the bar coalgebra. Its intrinsic output is a coderived/contraderived equivalence for $\bar{B}^{\text{ch}}(\mathcal{A})$ and its contra-modules; only on additional finite-type or genus-0 bar-dual surfaces may one rewrite the target in terms of ordinary modules over an explicit dual algebra.

THEOREM 8.5.23 (*Positselski equivalence for the chiral bar coalgebra;*). For a Koszul chiral algebra $\mathcal{A}$ on a smooth curve X with curved bar complex $C = \bar{B}^{\text{ch}}(\mathcal{A})$ (a conilpotent chiral CDG-coalgebra by Example 8.5.3), there is an equivalence of triangulated categories:

$$D^{\text{co}}(C\text{-comod}^{\text{conil, ch}}) \simeq D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) \quad (8.14)$$

between the coderived category of conilpotent chiral CDG-comodules over the bar coalgebra C and the contraderived category of chiral CDG-contra-modules over the same CDG-coalgebra C .

When C has finite-dimensional graded pieces, the right-hand side may be rewritten as the contraderived category of complete modules over the graded dual algebra $C^* = \text{Hom}_{\mathcal{D}_X}(C, \omega_X)$ (Remark 8.5.7). On the

quadratic genus-0 bar-dual surface where Theorem 10.5.1 applies, C^* identifies with $\mathcal{A}^\dagger$, and one recovers the genus-0 module Koszul duality of Theorem 11.6.2. At genus $g \geq 1$, the coderived/contraderived categories are the correct ambient categories for this bar-coalgebra comparison.

Proof. Apply Theorem 8.5.21 with $C = \bar{B}^{\text{ch}}(\mathcal{A})$.

Conclusion. The hypotheses of Theorem 8.5.21 are satisfied: $\bar{B}^{\text{ch}}(\mathcal{A})$ is conilpotent (Theorem 10.4.3(4)) with finite-dimensional graded pieces (since $\mathcal{A}$ is finitely generated with finite-dimensional conformal weight spaces). The equivalence $D^{\text{co}}(C\text{-comod}^{\text{ch}}) \simeq D^{\text{ctr}}(C\text{-contra}^{\text{ch}})$ of Theorem 8.5.21 therefore yields (8.14).

When the finite-type hypothesis of Remark 8.5.7 applies, chiral CDG-contramodules over C are equivalently complete modules over the graded dual algebra C^* . The further genus-0 identification $C^* \cong \mathcal{A}^\dagger$ uses the quadratic-regime bar-dual theorem (Theorem 10.5.1), so it is recorded only on that bar-dual surface. $\square$

THEOREM 8.5.24 (*Flat finite-type reduction on the completed-dual side;*). Let $C = \bar{B}^{\text{ch}}(\mathcal{A})$ be the chiral bar coalgebra of a Koszul chiral algebra $\mathcal{A}$, and assume we are on a flat finite-type locus where Positselski's comparison theorem identifies the contraderived category of chiral CDG-contramodules over C with the ordinary bounded derived category of complete modules over the graded dual algebra C^* . Then there is a triangulated equivalence

$$D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) \simeq D^b(\text{Mod}^{\text{compl}}(C^*)). \quad (8.15)$$

Consequently, on that same locus, Theorem 8.5.23 reduces to an ordinary derived comparison between the coderived bar-coalgebra side and the bounded derived category of complete C^* -modules. On the quadratic genus-0 bar-dual surface where $C^* \cong \mathcal{A}^\dagger$, this recovers the usual module Koszul duality of Theorem 11.6.2.

Proof. Step 1. By Remark 8.5.7, under the standing finite-type hypothesis, chiral CDG-contramodules over C are equivalent to complete modules over the graded dual algebra C^* .

Step 2. On the additional flat finite-type locus assumed in the statement, Positselski's comparison theorem [350, §4.5, Theorem 4.5.1] identifies the contraderived category of these contramodules with the ordinary bounded derived category of complete C^* -modules. This gives (8.15).

Step 3. Combining (8.15) with Theorem 8.5.23 gives the stated ordinary derived reduction of the intrinsic coderived/contraderived equivalence. On the quadratic genus-0 bar-dual surface, the identification $C^* \cong \mathcal{A}^\dagger$ is supplied by Theorem 10.5.1, recovering Theorem 11.6.2. $\square$

Remark 8.5.25 (*Relation to genus-0 module Koszul duality*). At genus 0, the curvature $h = 0$, so CDG-comodules reduce to DG-comodules, the coderived category reduces to the ordinary derived category, and on the quadratic bar-dual surface the completed-dual algebra $C^* = \bar{B}^{\text{ch}}(\mathcal{A})^*$ identifies with $\mathcal{A}^\dagger$. Theorem 8.5.24 is precisely the flat finite-type reduction that then recovers the ordinary genus-0 module Koszul duality of Theorem 11.6.2. The coderived/contraderived framework generalizes to genus $g \geq 1$, where the curvature $m_0^{(g)} \neq 0$ prevents replacing the exotic categories by ordinary derived categories without extra flatness input.

Remark 8.5.26 (*The role of the configuration space geometry*). The proof of the chiral comodule-contramodule correspondence (Theorem 8.5.21) uses the geometry of configuration spaces in three places:

1. *Exactness of the chiral tensor product.* The tensor-hom adjunction for holonomic $\mathcal{D}_X$ -modules on $\bar{C}_n(X)$ ensures that cofree comodules are injective and free contramodules are projective (Proposition 8.5.16).

2. *Conilpotency from conformal weight.* The conformal weight grading on $\bar{B}^{\text{ch}}(\mathcal{A})$ (inherited from $\mathcal{A}$) ensures conilpotency (Theorem 10.4.3(4)), which is needed for the compact generation argument in Step 5 of the proof.
3. *Finite-dimensionality from holonomicity.* The holonomicity of the bar complex on each configuration space stratum (Lemma 7.0.12) ensures finite-dimensional graded pieces, which is needed for the duality between contramodules and complete modules (Remark 8.5.7).

These geometric inputs are specific to the chiral setting and have no analogue in Positselski's ground-field framework.

8.6 BAR-COBAR INVERSION

The comodule-contramodule correspondence of the preceding section provides the categorical framework in which bar-cobar inversion lives: at genus 0 the coderived category reduces to the ordinary derived category, and the inversion theorem is a quasi-isomorphism in the classical sense; at genus $g \geq 1$ the curvature forces passage to the coderived setting, and the inversion theorem becomes a statement about coderived equivalences. The central result of this chapter is the following.

8.6.1 STATEMENT OF THE MAIN RESULT

THEOREM 8.6.1 (*Bar-cobar inversion: strict on the Koszul locus, coderived off it;*). [Regime: quadratic on the strict lane; curved-central and filtered-complete on the coderived lane (cf. Convention 1.10.2).]

The Heisenberg inversion $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{H}_k)) \xrightarrow{\sim} \mathcal{H}_k$ (§2.6) generalizes to all Koszul chiral algebras.

Let $\mathcal{A}$ be a complete augmented chiral algebra on a Riemann surface X , with $\bar{B}^{\text{ch}}(\mathcal{A})$ conilpotent or $\mathcal{A}$ complete with respect to its augmentation ideal (§8.1.2), and with finite-dimensional graded bar pieces whenever the coderived clause below is invoked. The bar-cobar counit

$$\psi : \Omega(\bar{B}(\mathcal{A})) \longrightarrow \mathcal{A}$$

is the adjunction counit and hence a canonical morphism of chiral algebras. Its strongest proved form is:

1. *Strict Koszul lane.* If $\mathcal{A}$ is Koszul (Definition 3.1.6; equivalently, $\mathcal{A} \in \text{Kosz}(X)$), then the genus-0 counit

$$\psi_0 : \Omega_0(\bar{B}_0(\mathcal{A})) \longrightarrow \mathcal{A}$$

is a quasi-isomorphism of chiral algebras. If, in addition, $\mathcal{A}$ lies on the higher-genus Koszul locus of Theorem 13.18.4 (for the standard landscape, by Theorems 13.21.23–13.21.16), then each genus component

$$\psi_g : \Omega_g(\bar{B}_g(\mathcal{A})) \longrightarrow \mathcal{A}_g$$

and the completed series

$$\psi = \sum_{g=0}^{\infty} \hbar^{2g-2} \psi_g$$

are quasi-isomorphisms.

2. *Coderived off-Koszul lane.* For arbitrary complete augmented $\mathcal{A}$ with finite-dimensional graded bar pieces, the factorization counit

$$\psi_X: \Omega_X \bar{B}_X(\mathcal{A}) \longrightarrow \mathcal{A}$$

is a coacyclic-equivalence: its cone

$$K_\psi := \text{cone}(\Omega_X \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A})$$

is coacyclic. Equivalently, ψ_X is an isomorphism in $D^{\text{co}}(\bar{B}\text{-CoFact})$, without any Koszulness hypothesis.

3. *Coderived bar-degree filtration.* On the curved cone K_ψ , the bar-degree filtration yields the coderived spectral sequence of Proposition ?? . Its E_1 page is computed from the strict associated-graded differential $\text{gr}^0 d$; the curvature relation $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ is absorbed into positive filtration and does not obstruct the E_1 page. On the square-zero Koszul lane this reduces to Theorems 8.6.15 and 8.6.16.
4. *Promotion back to ordinary quasi-isomorphism.* If $\kappa(\mathcal{A}) = 0$, or more generally if the coderived bar-degree spectral sequence degenerates to ordinary cohomology on the relevant off-Koszul locus (the class G/L collapse input), then the coderived equivalence of (2) upgrades to a chain-level quasi-isomorphism. Outside those collapse loci this theorem does not assert an ordinary quasi-isomorphism.

Scope. The Koszul hypothesis is essential: for simple admissible affine quotients and minimal-model Virasoro/W-algebras the PBW/Shapovalov argument is unavailable, the square-zero bar spectral sequence can carry extra higher-differential data, and this chapter does *not* claim that the counit ψ is a quasi-isomorphism there (see Remark G.12.4 and 15.6.22). In those regimes one must work with the completed correspondence of Corollary 7.0.37 and the intrinsic coderived/contraderived bar-coalgebra comparison of Theorems 8.5.23 and 8.5.24; this theorem asserts the coderived statement of (2), and isolates in (4) the extra input needed to recover an ordinary quasi-isomorphism there.

Dependency-closed proof. We verify each numbered clause by previously established results in this chapter and in the coderived appendix.

- (D1) *Strict Koszul lane.* The genus-0 quasi-isomorphism is proved independently by Theorem 6.1.21 and Theorem 11.3.7; equivalently, it is the implication (i) $\Rightarrow$ (ii) of the fundamental theorem of chiral twisting morphisms (Theorem 11.1.9). Under the higher-genus hypotheses of Theorem 13.18.4, the genus- g components ψ_g for $g \geq 1$ are quasi-isomorphisms by induction on genus, and Theorem 8.6.18 supplies the completed series statement.
- (D2) *Coderived off-Koszul lane.* Theorem ?? proves that the factorization counit ψ_X is an isomorphism in the coderived category for every complete augmented input with finite-dimensional graded bar pieces. Its proof is independent of Theorem 13.18.4: it identifies the cone of ψ_X as coacyclic by stratified Positselski inversion and the Verdier-quotient criterion for $D^{\text{co}}(\bar{B}\text{-CoFact})$.
- (D3) *Coderived bar-degree filtration.* On the strict square-zero surface, existence and collapse are exactly Theorems 8.6.15 and 8.6.16. On the curved surface, Proposition ?? replaces ordinary abutment by coacyclicity of the cone: the associated-graded E_1 page is strict because the curvature term lies in positive filtration.

(D4) *Promotion lane.* If $\kappa(\mathcal{A}) = 0$, then the curved differential becomes square-zero, so Theorem ?? identifies the coderived and ordinary derived categories and the coderived equivalence of (D2) is an ordinary quasi-isomorphism. More generally, any class G/L collapse input for the coderived bar-degree spectral sequence turns coacyclicity of the cone into acyclicity, hence into an ordinary quasi-isomorphism. This is the exact extra hypothesis isolated in clause (4).

Combining (D1)–(D4) gives the strongest proved package stated in the theorem. $\square$

Example 8.6.2 (Admissible-level failure of bar-cobar inversion). Consider $L_{-1/2}(\mathfrak{sl}_2)$, the simple affine vertex algebra at the admissible level $k = -1/2$ for $\widehat{\mathfrak{sl}}_2$ (here $h^\vee = 2$, so $k + h^\vee = 3/2$; the admissible parametrization is $k = -h^\vee + p/q$ with $p = 3, q = 2$). This algebra is excluded from the Koszul locus of Theorem 8.6.1; the concrete mechanism by which bar-cobar inversion fails is the following.

Singular vector in the bar-relevant range. The vacuum Verma module $M(k\Lambda_0)$ at $k = -1/2$ has a singular vector at conformal weight $(p-1)q = 2 \cdot 2 = 4$, produced by the Kac–Kazhdan root $\beta_{q,-} = q\delta - \alpha$ at KK value $j = p - 1 = 2$ (Kac–Wakimoto [241]; cf. Remark G.12.4). Since the strong generators J^+, J^0, J^- of $\widehat{\mathfrak{sl}}_2$ all have conformal weight 1, the bar-relevant range begins at conformal weight 2 (bar degree ≥ 2), so this singular vector at weight 4 lies squarely in the bar-relevant range.

Effect on the bar complex. Passing to the simple quotient $L_{-1/2}(\mathfrak{sl}_2)$ kills this singular vector, introducing an extra relation not present at generic level. In the bar complex $\bar{B}^{\text{ch}}(L_{-1/2}(\mathfrak{sl}_2))$, this relation produces bar cohomology off the Koszul diagonal: at generic level k , the Koszul property concentrates $H^n(\bar{B}^{\text{ch}}(V_k(\mathfrak{sl}_2)))$ in internal degree n (the “Koszul diagonal”), whereas at $k = -1/2$ the null vector at weight 4 generates an off-diagonal class that persists in $H^\bullet(\bar{B}^{\text{ch}})$.

Spectral sequence non-collapse. The square-zero bar-cobar spectral sequence of Theorems 8.6.15 and 8.6.16 relies on Koszul-diagonal concentration for its E_2 collapse. The off-diagonal class at weight 4 supports a non-trivial higher differential, so the spectral sequence does not collapse at E_2 . The counit $\psi: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(L_{-1/2}(\mathfrak{sl}_2))) \rightarrow L_{-1/2}(\mathfrak{sl}_2)$ fails to be a quasi-isomorphism: the surviving off-diagonal class generates a non-trivial extension in $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(L_{-1/2}(\mathfrak{sl}_2)))$ that has no preimage in $L_{-1/2}(\mathfrak{sl}_2)$.

Consistency with the Koszul-locus hypothesis. At generic level, the vacuum Verma module $M(k\Lambda_0)$ has no singular vectors in the bar-relevant range, $H^\bullet(\bar{B}^{\text{ch}}(V_k(\mathfrak{sl}_2)))$ is concentrated on the Koszul diagonal, and Theorem 8.6.1 applies. The admissible level $k = -1/2$ lies outside the Koszul locus because the representation category $\text{KL}_{-1/2}(\mathfrak{sl}_2)$ (Arakawa [18, 17]) is a non-semisimple finite tensor category whose singular vectors obstruct the diagonal concentration. For the critical-level analogue $k = -h^\vee = -2$, the Feigin–Frenkel center [160] causes an even more dramatic failure: the center of $V_{-2}(\mathfrak{sl}_2)$ jumps in dimension and the bar complex acquires infinitely many off-diagonal classes.

Conjecture 8.6.3 (2-Koszulness at admissible level;). The preceding example shows that $L_{-1/2}(\mathfrak{sl}_2)$ fails classical Koszulness: bar cohomology $H^*(\bar{B}^{\text{ch}}(L_{-1/2}(\mathfrak{sl}_2)))$ is not concentrated in degree 1. The off-diagonal class produced by the singular vector at conformal weight 4 lives in bar degree 2. A stronger expectation is that the bar cohomology is concentrated in degrees $\{1, 2\}$, making $L_{-1/2}(\mathfrak{sl}_2)$ a 2-Koszul (or N -Koszul with $N = 2$) chiral algebra in the sense of Berger [491]: the square-zero bar-cobar spectral sequence (Theorems 8.6.15 and 8.6.16) collapses at a finite page E_N rather than at E_2 .

This is consistent with the representation-theoretic structure. The category $\text{KL}_{-1/2}(\mathfrak{sl}_2)$ has exactly two simple objects (vacuum and one non-vacuum admissible module), and the extension algebra between them is generated in degrees 1 and 2 with relations in degree 3; the N -Koszul pattern $H^n(\bar{B}^{\text{ch}}) = 0$ for $n \geq 3$ would then follow from the absence of higher singular vectors in the bar-relevant range beyond the weight-4 vector identified above. If confirmed, this places admissible-level algebras in a hierarchy: classical

Koszul (generic level, E_2 collapse) $\subset$ N -Koszul (admissible level, E_N collapse) $\subset$ non-Koszul (critical level, no finite collapse).

Remark 8.6.4 (Alternative proof via formality). The strict Koszul lane of Theorem 8.6.1 admits a second proof that bypasses Theorems 8.6.15 and 8.6.16. The point is to replace the spectral-sequence argument by the deformation problem controlled by the bar coalgebra. Write

$$\psi : \Omega(\overline{B}(\mathcal{A})) \longrightarrow \mathcal{A}$$

for the counit. After passing to the PBW-associated graded quadratic model, one is working in the formal neighborhood governed by the quadratic closure

$$\mathcal{A}^i = H^*(\overline{B}(\mathcal{A})),$$

and the homotopy transfer theorem (Theorem 9.2.1) supplies maps

$$\mathcal{A} \begin{matrix} \xrightarrow{i} \\ \xleftarrow{\psi} \end{matrix} \Omega(\overline{B}(\mathcal{A}))$$

with $\psi i = \text{id}$ and $i\psi \sim \text{id}$ on the tangent complex of the bar-cobar deformation problem. In Keller's deformation-theoretic language, this identifies the formal moduli problem of $\Omega(\overline{B}(\mathcal{A}))$ with the one controlled by the transferred A_∞ -structure on $\mathcal{A}^i$; on the Koszul locus, PBW concentration says that this tangent complex is already governed by the quadratic closure.

The remaining step is formality of the transferred A_∞ -structure on $\mathcal{A}^i$. The E_2 -formality map realized by Kontsevich-type configuration-space integrals on Fulton–MacPherson models (Proposition A.6.10), and the fiberwise identification of transferred higher operations with the corresponding FM-stratum operations (Proposition 13.22.107), identify the higher m_n with the FM formality obstructions. Theorem 11.1.28 then says that on the Koszul locus these obstructions vanish, so the transferred A_∞ -structure on $\mathcal{A}^i$ is formal. Keller's classicality theorem for formal A_∞ -algebras [259] upgrades the tangent-level retract to an A_∞ quasi-isomorphism. Applying Ω gives

$$\Omega(\overline{B}(\mathcal{A})) \simeq \Omega(\mathcal{A}^i) \xrightarrow{\sim} \mathcal{A},$$

where the last quasi-isomorphism is the twisting-morphism/Koszul-duality identification of Theorem 11.1.9 (equivalently, Theorem 11.3.7 on the quadratic lane). This recovers clause (1).

Off the Koszul locus the same deformation-retract package survives after passing to filtered curved models. The transfer data respects the bar-degree filtration, and the curvature term lies in positive filtration, so the associated graded retract is strict. Proposition ?? then identifies the cone of the factorization counit as coacyclic, and Theorem ?? recovers the coderived statement of clause (2). This does not remove the extra hypothesis in clause (4): promotion from coderived equivalence to an ordinary quasi-isomorphism still requires the same collapse input, or the flat case $\kappa(\mathcal{A}) = 0$.

Remark 8.6.5 (Research remark: the Koszul locus and the off-locus obstruction). The phrase “Koszul locus” in Theorem 8.6.1 has two layers that should be kept separate: the genus-0 Koszul condition of Definition 3.1.7, and the higher-genus coderived continuation of the same bar-cobar comparison. The research picture is therefore:

- (1) *Precise genus-0 locus.* The Koszul locus is the full subcategory $\text{Kosz}(X)$ of augmented chiral algebras for which the counit

$$\Omega_X(\overline{B}_X(\mathcal{A})) \longrightarrow \mathcal{A}$$

is a quasi-isomorphism at genus 0 (Definition 3.1.7, Remark 3.1.9). Equivalently, the PBW/bar spectral sequence collapses at E_2 ; and equivalently, $H^*(\bar{B}_X(\mathcal{A}))$ is concentrated on the Koszul diagonal (bar degree equal to internal degree, or after the reindexing of Theorem 8.6.15, concentrated in bar degree 1). For a quadratic A_∞ model this is exactly the classical Priddy/BGS criterion: bar cohomology concentrated in degree 1.

- (2) *Off-locus obstruction.* The first obstruction is the first bar class off the Koszul diagonal. Once $H^*(\bar{B}_X(\mathcal{A}))$ contains a class in bidegree (p, q) with $q \neq 0$ after the standard reindexing, diagonal concentration is lost, the square-zero E_2 -collapse proof breaks, and the genus-0 counit need not be a quasi-isomorphism. After homotopy transfer, the same obstruction appears as the first non-vanishing higher multiplication m_r on $\mathcal{A}^i = H^*(\bar{B}_X(\mathcal{A}))$ with $r \geq 3$. This is distinct from the higher-genus curvature $m_0^{(g)} = \kappa(\mathcal{A})\omega_g$: curvature forces coderived methods even on the Koszul locus, while the off-diagonal bar class is what removes strict genus-0 inversion.
- (3) *How far the quasi-isomorphism extends.* Off the locus, the strongest unconditional statement is already clause (2) of Theorem 8.6.1: for every complete augmented input with finite-dimensional graded bar pieces, the cone of the factorization counit is coacyclic, hence the counit is an isomorphism in the coderived category. The natural enlargement of $\text{Kosz}(X)$ is therefore a *conjectural derived Koszul locus*: the full derived substack on which this coacyclic cone is still detected by ordinary cohomology. Conjecture 8.6.6 formulates that derived wall. The proved promotion surface is narrower: clause (4) upgrades the coderived equivalence only on collapse loci where the coderived bar-degree filtration degenerates to ordinary cohomology. No specific non-Koszul family is presently proved by a separate family-level argument to satisfy that promotion hypothesis. The live theorem is the abstract collapse criterion of clause (4). In particular, this does *not* remove the genus-0 Koszul hypothesis of Definition 3.1.7; it only says that after one passes to the curved or completed factorization surface, some off-locus families may still lie on the derived side of the wall.
- (4) *Which families are expected to leave the locus.* On the live proved surface, the restrictive boundary is not the universal or freely strongly generated landscape but its singular quotient boundary. Heisenberg, universal affine $V_k(\mathfrak{g})$, generic Virasoro, and the principal $\mathcal{W}$ -families enter through PBW-flat models and are treated as on-locus. The genuine off-locus candidates are quotient algebras with null-vector ideals in the bar-relevant range: simple admissible affine quotients, minimal-model Virasoro and $\mathcal{W}$ -quotients, critical-level enlargements with extra center, and other non-flat PBW degenerations. For such families the coderived comparison remains available; what is missing is ordinary cohomological detectability of the coacyclic cone. The admissible $\widehat{\mathfrak{sl}}_2$ example of Conjecture 8.6.3 is the model case: proving its conjectural 2-Koszul behavior would move it closer to the derived wall, but by itself would not yet supply the promotion required in clause (4).

Conjecture 8.6.6 (Derived Koszul wall;). Let $\text{ChAlg}^{\text{aug}}$ be the derived moduli stack of augmented chiral algebras, and let

$$\text{Kos} := \left\{ \mathcal{A} \in \text{ChAlg}^{\text{aug}} \mid \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A} \right\}$$

be the bar-cobar inversion locus of Theorem 8.6.1. Then:

- (i) (Derived openness) Kos is an open derived substack of $\text{ChAlg}^{\text{aug}}$. Equivalently, for every $[\mathcal{A}] \in \text{Kos}$, the formal completion $\widehat{\text{ChAlg}^{\text{aug}}}_{[\mathcal{A}]}$ is contained in Kos , so every derived square-zero deformation of $\mathcal{A}$ still satisfies bar-cobar inversion.

- (ii) (PBW wall stratification) The complement $\text{ChAlg}^{\text{aug}} \setminus \text{Kos}$ is a divisor-like wall, but it is not in general of pure codimension 1. It carries a canonical stratification by the first failure of PBW concentration: a point lies in the stratum $\mathfrak{B}_{r,w}$ when the bar spectral sequence first acquires off-diagonal bar cohomology, equivalently the first nonzero higher differential obstructing E_2 -collapse, on page r and conformal weight w .
- (iii) (Admissible boundary) The first affine-admissible boundary model is the $\widehat{\mathfrak{sl}}_2$ family at level $k = -1/2$. In the passage from the universal algebra $V_{-1/2}(\mathfrak{sl}_2)$ to its admissible quotient, the associated variety in the sense of Arakawa is expected to jump from the full nilpotent cone to the closure of a proper orbit; at that same boundary one expects new off-diagonal bar classes and the failure of PBW concentration. Compare Arakawa's admissible and associated-variety package [15, 13, 16, 17].
- (iv) (Singular-support control) More generally, if $X_{\mathcal{A}}$ denotes the associated variety of $\mathcal{A}$, then the Koszul wall is controlled by the singular-support condition on $X_{\mathcal{A}}$: the wall is cut out by the failure of the singular support to remain the reduced conormal lift of $X_{\mathcal{A}}$, and its strata are indexed by the excess microlocal components that appear above the singular locus.

Remark 8.6.7 (Relation to the fundamental theorem A_0). At genus 0, Theorem 8.6.1 is a consequence of the fundamental theorem of chiral twisting morphisms (Theorem 11.1.9): the counit $\Omega_X(\bar{B}_X(\mathcal{A})) \rightarrow \mathcal{A}$ being a quasi-isomorphism is one of the four equivalent characterizations of Koszulity established there. The present theorem extends this to all genera via the genus induction of clause (D2).

Remark 8.6.8 (Non-circularity: twisted-tensor cone as primitive anchor). A reader tracking the proof chain might worry that Theorem 8.6.1 is invoked to verify clause (v) of the Koszul-equivalences meta-theorem (Theorem 11.1.50), while Definition 3.1.6 was initially phrased in bar-cobar terms; this would create an apparent circularity. The circularity is only apparent. The canonical anchor is the twisted-product cone identification Lemma 11.1.5, which computes $K_{\tau}^L \simeq \text{Cone}(\varepsilon_{\tau})[-1]$ by a direct chain-level decomposition of $d_{\mathcal{A}} + d_C + d_{\tau}^L$ (transport of Loday–Vallette [299] §2.2.5); this lemma cites no bar-cobar theorem and no Koszul equivalence. The implication (ii) $\Rightarrow$ (v) routes through this cone identification, not through the present inversion theorem: the twisting-morphism condition $d_{\tau} = m_2 \circ (\text{id} \otimes \tau) \circ \Delta$ forces acyclicity of K_{τ}^L via Lemma 11.1.5, and acyclicity of the cone is equivalent to the counit ε_{τ} being a quasi-isomorphism. Theorem 8.6.1 is therefore a *consequence* of the twisted-tensor anchor, not an input to the definition it appears to verify.

Remark 8.6.9 (Higher-genus conditionality on MK_3). At genus 0, Theorem 8.6.1 is unconditional: it follows from genus-0 Koszulity (axiom (MK1)) alone, via the fundamental theorem of chiral twisting morphisms (Theorem 11.1.9). At genus $g \geq 1$, the proof of clause (2) invokes axiom (MK3) (modular Koszulity: PBW degeneration at genus g , equivalently diagonal Ext vanishing; Definition 13.21.9), which is verified for Heisenberg, affine Kac–Moody at non-critical level, Virasoro, and principal $\mathcal{W}$ -algebras (Theorems 13.21.23–13.21.16). For an arbitrary Koszul chiral algebra not on this list, higher-genus inversion is *conditional* on (MK3). The genus-0 statement and the spectral-sequence collapse (clause (4)) remain unconditional.

Remark 8.6.10 (Homotopy level of bar-cobar inversion). The quasi-isomorphism $\Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ lifts to an L_{∞} -quasi-isomorphism at the homotopy level, by functoriality of bar-cobar through the L_{∞} -convolution Conv_{∞} (Theorem 3.1.24). In particular, bar-cobar inversion preserves the full quantum L_{∞} structure, not merely the dg Lie shadow.

Remark 8.6.11 (Quasi-isomorphism of chain complexes vs chiral algebras). The distinction is between two levels of structure:

Chain complex quasi-isomorphism. A chain map $\psi : C^\bullet \rightarrow D^\bullet$ inducing an isomorphism $H^\bullet(\psi) : H^\bullet(C) \xrightarrow{\cong} H^\bullet(D)$ on cohomology. This is the standard notion; a “homology isomorphism” and a “quasi-isomorphism” are the *same thing* at the chain complex level.

Chiral algebra quasi-isomorphism. An A_∞ (or chiral algebra) morphism $\psi : \mathcal{A} \rightarrow \mathcal{B}$ whose linear component $\psi_1 : \mathcal{A} \rightarrow \mathcal{B}$ is a chain complex quasi-isomorphism. Such a map preserves the full A_∞ structure up to coherent homotopy. The distinction matters: A chain complex quasi-isomorphism tells us only about $H^\bullet$ and need not respect multiplicative or A_∞ structure, whereas a chiral algebra quasi-isomorphism gives a full equivalence in the derived category of chiral algebras, preserving all homotopy-theoretic information. For bar-cobar inversion to establish derived equivalences, the map $\Omega(B(\mathcal{A})) \rightarrow \mathcal{A}$ must be a quasi-isomorphism of *chiral algebras*, not of chain complexes alone.

Example. Consider a dga $(C^\bullet, d, \mu)$ with:

$$\cdots \rightarrow 0 \rightarrow \mathbb{C} \xrightarrow{0} \mathbb{C} \rightarrow 0 \rightarrow \cdots$$

This has $H^0 = \mathbb{C}$, $H^i = 0$ for $i \neq 0$.

Compare with the algebra $(D^\bullet, 0, \nu) = (\mathbb{C}, 0, 0)$ in degree 0. The projection $\pi : C^\bullet \rightarrow D^\bullet$ is a quasi-isomorphism of chain complexes (both have $H^0 = \mathbb{C}$), but π does *not* respect the multiplication (π need not intertwine μ and ν at the chain level). To obtain a quasi-isomorphism of *algebras*, one must work with A_∞ morphisms, which encode the higher homotopies relating the two multiplicative structures.

Conjecture 8.6.12 (Derived Morita equivalence and the Koszul conductor). Theorem 8.6.1 converts the bar coalgebra into a complete derived invariant: two Koszul chiral algebras $\mathcal{A}, \mathcal{B}$ are derived Morita equivalent (quasi-isomorphic as objects of the bar-cobar localization) if and only if their bar coalgebras $\bar{B}^{\text{ch}}(\mathcal{A})$ and $\bar{B}^{\text{ch}}(\mathcal{B})$ are quasi-isomorphic as dg coalgebras. The Koszul conductor $K(\mathcal{A}) = \kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger)$ (§.2) controls the rigidity of this identification.

When $K = 0$ (affine Kac–Moody at non-critical level, Heisenberg, free fields), the complementarity $\kappa(\mathcal{A}^\dagger) = -\kappa(\mathcal{A})$ permits non-trivial bar-coalgebra identifications $\bar{B}^{\text{ch}}(\mathcal{A}) \simeq \bar{B}^{\text{ch}}(\mathcal{B})$ with $\mathcal{A} \neq \mathcal{B}$ as chiral algebras; level-rank duality provides the prototype. When $K \neq 0$ (Virasoro with $K = 13$, Bershadsky–Polyakov with $K = 196$), a quasi-isomorphism of bar coalgebras forces $\kappa(\mathcal{A}) = \kappa(\mathcal{B})$ and $\kappa(\mathcal{A}^\dagger) = \kappa(\mathcal{B}^\dagger)$ simultaneously, since K is an invariant of the bar coalgebra. The non-vanishing conductor therefore provides a numerical obstruction to derived Morita equivalence that has no counterpart in the $K = 0$ families.

8.6.2 PROOF STRATEGY AND FILTRATION

Definition 8.6.13 (Bar-cobar filtration). Define a decreasing filtration on $\Omega(\bar{B}(\mathcal{A}))$ by:

$$F^p \Omega(\bar{B}(\mathcal{A})) = \bigoplus_{n \geq p} \Omega^n(\bar{B}^n(\mathcal{A}))$$

This is the filtration by *bar degree* (= cobar degree).

Geometric meaning. F^p consists of elements involving at least p points in configuration space. As $p \rightarrow \infty$, we are considering increasingly complicated configurations.

Properties.

1. $F^0 \supseteq F^1 \supseteq F^2 \supseteq \cdots$
2. $\bigcap_{p=0}^\infty F^p = 0$ (completeness)

3. The differential respects filtration: $d(F^p) \subseteq F^p$
4. The natural map factors through the filtration

LEMMA 8.6.14 (*Associated graded;*). The associated graded of the bar-cobar filtration is:

$$\mathrm{Gr}^p \Omega(\bar{B}(\mathcal{A})) = \Omega^p(\bar{B}^p(\mathcal{A}))$$

The induced differential on $\mathrm{Gr}^\bullet$ is the *bar complex differential* $d_{\bar{B}} = d_{\text{internal}} + d_{\text{bar}}$ (i.e., the full differential on $\bar{B}(\mathcal{A})$, lifted to each cobar tensor factor).

Proof. By definition of associated graded:

$$\mathrm{Gr}^p = F^p / F^{p+1} = \Omega^p(\bar{B}^p(\mathcal{A}))$$

The full differential on $\Omega(\bar{B}(\mathcal{A}))$ decomposes as $d = d_{\bar{B}} + d_{\text{cobar}}$, where $d_{\bar{B}} = d_{\text{internal}} + d_{\text{bar}}$ is the lift of the bar complex differential to each cobar tensor factor and preserves cobar degree p . The comultiplication term d_{cobar} raises cobar degree by 1, so it sends F^p into F^{p+1} and vanishes on $F^p / F^{p+1} = \mathrm{Gr}^p$. Therefore the induced differential on the associated graded is exactly $d_{\bar{B}}$, which is the d_0 differential of the spectral sequence. $\square$

8.6.3 SPECTRAL SEQUENCE CONSTRUCTION

THEOREM 8.6.15 (*Bar-cobar spectral sequence;*). [Regime: square-zero total differential on the filtered bar-cobar complex.] Assume the total differential on $\Omega(\bar{B}(\mathcal{A}))$ satisfies $d^2 = 0$ and preserves the filtration from Definition 8.6.13. Then the filtration from Definition 8.6.13 induces a spectral sequence:

$$E_0^{p,q} = \left(F^p / F^{p+1} \right)^{p+q} \implies H^{p+q}(\Omega(\bar{B}(\mathcal{A})))$$

converging to the cohomology of $\Omega(\bar{B}(\mathcal{A}))$. Here p is the filtration degree (cobar degree) and q is the complementary degree (from the internal and bar gradings), so the total degree is $p + q$.

Explicit description of pages.

$$\begin{aligned} E_0^{p,q} &= \left(F^p \Omega^{p+q}(\bar{B}(\mathcal{A})) / F^{p+1} \Omega^{p+q}(\bar{B}(\mathcal{A})) \right) \quad (\text{associated graded}) \\ E_1^{p,q} &= H^{p+q}(E_0^{p,\bullet}, d_{\bar{B}}) \quad (\text{bar cohomology at fixed cobar degree } p) \\ E_2^{p,q} &= H^p(E_1^{\bullet,q}, d_{\text{cobar}}) \quad (\text{cohomology w.r.t. comultiplication-induced differential}) \\ E_\infty^{p,q} &= \mathrm{Gr}^p H^{p+q}(\Omega(\bar{B}(\mathcal{A}))) \quad (\text{limiting page}) \end{aligned}$$

Proof. This is a standard spectral sequence associated to a filtered complex (Weibel [395], Chapter 5). We verify the key properties:

Step 1: E_0 page. This is just the raw complex with its bigrading:

$$E_0^{p,q} = F^p \Omega^{p+q}(\bar{B}(\mathcal{A})) / F^{p+1} \Omega^{p+q}(\bar{B}(\mathcal{A}))$$

By definition of the filtration, this isolates the piece in cobar degree p and total degree $p + q$.

Step 2: d_0 differential. On the E_0 page:

$$d_0 : E_0^{p,q} \rightarrow E_0^{p,q+1}$$

is the bar complex differential $d_{\bar{B}} = d_{\text{internal}} + d_{\text{bar}}$, lifted to each cobar tensor factor. This is the filtration-preserving component of d : both d_{internal} (from the differential on $\mathcal{A}$) and d_{bar} (from the multiplication of $\mathcal{A}$, encoding collisions) preserve cobar degree.

Taking cohomology gives the E_1 page: bar cohomology at each fixed cobar degree.

Step 3: d_1 differential. On the E_1 page:

$$d_1 : E_1^{p,q} \rightarrow E_1^{p+1,q}$$

is induced by d_{cobar} (the comultiplication on $\bar{B}(\mathcal{A})$, which increases cobar degree by 1).

Taking cohomology gives the E_2 page.

Step 4: Higher differentials. For $r \geq 2$:

$$d_r : E_r^{p,q} \rightarrow E_r^{p+r,q-r+1}$$

These differentials encode higher-order interactions between bar and cobar operations.

Step 5: Convergence. The spectral sequence converges because: For the application to Theorem 8.6.1, the completeness statement in Definition 8.6.13(2) is supplied by its conilpotency/completion hypothesis: if $\bar{B}(\mathcal{A})$ is conilpotent in the sense of Definition 8.1.17, every element has finite bar degree, while in the augmentation-ideal completion regime the filtration is complete by construction.

1. The filtration is complete: $\bigcap_p F^p = 0$
2. The filtration is exhaustive: $\bigcup_p F^p = \Omega(\bar{B}(\mathcal{A}))$
3. The complex is bounded in each column (fixed p)

By standard spectral sequence theory (Weibel [395], Chapter 5), this ensures:

$$E_{\infty}^{p,q} = \text{Gr}^p H^{p+q}(\Omega(\bar{B}(\mathcal{A})))$$

□

THEOREM 8.6.16 (*Collapse at E_2 ;*). [Regime: quadratic, Koszul locus, square-zero total differential (Convention 1.10.2).]

For the Heisenberg algebra, the spectral sequence collapsed trivially because $d_{\text{bracket}} = 0$ (no simple poles): the bar cohomology was concentrated in degrees 0 and 2 without further work (§2.3). For non-abelian algebras, the collapse is a consequence of the Koszul property.

For a Koszul chiral algebra $\mathcal{A}$ (Remark 7.3.1) on the strict square-zero surface of Theorem 8.6.15, the spectral sequence from Theorem 8.6.15 collapses at the E_2 page:

$$E_2^{p,q} = E_{\infty}^{p,q}.$$

Proof. The Koszul property gives a quasi-isomorphism $\iota : \mathcal{A}^! \hookrightarrow \bar{B}(\mathcal{A})$ from the quadratic dual into the bar complex [299, Theorem 3.4.1]; Chapter 11 gives the chiral version used here. Because $\mathcal{A}^!$ is generated in weight 1 with quadratic relations, the bar cohomology is concentrated on the diagonal in the bigrading by cobar degree and internal degree. Thus on the E_1 page, where the differential is $d_0 = d_{\bar{B}}$, one has $E_1^{p,q} = 0$ for $q \neq 0$. The d_1 differential comes from d_{cobar} , so the same diagonal concentration persists to E_2 . For $r \geq 2$, the differential $d_r : E_r^{p,q} \rightarrow E_r^{p+r,q-r+1}$ changes the second grading, so with $E_2^{p,q}$ supported only at $q = 0$, either its source or its target vanishes. Hence every d_r for $r \geq 2$ is zero, and the spectral sequence collapses at E_2 . □

Remark 8.6.17 (Square-zero boundary of the spectral-sequence proof). Theorems 8.6.15 and 8.6.16 are statements about filtered complexes with square-zero total differential. In this chapter they apply to the strict genus-0 bar-cobar complex, and to any completed/corrected model whose total differential squares to zero. They do *not* apply to the curved fiberwise higher-genus differential d_{fib} with $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$. Off the Koszul locus, the proved replacement is the coderived bar-degree filtration of Proposition ??, together with the intrinsic coderived/contraderived bar-coalgebra comparison of Theorem 8.5.23. Ordinary derived reduction remains available only on the flat finite-type completed-dual loci of Theorem 8.5.24 or when the curvature collapses.

8.6.4 CONVERGENCE AT ALL GENERA

THEOREM 8.6.18 (*Genus-graded convergence;*). [Regime: curved-central on the Koszul locus (Convention 1.10.2).]

Let $\mathcal{A}$ be a Koszul chiral algebra satisfying the strict Koszul-lane hypotheses of Theorem 8.6.1. The bar-cobar inversion $\psi : \Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$ converges at each genus g , and the full genus-graded sum converges in the $\hbar$ -adic completion.

More precisely:

1. *Genus zero:*

$$\psi_0 : \Omega_0(\bar{B}_0(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$$

is a quasi-isomorphism (classical result, BD §3.7)

2. *Fixed genus g :*

$$\psi_g : \Omega_g(\bar{B}_g(\mathcal{A})) \rightarrow \mathcal{A}_g$$

is a quasi-isomorphism after appropriate quantum corrections (here $\mathcal{A}_g$ denotes the genus- g component of the genus-graded chiral algebra)

3. *Genus series:*

$$\psi = \sum_{g=0}^{\infty} \hbar^{2g-2} \psi_g$$

converges in the $\hbar$ -adic completion for $|\hbar| < R$ (radius determined by growth of moduli spaces)

Proof. We prove each case separately.

Case 1: Genus zero on $\mathbb{P}^1$.

At genus zero, the chiral bar complex lives on configuration spaces of the rational curve:

$$\bar{B}_0^n(\mathcal{A}) = \Gamma\left(\bar{C}_n(\mathbb{P}^1), \mathcal{A}^{\boxtimes n} \otimes \Omega^\bullet\right)$$

This is *not* the classical bar complex over a point: the Fulton–MacPherson compactifications $\bar{C}_n(\mathbb{P}^1)$, the logarithmic propagator $\eta_{ij} = d \log(z_i - z_j)$, and the Arnold relations in the cohomology of configuration spaces are all genuinely present and have no classical analogue. The classical bar over a point embeds via formal-disk restriction followed by homotopy transfer, but this comparison requires specifying the retraction $\mathbb{A}^1 \rightarrow \text{pt}$ and its attendant chain homotopy (see the discussion following Definition 11.1.15).

Beilinson–Drinfeld proved [40] Theorem 3.7.11:

$$\Omega_0(\bar{B}_0(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$$

Their proof uses the Chevalley–Cousin resolution, the Ran space formalism on $\mathbb{P}^1$, and descent from the FM compactifications of configuration spaces; it is inherently a statement about the curve $\mathbb{P}^1$, not about a point.

We have verified (Theorem 13.16.6) that all technical conditions hold at genus zero.

Case 2: Fixed genus $g \geq 1$.

The genus- g quasi-isomorphism ψ_g is proved as Theorem 13.18.4 by induction on g . The proof proceeds in three steps, none of which invoke bar-cobar inversion at genus g as input:

1. *Open stratum.* On the locus $U_g \subset \overline{\mathcal{M}}_g$ of smooth curves, the fiberwise bar-cobar counit on each fixed curve X_s is a quasi-isomorphism by axiom (MK₃) (PBW concentration at genus g , verified independently by Theorems 13.21.23–13.21.16) and the fundamental theorem of chiral twisting morphisms (Theorem 11.1.9). See Lemma 13.18.1.
2. *Boundary strata.* Each boundary stratum $D_\Gamma \subset \partial \overline{\mathcal{M}}_g$ decomposes via nodal gluing into lower-genus pieces. The induction hypothesis gives a quasi-isomorphism on each vertex, and Künneth at nodes assembles the global statement (Lemma 13.18.2).
3. *Extension.* The open-stratum and boundary quasi-isomorphisms together cover the normal-crossing stratification of $\overline{\mathcal{M}}_g$. A Mayer–Vietoris argument extends to a global quasi-isomorphism (Lemma 13.18.3).

The logical chain is non-circular: the antecedent hypotheses (MK₁)–(MK₃) of Definition 13.21.9 are verified independently of bar-cobar inversion, and Theorem 13.18.4 derives inversion as a consequence.

LEMMA 8.6.19 (*Proper pushforward preserves quasi-isomorphisms*). Let $f: Y \rightarrow S$ be a proper morphism of finite type and $\phi: \mathcal{F} \rightarrow \mathcal{G}$ a quasi-isomorphism of bounded-below complexes of coherent sheaves on Y . Then $Rf_*(\phi): Rf_*\mathcal{F} \xrightarrow{\sim} Rf_*\mathcal{G}$ is a quasi-isomorphism.

Proof. This is proper base change for the derived pushforward (see e.g. [304, Proposition 3.4.4]). □

Case 3: Genus series convergence.

Consider the formal series:

$$\psi(\hbar) = \sum_{g=0}^{\infty} \hbar^{2g-2} \psi_g$$

Growth estimate. By Mirzakhani’s results [318], Weil–Petersson volumes satisfy

$$\text{Vol}(\overline{\mathcal{M}}_g) \sim (2g)!$$

with factorial growth. Consequently the formal genus series has zero radius of analytic convergence, consistent with the non-Borel-summability of the perturbative string expansion.

$\hbar$ -adic completion. For rigorous formal computations, work in:

$$\widehat{\Omega}(\bar{B}(\mathcal{A}))_{\hbar} = \varprojlim_n \Omega(\bar{B}(\mathcal{A}))/\hbar^n$$

In this completion, the series converges unconditionally. □

8.6.5 THE COUNIT OF THE ADJUNCTION

PROPOSITION 8.6.20 (*Counit is quasi-isomorphism*;). The counit of the bar-cobar adjunction:

$$\epsilon : \bar{B}(\Omega(C)) \longrightarrow C$$

for a chiral coalgebra C is also a quasi-isomorphism (dual statement).

Proof. Verdier duality identifies the counit $\epsilon_C : \bar{B}^{\text{ch}}(\Omega^{\text{ch}}(C)) \rightarrow C$ with the dual of the unit map on the dual algebra side (Theorem 7.0.36). The unit is a quasi-isomorphism by Theorem 7.0.51. The same Verdier-duality theorem shows that duality on the relevant Fulton–MacPherson complexes preserves quasi-isomorphisms. Applying Verdier duality to the unit therefore yields that the counit is also a quasi-isomorphism. $\square$

8.6.6 FUNCTORIALITY OF THE QUASI-ISOMORPHISM

THEOREM 8.6.21 (*Functoriality of bar-cobar inversion*;). The quasi-isomorphism $\psi : \Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ is *functorial*: for any morphism $f : \mathcal{A} \rightarrow \mathcal{A}'$ of chiral algebras, the diagram commutes:

$$\begin{array}{ccc} \Omega(\bar{B}(\mathcal{A})) & \xrightarrow{\psi} & \mathcal{A} \\ \downarrow \Omega(\bar{B}(f)) & & \downarrow f \\ \Omega(\bar{B}(\mathcal{A}')) & \xrightarrow{\psi'} & \mathcal{A}' \end{array}$$

Proof. This follows from the functoriality of the bar construction (Theorem 6.1.43) and the universal property of the bar-cobar adjunction (Theorem 7.0.51).

Step 1: The bar construction is functorial:

$$\bar{B}(f) : \bar{B}(\mathcal{A}) \rightarrow \bar{B}(\mathcal{A}')$$

Step 2: The cobar construction is functorial:

$$\Omega(g) : \Omega(C) \rightarrow \Omega(C')$$

for any coalgebra morphism g .

Step 3: The natural transformation ψ is defined universally via the adjunction, hence commutes with all morphisms.

Step 4: At each genus, ψ_g is natural in $\mathcal{A}$, so the genus-graded sum is also natural. $\square$

8.6.7 APPLICATIONS TO MODULE CATEGORIES

REMARK 8.6.22 (*Ordinary module Koszul duality is a separate genus-0 surface*). The intrinsic higher-genus comparison proved in this chapter is the bar-coalgebra statement of Theorems 8.5.23 and 8.5.24: coderived/contraderived on the bar-coalgebra surface, with ordinary derived reduction only on the flat finite-type completed-dual loci. That does *not* by itself prove a broad ordinary-derived equivalence between general chiral $\mathcal{A}$ -modules and $\mathcal{A}^!$ -comodules.

The ordinary module-theoretic Koszul duality used elsewhere in the manuscript is the separate E_1 complete/conilpotent theorem Theorem 11.6.2 on the quadratic genus-0 bar-dual lane. Outside that lane, one must keep the intrinsic bar-coalgebra comparison, and any additional module-category rewrite requires extra hypotheses not supplied by the present chapter.

Remark 8.6.23 (Physical significance). From the physics perspective, the distinction between homology isomorphism and quasi-isomorphism corresponds to:

A homology isomorphism gives only on-shell equivalence: physical states match, but scattering amplitudes and quantum corrections are inaccessible. A quasi-isomorphism gives off-shell equivalence: correlation functions, amplitudes, quantum corrections (encoded in the higher homotopies), and the path integral measure all transfer.

8.6.8 COMPLETED BAR-COBAR INVERSION

The finite-stage inversion theorem (Theorem 8.6.1) establishes the quasi-isomorphism $\Omega(\bar{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ on the Koszul locus of finite-type chiral algebras. The programmatic regime ($\mathcal{W}_\infty$, affine Yangians, RTT towers) requires an extension of inversion to separated complete inverse limits. The key structural input is the strong completion-tower framework developed in §8.1 (Definition 8.1.25, Theorem 8.1.27); what follows gives the homological comparison lemma that underlies the inverse-limit passage and develops the inversion-side consequences of the completion closure $\text{CompCl}(F_{\text{ft}})$ (Definition 8.1.44).

LEMMA 8.6.24 (*Complete filtered comparison lemma*;). Let $f: C \rightarrow D$ be a morphism of separated complete filtered cochain complexes, with descending filtrations $F^\bullet C$ and $F^\bullet D$ satisfying:

- (i) the quotient towers are surjective: for every N , the transition maps $C/F^{N+2}C \twoheadrightarrow C/F^{N+1}C$ and $D/F^{N+2}D \twoheadrightarrow D/F^{N+1}D$ are surjections;
- (ii) every quotient map is a quasi-isomorphism:

$$f_N: C/F^{N+1}C \xrightarrow{\sim} D/F^{N+1}D$$

for all $N \geq 0$.

Then f is a quasi-isomorphism.

Proof. Consider the mapping cone $\text{Cone}(f)$, which inherits a separated complete filtration from C and D . Each quotient $\text{Cone}(f)/F^{N+1} \cong \text{Cone}(f_N)$ is acyclic because f_N is a quasi-isomorphism by hypothesis (ii). The Milnor exact sequence for the inverse system $\{\text{Cone}(f_N)\}_{N \geq 0}$ reads

$$0 \rightarrow \varprojlim_N H^{m-1}(\text{Cone}(f_N)) \rightarrow H^m(\text{Cone}(f)) \rightarrow \varprojlim_N H^m(\text{Cone}(f_N)) \rightarrow 0.$$

The right-hand term vanishes because every $H^m(\text{Cone}(f_N)) = 0$. For the left-hand term: the quotient tower is surjective by hypothesis (i), so the transition maps on each cohomology group form a surjective inverse system of zero groups, and the Mittag–Leffler condition is satisfied trivially. Hence $\varprojlim^1 = 0$. It follows that $H^m(\text{Cone}(f)) = 0$ for all m , so f is a quasi-isomorphism. $\square$

Remark 8.6.25 (Role in the completed bar-cobar theorem). Lemma 8.6.24 is the homological workhorse of the completed bar-cobar theorem (Theorem 8.1.27). In that application, $C = \widehat{\Omega}^{\text{ch}}(\widehat{B}^{\text{ch}}(\mathcal{A}))$, $D = \mathcal{A}$, and the quotient quasi-isomorphisms f_N are the finite-stage counits $\epsilon_N: \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}_{\leq N})) \xrightarrow{\sim} \mathcal{A}_{\leq N}$, which are quasi-isomorphisms by the finite-type regime. The surjectivity of the quotient tower follows from the strong completion-tower axiom: the projections $\mathcal{A}_{\leq N+1} \twoheadrightarrow \mathcal{A}_{\leq N}$ are strict surjections by construction. The lemma then gives the completed counit $\widehat{\epsilon}$ is a quasi-isomorphism; this is Step 3 of the proof of Theorem 8.1.27.

Remark 8.6.26 (Completed inversion: the inversion-side summary). The completion closure theory (Definition 8.1.44–Theorem 8.1.51, developed in §8.1) gives a complete inversion package for the programmatic regime:

1. *Domain.* $\text{CompCl}(\mathbf{F}_{\text{ft}})$ is the class of strong completion towers (Definition 8.1.25) with finite-type quotients.
2. *Inversion.* Completed bar and cobar are quasi-inverse on $\text{CompCl}(\mathbf{F}_{\text{ft}})$ (Theorem 8.1.27).
3. *Homotopy category.* Localizing by quotientwise quasi-isomorphisms gives an equivalence of homotopy categories (Corollary 8.1.45).
4. *Stability under twisting.* If $\alpha \in F^1\mathcal{A}^1$ is a continuous Maurer–Cartan element, then $\mathcal{A}_\alpha \in \text{CompCl}(\mathbf{F}_{\text{ft}})$ and inversion persists (Theorem 8.1.50).
5. *Representability.* Algebra and coalgebra maps between completed objects are represented by continuous twisting morphisms (Theorem 8.1.49).
6. *Verification criteria.* Coefficient stability (Theorem 8.1.48) reduces completed inversion to stabilization of finite matrix entries on windows; the uniform PBW bridge (Theorem 8.1.51) connects PBW concentration (MC1) directly to completed duality (MC4).

Together with the finite-stage inversion theorem (Theorem 8.6.1), these results close Ring 1 of the monograph across all four regimes: quadratic, curved-central, filtered-complete, and programmatic.

COROLLARY 8.6.27 (*Completed derived equivalence; .*) Let $\mathcal{A} \in \text{CompCl}(\mathbf{F}_{\text{ft}})$ be a strong completion tower on a smooth curve X . Then the completed bar and cobar functors induce an equivalence of triangulated categories

$$\mathcal{D}^b(\text{Mod}^{\text{cts}}(\mathcal{A})) \simeq \mathcal{D}^b(\text{Comod}^{\text{pronil}}(\widehat{\mathcal{B}}^{\text{ch}}(\mathcal{A}))),$$

where Mod^{cts} denotes continuous modules over the complete algebra and $\text{Comod}^{\text{pronil}}$ denotes pronilpotent comodules over the completed bar coalgebra. The twisting morphism $\widehat{\tau}: \widehat{\mathcal{B}}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ mediates the equivalence via completed extension of scalars.

Proof. The completed counit and unit are quasi-isomorphisms by Theorem 8.1.27(3)–(4). The passage to module/comodule categories follows from completed twisting representability (Theorem 8.1.49), which ensures that the completed bar and cobar functors on module categories are adjoint and that the unit/counit natural transformations are quasi-isomorphisms quotientwise. Applying Lemma 8.6.24 to each module/comodule then gives the equivalence. The argument parallels Theorem 8.5.24, with finite-generation replaced by continuity and conilpotence replaced by pronilpotence. $\square$

Remark 8.6.28 (From finite-type to programmatic: the four-regime inversion table). The following table summarizes the inversion theorem across all four regimes (Convention 1.10.2):

Regime	Input	Category	Inversion
Quadratic	Koszulness	$D^b(\text{Mod}^{\text{fg}})$	Thm 8.6.1
Curved-central	+ I -adic completion	coderived	Cor 7.0.37
Filtered-complete	+ pronilpotent filtration	contraderived	§8.5.8
Programmatic	strong completion tower	$D^b(\text{Mod}^{\text{cts}})$	Thm 8.1.27

The first three rows are available at finite type; the fourth extends to infinite-generator algebras via the completion closure $\text{CompCl}(\mathcal{F}_{\text{ft}})$. The passage from row 1 to row 4 is mediated by the degree cutoff (Lemma 8.1.26), which makes the infinite bar differential into a quotientwise finite sum, and the complete filtered comparison lemma (Lemma 8.6.24), which passes the quotientwise quasi-isomorphisms to the inverse limit.

8.6.9 GEOMETRIC AND CATEGORICAL CHARACTERIZATIONS OF CHIRAL KOSZULNESS

The inversion theorem (Theorem 8.6.1) identifies chiral Koszulness as the condition under which bar-cobar inversion is a quasi-isomorphism. We give five characterizations of this condition (descent, factorization homology, FM boundary acyclicity, $\mathcal{D}$ -module purity, Lagrangian geometry): three are proved equivalent to Koszulness (Theorem 11.1.50), one is conditional on perfectness, and one ($\mathcal{D}$ -module purity) remains partially proved (forward direction only). Their common theme is that Koszulness is a *finiteness and regularity* condition: the bar complex has the simplest possible behavior.

8.6.9.1 Barr–Beck–Lurie characterization

Lurie’s ∞ -categorical Barr–Beck theorem [303, Theorem 4.7.3.5] characterizes (co)monadic adjunctions by conservativity and totalization preservation. We conjecture that $B_K \dashv \Omega_K^1$ satisfies these conditions precisely on the Koszul locus.

THEOREM 8.6.29 (*Barr–Beck–Lurie characterization of chiral Koszulness*;). Let $\mathcal{A}$ be a chiral algebra on a smooth curve X satisfying the standing hypotheses of Theorem 8.6.1. The bar-cobar adjunction $B_K \dashv \Omega_K$ satisfies the Barr–Beck–Lurie conditions:

- (i) (Conservativity) B_K detects equivalences: a morphism $f: \mathcal{A} \rightarrow \mathcal{A}'$ of chiral algebras is a quasi-isomorphism if and only if $B_K(f)$ is.
- (ii) (Totalization preservation) B_K preserves totalizations of B_K -split cosimplicial objects in the ∞ -category of chiral algebras.
- (iii) (Comparison equivalence) $\mathcal{A}$ is chirally Koszul if and only if the Barr–Beck–Lurie comparison functor

$$\Phi: \text{Mod}(\mathcal{A}) \longrightarrow \text{Comod}^{B_K}(B(\mathcal{A}))$$

is an equivalence.

¹Following Remark 8.1.46, the canonical direction is $\Omega_K \dashv B_K$ (cobar left adjoint to bar). The notation $B_K \dashv \Omega_K$ used here lists the right adjoint first; the mathematical content (unit, counit, Barr–Beck conditions on B_K) is the same.

Here the comonad is $G = B_\kappa \circ \Omega_\kappa$, and $\text{Comod}^{B_\kappa}(B(\mathcal{A}))$ denotes G -coalgebras in conilpotent comodules over the bar coalgebra. The comparison functor sends a module M to the totalization of the cosimplicial bar-cobar resolution $G^{\bullet+1}(M)$.

Proof. Conservativity. On the Koszul locus, bar-cobar inversion (Theorem 8.6.1) gives that the counit $\varepsilon_{\mathcal{A}}: \Omega_\kappa(B_\kappa(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ is a quasi-isomorphism for every Koszul $\mathcal{A}$. Suppose $f: \mathcal{A} \rightarrow \mathcal{A}'$ is a morphism such that $B_\kappa(f)$ is a quasi-isomorphism. Since Ω_κ is a functor, $\Omega_\kappa(B_\kappa(f))$ is also a quasi-isomorphism. The naturality square for the counit gives $f \circ \varepsilon_{\mathcal{A}} = \varepsilon_{\mathcal{A}'} \circ \Omega_\kappa(B_\kappa(f))$; the right-hand side is a composite of two quasi-isomorphisms ($\varepsilon_{\mathcal{A}'}$ by bar-cobar inversion for $\mathcal{A}'$, and $\Omega_\kappa(B_\kappa(f))$ by the hypothesis on f), so $f \circ \varepsilon_{\mathcal{A}}$ is a quasi-isomorphism. Since $\varepsilon_{\mathcal{A}}$ is a quasi-isomorphism, f is as well.

Totalization preservation. We must verify that B_κ preserves the totalization of any B_κ -split cosimplicial object $\mathcal{A}^\bullet$. The bar complex is computed fiberwise on configuration spaces: $B_\kappa(\mathcal{A})_n = \Gamma(\overline{\text{Conf}}_n(X), \mathcal{F}_n)$. On each fiber over a stratum of $\overline{\text{Conf}}_n(X)$, the bar construction is a finite-dimensional chain complex: by hypothesis, each conformal weight space of $\mathcal{A}$ is finite-dimensional, and at each degree n the bar differential preserves the conformal weight grading, so $\mathcal{F}_n$ is a bounded complex of finite-dimensional fibers. For a B_κ -split cosimplicial diagram, the splittings restrict to each fiber, and the resulting inverse system of partial totalizations consists of finite-dimensional cochain complexes at each conformal weight. Since finite-dimensional vector spaces satisfy the Mittag-Leffler condition trivially (cf. [395, Proposition 3.5.7]), we have $\varprojlim^1 = 0$ for each weight space, whence totalization commutes with the passage to global sections.

Comparison equivalence. By [303, Theorem 4.7.3.5], conservativity and totalization preservation of B_κ on the Koszul locus imply that the comparison functor Φ is an equivalence. Conversely, if Φ is an equivalence then B_κ is necessarily conservative; the bar spectral sequence must collapse, giving Koszulness by Theorem 11.1.18. $\square$

Remark 8.6.30 (Three-pillar interaction and effective descent). The three BBL conditions align with the three-pillar architecture (§K.7.1): conservativity (i) is Pillar B (the convolution algebra detects quasi-isomorphisms), totalization preservation (ii) is Pillar C (log FM fibers are contractible), and the comparison equivalence (iii) is Pillar A (Ch_∞ rectifies to strict chiral). Chiral Koszulness *is* effective descent for B_κ : on the Koszul locus the cosimplicial bar-cobar resolution converges and Φ is an equivalence; off it, passage to the coderived category is required (§8.5.8).

8.6.9.2 Factorization homology concentration

Since the bar complex *is* factorization homology (Proposition 8.8.4), Koszulness acquires a homological characterization.

THEOREM 8.6.31 (*Factorization homology concentration*;). Let $\mathcal{A}$ be a chiral algebra on a smooth curve X satisfying the standing hypotheses. Then $\mathcal{A}$ is chirally Koszul if and only if for every smooth projective curve Σ_g of genus $g \geq 0$:

$$H^k\left(\int_{\Sigma_g} \mathcal{A}\right) = 0 \quad \text{for all } k \neq 0.$$

Equivalently, the factorization homology $\int_{\Sigma_g} \mathcal{A}$ is concentrated in cohomological degree zero for all genera.

Proof. Forward: the bar complex is factorization homology (Proposition 8.8.4); E_2 -collapse (Theorem 11.1.18) concentrates $H^*(\int_{\Sigma_g} \mathcal{A})$ in degree 0. Converse: at $g = 0$, concentration of $\int_{\mathbb{P}^1} \mathcal{A} \simeq |\bar{\mathbf{B}}(\mathcal{A})|$ forces the bar spectral sequence to collapse, giving Koszulness by Theorem 11.1.18. $\square$

Remark 8.6.32 (Goodwillie filtration). The factorization homology $\int_X \mathcal{A}$ admits a Goodwillie-type filtration by configuration number:

$$\int_X \mathcal{A} \simeq \mathcal{A} \oplus C_2(X) \otimes_{S_2} (s^{-1} \bar{\mathcal{A}})^{\otimes 2} \oplus C_3(X) \otimes_{S_3} (s^{-1} \bar{\mathcal{A}})^{\otimes 3} \oplus \dots$$

The bar spectral sequence (Theorem 8.6.1) is the spectral sequence of this filtration. PBW concentration (Theorem 11.1.18) forces E_2 -collapse, giving $H^k(\int_X \mathcal{A}) = 0$ for $k \neq 0$; non-collapse witnesses failure of Koszulness.

Remark 8.6.33 (Poincaré/Koszul duality). Ayala–Francis [30] give $\int_X \mathcal{A} \simeq \int^X \mathcal{A}^\dagger$, the factorization-homology incarnation of Theorem C. On the Koszul locus, $Q_g(\mathcal{A}) = H^0(\int_{\Sigma_g} \mathcal{A})$: conformal blocks are the full chiral homology, with no higher corrections.

8.6.9.3 Fulton–MacPherson boundary acyclicity

The bar complex lives on $\bar{C}_n(X)$; restriction to boundary strata encodes OPE residues. Koszulness should be equivalent to acyclicity of all such restrictions.

THEOREM 8.6.34 (FM boundary acyclicity;). Let $\mathcal{A}$ be a chiral algebra on X satisfying the standing hypotheses. Then $\mathcal{A}$ is chirally Koszul if and only if for all $n \geq 2$ and every boundary stratum $S \subset \partial \bar{C}_n(X)$ with inclusion $i_S: S \hookrightarrow \bar{C}_n(X)$:

$$H^k(i_S^! \bar{B}_n^{\text{ch}}(\mathcal{A})) = 0 \quad \text{for all } k \neq 0.$$

In words: the restriction of the n -th bar component to every boundary stratum of the Fulton–MacPherson compactification is cohomologically concentrated in degree zero.

Proof. Each boundary stratum $S_T \cong \prod_{v \in V(T)} \bar{C}_{|v|}(X_v)$ is indexed by a tree T . The restriction $i_{S_T}^! \bar{B}_n^{\text{ch}}(\mathcal{A})$ decomposes as the tensor product $\bigotimes_{v \in V(T)} i_v^! \bar{B}_{|v|}^{\text{ch}}(\mathcal{A})$, where each factor is a lower-degree bar component restricted to $\bar{C}_{|v|}(X_v)$.

Forward: E_2 -collapse (Theorem 11.1.18) concentrates each bar component in degree 0; restrictions of degree-0 objects remain in degree 0.

Converse: at the deepest stratum $S = D_{\{i,j\}}$ (binary collision), $i_S^! \bar{B}_n^{\text{ch}}$ computes the OPE residue $a_{(k)} b$ at a single collision. Acyclicity for all binary strata forces the PBW comparison map to be injective at every weight, giving E_2 -collapse. $\square$

8.6.9.4 D-module purity criterion

The bar components $\bar{B}_n^{\text{ch}}(\mathcal{A})$ are regular holonomic $\mathcal{D}$ -modules (Lemma 7.0.12). The classical Beilinson–Ginzburg–Soergel purity theorem [41] lifts to the chiral setting as follows.

Conjecture 8.6.35 (D-module purity criterion;). Let $\mathcal{A}$ be a chiral algebra on X satisfying the standing hypotheses. Then $\mathcal{A}$ is chirally Koszul if and only if the following two conditions hold for all $n \geq 1$:

- (i) (Purity) Each bar component $\bar{B}_n^{\text{ch}}(\mathcal{A})$, viewed as a mixed Hodge module on $\bar{C}_n(X)$, is *pure* of weight n .

- (ii) (Characteristic variety alignment) The characteristic variety $\text{Ch}(\bar{B}_n^{\text{ch}}(\mathcal{A})) \subset T^*\bar{C}_n(X)$ is contained in the union of conormal bundles to boundary strata:

$$\text{Ch}(\bar{B}_n^{\text{ch}}(\mathcal{A})) \subset \bigcup_{S \subset \partial \bar{C}_n(X)} T_S^* \bar{C}_n(X).$$

Remark 8.6.36 (Content and implications). Condition (i) is the chiral analogue of the BGS diagonal purity: $\text{Ext}_A^i(k, k)$ carries a pure Hodge structure of weight i if and only if A is Koszul [41]. Condition (ii) asserts that all OPE singularities are visible on the FM boundary, with no hidden singularities in the interior of configuration space. For regular holonomic $\mathcal{D}$ -modules, this forces $\bar{B}_n^{\text{ch}}(\mathcal{A})$ to be a successive extension of rank-one flat connections along boundary strata.

Together, (i) and (ii) imply FM boundary acyclicity (Theorem 8.6.34): purity forces the Leray spectral sequence for $i_S^! \bar{B}_n^{\text{ch}}$ to degenerate at E_1 , and alignment puts the E_1 terms in degree zero. In the representation-theoretic context, alignment translates to the BGG resolution property: highest-weight modules have finite Verma filtrations.

8.6.9.5 Lagrangian criterion in the shifted-symplectic deformation space

Ambient complementarity (Conjecture 14.10.5, Theorem 13.19.5) equips the modular deformation space with a (-1) -shifted symplectic structure. Koszulness should be Lagrangian transversality.

Conjecture 8.6.37 (Conditional Lagrangian characterization of chiral Koszulness;). Suppose the ambient complementarity tangent complex $T_{\text{comp}}(\mathcal{A})$ carries a (-1) -shifted symplectic structure ω (as in Theorem 13.19.5), and the one-sided deformation maps

$$i_{\mathcal{A}}: \mathcal{M}_{\mathcal{A}} \longrightarrow \mathcal{M}_{\text{comp}}, \quad i_{\mathcal{A}^!}: \mathcal{M}_{\mathcal{A}^!} \longrightarrow \mathcal{M}_{\text{comp}}$$

are isotropic embeddings. Then $\mathcal{A}$ is chirally Koszul if and only if both $i_{\mathcal{A}}$ and $i_{\mathcal{A}^!}$ are *Lagrangian* (isotropic of maximal dimension). Equivalently: the bar-cobar adjunction defines a Lagrangian correspondence in the (-1) -shifted symplectic deformation space.

Remark 8.6.38 (Evidence). Forward: on the Koszul locus, the bar-cobar adjunction gives a free resolution and the complementarity splitting $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!) \simeq H^*(\bar{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$ (Theorem C) identifies $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ as complementary subspaces. The shifted-symplectic structure (Theorem 13.19.5) makes them isotropic; complementarity gives maximal dimension, hence Lagrangian.

Converse: transverse Lagrangians in a (-1) -shifted symplectic space have derived intersection of expected dimension 0. This derived intersection is the twisted tensor product $K_{\tau}(\mathcal{A}, \mathcal{A}^!)$; its acyclicity is Koszulness. This is a Koszul-locus argument. Off the Koszul locus, the chapter proves only the intrinsic coderived/contraderived bar-coalgebra comparison of Theorem 8.5.23, not an ordinary twisted-tensor-product or free-resolution statement.

Remark 8.6.39 (PTVV interpretation). In the PTVV framework [340], the derived intersection $\mathcal{M}_{\mathcal{A}} \times_{\mathcal{M}_{\text{comp}}}^h \mathcal{M}_{\mathcal{A}^!}$ computes the twisted tensor product $K_{\tau}(\mathcal{A}, \mathcal{A}^!)$ on the Koszul surface of Theorem 8.6.1; its acyclicity (equivalent to Koszulness) is precisely the transversality of the two Lagrangians. The proved linear shadow is Theorem C: $\mathcal{Q}_g(\mathcal{A}) \oplus \mathcal{Q}_g(\mathcal{A}^!) \cong H^*(\bar{\mathcal{M}}_g, \mathcal{Z}(\mathcal{A}))$. The off-locus coderived surface is not identified here with an ordinary twisted tensor product.

Remark 8.6.40 (Conditional hypotheses and their verification). Conjecture 8.6.37 is conditional on three sub-hypotheses of the ambient complementarity programme: perfectness of the deformation complex, non-degeneracy of the shifted-symplectic pairing, and finiteness of the modular envelope. The tangent-level Lagrangian structure (Theorem 13.19.5) is proved unconditionally at the ambient cyclic-deformation level; the characterization of Koszulness as Lagrangian transversality then follows from the PTVV derived-intersection computation (Remark 8.6.39) once the three sub-hypotheses are verified. Global Lagrangian at the tangent level and globally Lagrangian are equivalent when the derived intersection is discrete.

Verification for the standard landscape. Proposition 8.6.41 verifies perfectness for the standard landscape at non-critical, non-degenerate levels. The proof proceeds in four steps: (1) finite-dimensionality of the deformation complex at each weight level (from (P1)); (2) chain-level nondegeneracy of the cyclic pairing (the pairing on $\mathfrak{g} = \text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A})$ is block-diagonal in the (g, r) -decomposition, and each block is a convolution of nondegenerate pairings on finite-dimensional spaces (the invariant form (P2) and the cyclic trace on the modular cooperad)); (3) skew-adjointness of the differential with respect to the pairing (a defining property of invariant pairings on dg Lie algebras); (4) the induced map $\mathfrak{g}|_n \rightarrow (\mathfrak{g}|_n)^\vee[-1]$ is a chain isomorphism (a chain map that is a graded isomorphism is automatically a quasi-isomorphism), hence the pairing is perfect. Once perfectness holds, the PTVV principle gives $\mathcal{M}_{\text{comp}}$ its (-1) -shifted symplectic structure; finiteness of the modular envelope is immediate from (P1). Corollary 8.6.42 upgrades the Lagrangian criterion to an unconditional equivalence for the standard-landscape Koszul cases covered by Theorem 8.6.1. The filtered-complete off-locus regime remains on the intrinsic coderived/contraderived bar-coalgebra surface of Theorem 8.5.23 and is not part of that upgrade.

PROPOSITION 8.6.41 (*Perfectness for the standard landscape*). Let $\mathcal{A}$ satisfy the standing hypotheses and the following:

- (P1) (Finite weight spaces) The conformal weight spaces $\mathcal{A}_n$ are finite-dimensional for all n , and $\mathcal{A}_n = 0$ for $n \ll 0$.
- (P2) (Nondegenerate invariant form) The invariant bilinear form $\langle -, - \rangle : \mathcal{A} \otimes \mathcal{A} \rightarrow \omega_X$ restricts to a nondegenerate pairing on each weight space $\mathcal{A}_n$.
- (P3) (Dual regularity) The Koszul dual $\mathcal{A}^!$ also satisfies (P(P1)) and (P(P2)).

Then the cyclic pairing on the ambient complementarity datum (Definition 13.19.2(v)) is perfect in the weight-graded pro-complete sense: at each conformal weight level n , the induced map

$$(L_{\mathcal{A}} \oplus K_{\mathcal{A}} \oplus L_{\mathcal{A}^!})|_n \longrightarrow (L_{\mathcal{A}} \oplus K_{\mathcal{A}} \oplus L_{\mathcal{A}^!})^\vee[-1]|_n$$

is an isomorphism of finite-dimensional vector spaces.

Proof. The total complex $L_{\mathcal{A}} \oplus K_{\mathcal{A}} \oplus L_{\mathcal{A}^!}$ of the ambient complementarity datum decomposes the modular cyclic deformation complex $\mathfrak{g} := \text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A})$ (Definition 14.5.12) relative to the Koszul duality structure: $L_{\mathcal{A}}$ governs $\mathcal{A}$ -deformations, $L_{\mathcal{A}^!}$ governs $\mathcal{A}^!$ -deformations, $K_{\mathcal{A}}$ governs the twisting interaction. The cyclic pairing on $L_{\mathcal{A}} \oplus K_{\mathcal{A}} \oplus L_{\mathcal{A}^!}$ (Definition 13.19.2(v)) is the invariant pairing on $\mathfrak{g}$ expressed in this decomposition. We prove perfectness of this pairing weight-by-weight.

Fix a conformal weight level n .

Step 1: finite-dimensionality. By (P(P1)), each $\mathcal{A}_m$ is finite-dimensional and vanishes for $m \ll 0$. The complex $\mathfrak{g}$ decomposes at weight n as

$$\mathfrak{g}|_n = \bigoplus_{\substack{g,r \\ 2g-2+r>0}} \text{CoDer}^{\text{cyc}}(\overline{B}^{(g,r)}(\mathcal{A}))[1]|_n,$$

a finite direct sum (only finitely many stable pairs (g, r) contribute at weight n) of finite-dimensional spaces (each cyclic coderivation space is finite-dimensional because $\mathcal{A}_m$ is, and the bar complex at fixed (g, r) is built from finite tensor products of the $\mathcal{A}_m$). Hence $\dim \mathfrak{g}|_n < \infty$.

Step 2: chain-level nondegeneracy. The degree -1 cyclic pairing ω on $\mathfrak{g}$ is induced from two inputs:

- (a) the invariant form $\langle -, - \rangle_{\mathcal{A}}$ on $\mathcal{A}$, which is nondegenerate on each weight space by $(P(P_2))$;
- (b) the cyclic trace $\mathrm{tr}_{(g,r)}$ on each component of the modular cooperad $\mathcal{P}_{(g,r)}^!$, which is nondegenerate by the cyclic modular operad axioms (Serre duality on $\overline{\mathcal{M}}_{g,r}$).

At each (g, r) , the pairing on $\mathrm{CoDer}^{\mathrm{cyc}}(\overline{\mathcal{B}}^{(g,r)}(\mathcal{A}))[1]|_n \cong \mathrm{Hom}(\mathcal{P}_{(g,r)}^!, \mathrm{End}_{\mathcal{A}}^{\mathrm{cyc}})|_n$ is the convolution of (a) and (b): explicitly, $\omega(\alpha, \beta) = \mathrm{tr}_{(g,r)}(\langle \alpha(-), \beta(-) \rangle_{\mathcal{A}})$. This is nondegenerate because it is the composite of the canonical isomorphism $\mathrm{Hom}(V, W) \cong V^\vee \otimes W$ with the tensor-product pairing, and the tensor product of two nondegenerate finite-dimensional bilinear forms is nondegenerate. Because the total pairing on $\mathfrak{g}|_n$ is the direct sum over (g, r) of these component pairings (different (g, r) -components are ω -orthogonal by the grading), the total chain-level pairing is nondegenerate.

Step 3: skew-adjointness of the differential. The differential $d = d_{\mathrm{int}} + d_{\mathrm{sew}}$ on $\mathfrak{g}$ is skew-adjoint with respect to ω :

$$\omega(d\alpha, \beta) + (-1)^{|\alpha|} \omega(\alpha, d\beta) = 0.$$

This is the defining property of an invariant pairing on a dg Lie algebra and follows from $\omega([\Theta, \alpha], \beta) = \omega(\alpha, [\Theta, \beta])$ applied to the Maurer–Cartan element $\Theta_{\mathcal{A}}$ that twists the differential.

Step 4: perfectness. The pairing ω induces a chain map $\varphi: \mathfrak{g}|_n \rightarrow (\mathfrak{g}|_n)^\vee[-1]$ defined by $\varphi(\alpha)(\beta) := \omega(\alpha, \beta)$. That φ is a chain map follows from the skew-adjointness in Step 3: $\varphi \circ d = d^\vee \circ \varphi$. By Step 2, φ is an isomorphism of graded vector spaces at each chain degree (nondegenerate finite-dimensional bilinear form $\Leftrightarrow$ the induced linear map is bijective). A chain map that is an isomorphism of underlying graded vector spaces is a chain isomorphism, hence a fortiori a quasi-isomorphism. Therefore the pairing on $\mathfrak{g}|_n$ is perfect.

Taking the pro-complete limit over all weight levels: ω is perfect at each n , so the pro-complete pairing on $\mathfrak{g} = \varprojlim_n \mathfrak{g}/F_n$ is perfect. $\square$

COROLLARY 8.6.42 (*Unconditional Lagrangian criterion for the standard landscape*). Under hypotheses (P_1) – (P_3) , and on the Koszul locus to which Theorem 8.6.1 applies, the Lagrangian criterion (item (xi) of the meta-theorem, Theorem 11.1.50) is an unconditional equivalence: $\mathcal{A}$ is chirally Koszul if and only if $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ are transverse Lagrangians in the (-1) -shifted symplectic deformation space $\mathcal{M}_{\mathrm{comp}}$.

In particular, this applies unconditionally to every algebra in the standard landscape at the non-critical, non-degenerate levels for which Theorem 8.6.1 applies: Heisenberg at $k \neq 0$, affine Kac–Moody $V_k(\mathfrak{g})$ at $k \neq -h^\vee$, Virasoro at generic c , principal $\mathcal{W}$ -algebras at non-critical level, and all free-field families $bc, \beta\gamma$.

Proof. We verify the shifted-symplectic hypotheses and then prove the two implications directly on the Koszul surface covered by Theorem 8.6.1.

(1) *Formal moduli problem with (-1) -shifted symplectic structure.* The dg Lie algebra $\mathfrak{g} := \mathrm{Def}_{\mathrm{cyc}}^{\mathrm{mod}}(\mathcal{A})$ is complete and filtered (by genus). By the Lurie–Pridham correspondence [305, 360], $\mathfrak{g}$ integrates to a formal moduli problem $\mathcal{M}_{\mathrm{comp}}(\mathcal{A})$ with tangent complex $\mathfrak{g}[1]$. Proposition 8.6.41 gives perfectness of the degree -1 invariant pairing on $\mathfrak{g}$ under (P_1) – (P_3) . By the PTVV/Kontsevich–Pridham principle [340, 360], a perfect invariant pairing of degree -1 on a dg Lie algebra induces a (-1) -shifted symplectic structure on

the corresponding formal moduli problem. Hence $\mathcal{M}_{\text{comp}}(\mathcal{A})$ carries a canonical (-1) -shifted symplectic structure.

(2) *Isotropy*. The one-sided deformation maps $i_{\mathcal{A}}, i_{\mathcal{A}^\dagger}$ are isotropic embeddings: this is Theorem 13.19.4(ii), proved unconditionally.

(3) *Equivalence on the Koszul surface*.

- *Forward* (Koszul $\Rightarrow$ Lagrangian). On the Koszul locus, the twisted tensor product $K_\tau(\mathcal{A}, \mathcal{A}^\dagger)$ is acyclic. The complementarity splitting (Theorem C) gives a direct-sum decomposition $T_{\text{comp}} \simeq T_{\mathcal{A}} \oplus T_{\mathcal{A}^\dagger}$: the one-sided tangent complexes are complementary subspaces. By (2) they are isotropic; by complementarity they are half-dimensional. Isotropic + half-dimensional = Lagrangian.
- *Converse* (Lagrangian $\Rightarrow$ Koszul). Transverse Lagrangians in a (-1) -shifted symplectic formal moduli problem have discrete derived intersection [340]. The derived intersection $\mathcal{M}_{\mathcal{A}} \times_{\mathcal{M}_{\text{comp}}}^h \mathcal{M}_{\mathcal{A}^\dagger}$ computes $K_\tau(\mathcal{A}, \mathcal{A}^\dagger)$ (this is the formal content of the ambient complementarity construction: the derived fiber product of the two one-sided deformation problems is the twisted tensor product). Discreteness (virtual dimension 0) gives acyclicity of K_τ , which is Koszulness (Definition 11.1.3).

This step uses the ordinary twisted-tensor-product interpretation on the Koszul surface. Off that surface, the file proves only the intrinsic coderived/contraderived bar-coalgebra comparison of Theorem 8.5.23.

Standard-landscape verification. Hypotheses (P1)–(P3) are satisfied by every listed family. (P(P1)): all standard families have positive-energy grading with finite-dimensional weight spaces. (P(P2)): the invariant form is the Killing form (nondegenerate at $k \neq -h^\vee$ for Kac–Moody), the Shapovalov form (nondegenerate at generic c for Virasoro), or the canonical pairing for free fields. (P(P3)): Koszul duality preserves the positive-energy grading and finite-dimensionality of weight spaces; the dual pairing inherits nondegeneracy from the original. $\square$

Remark 8.6.43 (Scope and degeneration locus). The Lagrangian criterion degenerates precisely where the invariant form degenerates: at the critical level $k = -h^\vee$ for Kac–Moody, and at central charges where the Kac determinant $\det G_h(c)$ vanishes (admissible levels for Virasoro). At these points, the cyclic pairing develops a kernel and perfectness fails, so the formal moduli problem $\mathcal{M}_{\text{comp}}$ may not carry a well-defined (-1) -shifted symplectic structure. This degeneration locus is the same locus where the Shapovalov form degenerates and null vectors appear: both phenomena reflect the breakdown of the PBW structure.

Remark 8.6.44 (Calabi–Yau interpretation of perfectness). Holstein–Rivera [352] prove that Koszul duality exchanges smooth and proper Calabi–Yau structures in the dg setting. Hypothesis (P(P2)) (nondegenerate invariant form) gives the chiral algebra $\mathcal{A}$ a smooth CY structure; the Holstein–Rivera exchange then implies that $\overline{B}(\mathcal{A})$ carries a proper CY structure, which is precisely the fiber-level perfectness used in Step 4 of the proof of Proposition 8.6.41. This does *not* render the Lagrangian criterion (K11) fully unconditional: the family-level perfectness over $\overline{\mathcal{M}}_g$ (the pro-complete limit in Step 4) still requires (P(P1)) (finite weight spaces from PBW) and (P(P3)) (dual regularity via base change). The CY exchange explains the *mechanism* of perfectness at each fiber; the *uniformity* across the moduli family is a separate input.

Remark 8.6.45 (Synthesis: six faces of chiral Koszulness). Theorems 8.6.29–8.6.34, Conjecture 8.6.35, and Conjecture 8.6.37 give six characterizations of chiral Koszulness, which we summarize as follows. Let $\mathcal{A}$ be a chiral algebra satisfying the standing hypotheses. The following conditions are related as indicated (cf. the meta-theorem, Theorem 11.1.50):

- (a) (Algebraic) $\mathcal{A}$ is chirally Koszul: $\text{Ext}_{\mathcal{A}}^i(k, k)_j = 0$ for $i \neq j$ (meta-theorem item (i)).

- (b) (Descent-theoretic) The Barr–Beck–Lurie comparison functor for $B_\kappa \dashv \Omega_\kappa$ is an equivalence (Theorem 8.6.29; meta-theorem item (vi)).
- (c) (Homological) Factorization homology $\int_{\Sigma_g} \mathcal{A}$ is concentrated in degree 0 for all g (Theorem 8.6.31; meta-theorem item (vii)).
- (d) (Geometric) FM boundary restrictions $i_S^! \bar{B}_n^{\text{ch}}(\mathcal{A})$ are acyclic outside degree 0 (Theorem 8.6.34; meta-theorem item (x)).
- (e) (Hodge-theoretic) Bar components $\bar{B}_n^{\text{ch}}(\mathcal{A})$ are Hodge-pure with aligned characteristic variety (Conjecture 8.6.35; meta-theorem item (xii)).
- (f) (Symplectic) $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ are transverse Lagrangians in $\mathcal{M}_{\text{comp}}$ (Conjecture 8.6.37; meta-theorem item (xi); conditional on perfectness, unconditional for the standard landscape by Corollary 8.6.42).

The equivalences (a) $\Leftrightarrow$ (b) $\Leftrightarrow$ (c) $\Leftrightarrow$ (d) are proved (Theorems 8.6.29–8.6.34). The implication (e) $\Rightarrow$ (d) is proved; the converse is open. Item (f) is conditional on perfectness (proved unconditionally for the standard landscape, Corollary 8.6.42). The full equivalence of all six would parallel the classical theorem that Koszulness, purity, formality, and derived equivalence coincide for graded algebras arising from geometry [41].

8.7 RECOGNIZING KOSZUL DUALS IN PRACTICE

Remark 8.7.1 (Identifying $\mathcal{A}^!$ in practice). When encountering a coalgebra $\widehat{C}$ in geometry or physics, the following procedure identifies the algebra whose bar complex it is, and thence the Koszul dual. Three functors act on $\widehat{C}$, producing three distinct objects

- **Cobar:** $\Omega(\widehat{C})$ recovers the *original* algebra $\mathcal{A}$ when $\widehat{C} = \bar{B}(\mathcal{A})$.
- **Verdier dual:** $\mathbb{D}_{\text{Ran}}(\widehat{C}) \simeq \mathcal{A}_\infty^!$ produces the homotopy Koszul dual *algebra*; equivalently, $\mathbb{D}_{\text{Ran}}(\widehat{C}) \simeq \bar{B}(\mathcal{A}^!)$ as factorization coalgebras (Convention 6.0.2). These are two descriptions of the same object: the identification of $\mathcal{A}_\infty^!$ with $\bar{B}(\mathcal{A}^!)$ is the content of Theorem A.

Step 1: Check necessary conditions (Theorem H.4.3):

- ☐ Conilpotent? ($\bigcap_n \text{coker}(\Delta^n) = 0$)
- ☐ Connected? ($\epsilon: \widehat{C} \twoheadrightarrow \mathbb{C}$)
- ☐ Geometrically representable? (arises from configuration spaces)
- ☐ Curvature central? (if curved)
- ☐ Formally complete? (with respect to coaugmentation)

Step 2: Compute the original algebra via the cobar functor: $\mathcal{A}_{\text{cand}} = \Omega(\widehat{C})$.

Step 3: Verify: check that $\bar{B}(\mathcal{A}_{\text{cand}}) \simeq \widehat{C}$ (bar-cobar round-trip from the coalgebra side).

Step 4: If yes, then $\widehat{C} \simeq \bar{B}(\mathcal{A}_{\text{cand}})$ is the bar *coalgebra* of $\mathcal{A}_{\text{cand}}$. The Koszul dual *algebra* is obtained by the separate route of Verdier duality: $\mathcal{A}_{\text{cand}}^! \simeq \mathbb{D}_{\text{Ran}}(\widehat{C})$.

Examples.

- Heisenberg bar coalgebra $\rightarrow \mathcal{A} = \mathcal{H}_k$; Koszul dual $\mathcal{A}^\dagger = \text{Sym}^{\text{ch}}(V^*)$.
- Affine KM bar coalgebra $\rightarrow \mathcal{A} = \widehat{\mathfrak{g}}_k$; $\mathcal{A}^\dagger \simeq \widehat{\mathfrak{g}}_{-k-2h^\vee}$.
- Exterior coalgebra $\rightarrow \mathcal{A} = \text{free fermion } \beta\gamma$; $\mathcal{A}^\dagger$ is the corresponding commutative/symmetric dual.

Failure cases: non-nilpotent coalgebras and geometrically non-representable coalgebras.

8.8 THE RAN-SPACE PERSPECTIVE

The ∞ -categorical framework of factorization algebras on $\text{Ran}(X)$ provides the conceptual home for the bar-cobar adjunction.

Remark 8.8.1 (From configuration spaces to Ran space). The configuration spaces $C_n(X)$ and their FM compactifications $\overline{C}_n(X)$ are finite-dimensional approximations to the *Ran space* $\text{Ran}(X) = \text{colim}_n X^n / \Sigma_n$, the space of all finite non-empty subsets of X . The bar complex $\overline{B}(\mathcal{A}) = \bigoplus_n \overline{B}^n(\mathcal{A})$, with $\overline{B}^n(\mathcal{A})$ living on $\overline{C}_n(X)$, assembles into a single object on $\text{Ran}(X)$. The bar differential, given by residues at collision divisors (Definition 6.1.15), becomes the factorization structure map: when two points collide, the OPE produces the “fusion” of the corresponding tensor factors.

In this language, the Arnold relations that ensure $d^2 = 0$ (Theorem 6.1.21) are the coherence conditions for the factorization algebra axiom: the result of a three-point collision does not depend on the order in which pairs collide, because the relevant boundary strata of $\overline{C}_3(X)$ are related by the Arnold relation $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$.

Remark 8.8.2 (Verdier duality as the engine of Koszul duality). The bar-cobar adjunction

$$\overline{B}_X: \text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X)) : \Omega_X$$

is controlled by Verdier duality on $\text{Ran}(X)$. The key identification is:

$$\mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}) \simeq \mathcal{A}_\infty^\dagger$$

(factorization *algebra*, not coalgebra). At the chain level, this identity is the content of Theorem II.1.84: the Verdier dual of the bar *coalgebra* of $\mathcal{A}$ is the homotopy Koszul dual *algebra* $\mathcal{A}_\infty^\dagger$. The FM propagator η_{ij} and its Verdier dual $\eta_{ij}^\vee$ implement this duality on configuration spaces: the propagator mediates the passage from algebra to coalgebra, and Verdier duality exchanges the two.

This perspective makes the Poincaré–Koszul duality of Ayala–Francis [30] manifest: their equivalence $\int_M A \simeq (\int_{-M} A^\dagger)^\vee$ is the shadow, at the level of factorization homology, of the chain-level Verdier identification above.

The deeper point is that the bar complex $\overline{B}_X(\mathcal{A})$ is not a technical intermediary but the complete algebraic memory of $\mathcal{A}$: the deconcatenation coproduct on $T^c(s^{-1}\overline{\mathcal{A}})$ records, at each degree, precisely the collision data that the chiral product produces. Verdier duality on $\text{Ran}(X)$ then converts this coalgebraic memory into an algebraic one, turning $\overline{B}_X(\mathcal{A})$ into the dual algebra $\mathcal{A}_\infty^\dagger$ without any loss of information. The adjunction $\Omega^{\text{ch}} \dashv \overline{B}^{\text{ch}}$ and the intertwining $\mathbb{D}_{\text{Ran}} \circ \overline{B}_X \simeq \overline{B}_X \circ (-)^\dagger$ are therefore two faces of a single structure: the bar functor translates algebraic duality (Koszul) into geometric duality (Verdier), and the cobar functor translates back. Every other duality in the programme, whether Poincaré–Koszul on manifolds, Serre on moduli, or the $c \mapsto 26 - c$ involution on the Virasoro line, is a specialization of this single adjunction acting on different geometric inputs.

Remark 8.8.3 (Curvature and coderived categories). When curvature is present, i.e., when the genus-1 obstruction $m_0^{(1)} = \kappa(\mathcal{A}) \cdot \lambda_1 \neq 0$ (as it is for all Koszul chiral algebras with $\kappa(\mathcal{A}) \neq 0$; see Theorem 13.13.16), the bar complex satisfies $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_1 \cdot \text{id}$ rather than $d_{\text{fib}}^2 = 0$ (see Convention 13.0.2 for the notation). The ordinary derived category of $\mathcal{A}$ -modules is then the wrong quotient: it erases the distinction between “acyclic because of $d_{\text{fib}}^2 \neq 0$ ” and “acyclic because of genuine exactness.”

The correct ambient category is the *coderived category* in the sense of Positselski [350]. In this category, a curved complex (M, d_M) with $d_M^2 = \kappa \cdot \text{id}_M$ is *not* set to zero; it represents a genuine object encoding the curvature. On the intrinsic bar-coalgebra surface, the Positselski comparison yields an equivalence

$$\mathcal{D}^{\text{co}}(\overline{B}_X(\mathcal{A})\text{-comod}) \simeq \mathcal{D}^{\text{ctr}}(\overline{B}_X(\mathcal{A})\text{-contra}),$$

and, in finite type, the contraderived side may be rewritten as complete modules over the graded dual bar-dual algebra $\overline{B}_X(\mathcal{A})^*$. On the flat finite-type locus where the internal Positselski comparison applies, this exotic comparison can be reduced to ordinary derived categories on the completed-dual side; on the quadratic genus-0 bar-dual surface it further reduces to Theorem 11.6.2. Off these loci, the coderived formalism captures the “acyclic-but-not-contractible” phenomena that higher-genus curvature creates.

This perspective clarifies the physical meaning of curvature: the cosmological constant $\Lambda \sim \kappa(\mathcal{A})$ in the $\text{AdS}_3/\text{CFT}_2$ correspondence (Conjecture K.7.1) is the obstruction to reducing the coderived category to the derived category. Anomaly cancellation at $c = 26$ ($\kappa_{\text{eff}} = 0$; note $\kappa(\text{Vir}_{26}) = 13$) removes this scalar curvature obstruction on the effective scalar surface, but by itself it is not the full theorem-level criterion under which coderived and derived categories agree, nor does the manuscript identify the full bosonic-string theory as “on-shell” in a derived-categorical sense.

The bar-cobar adjunction for chiral algebras is now fully constructed: the bar differential is a residue on Fulton–MacPherson compactifications, $d^2 = 0$ follows from the Arnold relations, and Verdier duality on $\text{Ran}(X)$ intertwines the bar complexes of Koszul dual pairs: $\mathbb{D}_{\text{Ran}} \overline{B}^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!$ (factorization *algebra*, not coalgebra; Theorem 7.0.36). For Koszul pairs, the bar-cobar adjunction is an equivalence (Theorem 11.1.84). This is the genus-0 theory. Everything built so far lives on configuration spaces of the fixed curve X , with no reference to moduli of curves.

8.8.1 BAR-COBAR AS FACTORIZATION HOMOLOGY

The Ran-space remarks above assemble the bar complex into an object on $\text{Ran}(X)$. We now show that this assembly is not a reformulation but an *identification*: the bar construction *is* factorization homology, and the bar-cobar adjunction *is* the adjunction of factorization (co)homology functors.

PROPOSITION 8.8.4 (*Bar construction as factorization homology*;). Let $\mathcal{A}$ be an augmented E_1 -chiral algebra on a smooth curve X , and let $\overline{\mathcal{A}} = \ker(\epsilon : \mathcal{A} \rightarrow k)$ be the augmentation ideal. Then there is a natural equivalence

$$\overline{B}_X^{\text{geom}}(\mathcal{A}) \simeq \int_X \overline{\mathcal{A}}^{\text{Lie}}$$

where $\overline{\mathcal{A}}^{\text{Lie}}$ denotes $\overline{\mathcal{A}}$ viewed as an E_1 -Lie algebra via the commutator bracket, and the right-hand side is factorization homology in the sense of [30, 40]. More precisely:

- (i) **Finite approximations:** For each $n \geq 1$, the degree- n piece $\overline{B}_X^n(\mathcal{A}) = (s^{-1} \overline{\mathcal{A}})_{\overline{C}_n(X)}^{\otimes n}$ (the bar complex on n points, supported on the Fulton–MacPherson compactification $\overline{C}_n(X)$) is the restriction of the factorization homology $\int_X \overline{\mathcal{A}}$ to n -point configurations.

- (ii) **Assembly:** The bar differential $d_{\text{bar}} = \sum_{i < j} d_{ij}$ (residue along collision divisors, Definition 6.1.15) is the structure map of the factorization algebra: the collision $z_i \rightarrow z_j$ implements the factorization product $\int_{U_i} \overline{\mathcal{A}} \otimes \int_{U_j} \overline{\mathcal{A}} \rightarrow \int_{U_i \cup U_j} \overline{\mathcal{A}}$ for shrinking discs $U_i \ni z_i, U_j \ni z_j$.
- (iii) **Colimit:** The total bar complex $\bar{B}_X(\mathcal{A}) = \bigoplus_{n \geq 0} \bar{B}_X^n(\mathcal{A})$ is the colimit over n of the finite approximations, i.e., the factorization homology $\int_X \overline{\mathcal{A}} = \text{colim}_{S \in \text{Fin}/X} \bigotimes_{s \in S} \overline{\mathcal{A}}_s$.

Proof. The factorization homology of an E_n -algebra A on a manifold M is defined as

$$\int_M A = \text{colim}_{U_1 \sqcup \dots \sqcup U_k \hookrightarrow M} A(U_1) \otimes \dots \otimes A(U_k),$$

where the colimit is over rectilinear embeddings of disjoint discs [30, Definition 3.1]. For $n = 1$ on a curve X , this is the colimit over configurations of disjoint discs $D_1 \sqcup \dots \sqcup D_k \hookrightarrow X$, with $A(D_i) = \overline{\mathcal{A}}_{z_i}$ (the fiber of $\overline{\mathcal{A}}$ at the center z_i of D_i).

Part (i): The term $\bar{B}_X^n(\mathcal{A})$ places one copy of $s^{-1}\overline{\mathcal{A}}$ at each of n distinct points $z_1, \dots, z_n \in X$. The locus of distinct points is the open configuration space $C_n(X) = X^n \setminus \Delta$, and the extension to $\bar{C}_n(X)$ encodes the factorization product at coincident points.

Part (ii): When $z_i \rightarrow z_j$, the factorization structure map composes the two copies of $\overline{\mathcal{A}}$ using the chiral product. At the chain level, this composition is the OPE residue $\text{Res}_{z_i=z_j}(\mu^{\text{ch}}(\bar{a}_i, \bar{a}_j) \cdot \eta_{ij})$, which is exactly the bar differential d_{ij} .

Part (iii): The colimit over n in the bar complex is the colimit over the category Fin/X of finite subsets of X , which is the Ran space $\text{Ran}(X) = \text{colim}_n X^n / \Sigma_n$. The factorization homology $\int_X \overline{\mathcal{A}}$ is this colimit by definition. $\square$

PROPOSITION 8.8.5 (*Cobar as factorization cohomology*;). The cobar construction $\Omega_X(C)$ of a conilpotent E_1 -chiral coalgebra C is naturally equivalent to the *factorization cohomology*:

$$\Omega_X(C) \simeq \mathbb{R}\text{Hom}_{\text{Fact}(X)}(k, C) =: \int^X C,$$

the derived internal hom from the unit factorization algebra k to C in the ∞ -category of factorization coalgebras on X . Under Verdier duality $\mathbb{D}_{\text{Ran}}$, this becomes:

$$\Omega_X(C) \simeq \left(\int_X \mathbb{D}_{\text{Ran}}(C) \right)^\vee,$$

the linear dual of the factorization homology of the Verdier dual. For $C = \bar{B}_X(\mathcal{A})$, this gives

$$\Omega_X \bar{B}_X(\mathcal{A}) \simeq \left(\int_X \bar{B}_X(\mathcal{A}^\dagger) \right)^\vee,$$

which identifies the bar-cobar counit $\psi: \Omega_X \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ with the Poincaré–Koszul duality map of Ayala–Francis [30].

Proof. The cobar construction $\Omega_X(C) = T(s^{-1}\bar{C})$ with differential $d_{\text{cobar}} = d_{\text{coop}} + d_{\text{tw}}$ is the free algebra on $s^{-1}\bar{C}$, with the differential encoding the coalgebra structure of C . The free algebra on a module V is $\mathbb{R}\text{Hom}(k, T^c(V))$, and for $V = s^{-1}\bar{C}$ supported on $\text{Ran}(X)$, this is the factorization cohomology $\int^X C$ by [303, Proposition 5.5.2.5].

The Verdier duality identification follows from $\mathbf{D}_{\text{Ran}}(\bar{B}_X(\mathcal{A})) \simeq \bar{B}_X(\mathcal{A}^!)$ (Theorem 7.0.36) and the general adjunction $\text{Hom}(k, C) \simeq (\int_X \mathbf{DC})^\vee$. The identification with Poincaré–Koszul duality follows from [30, Theorem 4.13]: their equivalence $\int_M A \simeq (\int_{-M} A^\vee)^\vee$ is precisely the composition of Verdier duality on $\text{Ran}(X)$ with the bar-cobar adjunction. $\square$

Remark 8.8.6 (The bar-cobar adjunction as a duality of integration theories). Propositions 8.8.4 and 8.8.5 together identify the bar-cobar adjunction

$$\bar{B}_X: \text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X)) : \Omega_X$$

as the adjunction between two integration theories:

- The bar functor $\bar{B}_X$ is *factorization integration*: it computes $\int_X(\cdot)$ by summing over configurations of points on X , with the OPE providing the integrand.
- The cobar functor Ω_X is *factorization co-integration*: it computes $\int^X(\cdot)$ by taking the internal hom from the unit, with the coproduct providing the “inverse transform.”
- Koszul duality $\mathcal{A} \mapsto \mathcal{A}^!$ is the *Verdier transform* mediating between the two: $\bar{B}(\mathcal{A})$ and $\bar{B}(\mathcal{A}^!)$ are Verdier dual, so the bar of one algebra is the co-integration data for the dual.

This perspective reveals the bar-cobar machine as a *nonlinear Fourier duality* (cf. Remark E.4.8 and Chapter A): the OPE kernel $\eta_{ij} = d \log(z_i - z_j)$ plays the role of the Fourier kernel $e^{2\pi i x \xi}$, the bar construction is the “forward transform” (integration against the kernel), and the cobar is the “inverse transform.” Koszulness is the condition that the transform is invertible (Fourier inversion), and the bar-cobar counit $\Omega \bar{B}(\mathcal{A}) \rightarrow \mathcal{A}$ is the Fourier inversion formula.

Remark 8.8.7 (The master diagram at genus 0). The results of this chapter instantiate the master diagram (1.1) at genus 0:

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\bar{B}_X} & \bar{B}_X(\mathcal{A}) \\ (\cdot)^! \downarrow & & \downarrow \mathbf{D}_{\text{Ran}} \\ \mathcal{A}^! & \xrightarrow{\bar{B}_X} & \bar{B}_X(\mathcal{A}^!) \end{array}$$

The top row is the bar construction of this chapter; the right column is Verdier duality (Theorem 7.0.36); the commutativity $\mathbf{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \mathcal{A}^!_\infty$ (factorization *algebra*, not coalgebra) is Theorem A. The cobar functor Ω_X is left adjoint to $\bar{B}_X$, and the counit $\Omega_X \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ is an equivalence for Koszul algebras.

In the nilpotence-periodicity framework (Remark 6.1.9), this is the *single-valued regime* of the categorical logarithm: $d^2 = 0$ exactly (the Arnold relations give single-valuedness), so the logarithm has no monodromy and the diagram commutes strictly. At genus $g \geq 1$ (Chapter 13), the logarithm acquires monodromy (the square acquires curvature $\kappa(\mathcal{A}) \cdot \omega_g$), and strict commutativity is replaced by an intrinsic coderived/contraderived bar-coalgebra comparison. The single-valued/multi-valued logarithm language is heuristic motivation only: the theorem-level statement is that higher-genus curvature moves the bar object into the coderived framework, and only on the flat finite-type completed-dual loci does the manuscript reduce back to ordinary derived categories.

The factorization homology perspective (Propositions 8.8.4, 8.8.5) upgrades the diagram from a commutative square of chain complexes to a commutative square of *factorization algebra objects* on $\text{Ran}(X)$.

The Verdier duality $\mathbf{D}_{\text{Ran}}$ becomes an ∞ -categorical involution, and the commutativity is an equivalence of factorization algebras, not merely a quasi-isomorphism. This ∞ -categorical enhancement is the H-level datum that organizes the M-level constructions.

8.9 THE CATEGORICAL LOGARITHM

The constructions of this chapter (bar, cobar, Verdier intertwining, bar-cobar inversion, factorization homology) are aspects of a single structure: the *categorical logarithm* for factorization algebras on algebraic curves. The identification yields both the conceptual unity of the four main theorems and concrete predictions for higher-genus theory.

8.9.1 THE EXPONENTIAL-LOGARITHM CORRESPONDENCE

Definition 8.9.1 (Categorical logarithm and exponential). Let $\mathcal{A}$ be an augmented $\mathbf{E}_1$ -chiral algebra on a smooth curve X . The *categorical logarithm* of $\mathcal{A}$ is the bar construction

$$\log^{\text{cat}}(\mathcal{A}) := \overline{B}_X(\mathcal{A}),$$

viewed as a factorization coalgebra on $\text{Ran}(X)$ (Proposition 8.8.4). The *categorical exponential* is the cobar construction

$$\exp^{\text{cat}}(C) := \Omega_X(C),$$

viewed as a factorization algebra on $\text{Ran}(X)$ (Proposition 8.8.5).

This terminology is justified by the following dictionary, each entry of which is a theorem proved in this chapter or in Chapter 13:

Classical logarithm	Categorical logarithm
$\log: (\mathbb{C}^\times, \cdot) \rightarrow (C, +)$	$\overline{B}: \text{Alg}_{\text{aug}} \rightarrow \text{CoAlg}_{\text{conil}}$
Maps multiplicative to additive	Maps OPE (multiplicative) to bar differential (nilpotent/additive)
$\exp(\log(z)) = z$ on convergence disk	$\Omega(\overline{B}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ on Koszul locus (Theorem 8.6.1)
Power series $\log(1+z) = z - z^2/2 + \dots$	PBW spectral sequence: $E_1^{p,q} = H^q(\text{gr}^p \overline{B}(\mathcal{A}))$
Convergence radius	Koszul locus: E_2 degeneration (Theorem 8.6.16)
Analytic continuation past radius	Coderived category completion (§8.5.4)
$\log(ab) = \log(a) + \log(b)$	$\mathcal{Q}_g(\mathcal{A}) + \mathcal{Q}_g(\mathcal{A}^\dagger) = H^*(\overline{\mathcal{M}}_g, \mathbb{Z}_{\mathcal{A}})$ (Theorem 13.15.14)
Single-valued on simply connected domain	$d_0^2 = 0$ at genus 0 (Theorem 6.1.21)
Multi-valued on $\mathbb{C}^\times$; monodromy $2\pi i$	$d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ at genus $g \geq 1$
Residue at branch point	Curvature $\kappa(\mathcal{A})$
Leading coefficient of $\log(1+z) = z + \dots$	Modular characteristic $\kappa(\mathcal{A})$ (Theorem 13.21.44)

Remark 8.9.2 (The logarithmic kernel). The fact that the bar construction uses a *logarithmic* kernel $\eta_{ij} = d \log(z_i - z_j)$ is the surface manifestation of the categorical identification. The classical logarithm of a product is a sum: $\log(z_1 z_2) = \log z_1 + \log z_2$. The bar differential implements precisely this: the OPE (a product structure at colliding points) is converted, via the residue $\text{Res}_{z_i=z_j}(\mu^{\text{ch}} \cdot \eta_{ij})$, into a sum (the bar differential is a sum over pairwise collisions). The kernel η is the infinitesimal version of this conversion.

8.9.2 THE TAYLOR EXPANSION OF THE LOGARITHM

The PBW spectral sequence of a chiral algebra $\mathcal{A}$ (Definition II.1.15) is the Taylor expansion of the categorical logarithm.

More precisely: the weight filtration on the bar complex $\overline{B}(\mathcal{A}) = \bigoplus_{n \geq 0} (s^{-1} \overline{\mathcal{A}})^{\otimes n}$ induces a spectral sequence

$$E_1^{p,q} = H^q(\text{gr}^p \overline{B}(\mathcal{A})) \implies H^{p+q}(\overline{B}(\mathcal{A})).$$

In the exp/log framework, the filtration degree p is the *order of the Taylor expansion*: the p -th filtered piece $F^p \overline{B}(\mathcal{A})$ retains contributions from at most p points in configuration space, i.e., the first p terms of the logarithmic series. The differential d_1 on the E_1 -page extracts the *leading term* of the logarithm (the binary OPE residue); higher differentials d_r capture *higher-order corrections* from r -fold collisions.

PROPOSITION 8.9.3 (Convergence criterion; Theorems 8.6.16 and 8.6.1). The categorical logarithm *converges*, meaning $\exp \circ \log = \text{id}$, if and only if the PBW spectral sequence degenerates at E_2 . The E_2 degeneration is equivalent to:

- (i) The chiral algebra $\mathcal{A}$ lies on the *Koszul locus* (Definition II.1.15);
- (ii) The Taylor expansion has finitely many nonzero corrections at each filtration degree: the logarithm is “polynomial” in the filtration variable;
- (iii) The counit $\psi : \Omega \overline{B}(\mathcal{A}) \rightarrow \mathcal{A}$ is a quasi-isomorphism (Theorem 8.6.1).

Off the Koszul locus, the Taylor series diverges in the ordinary derived category. The coderived category (§8.5.4) provides the analytic continuation: it is the completion of the derived category that makes the divergent logarithm well-defined, exactly as the maximal analytic continuation of $\log z$ requires passage from $\mathbb{C}^\times$ to its universal cover.

Remark 8.9.4 (Convergence radius from OPE data). The analogy with power series provides a heuristic for the following conjectural expectation: the convergence radius of the categorical logarithm should be computable from the input data. For the classical logarithm $\log(1+z) = \sum (-1)^{n+1} z^n / n$, the radius is determined by the growth rate of the coefficients. For the categorical logarithm, the “coefficients” are the OPE residues, and the “growth rate” is the complexity of multi-point collisions.

In concrete terms: Kac–Moody algebras have first-order OPE poles (linear growth), and the categorical logarithm converges (Theorem K.7.1). The Virasoro algebra has a second-order pole from the central term, but the Sugawara constraint tames the growth, and convergence holds (Theorem II.1.21). For algebras where Koszulness fails (e.g., simple admissible-level quotients $L_k(\mathfrak{g})$, whose vacuum null vectors obstruct PBW; the universal algebra $V_k(\mathfrak{g})$ remains Koszul at all levels), the OPE singularity structure generates higher differentials in the spectral sequence: the Taylor coefficients grow too fast for convergence. A precise bound relating the OPE pole orders to the convergence radius of the categorical logarithm is a natural target for future work.

8.9.3 ADDITIVITY AND THE BRANCH STRUCTURE

The fundamental property of any logarithm is that it converts products to sums. For the categorical logarithm, this is the content of the complementarity theorem.

PROPOSITION 8.9.5 (*Additivity of the categorical logarithm; Theorem 13.15.14*). Let $(\mathcal{A}, \mathcal{A}^!)$ be a Koszul pair. The quantum corrections to the bar complex satisfy

$$Q_g(\mathcal{A}) + Q_g(\mathcal{A}^!) = H^*(\overline{\mathcal{M}}_g, Z_{\mathcal{A}}).$$

In the exp/log framework, this is the statement $\log^{\text{cat}}(\mathcal{A} \otimes \mathcal{A}^!) = \log^{\text{cat}}(\mathcal{A}) + \log^{\text{cat}}(\mathcal{A}^!)$: the logarithm of the Koszul product is the sum of the logarithms, and the right-hand side is the total logarithmic data $\log^{\text{cat}}(\mathcal{A} \otimes \mathcal{A}^!)$ computed from the center $Z_{\mathcal{A}}$ via the Hodge cohomology of $\overline{\mathcal{M}}_g$.

The Lagrangian decomposition $C_g(\mathcal{A}) = Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!)$ is the decomposition of the total logarithm into its two *branches*: the sheet associated to $\mathcal{A}$ and the sheet associated to its Koszul dual. The pairing between them is the monodromy acquired when analytically continuing from one branch to the other.

Remark 8.9.6 (The categorical Baker–Campbell–Hausdorff formula). For the classical logarithm, $\log(e^X e^Y) = X + Y + \frac{1}{2}[X, Y] + \cdots$ (the BCH formula). The categorical analogue is the twisted tensor product decomposition: for an extension $0 \rightarrow \mathcal{A}' \rightarrow \mathcal{A} \rightarrow \mathcal{A}'' \rightarrow 0$ of chiral algebras, the bar complex decomposes as $\overline{B}(\mathcal{A}) \simeq \overline{B}(\mathcal{A}'') \otimes_{\tau} \overline{B}(\mathcal{A}')$, where the twisting cochain τ encodes the extension data through iterated brackets, in direct analogy with the commutator corrections of BCH. This follows from the standard filtered bar construction applied to the extension filtration, and the twisting cochain τ can be computed order by order from the connecting maps of the extension. A systematic development of the categorical BCH, including explicit formulas for the first correction terms and their geometric content, is deferred to §8.1.6.

8.9.4 FROM SINGLE-VALUED TO MULTI-VALUED: THE GENUS TRANSITION

The central structural consequence of the exp/log identification is the genus transition.

Classical complex analysis	Categorical logarithm
Simply connected domain	Genus 0: $\pi_1(C_2(\mathbb{P}^1)) = 0$
log is single-valued, holomorphic	$d_0^2 = 0$ (Arnold relations), no curvature
Multiply connected domain $(\mathbb{C}^\times)$	Genus $g \geq 1$: $\pi_1(\Sigma_g) \neq 0$
log acquires monodromy $2\pi i n$	$d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$
Residue at branch point: $\text{Res}_{z=0}(dz/z) = 1$	Curvature class: $m_0^{(g)} = \kappa(\mathcal{A}) \cdot \lambda_g$, $\kappa(\mathcal{A}) \in \mathbb{C}$
Total differential $d \log z$ is exact on universal cover	Total differential $D_g^2 = 0$ after Gauss–Manin correction
Period matrix $\tau_{ij} = \oint_{B_j} \omega_i$	Modular package $(\kappa, \Delta, \Theta, \Pi)$
Torelli: τ determines the curve	Categorical Torelli: monodromy of $\overline{B}_g$ determines $\mathcal{A}$ up to quasi-isomorphism (via Theorem 8.6.1)

Remark 8.9.7 (The chiral Riemann–Hilbert correspondence, revisited). The Riemann–Hilbert correspondence identifies flat connections (nilpotent data: $\nabla^2 = 0$) with monodromy representations (periodic data: $\rho(\gamma^N) = 1$ for finite-order monodromy). The categorical logarithm instantiates this at the level of factorization algebras:

- (i) The *flat connection* is the total corrected differential D_g with $D_g^2 = 0$, a flat connection on the bar family $\overline{B}_g(\mathcal{A}) \rightarrow \overline{M}_g$.
- (ii) The *curvature* of the fiberwise differential $d_{\text{fib}}^2 = \kappa \cdot \omega_g$ is the infinitesimal generator of the monodromy.
- (iii) The *monodromy representation* is the action of the mapping class group Γ_g on $H^*(\overline{B}_g(\mathcal{A}))$, whose leading eigenvalues are $\exp(2\pi i \kappa(\mathcal{A}))$.

The three differentials d_0, d_{fib}, D_g (Convention 13.0.2) are three levels of the logarithm: the germ (d_0 , single-valued), the multi-valued lift (d_{fib} , curvature = residue), and the trivialization on the universal cover (D_g , flat).

8.9.5 THE CHARACTERISTIC HIERARCHY AS LOGARITHMIC DATA

The modular package $(\kappa, \Delta, \Theta, \Pi)$ of a chiral algebra is the data of the categorical logarithm, organized by order:

- Level 1: Scalar logarithmic data.** The modular characteristic $\kappa(\mathcal{A})$ is the leading coefficient of the categorical logarithm, the residue of the curvature. Its exponential is the scalar period N : the smallest integer for which $\exp(2\pi i N c/24) = 1$. This is the content of Theorem D (Theorem 13.21.44).
- Level 2: Spectral logarithmic data.** The spectral discriminant $\Delta(\mathcal{A})$ encodes the eigenvalues of the monodromy of the categorical logarithm. Its exponential is the periodicity profile $\Pi(\mathcal{A})$: the collection of periods of individual T-matrix eigenvalues $\lambda_i = \exp(2\pi i(h_i - c/24))$.
- Level 3: Full logarithmic data.** The universal Maurer–Cartan class $\Theta_{\mathcal{A}} \in H^2(\overline{M}_g, Z_{\mathcal{A}})$ (Theorem 13.21.117) is the complete categorical logarithm: it encodes all genus- g corrections to the bar differential. Its exponential is the full modular automorphy of $\mathcal{A}$: the action of Γ_g on the conformal blocks, i.e., the modular functor.

The hierarchy is controlled by a single principle: *each level is the leading term of the next*. The scalar characteristic κ is the trace of the spectral data Δ ; the spectral data is the eigenvalue decomposition of the full data Θ . In the language of complex analysis: κ is the winding number of the logarithm, Δ is the set of periods, and Θ is the full multi-valued function.

8.9.6 VISIBLE THEOREMS

The exp/log identification makes certain results visible that would otherwise have no natural formulation:

- (1) **Categorical Torelli.** If the monodromy of the categorical logarithm (the higher-genus corrections to the bar differential, encoded in $\Theta_{\mathcal{A}}$) determines $\mathcal{A}$ up to quasi-isomorphism, this is a *categorical Torelli theorem*. It follows from bar-cobar inversion (Theorem 8.6.1) plus the fact that the curvature determines the flat connection up to L_{∞} gauge equivalence on a simply connected base: since the Teichmüller space is contractible, the flat bar family is determined by its curvature, i.e., by $\kappa(\mathcal{A})$.

- (2) **Functional equation.** The complementarity theorem (Theorem 13.15.14) is the *functional equation* of the categorical logarithm: it relates $\log^{\text{cat}}(\mathcal{A})$ and $\log^{\text{cat}}(\mathcal{A}^!)$ through the total data $H^*(\overline{\mathcal{M}}_g, Z_{\mathcal{A}})$, exactly as the functional equation of the Riemann ζ -function relates $\zeta(s)$ and $\zeta(1-s)$ through the Γ -factor.
- (3) **Acyclicity of the trivial algebra.** For the unit (trivial) chiral algebra $\mathcal{A} = k$, the bar complex $\overline{B}(k)$ is acyclic: $H^*(\overline{B}(k)) = k$ concentrated in degree 0. In the $\exp/\log$ framework this is $\log(1) = 0$: the logarithm of the multiplicative identity is the additive identity.
- (4) **Convergence radius from OPE poles.** The Koszul locus should be characterized by the singularity structure of the OPE: the convergence radius of the categorical logarithm equals the inverse of the growth rate of multi-point OPE singularities, in analogy with the Cauchy–Hadamard formula.
- (5) **Screening as infinitesimal generator.** In the lattice setting (Construction B.II.19), the screening charges Q_i with $Q_i^2 = 0$ are the infinitesimal generators of the categorical logarithm; the quantum group relations $e_i^N = 0$ at $\zeta = e^{2\pi i/N}$ are their N -th powers; and the representation category $\text{Rep}(\mathfrak{u}_{\zeta}(\mathfrak{g}))$ carries the periodic (exponential) structure. The passage $Q^2 = 0 \rightarrow e^N = 0$ is literally exponentiation: the root of unity $\zeta = \exp(2\pi i/N)$ is the monodromy of the categorical logarithm around the N -th root.

Remark 8.9.8 (The bar complex as quantized symmetric power). The bar complex admits a unified interpretation as a *quantized symmetric power* of the curve. The three bar complexes $\text{Lie}^c \subset \text{Sym}^c \subset T^c$ on $s^{-1}\overline{\mathcal{A}}$ correspond to:

- Sym^c (the “classical symmetric power”): the coshuffle coalgebra, factorization on the unordered $\text{Ran}(X)$. Its generating function is the exponential: $\sum \chi(\text{Sym}^n) t^n = \text{PE}[\chi(\mathcal{A}) t]$.
- T^c (the “quantum symmetric power”): the deconcatenation coalgebra, factorization on ordered configurations $\text{Conf}_n^<(X)$. The R -matrix $R(z)$ is the quantization datum; the passage $T^c \rightarrow \text{Sym}^c$ is the Σ_n -coinvariant projection (the classical limit).
- Lie^c (the “primitive part”): the Harrison/coLie coalgebra, the infinitesimal generators of the logarithm.

The PBW spectral sequence is the Taylor expansion of the categorical logarithm: filtration degree p is the order of the expansion, and convergence (E_2 -collapse) means the Taylor series is polynomial. The shadow obstruction tower $\Theta_{\mathcal{A}}^{(\leq r)}$ is the r -th Taylor polynomial; the discriminant $\Delta = 8\kappa S_4$ governs whether the Taylor series terminates (classes G, L: polynomial) or is irrational (class M: transcendental). The Chern–Weil dictionary (Remark 13.22.40) is the characteristic class theory of this quantized symmetric power bundle over $\overline{\mathcal{M}}_g$.

Conjecture 8.9.9 (Factorization finiteness criterion;). Let $\mathcal{A}$ be a chiral algebra whose bar complex $\overline{B}(\mathcal{A})$ admits a bigrading $\overline{B}^{p,q}(\mathcal{A})$ with $\dim \overline{B}^{p,q} < \infty$ for all (p, q) . Suppose the associated spectral sequence $E_r^{p,q} \Rightarrow H^{p+q}(\overline{B}(\mathcal{A}))$ satisfies:

- (i) (Convergence) $E_r^{p,q} = E_{\infty}^{p,q}$ for each (p, q) at some finite page $r_0(p, q)$;
- (ii) (Sub-exponential growth) $\dim E_1^{0,p} < c^p$ for every $c > 1$ and all sufficiently large p .

Then the factorization bar-cobar adjunction restricts to an equivalence on the Koszul locus, and the factorization DK equivalence holds for $\mathcal{A}$ without thick generation.

Instances. For lattice algebras, (i)–(ii) are satisfied by the Λ -grading with E_1 degeneration (Theorem B.12.3). For Yangians, the root weight/loop degree bigrading of Proposition O.9.27 gives (i), and (ii) is proved in Proposition O.9.43: the growth rate is $\sim \exp(\pi\sqrt{rp/12})$, which is sub-exponential. For $\mathcal{W}$ -algebras, the DS filtration provides a candidate bigrading whose (ii) would follow from Kac–Kazhdan character estimates.

PROPOSITION 8.9.10 (*Sub-exponential growth is automatic;*). Let $\mathcal{A}$ be a positive-energy chiral algebra with $L_0 \geq 0$ and $\dim \mathcal{A}_n < \infty$ for all n . Then for every bigrading on the bar complex $\overline{B}^{p,q}(\mathcal{A})$ compatible with the conformal grading (i.e., the total conformal weight is bounded by a function of the bigrading), the growth bound

$$\dim E_1^{0,p} < c^p \quad \text{for every } c > 1 \text{ and all sufficiently large } p$$

holds automatically.

Proof. The bar complex at bar degree n and conformal weight h satisfies $\overline{B}_{[h]}^n \subset (\overline{\mathcal{A}})_{[h]}^{\otimes n}$, hence

$$\dim \overline{B}_{[h]}^n \leq \sum_{\substack{h_1 + \dots + h_n = h \\ h_i \geq 1}} \prod_{i=1}^n \dim \mathcal{A}_{h_i}.$$

By the positive-energy condition, $a_k := \dim \mathcal{A}_k$ satisfies $a_k \leq C e^{\alpha\sqrt{k}}$ for constants $C, \alpha > 0$ (Hardy–Ramanujan–Rademacher: $\alpha = \pi\sqrt{2c_{\text{eff}}/3}$ for effective central charge c_{eff}). Write $f(q) = \sum_{k \geq 1} a_k q^k$. Then $\sum_h \dim \overline{B}_{[h]}^n q^h \leq f(q)^n$ and

$$\sum_h (\sum_n \dim \overline{B}_{[h]}^n) q^h \leq \frac{1}{1-f(q)}$$

for $|q|$ small enough that $f(q) < 1$. The sub-exponential bound $a_k \leq C e^{\alpha\sqrt{k}}$ gives $\log f(q) = O(|\log q|^{-1})$ as $q \rightarrow 0^+$, so the total dimension at weight h satisfies $\log(\sum_n \dim \overline{B}_{[h]}^n) = O(\sqrt{h})$, which is $o(h)$. Since any compatible bigrading has $\dim E_1^{0,p}$ bounded by the total dimension at conformal weight p , sub-exponential growth follows. $\square$

COROLLARY 8.9.II. Conjecture 8.9.9 reduces to the spectral sequence degeneration condition (i) alone for all positive-energy chiral algebras. The residual content is a geometric assertion: that sectorwise degeneration on the bar complex lifts to compact generation of $\text{Fact}(X; \mathcal{A})$ on $\text{Ran}(X)$.

8.9.7 THE CATEGORICAL LOGARITHM AND ITS FOUR PROPERTIES

Taken at full depth, the four main theorems are the four fundamental properties of *any* logarithm:

- **Theorem A** (existence): the categorical logarithm and exponential exist, as a pair of adjoint functors between augmented factorization algebras and conilpotent factorization coalgebras.
- **Theorem B** (invertibility): on the convergence domain (the Koszul locus), $\exp \circ \log = \text{id}$, and the logarithm faithfully encodes its input.

- **Theorem C** (branch structure): the failure of strict convergence off the Koszul locus is recorded, on the complementarity surface, by complementary Lagrangian branches (the two branches of the multi-valued logarithm), and the total logarithmic data is the sum of the two branches.
- **Theorem D** (leading coefficient): the leading coefficient $\kappa(\mathcal{A})$ of the logarithmic expansion determines the full scalar package, just as the leading coefficient of $\log(1+z) = z + \dots$ determines the local behavior.

The five master conjectures are five aspects of a single question: *what is the categorical logarithm for factorization algebras on algebraic curves, completely?*

- **MC1**: does the logarithm converge? (PBW concentration)
- **MC3**: what is the convergence domain? (categorical CG closure via multiplicity-free ℓ -weights, proved for all simple types, Corollary O.9.73)
- **MC4**: does the logarithm extend to infinite rank? (stability of towers)
- **MC5**: does the physical logarithm (BRST) equal the mathematical one (bar)? (BV–BRST identification)
- **Periodicity**: what is the monodromy group of the categorical logarithm?

These are not five separate programmes. They are five windows onto a single object.

8.9.8 FROM TREE-LEVEL TO MODULAR HOMOTOPY THEORY

The constructions of this chapter are *tree-level*: the bar differential is indexed by collisions on a single smooth curve, and the operadic compositions are indexed by planar rooted trees. Three levels of homotopy-algebraic structure emerge as one opens the genus filtration.

Definition 8.9.12 (Tree-level operadic homotopy theory). A *tree-level operadic homotopy theory* for a cyclic operad P is an ∞ -category $\mathcal{H}$ with homotopy-coherent P -action: operations m_T indexed by P -decorated rooted trees T , satisfying the operadic master equation $\sum_T m_T = 0$ up to coherent homotopies. The bar-cobar constructions of this chapter produce such a theory for $P = \text{Com}^{\text{ch}}$ or $P = \text{Ass}^{\text{ch}}$.

Definition 8.9.13 (Modular homotopy theory, abstract). A *modular homotopy theory* for a modular operad M is an ∞ -category $\mathcal{H}$ with homotopy-coherent M -action: operations m_Γ indexed by M -decorated *stable graphs* Γ (graphs with genus labels g_v at each vertex, satisfying $\sum_v g_v + b_1(\Gamma) = g$), compatible with separating and nonseparating clutching (Definition 1.9.1).

Remark 8.9.14 (The formal step is small; the existence problem is hard). Replacing rooted trees by stable graphs is the *only* combinatorial change from tree-level to modular homotopy theory. The formal generalization is immediate. What is not immediate is *existence*: constructing the operations m_Γ for graphs with loops requires integration over $\overline{\mathcal{M}}_{g,n}$, which produces curvature ($d_{\text{fib}}^2 \neq 0$) and demands the full Maurer–Cartan package $\Theta_{\mathcal{A}}$. This is the content of Chapter 13.

In Chapter 13, the curve itself varies over $\overline{\mathcal{M}}_g$, and the bar differential inherits curvature from the open-sector trace and clutching data: the genus- g correction $m_0^{(g)}$ is a section of the obstruction sheaf on $\overline{\mathcal{M}}_g$, controlled at the scalar level by $\kappa(\mathcal{A})$ and at higher orders by the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ (Definition 13.22.46). The passage from this chapter to the next is the passage from operadic to *modular*

Koszul duality, from the combinatorics of associahedra to the geometry of the Deligne–Mumford compactification, or, in the language of the categorical logarithm, the passage from the single-valued to the multi-valued regime.

8.9.9 SCALAR RIGIDITY AND THE QUADRATIC FRONTIER

The categorical logarithm encodes a chiral algebra $\mathcal{A}$ as the bar complex $\overline{B}(\mathcal{A})$, whose Taylor expansion is the PBW spectral sequence, whose leading coefficient is the modular characteristic $\kappa(\mathcal{A})$, and whose curvature $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ governs the genus transition. On a locus where the full scalar package is known to be governed by $\kappa(\mathcal{A})$, this curvature controls the scalar genus tower.

We now consider what happens when that stronger scalar-package hypothesis is left. The Whitehead decomposition (Chapter 13) splits the cyclic deformation cohomology as

$$H_{\text{cyc}}^2(\mathcal{A}, \mathcal{A}) = \mathbb{C} \cdot \eta \oplus H_{\text{cyc, prim}}^2(\mathcal{A}),$$

where η is the level class and the primitive summand consists of $\mathfrak{g}$ -equivariant cocycles vanishing on current-containing pairs. Scalar saturation is the vanishing of the primitive summand. The first non-scalar phenomenon might, naïvely, be linear transport by the level class: the operator $l_2^{\text{tr}}(\eta, -)$ acting on primitive deformations. The geometric surprise is that this operator vanishes *for formal reasons* (the level class is cohomologically central), and the first genuine departure from scalarity is *quadratic*.

The invariant that governs this quadratic frontier is a bilinear form $H_{\eta, \mathcal{A}}$ on the primitive sector, the η -Hessian: the transferred ternary L_∞ bracket with one η -input. In the singularity-theoretic language that organizes the deformation theory, the Kodaira–Spencer centrality theorem kills the linear term of the expansion around the scalar branch, and the η -Hessian is the Hessian matrix of the resulting critical point. The quadratic cone $B_{\kappa, \mathcal{A}}(y, y) = 0$ in the primitive sector is the tangent cone to the first non-scalar branch of the moduli space.

The deformation-theoretic setup. Throughout this subsection, the transferred L_∞ operations $\{l_n^{\text{tr}}\}_{n \geq 1}$ are those of the minimal cyclic L_∞ -model on the cohomology $\mathcal{H} = H^*(\text{Def}_{\text{cyc}}(\mathcal{A}))$, constructed by homotopy transfer from a dg Lie model of the cyclic deformation complex. The model is minimal ($l_1^{\text{tr}} = 0$), and the binary bracket l_2^{tr} is the induced Lie bracket on cohomology. The distinguished class $\eta \in \mathcal{H}^2$ is the level class, and $s^{-1}\eta$ has odd degree in the desuspension $s^{-1}\mathcal{H}$.

THEOREM 8.9.15 (Kodaira–Spencer centrality;). Let $(C, \partial, [-, -])$ be a dg Lie algebra equipped with a one-parameter family of Maurer–Cartan elements $m_k \in C^1$ depending formally on a scalar parameter k , with the underlying graded vector space and bracket independent of k . Set $d_k := \partial + [m_k, -]$ and let $\eta_k := [\dot{m}_k] \in H^2(C, d_k)$ be the Kodaira–Spencer class. Then:

$$\text{ad}_{\eta_k} = 0 \quad \text{on } H^\bullet(C, d_k).$$

Equivalently, after passing to any transferred minimal L_∞ -model on the cohomology,

$$l_2^{\text{tr}}(\eta_k, -) = 0.$$

Proof. Differentiate the Maurer–Cartan equation $\partial m_k + \frac{1}{2}[m_k, m_k] = 0$ with respect to k :

$$\partial \dot{m}_k + [m_k, \dot{m}_k] = 0, \quad \text{i.e.,} \quad d_k \dot{m}_k = 0.$$

Thus $\eta_k = [\dot{m}_k]$ is a well-defined cohomology class.

Now let $x \in C$ be d_k -closed. Differentiating $d_k x = 0$ with respect to k yields

$$d_k \left(\frac{\partial x}{\partial k} \right) + [\dot{m}_k, x] = 0,$$

since the bracket is k -independent. Hence $[\dot{m}_k, x]$ is d_k -exact, so η_k acts trivially on $H^\bullet(C, d_k)$. The transferred binary bracket on the minimal model is the induced bracket on cohomology, giving $l_2^{\text{tr}}(\eta_k, -) = 0$. $\square$

LEMMA 8.9.16 (*Two- η vanishing*). Let $(\mathcal{H}, \{l_n\}_{n \geq 1})$ be a minimal L_∞ -model for a deformation problem in which the distinguished level class $\eta \in \mathcal{H}^2$ has odd suspension $s^{-1}\eta$. Then for every $n \geq 2$ and all $u_3, \dots, u_n \in \mathcal{H}$,

$$l_n(\eta, \eta, u_3, \dots, u_n) = 0.$$

In particular, $l_n(\eta, \dots, \eta) = 0$ for all $n \geq 2$.

Proof. In the desuspension $s^{-1}\mathcal{H}$, the element $s^{-1}\eta$ has odd degree. The L_∞ -operations are graded anti-symmetric on the desuspended coalgebra, so interchanging the first two identical odd inputs multiplies the expression by -1 without changing its value. Therefore it is zero. $\square$

REMARK 8.9.17 (*The scalar direction is affine, not invisible*). The two results above have an immediate structural consequence. For any $t \in \mathbb{C}$ and $y \in \mathcal{H}$, the Maurer–Cartan series satisfies

$$\text{MC}(t\eta + y) = \text{MC}(y) + t \Xi_\eta(y), \quad \Xi_\eta(y) := \sum_{m \geq 0} \frac{1}{m!} l_{m+1}(\eta, y^{\otimes m}).$$

There are no quadratic or higher powers of t : every term in the multilinear expansion containing two or more copies of η vanishes by Lemma 8.9.16. The scalar direction is not invisible (the insertion operator Ξ_η carries genuine structure), but it couples to the remaining directions only *affinely*. By Theorem 8.9.15, the unary part of the insertion vanishes on cohomology, so the first surviving scalar/non-scalar coupling begins quadratically in the primitive variables.

The coalgebra-level consequence of the affine normal form is a square-zero insertion differential, whose spectral sequence collapses at E_2 .

PROPOSITION 8.9.18 (*Square-zero insertion differential*). Let Q denote the coderivation on the cofree conilpotent coalgebra $T^c(s^{-1}\mathcal{H})$ determined by the Taylor coefficients $\{l_n\}_{n \geq 1}$, and define a second coderivation M_η by $(M_\eta)_n(u_1, \dots, u_n) := l_{n+1}(\eta, u_1, \dots, u_n)$. Then the twist of Q by the scalar Maurer–Cartan point $t\eta$ is

$$Q_t = Q + tM_\eta.$$

Consequently,

$$[Q, M_\eta] = 0, \quad M_\eta^2 = 0.$$

Proof. The Taylor coefficient of degree n in the twist by $t\eta$ is

$$l_n^{t\eta}(u_1, \dots, u_n) = \sum_{r \geq 0} \frac{1}{r!} l_{n+r}((t\eta)^{\otimes r}, u_1, \dots, u_n).$$

By Lemma 8.9.16, all terms with $r \geq 2$ vanish, so $l_n^{t\eta} = l_n + t l_{n+1}(\eta, -)$, which is the statement $Q_t = Q + tM_\eta$. Since $t\eta$ is Maurer–Cartan for every t , one has $Q_t^2 = 0$ for every t . Expanding $(Q + tM_\eta)^2 = Q^2 + t[Q, M_\eta] + t^2 M_\eta^2$ and comparing coefficients of $1, t, t^2$ yields the claims. $\square$

COROLLARY 8.9.19 (*Two-step scalar spectral sequence*;). Filter the family $(T^c(s^{-1}\mathcal{H})[[t]], Q_t)$ by powers of t . The associated spectral sequence has

$$E_1 \cong H^\bullet(T^c(s^{-1}\mathcal{H}), Q) \otimes \mathbb{C}[[t]],$$

its first differential is induced by M_η , and all higher differentials vanish: $d_r = 0$ for $r \geq 2$. The scalar-direction spectral sequence collapses at E_2 .

Proof. The twisted differential $Q_t = Q + tM_\eta$ has exactly two filtration pieces: Q (preserving the t -adic filtration) and tM_η (raising it by one). There is no component raising filtration by two or more, so the only nontrivial differential beyond the Q -cohomology stage is the first one. $\square$

The primitive quadratic cone. Theorems 8.9.15 and Lemma 8.9.16 have eliminated the linear frontier. The first place where non-scalar behavior can occur is the quadratic interaction between primitive directions and the scalar branch.

Notation 8.9.20 (Primitive sector and scalar basepoint). Write

$$\mathcal{P}_{\mathcal{A}} := H_{\text{cyc, prim}}^2(\mathcal{A})$$

for the primitive degree-two sector from the Whitehead decomposition. Suppress, for notational simplicity, the inert Hodge factor $\Lambda = \sum_{g \geq 1} \lambda_g$ and write

$$x_\kappa := \kappa(\mathcal{A}) \eta$$

for the scalar Maurer–Cartan point in the minimal model.

THEOREM 8.9.21 (*Quadratic frontier*;). Let $\mathcal{A}$ be any object for which the Whitehead decomposition holds and for which the scalar branch $x_\kappa = \kappa(\mathcal{A})\eta$ is Maurer–Cartan. Let $y \in \mathcal{P}_{\mathcal{A}}$. Then:

- (a) Every primitive direction is first-order unobstructed along the scalar branch:

$$l_1^{x_\kappa}(y) = 0.$$

- (b) The first nontrivial obstruction is quadratic:

$$\text{MC}(x_\kappa + y) = \frac{1}{2} B_{\kappa, \mathcal{A}}(y, y) + O(y^3),$$

where

$$B_{\kappa, \mathcal{A}}(u, v) := l_2^{\text{tr}}(u, v) + \kappa(\mathcal{A}) l_3^{\text{tr}}(\eta, u, v).$$

Consequently, the first non-scalar branch is governed by the quadratic cone

$$C_{\kappa, \mathcal{A}} := \{y \in \mathcal{P}_{\mathcal{A}} : B_{\kappa, \mathcal{A}}(y, y) = 0\}.$$

Proof. The twisted unary bracket is

$$l_1^{x_\kappa}(y) = \sum_{r \geq 0} \frac{1}{r!} l_{1+r}(x_\kappa^{\otimes r}, y).$$

The $r = 0$ term vanishes because the model is minimal. The $r = 1$ term is $\kappa(\mathcal{A}) l_2^{\text{tr}}(\eta, y)$, which vanishes by Theorem 8.9.15. All terms with $r \geq 2$ contain at least two copies of η and vanish by Lemma 8.9.16. This proves (a).

For the quadratic term, expand around x_κ :

$$\text{MC}(x_\kappa + y) = \underbrace{\text{MC}(x_\kappa)}_{=0} + \underbrace{l_1^{x_\kappa}(y)}_{=0} + \frac{1}{2} l_2^{x_\kappa}(y, y) + O(y^3).$$

Compute

$$l_2^{x_\kappa}(u, v) = \sum_{r \geq 0} \frac{1}{r!} l_{2+r}^{x_\kappa}(x_\kappa^{\otimes r}, u, v).$$

The $r = 0$ term is $l_2^{\text{tr}}(u, v)$; the $r = 1$ term is $\kappa(\mathcal{A}) l_3^{\text{tr}}(\eta, u, v)$; all $r \geq 2$ terms vanish by Lemma 8.9.16. $\square$

Definition 8.9.22 (η -Hessian). The η -Hessian of the family at $\mathcal{A}$ is the bilinear form on the primitive sector defined by

$$H_{\eta, \mathcal{A}}(u, v) := l_3^{\text{tr}}(\eta, u, v), \quad u, v \in \mathcal{P}_{\mathcal{A}}.$$

The quadratic frontier tensor decomposes as

$$B_{\kappa, \mathcal{A}} = l_2^{\text{tr}}|_{\mathcal{P}_{\mathcal{A}} \otimes \mathcal{P}_{\mathcal{A}}} + \kappa(\mathcal{A}) H_{\eta, \mathcal{A}}.$$

The first summand is the intrinsic binary bracket on primitive cohomology; the second is the new invariant introduced by the scalar curvature.

PROPOSITION 8.9.23 (*Homotopy-transfer construction of the η -Hessian*;). Let $(C, d, [-, -])$ be a dg Lie model for the cyclic deformation complex of $\mathcal{A}$, and choose a contraction

$$(\mathcal{P}_{\mathcal{A}} \oplus \mathbb{C}\eta) \xrightarrow{i} C \xrightarrow{p} (\mathcal{P}_{\mathcal{A}} \oplus \mathbb{C}\eta), \quad dh + hd = \text{id}_C - ip.$$

Then $H_{\eta, \mathcal{A}}$ is represented by the standard transferred rooted-tree formula:

$$\begin{aligned} H_{\eta, \mathcal{A}}(u, v) = & p([h[i(\eta), i(u)], i(v)]) + p([h[i(u), i(v)], i(\eta)]) \\ & + p([h[i(v), i(\eta)], i(u)]), \end{aligned}$$

with Koszul signs in the general graded case. The formula is independent of the choice of contraction, by the standard homotopy-transfer invariance of L_∞ -structures.

Proof. For a dg Lie algebra, the transferred ternary bracket on the minimal L_∞ -model is the sum over rooted binary trees with three leaves and one internal homotopy edge. Evaluating at the ordered triple (η, u, v) yields the displayed expression. Independence of the contraction is homotopy-transfer invariance. $\square$

LEMMA 8.9.24 (*Shifted symmetry on degree-two primitives*;). On the primitive degree-two sector $\mathcal{P}_{\mathcal{A}} \subset H_{\text{cyc}}^2(\mathcal{A}, \mathcal{A})$, both $l_2^{\text{tr}}(u, v)$ and $H_{\eta, \mathcal{A}}(u, v)$ are symmetric in the ordinary sense. Consequently, the quadratic frontier tensor $B_{\kappa, \mathcal{A}}(u, v)$ is symmetric on $\mathcal{P}_{\mathcal{A}}$.

Proof. After desuspension, degree-two classes become odd. The transferred bracket is graded antisymmetric in the shifted sense, so exchanging two odd inputs contributes the extra minus sign coming from their parity. That sign cancels the shifted antisymmetry sign, leaving ordinary symmetry on the primitive degree-two sector. The same argument applies to both $l_2^{\text{tr}}(u, v)$ and the Hessian $H_{\eta, \mathcal{A}}(u, v)$, so $B_{\kappa, \mathcal{A}}(u, v)$ is symmetric as well. $\square$

Remark 8.9.25 (The frontier has moved). The natural question was to compute $I_2^{\text{tr}}(\eta, -)$ and its induced quotient differential. Theorem 8.9.15 and Theorem 8.9.21 show that this is not the correct frontier. Linear transport by the level class vanishes formally. The first genuine deformation-theoretic information lives instead in the η -Hessian $H_{\eta, \mathcal{A}}$ and the resulting quadratic cone $C_{\kappa, \mathcal{A}}$. In the singularity-theoretic dictionary: one has killed the gradient of the Maurer–Cartan potential along the scalar branch; the η -Hessian is the Hessian at the resulting critical point; and the quadratic cone is the tangent cone to the critical locus.

Cyclic rigidity in the admissible sector. The one-channel locus extends well beyond the generic regime. Generic rigidity (Chapter 13) gives $H_{\text{cyc, prim}}^2(\mathcal{A}) = 0$ whenever the relevant module category is semisimple. The quadratic frontier therefore lies beyond the semisimple regime. Even admissible levels, where semisimplicity can fail, remain one-channel at the minimal cyclic level in their semisimple highest-weight sector.

THEOREM 8.9.26 (Admissible cyclic rigidity;). Let k be an admissible level for a simple Lie algebra $\mathfrak{g}$, and let $\mathcal{A} = L_k(\mathfrak{g})$ be the corresponding simple admissible affine vertex algebra. Consider the cyclic first-order deformation problem internal to the semisimple admissible highest-weight module category of [17]. Then

$$H_{\text{cyc}}^2(\mathcal{A}, \mathcal{A}) = \mathbb{C}\eta, \quad H_{\text{cyc, prim}}^2(\mathcal{A}) = 0.$$

In particular, the semisimple admissible highest-weight sector of the vacuum admissible affine algebra has one-dimensional cyclic line concentration.

Proof. The Whitehead decomposition applies at all non-critical levels, so only the vanishing of the primitive part must be addressed. The generic rigidity argument kills primitive cyclic deformations whenever the relevant module category is semisimple: the algebra object then has vanishing Hochschild Ext^2 in that semisimple tensor category. For admissible k , Arakawa [17] proves that the ordinary admissible highest-weight category is semisimple and that $L_k(\mathfrak{g})$ belongs to it. Running the generic rigidity argument inside that semisimple sector gives $H_{\text{cyc, prim}}^2(\mathcal{A}) = 0$. $\square$

COROLLARY 8.9.27 (Drinfeld–Sokolov reductions remain one-channel in the semisimple admissible sector;). Let k be admissible and $f \in \mathfrak{g}$ nilpotent. Then the $\mathcal{W}$ -algebra $\mathcal{W}^k(\mathfrak{g}, f) = \text{DS}_f(V_k(\mathfrak{g}))$ has one-dimensional cyclic direction in that semisimple sector. In particular, neither the vacuum admissible affine algebra nor its ordinary Drinfeld–Sokolov reductions provide the first admissible example with genuinely nonzero primitive sector.

Proof. Apply Theorem 8.9.26 and the BRST pullback argument of Proposition 13.21.133(a), which gives one-dimensional cyclic direction for the Drinfeld–Sokolov reduction. $\square$

Remark 8.9.28 (Where the true admissible frontier lies). The first admissible family with nonzero primitive sector must lie beyond the semisimple ordinary highest-weight regime. Natural targets include: logarithmic extensions of admissible affine algebras, admissible conformal cosets with Jordan blocks, relaxed highest-weight or nonordinary sectors, and nonrational $\mathcal{W}$ -algebras for which the ordinary category ceases to be semisimple. In every case, the route to the first non-scalar quadratic cone passes through the explicit computation described below.

The scalar genus as a classified multiplicative genus. On a locus where the scalar genus tower is known to depend only on the single number $\kappa(\mathcal{A})$, the following classification theorem makes this uniqueness precise: any multiplicative genus factoring through the modular characteristic must take the universal form.

THEOREM 8.9.29 (*Classification of scalar genera (uniform-weight);*). Let $\mathcal{U} := 1 + x^2\mathbb{C}[[x^2]]$ with multiplication of formal series. Suppose that to each object $\mathcal{A}$ in a one-scalar class one assigns an element $Z(\mathcal{A}; x) \in \mathcal{U}$ such that:

- (a) $Z(\mathcal{A} \star \mathcal{B}; x) = Z(\mathcal{A}; x) Z(\mathcal{B}; x)$ whenever $\kappa(\mathcal{A} \star \mathcal{B}) = \kappa(\mathcal{A}) + \kappa(\mathcal{B})$;
- (b) $Z(\mathcal{A}; x)$ depends on $\mathcal{A}$ only through $\kappa(\mathcal{A})$;
- (c) the dependence on κ is formal power-series dependence.

Then there exists a unique series $\Psi(x) \in x^2\mathbb{C}[[x^2]]$ such that

$$Z(\mathcal{A}; x) = \exp(\kappa(\mathcal{A}) \Psi(x))$$

for every $\mathcal{A}$. If the genus coefficients are normalized to the scalar genus formula

$$\sum_{g \geq 1} F_g(\mathcal{A}) x^{2g} = \kappa(\mathcal{A}) \left(\frac{x/2}{\sin(x/2)} - 1 \right),$$

then $\Psi(x) = \Phi_{\log}(x) := \frac{x/2}{\sin(x/2)} - 1$ and

$$Z(\mathcal{A}; x) = \exp(\kappa(\mathcal{A}) \Phi_{\log}(x)).$$

Proof. Write $Z_z(x)$ for the value of Z at an object of scalar characteristic z . Multiplicativity gives $Z_{z+w}(x) = Z_z(x) Z_w(x)$. Setting $f_z(x) := \log Z_z(x) \in x^2\mathbb{C}[[x^2]]$ yields $f_{z+w}(x) = f_z(x) + f_w(x)$. Expanding formally, $f_z(x) = \sum_{n \geq 0} c_n(x) z^n$; the additive functional equation forces $c_n = 0$ for $n \neq 1$, giving $f_z(x) = z \Psi(x)$ for a unique Ψ . The final statement follows from the scalar genus formula (Theorem 13.21.44). $\square$

Remark 8.9.30 (*Self-dual anomaly neutrality*). For algebras with $\kappa(\mathcal{A}^!) = -\kappa(\mathcal{A})$ (the exact anti-symmetry that holds for affine Kac–Moody and free fields; Theorem 13.21.44(iii)), Koszul self-duality $\mathcal{A} \simeq \mathcal{A}^!$ forces $\kappa(\mathcal{A}) = 0$ and hence $F_g(\mathcal{A}) = 0$ for all $g \geq 1$ (uniform-weight): the scalar logarithm of such a Koszul-self-dual chiral algebra vanishes identically. For $\mathcal{W}$ -algebras, the complementarity sum $\kappa + \kappa'$ is a nonzero constant (e.g. $\kappa + \kappa' = 13$ for Virasoro), so Koszul self-duality $\text{Vir}_{13} \simeq \text{Vir}_{26-13} = \text{Vir}_{13}$ (Koszul duality at $c = 13$) gives $\kappa(\text{Vir}_{13}) = 13/2 \neq 0$: the Virasoro Koszul self-dual point ($c = 13$) is *not* at critical level. See Theorem 13.15.14 for the full complementarity.

The platonic hierarchy. The results of this subsection organize the categorical logarithm at the deformation-theoretic level into five steps, each resolving a naïve expectation.

THEOREM 8.9.31 (*Five-step hierarchy of the categorical logarithm;*). Assume the Whitehead decomposition and the scalar genus formula (Chapter 13). Then the deformation theory of the categorical logarithm organizes itself as follows.

- (i) *Logarithmic linearization.* The bar construction is the categorical logarithm $\log^{\text{cat}}(\mathcal{A}) = \bar{B}_X(\mathcal{A})$ and the cobar construction is the categorical exponential $\exp^{\text{cat}}(C) = \Omega_X(C)$. The four main theorems are existence, local inversion, branch structure, and leading coefficient for this logarithm.
- (ii) *Scalar package.* On a locus where the full scalar genus tower is known to depend only on $\kappa(\mathcal{A})$, it is governed by the scalar logarithm

$$\kappa(\mathcal{A}) \left(\frac{x/2}{\sin(x/2)} - 1 \right).$$

The exponential $\exp(\kappa(\mathcal{A}) \Phi_{\log}(x))$ is the unique multiplicative genus factoring through κ (Theorem 8.9.29).

- (iii) *Vanishing of the linear frontier.* For every honest one-parameter level family, the Kodaira–Spencer class is cohomologically central: $l_2^{\text{tr}}(\eta, -) = 0$ (Theorem 8.9.15). There is no first-order non-scalar obstruction along the scalar branch.
- (iv) *First non-scalar invariant: the η -Hessian.* The first genuine departure from scalarity is the η -Hessian $H_{\eta, \mathcal{A}}(u, v) = l_3^{\text{tr}}(\eta, u, v)$, and the first non-scalar branch is governed by the quadratic cone $B_{\kappa, \mathcal{A}}(y, y) = 0$ (Theorem 8.9.21, Definition 8.9.22).
- (v) *Actual frontier.* In semisimple admissible highest-weight sectors the primitive cohomology still vanishes (Theorem 8.9.26), so the first family carrying genuine non-scalar data must be nonsemisimple admissible.

Proof. Parts (i)–(ii) are the scalar genus formula repackaged by Definition 8.9.1 and Theorem 8.9.29. Part (iii) is Theorem 8.9.15. Part (iv) is Theorem 8.9.21 and Definition 8.9.22. Part (v) is Theorem 8.9.26 and Corollary 8.9.27. $\square$

Remark 8.9.32 (Connection to the shadow obstruction tower). The η -Hessian $H_{\eta, \mathcal{A}}$ is the first non-scalar shadow in the obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ (Definition 13.22.46). At the scalar level ($r = 2$), the tower is determined by $\kappa(\mathcal{A})$. The quadratic frontier tensor $B_{\kappa, \mathcal{A}}$ records exactly the degree-3 correction: the transferred ternary bracket with one η -input. The hierarchy $\kappa \rightarrow H_{\eta, \mathcal{A}} \rightarrow \cdots$ is the leading-term expansion of the full shadow obstruction tower, and the η -Hessian is the first invariant that the scalar characteristic does not see. Beyond the quadratic level, the tower continues with the quartic resonance class $\mathcal{Q}_{\mathcal{A}}^{\text{contact}}$ and higher shadows, as developed in Chapter 13.

Remark 8.9.33 (Computing the first non-scalar frontier). The practical recipe for detecting the first non-scalar branch is:

- (1) Build a dg Lie or cyclic L_{∞} model C_k for $\text{Def}_{\text{cyc}}(\mathcal{A}_k)$ with fixed underlying graded space and explicit k -dependence in the Maurer–Cartan element.
- (2) Compute $\mathcal{P}_{\mathcal{A}_k} = H_{\text{cyc, prim}}^2(\mathcal{A}_k)$; if it vanishes, the family remains scalar-saturated.
- (3) Choose a contraction onto $\mathcal{P}_{\mathcal{A}_k} \oplus \mathbb{C}\eta_k$ and evaluate the transferred ternary tree formula (Proposition 8.9.23) to obtain $H_{\eta_k, \mathcal{A}_k}$.
- (4) Form $B_{\kappa, \mathcal{A}_k} = l_2^{\text{tr}} + \kappa(\mathcal{A}_k) H_{\eta_k, \mathcal{A}_k}$ and solve the quadratic cone $B_{\kappa, \mathcal{A}_k}(y, y) = 0$.

This is the exact analogue of computing the Hessian of a singularity once the linear term has been killed. One does not need the full nonlinear theory; the frontier is detected by a single transferred ternary bracket.

8.10 ČECH RESOLUTION AND HOMOTOPY CHIRAL ALGEBRAS

The preceding sections established bar-cobar inversion via configuration-space techniques on $\text{Ran}(X)$. A complementary approach works on the Zariski site of the curve itself: the Čech complex of a sheaf of chiral algebras. Malikov–Schechtman [309] prove that this Čech complex carries the structure of a *homotopy chiral algebra* (HCA), a chiral algebra up to coherent higher homotopies, with operadic control by the Lie Eilenberg–Zilber operad.

The HCA operations $\{F_n\}$ are the *components* of a single Maurer–Cartan element in an appropriate convolution dg Lie algebra, the Čech convolution algebra $\mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U})$ (§8.9, Chapter 13). The passage from local data (sections on affine opens) to global data (cohomology on X) carries algebraic structure through the Moore complex functor: an L_∞ enhancement of the Lie bracket in Beilinson–Drinfeld’s pseudo-tensor category [40].

8.10.1 THE COSIMPLICIAL LIE ALGEBRA OF SECTIONS

Let $\mathcal{A}$ be a sheaf of chiral algebras on a smooth curve X (or more generally on a smooth variety), and let $\mathcal{U} = \{U_i\}_{i \in I}$ be an affine open cover. The sections on iterated intersections assemble into a *cosimplicial* object in the pseudo-tensor category of $\mathcal{D}_X$ -modules:

Definition 8.10.1 (Cosimplicial Čech object). Define

$$\check{C}^p(\mathcal{U}; \mathcal{A}) = \bigoplus_{i_0 < \dots < i_p} \Gamma(U_{i_0} \cap \dots \cap U_{i_p}, \mathcal{A})$$

with coface maps $\partial^j : \check{C}^p \rightarrow \check{C}^{p+1}$ given by restriction (omitting the j -th index) and codegeneracy maps $\sigma^j : \check{C}^{p+1} \rightarrow \check{C}^p$ given by diagonal insertion. The alternating sum $d_{\check{C}} = \sum_{j=0}^{p+1} (-1)^j \partial^j$ is the Čech differential, and $d_{\check{C}}^2 = 0$ by the standard cosimplicial identities.

The chiral product on $\mathcal{A}$ endows each $\Gamma(U_{i_0 \dots i_p}, \mathcal{A})$ with a Lie bracket in the pseudo-tensor sense of Beilinson–Drinfeld [40]:

$$\mu_{i_0 \dots i_p} : j_* j^* (\mathcal{A}|_{U_{i_0 \dots i_p}} \boxtimes \mathcal{A}|_{U_{i_0 \dots i_p}}) \longrightarrow \Delta_* \mathcal{A}|_{U_{i_0 \dots i_p}}.$$

The restriction maps are compatible with these brackets, so $\check{C}^\bullet(\mathcal{U}; \mathcal{A})$ is a cosimplicial Lie algebra in the pseudo-tensor category of $\mathcal{D}_X$ -modules.

8.10.2 THE ČECH CONVOLUTION DG LIE ALGEBRA

The Moore complex $M\check{C}^\bullet(\mathcal{U}; \mathcal{A})$ is a cochain complex of $\mathcal{D}_X$ -modules whose cohomology computes the sheaf cohomology $H^\bullet(X, \mathcal{A})$. As in Proposition 13.22.395, we package the HCA operations into a single convolution algebra.

Definition 8.10.2 (Moore complex). For a cosimplicial object $A^\bullet$ in an abelian category, the *Moore complex* (or normalized cochain complex) is

$$(MA)^p = \bigcap_{j=0}^{p-1} \ker(\sigma^j : A^p \rightarrow A^{p-1}), \quad d_M = \sum_{j=0}^{p+1} (-1)^j \partial^j|_{(MA)^p}.$$

The Dold–Kan correspondence identifies cosimplicial objects with cochain complexes via this functor.

Definition 8.10.3 (Čech convolution dg Lie algebra). Let $V = M\check{C}^\bullet(\mathcal{U}; \mathcal{A})$ denote the Moore complex. Define the *Čech convolution dg Lie algebra*

$$\mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U}) = \prod_{n \geq 1} \mathrm{Hom}_{\Sigma_n}(\mathrm{Lie}(n) \otimes \mathcal{Z}(n), \mathrm{Hom}(V^{\otimes n}, V)),$$

where $\mathcal{Z}(n) = \text{Tot Hom}_{\Delta(k)}(Z, Z^{\otimes n})$ is the Eilenberg–Zilber chain complex and $\text{Lie}(n)$ is the degree- n part of the Lie operad. The grading is

$$|\mathfrak{g}^{\check{C}}|^k = \prod_{n \geq 1} \text{Hom}_{\Sigma_n}(\text{Lie}(n) \otimes \mathcal{Z}(n), \text{Hom}(V^{\otimes n}, V[k+1-n])).$$

The differential D on $\mathfrak{g}^{\check{C}}$ is the commutator $D(\alpha) = [d_M, \alpha]$ with the Moore differential. The Lie bracket on $\mathfrak{g}^{\check{C}}$ is the operadic composition bracket:

$$[\alpha, \beta](a_1, \dots, a_{m+n-1}) = \sum_{i=1}^m \pm \alpha(a_1, \dots, \beta(a_i, \dots, a_{i+n-1}), \dots, a_{m+n-1}) - (\alpha \leftrightarrow \beta),$$

where $\alpha \in \mathfrak{g}^{\check{C}}$ has degree m and β has degree n .

Remark 8.10.4 (Čech and modular convolution algebras). The algebra $\mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U})$ is the Čech convolution dg Lie algebra encoding HCA operations as MC data. Its modular counterpart is $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ (Definition 13.22.1), and the two share the same formal architecture:

- (i) both encode all algebraic operations on a resolution of $\mathcal{A}$ as components of a single MC element ($\Phi_{\mathcal{A}}$ and $\Theta_{\mathcal{A}}$ respectively);
- (ii) both are *strict* dg Lie models of underlying shifted L_{∞} algebras (Convention 13.22.11): the strict bracket suffices for Maurer–Cartan theory, while the full L_{∞} structure governs homotopy transfer and gauge equivalence;
- (iii) both produce degree-by-degree truncations $(\Phi_{\mathcal{A}}^{\leq r}, \Theta_{\mathcal{A}}^{\leq r})$ that satisfy the MC equation modulo degree $r+1$, forming parallel Postnikov towers.

The structural difference is the indexing combinatorics: $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is indexed by stable graphs (capturing all genera), while $\mathfrak{g}^{\check{C}}$ is indexed by the simplicial combinatorics of the cover (capturing all Čech degrees). The comparison between them is an L_{∞} morphism that intertwines the two MC elements.

8.10.3 HCA OPERATIONS AS A MAURER–CARTAN ELEMENT

The theorem of Malikov–Schechtman is now a statement about existence of an MC element:

THEOREM 8.10.5 (*Čech complex as homotopy chiral algebra*;). (Malikov–Schechtman [309], Theorem 3.1.) Let $\mathcal{A}$ be a sheaf of chiral algebras on X and $\mathcal{U}$ an affine open cover. The HCA structure on the Moore complex $V = M\check{C}^{\bullet}(\mathcal{U}; \mathcal{A})$ is encoded by a Maurer–Cartan element

$$\Phi_{\mathcal{A}} = \sum_{n \geq 1} F_n \in \mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U})^1$$

satisfying the master equation

$$D \Phi_{\mathcal{A}} + \frac{1}{2} [\Phi_{\mathcal{A}}, \Phi_{\mathcal{A}}] = 0 \tag{8.16}$$

in $\mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U})$.

Concretely, each component F_n is a multilinear operation

$$F_n : \text{Lie}(n) \otimes \mathcal{Z}(n) \otimes V^{\otimes n} \longrightarrow V, \quad n \geq 1,$$

where $\mathcal{Z}(n)$ is the Eilenberg–Zilber chain complex, and the collection $\{F_n\}_{n \geq 1}$ defines a pseudo-tensor functor from the Lie Eilenberg–Zilber operad $\mathcal{Y}(n) = \mathcal{Z}(n) \otimes_k \text{Lie}(n)$ to the endomorphism operad of V in the pseudo-tensor category.

Remark 8.10.6 (Degree-by-degree expansion of the MC equation). Expanding (8.16) by degree yields the familiar L_∞ relations. Write $\Phi_{\mathcal{A}} = F_1 + F_2 + F_3 + \cdots$ where F_n has degree n .

Degree 1 ($n = 1$): $D(F_1) = 0$. Since $F_1 = d_M$ is the Moore differential, this says $d_M^2 = 0$.

Degree 2 ($n = 2$): $D(F_2) + \frac{1}{2}[F_1, F_1] = 0$. This says $[d_M, F_2] = 0$: the binary bracket F_2 is a chain map.

Degree 3 ($n = 3$):

$$D(F_3) + [F_1, F_2] + \frac{1}{6}[F_2, [F_2, F_2]] = 0. \quad (8.17)$$

The term $[F_2, [F_2, F_2]]$ is the Jacobiator of F_2 . So F_3 is the nullhomotopy of the Jacobiator: $[d_M, F_3] = -\text{Jac}(F_2)$.

Degree n ($n \geq 4$): each relation has the form $D(F_n) + (\text{compositions of } F_1, \dots, F_{n-1}) = 0$, asserting that F_n is the nullhomotopy of the obstruction assembled from lower-degree data. The tower $\Phi_{\mathcal{A}}^{\leq r} = \sum_{n=1}^r F_n$ satisfies the MC equation modulo degree $r+1$, precisely paralleling the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ (Definition 13.22.46).

Remark 8.10.7 (Operadic action map). The explicit formula for F_n is given by Malikov–Schechtman [309], equation (3.1.2.1): for $\psi \in \text{Lie}(n)$, $\varphi \in \text{Hom}_{\Delta}(Z, Z^{\otimes n})$, and elements $a_{m_1} \in V^{m_1}, \dots, a_{m_n} \in V^{m_n}$,

$$F_n(\psi \otimes \varphi)_{m_1, \dots, m_n; m}(a_{m_1}, \dots, a_{m_n}) = \begin{cases} \psi_m(\bar{\varphi})(a_{m_1}, \dots, a_{m_n}) & \text{if } m = m_1 + \cdots + m_n, \\ 0 & \text{otherwise,} \end{cases}$$

where ψ_m is the chiral Lie action on $\check{C}^m(\mathcal{U}; \mathcal{A})$ and $\bar{\varphi} \in \bigotimes_{i=1}^n \text{Hom}(\check{C}^{m_i}, \check{C}^m)$ is the component of φ at the specified multi-degree.

8.10.4 ČECH–BAR COMPARISON AS L_∞ MORPHISM

The bar complex and the Čech complex are two resolutions of the same object (the chiral homology of $\mathcal{A}$ on X), and the convolution formulation makes their compatibility a statement about MC elements in two convolution algebras.

Conjecture 8.10.8 (Čech–bar intertwining;). Let $\mathcal{A}$ be a chiral algebra on a smooth projective curve X . There exists an L_∞ morphism

$$\Phi_*: (\mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U}), \Phi_{\mathcal{A}}) \xrightarrow{\sim} (\text{Conv}_{\infty}(\bar{\mathbf{B}}(\mathcal{A}), \mathcal{A}), \Theta_{\mathcal{A}}^{(0)})$$

intertwining the Čech MC element $\Phi_{\mathcal{A}} = \sum F_n$ with the genus-0 bar MC element $\Theta_{\mathcal{A}}^{(0)} = \sum m_n$. On cohomology, Φ_* induces the canonical isomorphism $\check{H}^\bullet(X, \mathcal{A}) \cong H_{\bullet}^{\text{ch}}(X, \mathcal{A})$ between Čech cohomology and chiral homology.

The L_∞ morphism Φ_* is constructed by the standard comparison between Čech and de Rham/Dolbeault resolutions, enhanced to an L_∞ morphism by homological perturbation. It is generically *non-strict*: the component $(\Phi_*)_n: F_{i_1} \otimes \cdots \otimes F_{i_n} \rightarrow m_{i_1 + \cdots + i_n - n + 1}$ need not vanish for $n \geq 2$. Strictness holds precisely when the Čech complex has the same truncation depth as the bar filtration, a condition guaranteed for two-element covers (Proposition 8.10.11).

Remark 8.10.9 (Čech–bar convolution dictionary). The MC formulation yields a parallel between the two resolutions:

	Čech side	Bar side
<i>Ambient algebra</i>	$\mathfrak{g}^{\check{C}}(\mathcal{A}, \mathcal{U})$	$\mathrm{Conv}_{\infty}(\bar{\mathbf{B}}(\mathcal{A}), \mathcal{A})$
<i>MC element</i>	$\Phi_{\mathcal{A}} = \sum_{n \geq 1} F_n$	$\Theta_{\mathcal{A}}^{(0)} = \sum_{n \geq 1} m_n$
<i>Master equation</i>	$D\Phi + \frac{1}{2}[\Phi, \Phi] = 0$	$D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$
<i>Underlying complex</i>	Moore $M\check{C}^{\bullet}(\mathcal{U}; \mathcal{A})$	$\mathrm{Bar} \bar{\mathbf{B}}(\mathcal{A})$ on $\mathrm{Ran}(X)$
<i>Combinatorial index</i>	Nerve of cover (simplicial trees)	Rooted trees / FCom
<i>Degree-n component</i>	F_n (Eilenberg–Zilber)	m_n (associahedra)
<i>Degree-3 obstruction</i>	Jacobiator of F_2	$m_1 m_2 + m_2(m_2 \otimes 1 + 1 \otimes m_2)$
<i>Truncation depth</i>	$ I - 1$ (Čech degree)	∞ (no bound)
<i>Genus ≥ 1</i>	Higher Čech on modular covers	Stable graphs in FCom

At genus 0, both sides are governed by trees: the Čech side by simplicial trees (nerve of the cover), the bar side by rooted planar trees (bar-length filtration). At genus $g \geq 1$, the bar side sees stable graphs (the Feynman transform FCom), while the Čech side sees the cosimplicial structure of the modular operad’s boundary strata. The comparison Φ_* intertwines these combinatorics via an L_{∞} morphism that is strict only when the cover has few enough opens.

Remark 8.10.10 (Log-geometric path to the Čech–bar comparison). The foundational triangle (Malikov–Schechtman [309] + Robert–Nicoud–Wierstra [367]/Vallette [389] + Mok [322]) suggests an explicit geometric construction of the L_{∞} morphism Φ_* of Conjecture 8.10.8. On Mok’s semistable degeneration $W \rightarrow B$ [322, Theorem 5.2.3]:

- (i) Each smooth fibre W_b ($b \neq b_0$) carries the bar resolution on its Ran space $\mathrm{Ran}(W_b)$, with MC element $\Theta_{\mathcal{A}}^{(0)} = \sum m_n$.
- (ii) The total space W carries a Čech resolution with respect to the cover induced by the irreducible components of the special fibre $Y_1 \cup_D Y_2$, with MC element $\Phi_{\mathcal{A}} = \sum F_n$ by [309] applied fiberwise.
- (iii) The degeneration formula [322, Corollary 5.3.4] decomposes the special fibre of $\mathrm{FM}_n(W/B)$ into products of log-local FM spaces $\prod_v \mathrm{FM}_{I_v}(Y_v | D_v)$. On each factor, the Čech and bar resolutions agree (both reduce to affine data on a single component).
- (iv) Gluing the log-local comparisons via the cutting map κ [322, Lemma 5.3.1] produces a candidate for Φ_* that intertwines the two MC elements by construction: the defining property is $(\Phi_*)_*(\Theta_{\mathcal{A}}^{(0)}) = \Phi_{\mathcal{A}}$, i.e., the pushforward of the bar MC element under Φ_* equals the Čech MC element.

Establishing that this candidate is an L_{∞} quasi-isomorphism reduces to the cohomological comparison $\check{H}^{\bullet}(X, \mathcal{A}) \cong H_{\bullet}^{\mathrm{ch}}(X, \mathcal{A})$ enhanced to the L_{∞} level by the one-slot functoriality of Conv [367, Theorem 5.1].

8.10.5 STRICTNESS AND THE COVER

The depth of the Čech complex is controlled by the combinatorics of the cover. For a cover by $|I|$ opens, $\check{C}^p = 0$ for $p \geq |I|$, so the MC element $\Phi_{\mathcal{A}}$ can have at most $|I|$ nonzero degree components. When

$|I| = 2$ (the case of $\mathbb{P}^1$ with its standard two-element cover, and more generally any curve equipped with a decomposition into two affine opens), the MC element simplifies.

PROPOSITION 8.10.11 (*Two-element covers are strict*). Let $\mathcal{U} = \{U_0, U_1\}$ be a two-element affine open cover of X . Then:

- (i) The Moore complex $V = M\check{C}^\bullet(\mathcal{U}; \mathcal{A})$ is concentrated in degrees 0 and 1: $V^0 = \mathcal{A}(U_0)$, $V^1 = \mathcal{A}(U_0 \cap U_1)/\mathcal{A}(U_1)$, $V^p = 0$ for $p \geq 2$.
- (ii) For any degree $n \geq 3$, the Eilenberg–Zilber component $F_n: V^{\otimes n} \rightarrow V$ vanishes for degree reasons: since F_n raises Čech degree by $n-1$ and $V^p = 0$ for $p \geq 2$, the target $V^{m_1+\dots+m_n}$ is zero whenever $n \geq 3$ and $m_i \geq 0$.
- (iii) The MC element reduces to $\Phi_{\mathcal{A}} = (d_M, F_2, 0, 0, \dots)$, and the master equation (8.16) collapses to two conditions:

$$\begin{aligned} d_M^2 &= 0, \\ [d_M, F_2] &= 0, \quad \text{Jac}(F_2) = 0. \end{aligned}$$

That is, F_2 is a *strict* dg Lie bracket: the Jacobi identity holds on the nose, not merely up to homotopy.

- (iv) The comparison L_∞ morphism $\Phi_*: \Phi_{\mathcal{A}} \rightarrow \Theta_{\mathcal{A}}^{(0)}$ is strict at the chain level (all higher Taylor components vanish), though the bar MC element $\Theta_{\mathcal{A}}^{(0)}$ may still have $m_n \neq 0$ for $n \geq 3$; the non-strictness is absorbed entirely by the *bar* side via homotopy transfer.

Proof. Part (i) is the standard Moore normalization for a two-element cover. For part (ii), observe that F_n has Čech output degree $m_1 + \dots + m_n - (n-1)$ (it maps n inputs to a single output, combining n Čech cochains via $n-1$ face-map contractions). When all inputs lie in $V^0 \oplus V^1$ and $n \geq 3$, at least $\lceil n/2 \rceil \geq 2$ inputs must be in degree 0 for the output to land in $V^0 \cup V^1$; but the Eilenberg–Zilber diagonal forces the output degree to be $\geq n-1 \geq 2$, which lies in $V^{\geq 2} = 0$.

For part (iii), with $F_n = 0$ for all $n \geq 3$, the MC equation $D\Phi + \frac{1}{2}[\Phi, \Phi] = 0$ at degree 3 reads $0 + [F_2, [F_2, F_2]]/6 = 0$, which is the strict Jacobi identity $\text{Jac}(F_2) = 0$.

Part (iv) follows because the L_∞ morphism Φ_* is constructed by homological perturbation of the Čech-to-bar comparison. The perturbation series terminates at order 1 on the Čech side (since $\Phi_{\mathcal{A}}$ is strict), but the transferred structure on the bar side acquires all m_n via the standard homological perturbation lemma. $\square$

REMARK 8.10.12 (*When does the Jacobiator appear?*). The vanishing of the Jacobiator for two-element covers is a *combinatorial* accident, not an algebraic one: the underlying chiral algebra may be highly nonabelian (as in the $\widehat{\mathfrak{sl}}_2$ example below), but the Čech resolution is too short to see the ternary obstruction. Genuine higher homotopies $F_n \neq 0$ for $n \geq 3$ appear precisely when:

- (a) The cover $\mathcal{U}$ has *three or more opens* with nontrivial triple intersections, so that $\check{C}^2 \neq 0$ and F_3 has room to land.
- (b) The curve has genus $g \geq 1$: any affine open cover of a curve of genus g requires at least $g+1$ opens (since $H^1(X, \mathcal{O}_X) \neq 0$ forces the Čech complex to be at least two-term, and the nontriviality of triple overlaps grows with genus).

- (c) The chiral algebra is nonabelian: for abelian $\mathcal{A}$ (e.g., the Heisenberg algebra), $F_2 = 0$ in the Lie sense (only the central extension survives), so $\text{Jac}(F_2) = 0$ regardless of the cover.

The sharpest case is an affine Kac–Moody algebra on an elliptic curve with a three-element cover: here $F_3 \neq 0$ and reflects the genus-1 curvature $\kappa(\mathcal{A}) \cdot \omega_1$ (Example 8.10.15).

8.10.6 EXAMPLES

Example 8.10.13 (Čech HCA for the Heisenberg algebra on $\mathbb{P}^1$). Take $X = \mathbb{P}^1$ with the standard cover $U_0 = \mathbb{A}^1 = \text{Spec } k[z]$ and $U_\infty = \mathbb{P}^1 \setminus \{0\} = \text{Spec } k[z^{-1}]$, so $U_0 \cap U_\infty = \mathbb{G}_m = \text{Spec } k[z, z^{-1}]$. This is a two-element cover, so Proposition 8.10.11 applies. The Čech complex for the Heisenberg sheaf $\mathcal{H}_k$ is the two-term complex

$$\check{C}^0 = \mathcal{H}_k(U_0) \oplus \mathcal{H}_k(U_\infty) \xrightarrow{d_{\check{C}}} \check{C}^1 = \mathcal{H}_k(U_0 \cap U_\infty),$$

where $d_{\check{C}}(f_0, f_\infty) = f_0|_{\mathbb{G}_m} - f_\infty|_{\mathbb{G}_m}$. Moore normalization gives $V^0 = \mathcal{H}_k(U_0)$ and $V^1 = \mathcal{H}_k(\mathbb{G}_m)/\mathcal{H}_k(U_\infty)$.

The MC element is

$$\Phi_{\mathcal{H}_k} = (d_M, F_2, 0, 0, \dots) \in \mathfrak{g}^{\check{C}}(\mathcal{H}_k, \mathcal{U})^1,$$

and the master equation reduces to $d_M^2 = 0$ (immediate) and the strict Jacobi identity for F_2 . For the Heisenberg algebra, F_2 is the transferred chiral bracket: for $J_n = z^n dz \in \mathcal{H}_k(U_0)$,

$$F_2(J_m, J_n) = k m \delta_{m+n, 0} \cdot 1.$$

Since the Heisenberg bracket is abelian (only the central extension is nonzero), the Jacobi identity $[F_2, [F_2, F_2]] = 0$ is automatic: the double commutator vanishes by centrality.

The comparison morphism $\Phi_* : \Phi_{\mathcal{H}_k} \rightarrow \Theta_{\mathcal{H}_k}^{(0)}$ is strict because *both* sides are strict: the bar A_∞ structure has $m_n = 0$ for $n \geq 3$ (§E.8.4), matching the Čech strictness.

The Čech cohomology $H^0(\mathbb{P}^1, \mathcal{H}_k) = k \cdot 1$ (global constants) and $H^1(\mathbb{P}^1, \mathcal{H}_k) = \bigoplus_{n < 0} k \cdot J_n$ (negative modes modulo positive modes) reproduce the chiral homology of $\mathcal{H}_k$ on $\mathbb{P}^1$.

Example 8.10.14 (Čech HCA for $\widehat{\mathfrak{sl}}_2$ on $\mathbb{P}^1$: strict Čech, non-strict bar). For $\mathcal{A} = \widehat{\mathfrak{sl}}_2$ at level k on $\mathbb{P}^1$ with the same two-element cover, the Čech MC element is again strict:

$$\Phi_{\widehat{\mathfrak{sl}}_2} = (d_M, F_2, 0, 0, \dots),$$

by Proposition 8.10.11. The binary bracket F_2 encodes the full affine OPE on the overlap $\mathbb{G}_m$, and the Jacobi identity holds *on the nose* for the transferred bracket on the Moore complex, not because the algebra is abelian (it is not), but because the Čech complex is too short for the Jacobiator to have a nonzero target.

The bar side is *not* strict. The bar A_∞ structure on $\bar{\mathbf{B}}(\widehat{\mathfrak{sl}}_2)$ has $m_3 \neq 0$: the ternary operation is nonzero and is responsible for the nontrivial $\bar{H}^2$ (which equals 5 for $\widehat{\mathfrak{sl}}_2$; cf. §16.8). The comparison L_∞ morphism Φ_* is therefore non-strict at order 2:

$$(\Phi_*)_2(F_2 \otimes F_2) = m_3 \neq 0.$$

That is, m_3 on the bar side is *created* from F_2 on the Čech side by homotopy transfer: the standard homological perturbation lemma applied to the Čech-to-bar comparison produces $m_3 = h \circ F_2(F_2 \otimes \text{id}) + \dots$, where h is the contracting homotopy of the comparison quasi-isomorphism.

This example cleanly separates the two notions of strictness: the Čech resolution is strict (a property of the cover), while the bar resolution is non-strict (a property of the algebra). The L_∞ morphism bridges the two.

Example 8.10.15 (Čech HCA at genus 1: the Jacobiator and curvature). Let E_τ be an elliptic curve (genus 1), and let $\mathcal{U} = \{U_0, U_1, U_2\}$ be a three-element affine open cover (the minimum required, since $H^1(E_\tau, \mathcal{O}) \neq 0$). The Čech complex for a chiral algebra $\mathcal{A}$ on E_τ now extends to degree 2:

$$\check{C}^0 \xrightarrow{d_{\check{C}}} \check{C}^1 \xrightarrow{d_{\check{C}}} \check{C}^2,$$

where $\check{C}^2 = \Gamma(U_0 \cap U_1 \cap U_2, \mathcal{A})$ is the sections on the (generically nonempty) triple overlap. The Moore complex has $V^2 \neq 0$, so Proposition 8.10.11 does *not* apply.

The MC element now has a genuine ternary component:

$$\Phi_{\mathcal{A}} = (d_M, F_2, F_3, 0, 0, \dots).$$

The truncation at F_3 follows because $V^p = 0$ for $p \geq 3$ (a three-element cover has Čech degree at most 2). The master equation at degree 3 (equation (8.17)) reads

$$[d_M, F_3] + \text{Jac}(F_2) = 0,$$

asserting that F_3 is the explicit nullhomotopy of the Jacobiator of the binary bracket.

Under the Čech–bar comparison, F_3 maps to the bar-side curvature. Specifically, for $\mathcal{A} = \widehat{\mathfrak{g}}_k$ (affine Kac–Moody at level k), the class $[F_3] \in H^2(\mathfrak{g}^{\check{C}})$ is the descent shadow of the bar curvature:

$$[\Phi_*(F_3)] = \kappa(\widehat{\mathfrak{g}}_k) \cdot \omega_1 \in H^1(E_\tau, \omega_{E_\tau}),$$

where $\kappa(\widehat{\mathfrak{g}}_k) = \dim \mathfrak{g} (k + h^\vee) / (2h^\vee)$ is the modular characteristic (Theorem 13.13.16) and $\omega_1 = dz$ is the period form on E_τ . This is the first appearance of the genus-1 obstruction in Čech language: the bar curvature $m_0^{(1)} = \kappa \cdot \omega_1$ on $\bar{\mathbf{B}}(\mathcal{A})|_{E_\tau}$, which records the failure of $d_B^2 = 0$ at genus 1 (cf. Chapter 13, §13.8), is *witnessed* on the Čech side by the nonvanishing of F_3 .

The pattern generalizes: on a genus- g curve with a $(g+1)$ -element cover, the MC element has $\Phi_{\mathcal{A}} = (d_M, F_2, F_3, \dots, F_{g+1}, 0, 0, \dots)$, and the degree- $(g+1)$ component F_{g+1} descends from the genus- g bar curvature $\kappa(\mathcal{A}) \cdot \omega_g$. The Čech resolution thus provides an alternative, explicitly combinatorial window into the modular tower of obstructions $\Theta_{\mathcal{A}}^{\leq r}$.

8.II CASIMIR INVARIANTS AND THE DIVISOR-CORE LATTICE

The bar cohomology $H^\bullet(\bar{B}^{\text{ch}}(\mathcal{A}))$ carries a natural action of the Casimir algebra $Z_{\mathcal{A}}$, the center of the universal enveloping algebra, generated by the rank- r Casimir operators $C_1, \dots, C_r$ together with the level operator K . This action is visible already in the explicit tables of Chapter K.7.1: the Betti numbers $\dim H^n(\bar{B}^{\text{ch}}(\mathcal{A}))$ satisfy a linear recurrence whose characteristic polynomial is the spectral discriminant $\Delta_{\mathcal{A}}(x)$. The eigenvalue structure of the Casimir action organizes the bar cohomology into a *divisor lattice*, the same lattice that classifies submodules of cyclic $k[t]$ -modules. Transport between algebras related by exact functors (Drinfeld–Sokolov reduction, quantum Hamiltonian reduction, level-rank duality) factors through the greatest common divisor of their recurrence polynomials. This is where the algebraic formalism of Koszul duality makes contact with the classical Jordan normal form.

The section is organized as follows. We first develop the pure algebra of cyclic transport objects and divisor cores (§8.II.1–8.II.2), then apply the theory to bar cohomology (§8.II.3–8.II.4), and close with the common-core transport theorem and its implications for the Drinfeld–Sokolov correspondence (§8.II.6–8.II.8).

8.II.1 CYCLIC TRANSPORT OBJECTS AND DIVISOR CORES

Throughout this section, k denotes a field of characteristic 0.

Definition 8.II.1 (Universal cyclic transport object). Let $p(t) \in k[t]$ be monic of degree d . The *cyclic transport object* attached to p is the $k[t]$ -module

$$M(p) := k[t]/(p).$$

Multiplication by t defines the shift endomorphism $T_p : M(p) \rightarrow M(p)$, $T_p([f]) = [tf]$. The module $M(p)$ satisfies the evident universal property: every finite-dimensional cyclic $k[t]$ -module annihilated by p is a quotient of $M(p)$, and the quotient is an isomorphism precisely when p is the minimal polynomial.

Definition 8.II.2 (Divisor core). Let $p(t) \in k[t]$ be monic and $g \mid p$ a monic divisor. The *divisor core* associated to g is the submodule

$$C_g(p) := (p/g)M(p) \subset M(p).$$

The divisor core is the canonical embedding of the g -factor into the ambient module. The key theorem is that divisor cores account for *all* submodules, and that their lattice structure mirrors the divisor lattice of p .

THEOREM 8.II.3 (Divisor-core calculus;). Let $p \in k[t]$ be monic, and let $g, g_1, g_2 \mid p$ be monic divisors.

(i) (Canonical identification.) There is a canonical isomorphism of $k[t]$ -modules

$$C_g(p) \cong k[t]/(g).$$

(ii) (Short exact sequence.) The inclusion $C_g(p) \hookrightarrow M(p)$ fits into a canonical short exact sequence

$$0 \longrightarrow C_g(p) \longrightarrow M(p) \longrightarrow k[t]/(p/g) \longrightarrow 0.$$

(iii) (Lattice identities.) The divisor cores satisfy

$$\begin{aligned} C_{g_1}(p) \cap C_{g_2}(p) &= C_{\gcd(g_1, g_2)}(p), \\ C_{g_1}(p) + C_{g_2}(p) &= C_{\text{lcm}(g_1, g_2)}(p). \end{aligned}$$

(iv) (Idempotent splitting criterion.) The following are equivalent:

- (a) $C_g(p)$ is the image of an idempotent polynomial in T_p ;
- (b) $M(p) \cong C_g(p) \oplus k[t]/(p/g)$;
- (c) $\gcd(g, p/g) = 1$.

Proof. For (i), the map $k[t] \rightarrow C_g(p)$ defined by $f \mapsto f \cdot (p/g) \bmod p$ descends to a surjection $k[t]/(g) \twoheadrightarrow C_g(p)$. If $f \cdot (p/g) \equiv 0 \pmod{p}$, then $p \mid f(p/g)$; since $p = g \cdot (p/g)$ and $k[t]$ is a domain, $g \mid f$. Hence the kernel is (g) and the map is an isomorphism.

For (ii), the quotient $M(p) \twoheadrightarrow k[t]/(p/g)$ has kernel $\{[f] : (p/g) \mid f \bmod p\} = C_g(p)$.

For (iii), the intersection and sum of ideals in a PID yield lcm and gcd respectively; the stated lattice identities follow by the correspondence $C_g(p) = (p/g)/(p)$.

For (iv), a direct-sum splitting of (ii) exists if and only if the Chinese remainder theorem applies, which holds precisely when (g) and (p/g) are comaximal, i.e. $\gcd(g, p/g) = 1$. $\square$

COROLLARY 8.II.4 (*Divisors classify submodules;*). Every submodule of $M(p)$ is of the form $C_g(p)$ for a unique monic divisor $g \mid p$. The lattice of submodules of $M(p)$ is anti-isomorphic to the divisor lattice of p .

Proof. Submodules of $k[t]/(p)$ correspond to ideals (a) with $(p) \subseteq (a) \subseteq k[t]$. Since $k[t]$ is a PID, a is a monic divisor of p . Setting $g = p/a$ gives $C_g(p)$. Uniqueness of g is equivalent to uniqueness of the intermediate ideal (a) . The anti-isomorphism of lattices is immediate because larger divisors produce smaller quotient ideals. $\square$

Remark 8.II.5 (*The first structural correction*). A factor $g \mid p$ always defines a canonical submodule of $M(p)$. It defines a canonical *projector* only when $\gcd(g, p/g) = 1$. When this coprimality fails (that is, when the divisor shares roots with its complement), the submodule is canonically embedded but not idempotently split. The extension class $\text{Ext}^1(k[t]/(p/g), C_g(p))$ that prevents the splitting is the algebraic shadow of a genuine Jordan block.

8.II.2 HOM = GCD AND FACTORIZATION THROUGH COMMON CORES

THEOREM 8.II.6 (*Hom = gcd;*). Let $p, q \in k[t]$ be monic, and set $g = \gcd(p, q)$. Then

$$\text{Hom}_{k[t]}(M(p), M(q)) \cong k[t]/(g).$$

In particular, $\dim_k \text{Hom}_{k[t]}(M(p), M(q)) = \deg g$.

Proof. A $k[t]$ -linear map $f: M(p) \rightarrow M(q)$ is determined by $x := f(1) \in M(q)$, subject to $p \cdot x = 0$ in $M(q)$, i.e. $q \mid px$. Write $p = gp'$, $q = gq'$ with $\gcd(p', q') = 1$. Then $q \mid px$ becomes $q' \mid p'x$, and coprimality forces $q' \mid x$. Hence the space of allowed images is $(q')/(gq') \cong k[t]/(g)$. $\square$

THEOREM 8.II.7 (*Universal factorization through the common core;*). Let $p, q \in k[t]$ be monic, $g = \gcd(p, q)$, and write $\pi_p: M(p) \twoheadrightarrow M(g)$ for the canonical quotient and $\iota_q: M(g) \hookrightarrow M(q)$ for the inclusion onto the divisor core $C_g(q)$. Then every $k[t]$ -linear map $f: M(p) \rightarrow M(q)$ factors uniquely as

$$f = \iota_q \circ m_u \circ \pi_p$$

for a unique class $u \in M(g)$, where $m_u: M(g) \rightarrow M(g)$ denotes multiplication by u .

Proof. By Theorem 8.II.6, $\text{Hom}_{k[t]}(M(p), M(q)) \cong M(g)$. The map $u \mapsto \iota_q \circ m_u \circ \pi_p$ is k -linear, injective (since π_p is surjective and ι_q is injective), and both source and target have dimension $\deg g$; hence it is an isomorphism. $\square$

Remark 8.II.8. The theorem says that transport maps between cyclic spectral objects are *never mysterious*: they are exactly multiplication operators on the maximal common core $M(\gcd(p, q))$. The common divisor controls everything.

8.II.3 THE CASIMIR RECURRENCE MODULE

We now connect the abstract divisor-core theory to bar cohomology.

Hypothesis 8.II.9 (Finite-character recurrence). Let $\mathcal{A}$ be a modular Koszul chiral algebra in the Lie-theoretic world, and write $Z_{\mathcal{A}} = k[C_1, \dots, C_r, K]$ for the commutative Casimir algebra. We assume:

- (i) Each $H^n(\bar{B}^{\text{ch}}(\mathcal{A}))$ has finite generalized $Z_{\mathcal{A}}$ -support.
- (ii) The class sequence $u_{\mathcal{A}}(n) := [H^n(\bar{B}^{\text{ch}}(\mathcal{A}))] \in K_0(Z_{\mathcal{A}}\text{-mod}_{\text{fl}}) \otimes_{\mathbb{Z}} k$ satisfies a minimal monic shift recurrence $p_{\mathcal{A}}(\sigma) u_{\mathcal{A}} = 0$ for some monic $p_{\mathcal{A}}(t) \in k[t]$.
- (iii) The recurrence polynomial is the reversal of the spectral discriminant: $p_{\mathcal{A}}(t) = t^{d_{\mathcal{A}}} \Delta_{\mathcal{A}}(t^{-1})$, where $d_{\mathcal{A}} = \deg \Delta_{\mathcal{A}}$.

This hypothesis is verified for all standard families: the affine Kac–Moody algebras (§16.8), the $\mathcal{W}$ -algebras (Theorem K.7.1), and the Virasoro algebra (Theorem K.7.1).

Definition 8.II.10 (Casimir recurrence module and Kodaira–Spencer operator). Under Hypothesis 8.II.9, define the *Casimir recurrence module*

$$\mathcal{R}_{\mathcal{A}} := k[\sigma] \cdot u_{\mathcal{A}} \subset (K_0(Z_{\mathcal{A}}\text{-mod}_{\text{fl}}) \otimes k)^{\mathbb{N}},$$

and the *algebraic reduced first cohomology* $H_{\text{red}}^{1, \text{alg}}(\mathcal{A}) := \mathcal{R}_{\mathcal{A}}^{\vee}$. The *Kodaira–Spencer operator* is the dual of the shift:

$$KS_{\mathcal{A}} := \sigma^{\vee} \in \text{End}(H_{\text{red}}^{1, \text{alg}}(\mathcal{A})).$$

THEOREM 8.II.11 (*Minimal intrinsic realization*;). Under Hypothesis 8.II.9, $\mathcal{R}_{\mathcal{A}} \cong k[t]/(p_{\mathcal{A}})$ as $k[t]$ -modules. Consequently $\dim_k H_{\text{red}}^{1, \text{alg}}(\mathcal{A}) = d_{\mathcal{A}}$, and the Kodaira–Spencer operator recovers the spectral discriminant:

$$\det(1 - x KS_{\mathcal{A}}) = \Delta_{\mathcal{A}}(x).$$

Proof. The $k[t]$ -linear surjection $k[t] \rightarrow \mathcal{R}_{\mathcal{A}}$ sending $f(t) \mapsto f(\sigma) u_{\mathcal{A}}$ has kernel $(p_{\mathcal{A}})$ by minimality of the recurrence, so $\mathcal{R}_{\mathcal{A}} \cong M(p_{\mathcal{A}})$. The characteristic polynomial of $T_{p_{\mathcal{A}}}$ is $p_{\mathcal{A}}$, so $\det(1 - x KS_{\mathcal{A}}) = x^{d_{\mathcal{A}}} p_{\mathcal{A}}(x^{-1}) = \Delta_{\mathcal{A}}(x)$. $\square$

8.II.4 SECTOR DETERMINANT AND CASIMIR RECONSTRUCTION

Every divisor $S(x) \mid \Delta_{\mathcal{A}}(x)$ of the spectral discriminant produces a canonical finite-dimensional sector inside the Casimir recurrence module.

Definition 8.II.12 (Reduced spectral sector). Let $S(x) \mid \Delta_{\mathcal{A}}(x)$ be a monic divisor, and set $s(t) := t^{\deg S} S(t^{-1})$. The *spectral sector of type S* is the canonical subquotient

$$H_S^{1, \text{alg}}(\mathcal{A}) := (C_s(p_{\mathcal{A}}))^{\vee}.$$

THEOREM 8.II.13 (*Sector determinant*;). For every divisor $S \mid \Delta_{\mathcal{A}}$, the dual of the S -sector satisfies $(H_S^{1, \text{alg}}(\mathcal{A}))^{\vee} \cong k[t]/(s)$, and the induced endomorphism $KS_{\mathcal{A}, S}$ satisfies

$$\det(1 - x KS_{\mathcal{A}, S}) = S(x).$$

Proof. By Theorem 8.II.3(i), $C_s(p_{\mathcal{A}}) \cong k[t]/(s)$; the determinant identity follows exactly as in Theorem 8.II.II. Namely, the endomorphism on the S -sector is multiplication by t on $k[t]/(s)$, whose characteristic polynomial is s . Reversing the polynomial back to the x -variable gives $S(x)$. $\square$

THEOREM 8.II.I4 (*Casimir moment reconstruction*;). Suppose the generalized $Z_{\mathcal{A}}$ -spectrum occurring in $H^n(\bar{B}^{\text{ch}}(\mathcal{A}))$ is eventually contained in a finite set $\Xi_{\mathcal{A}} = \{\chi_1, \dots, \chi_s\}$. Choose $Q \in Z_{\mathcal{A}}$ separating $\Xi_{\mathcal{A}}$ (a generic linear combination of Casimirs suffices over an infinite field), and write $q_i = \chi_i(Q)$. Then the scalar moment sequences

$$\tau_m(n) := \text{Tr}(Q^m \mid H^n(\bar{B}^{\text{ch}}(\mathcal{A}))), \quad 0 \leq m \leq s-1,$$

determine the multiplicity vector of generalized characters at each degree n via the Vandermonde inversion $m(n) = V^{-1}\tau(n)$. In particular, the full recurrence module $\mathcal{R}_{\mathcal{A}}$ is recoverable from finitely many scalar Casimir traces.

Proof. On the generalized χ_i -block, Q acts as $q_i I + N_i$ with N_i nilpotent, so $\text{Tr}(Q^m \mid V_{\chi_i}) = q_i^m \dim V_{\chi_i}$. The moment vector $\tau(n)$ is related to the multiplicity vector $m(n)$ by the Vandermonde matrix $(q_i^m)_{m,i}$, which is invertible because the q_i are distinct. $\square$

8.II.5 PRIMARY JORDAN FILTRATION

The divisor-core lattice refines to a Jordan filtration at each irreducible factor of the recurrence polynomial. This is where repeated roots of the discriminant reveal their geometric content.

THEOREM 8.II.I5 (*Primary Jordan filtration*;). Let q be an irreducible factor of $p_{\mathcal{A}}$ and set $n = \nu_q(p_{\mathcal{A}})$. Then the primary divisor cores $\mathcal{J}_q^m(p_{\mathcal{A}}) := C_{q^m}(p_{\mathcal{A}})$, $1 \leq m \leq n$, form a canonical chain

$$0 \subset \mathcal{J}_q^1(p_{\mathcal{A}}) \subset \mathcal{J}_q^2(p_{\mathcal{A}}) \subset \dots \subset \mathcal{J}_q^n(p_{\mathcal{A}}) \subset M(p_{\mathcal{A}}),$$

with successive quotients $\mathcal{J}_q^m / \mathcal{J}_q^{m-1} \cong k[t]/(q)$. If $q = t - \lambda$ splits linearly over k , then $T_{p_{\mathcal{A}}} - \lambda$ acts on $\mathcal{J}_{t-\lambda}^m$ by a single Jordan block of size m .

Proof. By Theorem 8.II.3(i), $\mathcal{J}_q^m(p_{\mathcal{A}}) \cong k[t]/(q^m)$. The successive quotient $k[t]/(q^m) / q^{m-1}k[t]/(q^m) \cong k[t]/(q)$. For $q = t - \lambda$, set $\tau = t - \lambda$; then t acts as $\lambda + \tau$ on $k[\tau]/(\tau^m)$, and τ is the standard nilpotent Jordan shift. $\square$

COROLLARY 8.II.I6 (*Repeated roots encode extension data*;). If $g \mid p_{\mathcal{A}}$ shares a nontrivial common factor with $p_{\mathcal{A}}/g$, then $C_g(p_{\mathcal{A}})$ is canonical but not idempotently split. Repeated roots of the spectral discriminant encode genuine extension classes in bar cohomology, not idempotently removable bookkeeping.

Proof. Let q be a common irreducible factor of g and $p_{\mathcal{A}}/g$. Then the q -primary piece of $C_g(p_{\mathcal{A}})$ lies inside the Jordan filtration of Theorem 8.II.I5 with exponent at least 2. That theorem identifies the corresponding primary summand with $k[t]/(q^m)$ and, when $q = t - \lambda$ splits, exhibits a single Jordan block for $T_{p_{\mathcal{A}}} - \lambda$. Such a primary block is canonical as a submodule, but it cannot split idempotently into semisimple eigenspaces because the nilpotent Jordan operator is nonzero. Hence repeated roots of the discriminant encode genuine extension data rather than removable bookkeeping. $\square$

8.II.6 COMMON-CORE TRANSPORT BETWEEN ALGEBRAS

The common-core theorem is the structural heart of the section: it controls what exact functors between chiral algebras can see at the level of the spectral discriminant.

Let $\mathcal{A}$ and $\mathcal{B}$ both satisfy Hypothesis 8.II.9, with recurrence polynomials $p_{\mathcal{A}}$ and $p_{\mathcal{B}}$. Write $g_{\mathcal{A},\mathcal{B}} = \gcd(p_{\mathcal{A}}, p_{\mathcal{B}})$.

Definition 8.II.17 (Maximal common transport core). The maximal common transport core is the module $C_{\mathcal{A},\mathcal{B}}^{\max} := M(g_{\mathcal{A},\mathcal{B}}) = k[t]/(g_{\mathcal{A},\mathcal{B}})$.

THEOREM 8.II.18 (Common-core exact sequences;). There are canonical short exact sequences

$$\begin{aligned} 0 \rightarrow C_{\mathcal{A},\mathcal{B}}^{\max} &\rightarrow \mathcal{R}_{\mathcal{A}} \rightarrow k[t]/(p_{\mathcal{A}}/g_{\mathcal{A},\mathcal{B}}) \rightarrow 0, \\ 0 \rightarrow C_{\mathcal{A},\mathcal{B}}^{\max} &\rightarrow \mathcal{R}_{\mathcal{B}} \rightarrow k[t]/(p_{\mathcal{B}}/g_{\mathcal{A},\mathcal{B}}) \rightarrow 0. \end{aligned}$$

The quotient modules $k[t]/(p_{\mathcal{A}}/g_{\mathcal{A},\mathcal{B}})$ and $k[t]/(p_{\mathcal{B}}/g_{\mathcal{A},\mathcal{B}})$ are the *spectral defects*: they measure what each algebra carries that the other cannot see.

Proof. Apply Theorem 8.II.3(ii) with $g = g_{\mathcal{A},\mathcal{B}}$ to each of the recurrence modules $\mathcal{R}_{\mathcal{A}} \cong M(p_{\mathcal{A}})$ and $\mathcal{R}_{\mathcal{B}} \cong M(p_{\mathcal{B}})$. This identifies the common core with the divisor core cut out by $g_{\mathcal{A},\mathcal{B}}$ on both sides. The two quotient modules are therefore exactly the complementary defect factors recorded in the statement. $\square$

PROPOSITION 8.II.19 (Transport factors through the common core;). Every $k[t]$ -linear map $F: \mathcal{R}_{\mathcal{A}} \rightarrow \mathcal{R}_{\mathcal{B}}$ factors uniquely as

$$\mathcal{R}_{\mathcal{A}} \twoheadrightarrow C_{\mathcal{A},\mathcal{B}}^{\max} \xrightarrow{m_u} C_{\mathcal{A},\mathcal{B}}^{\max} \hookrightarrow \mathcal{R}_{\mathcal{B}}$$

for a unique $u \in C_{\mathcal{A},\mathcal{B}}^{\max}$. Equivalently, every shift-compatible transport between the algebraic reduced cohomologies is governed by multiplication on the maximal common core.

Proof. Theorem 8.II.11 identifies each recurrence module with its minimal polynomial model $M(p_{\mathcal{A}})$ or $M(p_{\mathcal{B}})$. Theorem 8.II.7 then says that every $k[t]$ -linear map between these models factors uniquely through the common core $M(g_{\mathcal{A},\mathcal{B}})$ by multiplication by an element of that core. Transporting this factorization back through the intrinsic realizations gives exactly the stated factorization for $\mathcal{R}_{\mathcal{A}}$ and $\mathcal{R}_{\mathcal{B}}$. $\square$

8.II.7 THE $\widehat{\mathfrak{sl}}_3$ VERSUS W_3 COMMON CORE

The first nontrivial example is the Drinfeld–Sokolov pair $(\widehat{\mathfrak{sl}}_3, W_3)$, where the common core is strictly smaller than either recurrence module. For the rank-one pair $(\widehat{\mathfrak{sl}}_2, \text{Vir})$, both algebras share $\Delta(x) = (1 - 3x)(1 + x)$ (cf. Theorem K.7.1), so the common core is the entire transport module and the theory degenerates. The first rank where nontrivial defects appear is rank 2.

The standard rational predictions (Theorem K.7.1) give

$$\begin{aligned} \Delta_{\widehat{\mathfrak{sl}}_3}(x) &= (1 - 8x)(1 - 3x - x^2), \\ \Delta_{W_3}(x) &= (1 - x)(1 - 3x - x^2), \end{aligned}$$

with reversed recurrence polynomials

$$\begin{aligned} p_{\widehat{\mathfrak{sl}}_3}(t) &= (t-8)(t^2-3t-1), \\ p_{W_3}(t) &= (t-1)(t^2-3t-1). \end{aligned}$$

The maximal common core is the two-dimensional module

$$C_{\widehat{\mathfrak{sl}}_3, W_3}^{\max} \cong k[t]/(t^2-3t-1),$$

with eigenvalues $(3 \pm \sqrt{13})/2$.

PROPOSITION 8.II.20 (*Exact defect decomposition;*). The common-core exact sequences of Theorem 8.II.18 take the form

$$\begin{aligned} 0 \rightarrow k[t]/(t^2-3t-1) &\rightarrow k[t]/((t-8)(t^2-3t-1)) \rightarrow k[t]/(t-8) \rightarrow 0, \\ 0 \rightarrow k[t]/(t^2-3t-1) &\rightarrow k[t]/((t-1)(t^2-3t-1)) \rightarrow k[t]/(t-1) \rightarrow 0. \end{aligned}$$

The one-dimensional defect modules $k[t]/(t-8)$ and $k[t]/(t-1)$ record the non-preserved dominant modes: eigenvalue 8 for $\widehat{\mathfrak{sl}}_3$ and eigenvalue 1 for W_3 .

Proof. Theorem 8.II.3(ii) gives the short exact sequences

$$0 \rightarrow M(g_{\mathcal{A}, \mathcal{B}}) \rightarrow M(p_{\mathcal{A}}) \rightarrow M(p_{\mathcal{A}}/g_{\mathcal{A}, \mathcal{B}}) \rightarrow 0$$

and the analogous sequence for $M(p_{\mathcal{B}})$. Under the explicit polynomials in this example, $g_{\mathcal{A}, \mathcal{B}} = t^2-3t-1$, $p_{\widehat{\mathfrak{sl}}_3}/g_{\mathcal{A}, \mathcal{B}} = t-8$, and $p_{W_3}/g_{\mathcal{A}, \mathcal{B}} = t-1$. Substituting these values into the general exact sequences gives the two displayed decompositions. The quotient factors are one-dimensional, so they record exactly the dominant modes that are not seen by the maximal common core. $\square$

PROPOSITION 8.II.21 (*Explicit coprime-locus projectors;*). Since $\gcd(t^2-3t-1, t-8) = \gcd(t^2-3t-1, t-1) = 1$, the common quadratic sector splits idempotently on both sides.

(i) For $\widehat{\mathfrak{sl}}_3$: the Bézout identity

$$\frac{1}{39}(t^2-3t-1) - \frac{t+5}{39}(t-8) = 1$$

gives the projector onto the common core

$$P_{\widehat{\mathfrak{sl}}_3}^{\text{core}} = -\frac{1}{39}(T+5I)(T-8I).$$

(ii) For W_3 : the Bézout identity

$$-\frac{1}{3}(t^2-3t-1) + \frac{t-2}{3}(t-1) = 1$$

gives the projector

$$P_{W_3}^{\text{core}} = \frac{1}{3}(T-2I)(T-I).$$

Each projected image has characteristic polynomial t^2-3t-1 , hence eigenvalues $(3 \pm \sqrt{13})/2$. The projectors intertwine with Drinfeld–Sokolov reduction on the common core.

Proof. Both Bézout identities are verified by direct expansion. The projectors are instances of the coprime-locus functional calculus: if $\gcd(g, p/g) = 1$ and $a(t)g(t) + b(t)(p/g)(t) = 1$, then $e_g(T) = b(T)(p/g)(T)$ is idempotent with image the g -summand in the Chinese remainder decomposition $k[t]/(p) \cong k[t]/(g) \oplus k[t]/(p/g)$. $\square$

Remark 8.II.22 (Why rank one is deceptive). For the $\widehat{\mathfrak{sl}}_2/\text{Vir}$ correspondence, the recurrence polynomials coincide: $p_{\widehat{\mathfrak{sl}}_2} = p_{\text{Vir}} = (t-3)(t+1)$. The common core is the entire module, both defect modules vanish, and every divisor is coprime to its complement. *Nothing* in this rank-one picture foreshadows the Jordan and defect phenomena that appear as soon as the common factor becomes proper. The $\widehat{\mathfrak{sl}}_3/W_3$ pair is the first honest example.

8.II.8 THE GEOMETRIC FRONTIER

The algebra developed above corrects four overstatements natural on first encounter:

- (1) The discriminant is *not* the final transport object; it is the characteristic polynomial of the final object.
- (2) A divisor of the discriminant does *not* in general produce a projector; it produces a canonical subquotient.
- (3) Repeated roots are *not* a pathology to be deformed away; they are the source of genuine indecomposable transport sectors.
- (4) Drinfeld–Sokolov transport in rank ≥ 2 is *not* full operator similarity; the corrected invariant is the common divisor-core.

We record the conjectural geometric lifts.

Conjecture 8.II.23 (Geometric divisor-core lift;). For every modular Koszul chiral algebra $\mathcal{A}$, there exists a natural finite-dimensional subquotient $H_{\text{red}}^1(\mathcal{A})$ of $H^1(\bar{B}^{\text{ch}}(\mathcal{A}))$, together with an endomorphism $KS_{\mathcal{A}} \in \text{End}(H_{\text{red}}^1(\mathcal{A}))$, such that:

- (i) $(H_{\text{red}}^1(\mathcal{A}))^\vee \cong \mathcal{R}_{\mathcal{A}}$ as $k[t]$ -modules;
- (ii) for every $S \mid \Delta_{\mathcal{A}}$, there is a canonical subquotient $H_S^1(\mathcal{A}) \subset H_{\text{red}}^1(\mathcal{A})$ with $(H_S^1(\mathcal{A}))^\vee \cong C_S(p_{\mathcal{A}})$;
- (iii) these sectors satisfy the lattice identities of Theorem 8.II.3;
- (iv) an idempotent splitting of $H_S^1(\mathcal{A})$ exists if and only if $\gcd(S, \Delta_{\mathcal{A}}/S) = 1$.

Conjecture 8.II.24 (Jordan-lift conjecture;). Let q be an irreducible factor of $p_{\mathcal{A}}$. For each $1 \leq m \leq \nu_q(p_{\mathcal{A}})$, the primary divisor core $\mathcal{J}_q^m(p_{\mathcal{A}})$ lifts to a canonical filtered subquotient

$$0 \subset H_{q,1}^1(\mathcal{A}) \subset \cdots \subset H_{q,m}^1(\mathcal{A}) \subset H_{\text{red}}^1(\mathcal{A})$$

whose successive quotients realize the q -primary Jordan filtration geometrically. When $q = t - \lambda$ splits linearly, the nilpotent operator $KS_{\mathcal{A}} - \lambda$ on this sector realizes the Jordan block directly on reduced bar cohomology.

Remark 8.II.25 (Place in the characteristic hierarchy). The Casimir recurrence module $\mathcal{R}_{\mathcal{A}}$ sits at the L_2 level of the characteristic hierarchy (cf. the concordance, §K.7.1): the scalar level L_1 is the modular characteristic $\kappa(\mathcal{A})$ (Theorem 13.13.16), while L_2 is the spectral discriminant $\Delta_{\mathcal{A}}$ together with its module structure. The passage from $\Delta_{\mathcal{A}}$ as a polynomial to $\mathcal{R}_{\mathcal{A}}$ as a module is exactly the categorification step that the shadow obstruction tower (Definition 13.22.46) anticipates at the scalar level: the scalar shadow κ is the decategorified trace of $\Theta_{\mathcal{A}}^{\leq 2}$, and the spectral sheet is the decategorified trace of $\Theta_{\mathcal{A}}^{\leq 3}$. The divisor-core lattice lifts the trace to the module. The next layer, the periodic table $\Pi_{\mathcal{A}}$ at L_3 , should admit a similar refinement from generating function to multilinear transport object, but this lies beyond the present section.

Chapter 9

Homotopy transfer

The homotopy transfer theorem is the mechanism by which classical Koszul duality acquires quantum corrections. Passing from a chain complex to its cohomology via a deformation retract necessarily introduces higher operations m_k for $k \geq 3$; these are precisely the genus-0 quantum corrections of the bar complex (Theorem 13.2.4).

PROPOSITION 9.0.1 (*Homotopy transfer as rectification mechanism*). The homotopy transfer theorem is the technical engine of the rectification meta-theorem (Theorem 13.22.388): given a deformation retract $V \xrightarrow{p} H \xrightarrow{i} V$ with $pi = \text{id}$ and homotopy h , the transferred A_∞/L_∞ structure on H rectifies to the strict dg structure on V via bar-cobar. The explicit tree formula

$$m_n^{\text{tr}} = p \circ m_n^V \circ (i^{\otimes n}) + \sum_{\text{planar trees } \tau} p \circ m_{\text{val}(\tau)}^V (\text{id}^{\otimes r_1} \otimes h T_{s_1} \otimes \cdots) \circ i^{\otimes n}$$

produces the n -ary brackets that bar-cobar inversion (Theorem B) eliminates.

Proof. The statement has three parts.

- (i) The homotopy transfer theorem (Theorem 9.2.1) endows H with a $\mathcal{P}_\infty$ -structure $\{\tilde{m}_n\}_{n \geq 1}$ such that p and i extend to ∞ -quasi-isomorphisms.
- (ii) The bar-cobar adjunction (Theorem A) produces a strict dg algebra $\Omega(B(H, \{\tilde{m}_n\}))$ from the transferred homotopy data. Bar-cobar inversion (Theorem B) gives a quasi-isomorphism $\Omega(B(H)) \xrightarrow{\sim} H$.
- (iii) Composing: the transferred structure on H rectifies through bar-cobar to a strict model quasi-isomorphic to V , since $H \simeq V$ by the deformation retract. The tree formula for m_n^{tr} is the explicit form of the tensor trick ([299] §10.3), whose summands are indexed by planar trees with internal vertices decorated by the operations m_k^V and internal edges decorated by the homotopy h . Bar-cobar inversion re-absorbs these higher operations into the differential of $\Omega(B(H))$.

□

9.1 HISTORICAL ORIGINS

A_∞ algebras were introduced by Stasheff [382] to encode the homotopy-coherent associativity of loop space multiplication. The operadic viewpoint identifies them as algebras over the homology of the little intervals operad. For the role of bar-cobar duality in the chiral setting, see Chapter 13.

9.2 THE HOMOTOPY TRANSFER THEOREM

THEOREM 9.2.1 (*Homotopy transfer theorem* [299, 242];). Let (V, d_V) and (W, d_W) be chain complexes with:

- (i) A chain map $p : V \rightarrow W$ (projection).
- (ii) A chain map $\iota : W \rightarrow V$ (inclusion).
- (iii) A chain homotopy $h : V \rightarrow V[-1]$ satisfying $\text{id}_V - \iota p = d_V h + h d_V$.
- (iv) The *side conditions* (compatibility of h with p, ι): $p\iota = \text{id}_W$, $h\iota = 0$, $ph = 0$, $h^2 = 0$.

Such data is called a *strong deformation retract* (SDR).

If V carries a $\mathcal{P}_\infty$ -algebra structure (for $\mathcal{P}$ a Koszul operad), then W inherits a $\mathcal{P}_\infty$ -algebra structure such that p and ι extend to ∞ -quasi-isomorphisms of $\mathcal{P}_\infty$ -algebras.

Proof. The transferred structure on W is constructed via the *tensor trick* ([299] §10.3). For an A_∞ -algebra structure on V with operations $m_n : V^{\otimes n} \rightarrow V$, define $T_n : V^{\otimes n} \rightarrow V$ recursively by:

$$T_n = m_n + \sum_{\substack{r+s+t=n \\ s < n}} m_{r+1+t}(\text{id}^{\otimes r} \otimes h T_s \otimes \text{id}^{\otimes t}).$$

This converges since T_s with $s < n$ is already defined and h absorbs the degree. The transferred operations are $\tilde{m}_n := p \circ T_n \circ \iota^{\otimes n}$. Explicitly:

$$\begin{aligned} \tilde{m}_1 &= p d_V \iota = d_W, \\ \tilde{m}_2 &= p m_2 \iota^{\otimes 2}, \\ \tilde{m}_3 &= p m_3 \iota^{\otimes 3} + p m_2(h m_2 \otimes \text{id}) \iota^{\otimes 3} + p m_2(\text{id} \otimes h m_2) \iota^{\otimes 3}. \end{aligned}$$

Verification of A_∞ -relations. The A_∞ -relation at degree n for $\{\tilde{m}_k\}$ requires:

$$\sum_{r+s+t=n} (-1)^{r+s+t} \tilde{m}_{r+1+t}(\text{id}^{\otimes r} \otimes \tilde{m}_s \otimes \text{id}^{\otimes t}) = 0.$$

Substituting $\tilde{m}_k = p \circ T_k \circ \iota^{\otimes k}$ and using the SDR identity $\iota p = \text{id}_V - (d_V h + h d_V)$, each internal composition ιp between an outer T_{r+1+t} and inner T_s decomposes as:

- a term id_V , which together with the A_∞ -relations for $\{m_k\}$ gives cancelling contributions;
- a term $-d_V h - h d_V$, which telescopes by the side conditions $h^2 = 0$, $ph = 0$, $h\iota = 0$.

Concretely, the terms involving id_V reassemble into $p \circ (A_\infty \text{ relation for } \{m_k\}) \circ \iota^{\otimes n} = 0$, while the terms involving $d_V h + h d_V$ cancel pairwise: $h^2 = 0$ prevents double homotopy insertions, and $ph = hu = 0$ kill boundary terms. Thus $\{\tilde{m}_n\}$ satisfies the A_∞ -relations.

The maps p and ι extend to ∞ -morphisms $\tilde{p}_n$ and $\tilde{\iota}_n$ by the same tree formula with p (resp. ι) at the root (resp. leaves), and the composite $\tilde{p} \circ \tilde{\iota} = \text{id}_W$ by $p\iota = \text{id}_W$, while $\tilde{\iota} \circ \tilde{p} \sim \text{id}_V$ via the homotopy built from h . $\square$

Definition 9.2.2 (Strong deformation retract data). A *strong deformation retract* (SDR) from V to W is a tuple (V, W, p, ι, h) satisfying the conditions of Theorem 9.2.1. We denote this by:

$$(V, d_V) \xrightleftharpoons[\iota]{p} (W, d_W) \quad h : V \rightarrow V[-1], \quad \text{id} - \iota p = dh + hd.$$

The diagram commutes up to homotopy h .

LEMMA 9.2.3 (Existence of SDR;). If $V \xrightarrow{\sim} W$ is a quasi-isomorphism of chain complexes over a field k , then:

- (i) There exists an SDR from V to $H_*(V) = H_*(W)$.
- (ii) If V and W are both semi-free (or projective as graded modules), there exists an SDR between them.

Proof. (i) Choose a splitting $V = H_*(V) \oplus B \oplus C$ where $d : C \xrightarrow{\sim} B$ is an isomorphism (decomposition into homology, boundaries, and “extra” cycles that become boundaries). Define:

$$\iota : H_*(V) \hookrightarrow V, \quad p : V \twoheadrightarrow H_*(V), \quad h : V \rightarrow V[-1]$$

where h sends B to C via the inverse of $d|_C$, and is zero on $H_*(V) \oplus C$. We verify each condition. (a) $p \circ \iota = \text{id}_{H_*(V)}$: the inclusion ι maps $H_*(V)$ into V as a direct summand, and p projects back. (b) $\text{id}_V - \iota \circ p = d \circ h + h \circ d$: we check on each summand. On $H_*(V)$: both d and h vanish, so $dh + hd = 0 = \text{id} - \iota p$. On B : $h|_B = 0$ gives $dh(b) = 0$, while $d(b) \in H_* \oplus C$ and the C -component maps back via $h = (d|_C)^{-1}$, so $hd(b) = b$; since $\iota p(b) = 0$ we get $(dh + hd)(b) = b = (\text{id} - \iota p)(b)$. On C : $h|_C = 0$ gives $dh(c) = 0$, while $d(c) \in B$ and $hd(c) = (d|_C)^{-1}(d(c)) = c$; since $\iota p(c) = 0$ we get $(dh + hd)(c) = c = (\text{id} - \iota p)(c)$. (c) $h^2 = 0$: h maps $B \rightarrow C$ and $h|_C = 0$; $h \circ \iota = 0$: ι lands in $H_*(V)$ and $h|_{H_*} = 0$; $p \circ h = 0$: h maps into C and $p|_C = 0$.

(ii) The Comparison Theorem for projective resolutions provides the maps; standard homological algebra constructs the homotopy. $\square$

9.3 EXPLICIT FORMULAS FOR TRANSFERRED STRUCTURES

Construction 9.3.1 (Transferred A_∞ -structure). Let $(A, \{m_n\})$ be an A_∞ -algebra and (A, H, p, ι, h) an SDR to the homology $H = H_*(A)$. The transferred A_∞ -structure $\{\tilde{m}_n\}$ on H is given by:

$\tilde{m}_1 = 0$. The differential on homology vanishes.

$\tilde{m}_2$. The induced product:

$$\tilde{m}_2(a, b) = p m_2(\iota(a), \iota(b)).$$

$\tilde{m}_3$. The Massey product or A_∞ -associator:

$$\begin{aligned} \tilde{m}_3(a, b, c) = & p m_3(\iota(a), \iota(b), \iota(c)) \\ & + p m_2(h m_2(\iota(a), \iota(b)), \iota(c)) \\ & + (-1)^{|a|} p m_2(\iota(a), h m_2(\iota(b), \iota(c))). \end{aligned}$$

The sign $(-1)^{|a|}$ arises from commuting the homotopy h (degree -1) past $\iota(a)$ (degree $|a|$) via the Koszul sign rule.

$\tilde{m}_n$ (general). Sum over planar rooted trees T with n leaves:

$$\tilde{m}_n = \sum_{T \in \text{PRT}_n} p T(m_\bullet, h, \iota)$$

where $T(m_\bullet, h, \iota)$ places ι at leaves, m_k at vertices of valence k , and h on internal edges.

THEOREM 9.3.2 (*Tree formula for transferred operations [299];*). The transferred n -ary operation is:

$$\tilde{m}_n = \sum_{T \in \text{PRT}_n} \epsilon(T) \cdot p \circ \prod_{v \in V(T)} m_{|v|} \circ \prod_{e \in E_{\text{int}}(T)} h \circ \iota^{\otimes n}$$

where:

- (i) PRT_n is the set of planar rooted trees with n leaves.
- (ii) $V(T)$ is the set of internal vertices; $|v|$ is the valence of v .
- (iii) $E_{\text{int}}(T)$ is the set of internal edges.
- (iv) $\epsilon(T) \in \{\pm 1\}$ is a sign determined by the Koszul rule.

Remark 9.3.3 (*Tree-level only*). Only tree-level graphs contribute to homotopy transfer: the sum in Theorem 9.3.2 runs over trees (acyclic connected graphs), never over graphs with loops. This is because the three side conditions $h^2 = 0$, $ph = 0$, and $hu = 0$ together ensure that any graph with a cycle vanishes: $h^2 = 0$ kills paths with consecutive homotopies, $ph = 0$ kills graphs where h appears at the output edge, and $hu = 0$ kills graphs where h appears at an input edge. In the chiral algebra setting, this means the transferred operations are algebraic (finite sums), not analytic, and no renormalization issues arise.

Example 9.3.4 (*Trees for $\tilde{m}_4$*). The trees contributing to $\tilde{m}_4$ are:

- (1) One vertex of valence 4:

$$\begin{array}{c} \bullet \\ \diagup \\ 1 \quad 2 \quad 3 \quad 4 \end{array} \rightsquigarrow p m_4 \iota^{\otimes 4}$$

- (2) One vertex of valence 3, one of valence 2 (5 configurations: the binary vertex can be a child of the ternary in 3 ways, or the ternary can be a child of the binary in 2 ways):

$$p m_3(h m_2 \otimes \text{id} \otimes \text{id}) \iota^{\otimes 4}, \quad p m_2(h m_3 \otimes \text{id}) \iota^{\otimes 4}, \quad \dots$$

- (3) Three vertices of valence 2 (5 configurations: the Catalan number $C_3 = 5$ binary trees with 4 leaves).

Total: $1 + 5 + 5 = 11$ planar rooted trees with 4 leaves and all internal vertices of degree ≥ 2 .

PROPOSITION 9.3.5 (*Sign computation [299];*). The sign $\epsilon(T)$ in the tree formula is:

$$\epsilon(T) = (-1)^{\sum_{e \in E_{\text{int}}(T)} (|e|_{\text{left}} + 1)}$$

where $|e|_{\text{left}}$ is the sum of degrees of inputs to the left of edge e (counting the edge as separating left from right at its source vertex).

9.4 APPLICATIONS TO MINIMAL MODELS

Definition 9.4.1 (Minimal model). A *minimal model* of a dg-algebra A is an A_∞ -algebra M with:

- (i) M has zero differential: $m_1 = 0$.
- (ii) There is an A_∞ -quasi-isomorphism $M \xrightarrow{\sim} A$.

A minimal model is unique up to A_∞ -isomorphism.

THEOREM 9.4.2 (*Existence of minimal models [242];*). Every A_∞ -algebra over a field admits a minimal model. Explicitly, if A is an A_∞ -algebra:

- (i) Take $M = H_*(A)$ as a graded vector space.
- (ii) Choose an SDR $(A, H_*(A), p, \iota, h)$.
- (iii) Apply the homotopy transfer theorem to get $\{m_n\}_{n \geq 2}$ on M .
- (iv) The resulting $(M, 0, m_2, m_3, \dots)$ is the minimal model.

COROLLARY 9.4.3 (*Formality [125, 275];*). An A_∞ -algebra A is *formal* if its minimal model has $m_n = 0$ for all $n \geq 3$, i.e., the minimal model is a graded associative algebra with trivial differential and no higher operations.

Equivalently, A is formal if $A \simeq H_*(A)$ as A_∞ -algebras, where $H_*(A)$ has the trivial A_∞ -structure from its product.

Example 9.4.4 (Minimal model of de Rham complex). For $X = S^1$ (circle), the de Rham complex is:

$$(\Omega^*(S^1), d) = (k \xrightarrow{0} k, \quad 1 \mapsto 0, \quad d\theta \mapsto 0)$$

with cohomology $H^* = k \oplus k[-1]$.

The minimal model has:

- (i) $M = k \cdot 1 \oplus k \cdot x$ with $|1| = 0, |x| = 1$.
- (ii) $m_2(1, 1) = 1, m_2(1, x) = m_2(x, 1) = x, m_2(x, x) = 0$.
- (iii) $m_n = 0$ for $n \geq 3$ (the circle is formal).

Application 9.4.5 (Minimal model for chiral algebras). For a chiral algebra $\mathcal{A}$, the homotopy transfer theorem provides:

- (i) A minimal A_∞ -chiral structure on $H_*^{\text{ch}}(\mathcal{A})$.
- (ii) The higher operations $\{m_n\}_{n \geq 3}$ encode obstructions to formality.
- (iii) For Koszul chiral algebras, the minimal model simplifies (higher operations vanish).

For the Heisenberg algebra $\mathcal{H}$:

$$H_*^{\text{ch}}(\mathcal{H}) = k$$

is 1-dimensional (Koszul), and the minimal model is the ground field with trivial structure.

THEOREM 9.4.6 (*Homotopy transfer for operadic algebras [299];*). Let $\mathcal{P}$ be a Koszul operad and (A, W, p, ι, h) an SDR with A a $\mathcal{P}$ -algebra. The transferred $\mathcal{P}_\infty$ -structure on W satisfies:

- (i) The $\mathcal{P}_\infty$ -relations hold strictly (not just up to homotopy).
- (ii) The maps ι and p extend to ∞ -morphisms.
- (iii) If A is already $\mathcal{P}_\infty$ (not just $\mathcal{P}$), the transfer still works.

9.5 EXTENDED FORMULAS AND COMPUTATIONAL TECHNIQUES

Extended formulas for homotopy transfer essential for explicit computations in chiral Koszul duality follow.

Construction 9.5.1 (*Homotopy transfer for L_∞ -algebras*). Let $(\mathfrak{g}, \{l_n\})$ be an L_∞ -algebra and $(\mathfrak{g}, H, p, \iota, h)$ an SDR. The transferred L_∞ -structure on H has brackets:

$\tilde{l}_1 = 0$. Differential vanishes on homology.

$\tilde{l}_2$. The induced Lie bracket:

$$\tilde{l}_2(a, b) = p l_2(\iota(a), \iota(b)).$$

$\tilde{l}_3$. The *Massey–Lie bracket* or Jacobiator:

$$\begin{aligned} \tilde{l}_3(a, b, c) = & p l_3(\iota(a), \iota(b), \iota(c)) \\ & + p l_2(h l_2(\iota(a), \iota(b)), \iota(c)) \\ & + (-1)^{|b||c|} p l_2(h l_2(\iota(a), \iota(c)), \iota(b)) \\ & + (-1)^{|a|(|b|+|c|)} p l_2(h l_2(\iota(b), \iota(c)), \iota(a)). \end{aligned}$$

The signs arise from the graded antisymmetry of the Lie bracket.

PROPOSITION 9.5.2 (*L_∞ -relations for transferred structure [299];*). The transferred brackets $\{\tilde{l}_n\}$ satisfy the L_∞ -relations:

$$\sum_{i+j=n+1} \sum_{\sigma \in \text{Sh}(i, n-i)} \epsilon(\sigma) \tilde{l}_j(\tilde{l}_i(x_{\sigma(1)}, \dots, x_{\sigma(i)}), x_{\sigma(i+1)}, \dots, x_{\sigma(n)}) = 0$$

where $\text{Sh}(i, n-i)$ denotes $(i, n-i)$ -unshuffles and $\epsilon(\sigma)$ is the Koszul sign.

COMPUTATION 9.5.3 (*Explicit $\tilde{l}_4$ formula*). The 4-ary transferred bracket is:

$$\begin{aligned} \tilde{l}_4(a, b, c, d) = & p l_4(\iota a, \iota b, \iota c, \iota d) \\ & + \sum_{\sigma \in S_4} \epsilon_\sigma p l_3(h l_2(\iota x_{\sigma_1}, \iota x_{\sigma_2}), \iota x_{\sigma_3}, \iota x_{\sigma_4}) \\ & + \sum_{\text{pairings}} \epsilon p l_2(h l_2(\iota a, \iota b), h l_2(\iota c, \iota d)) \\ & + \sum_{\sigma} \epsilon_\sigma p l_2(h l_3(\iota x_{\sigma_1}, \iota x_{\sigma_2}, \iota x_{\sigma_3}), \iota x_{\sigma_4}) \\ & + (\text{trees with two internal edges}) \end{aligned}$$

The full formula involves 25 terms corresponding to trees with 4 leaves.

THEOREM 9.5.4 (*Uniqueness of minimal L_∞ -model [299];*). If $(\mathfrak{g}, \{l_n\})$ is an L_∞ -algebra over a field:

- (i) A minimal L_∞ -model $(H, \{\tilde{l}_n\})$ exists with $\tilde{l}_1 = 0$.
- (ii) Any two minimal L_∞ -models are L_∞ -isomorphic.
- (iii) The isomorphism is unique up to L_∞ -homotopy.

Construction 9.5.5 (Homotopy transfer for coalgebras). For a dg-coalgebra (C, Δ, d) and SDR (C, H, p, ι, h) , the transferred A_∞ -coalgebra structure on H has coproducts:

$\tilde{\Delta}_1 = 0$. No differential on homology.

$\tilde{\Delta}_2$. The induced coproduct:

$$\tilde{\Delta}_2(c) = (p \otimes p)\Delta(\iota(c)).$$

$\tilde{\Delta}_n$ for $n \geq 3$. Higher coproducts from trees:

$$\tilde{\Delta}_n = \sum_{T \in \text{Trees}_n} \epsilon(T) \cdot (p^{\otimes n}) \circ T(\Delta, h) \circ \iota$$

where trees now have edges “pointing down” (toward outputs) rather than up.

Example 9.5.6 (Transfer for symmetric coalgebra). Let $C = S^c(V)$ be the symmetric coalgebra on a chain complex (V, d_V) . The coproduct is deconcatenation:

$$\Delta(v_1 \cdots v_n) = \sum_{I \sqcup J = [n]} v_I \otimes v_J$$

where $v_I = \prod_{i \in I} v_i$ (in order).

If $V \xrightarrow{p} H_*(V) =: W$ is a deformation retract:

- (i) $\tilde{\Delta}_2$ on $S^c(W)$ is the standard deconcatenation (symmetric coalgebra).
- (ii) $\tilde{\Delta}_3$ involves Massey products: corrections arise when d_V is nontrivial.
- (iii) If V is formal (quasi-isomorphic to $H_*(V)$ with zero differential), then $\tilde{\Delta}_n = 0$ for $n \geq 3$.

9.6 APPLICATIONS TO CHIRAL ALGEBRAS

THEOREM 9.6.1 (*Chiral homotopy transfer*). Let $\mathcal{A}$ be an E_1 -chiral algebra on a curve X and suppose we have an SDR of the underlying D-module:

$$(\mathcal{A}, H, p, \iota, h) \quad \text{with } H = H_*^{\text{ch}}(\mathcal{A}).$$

Then:

- (i) H inherits an A_∞ -chiral algebra structure.
- (ii) The higher operations $\{m_n^{\text{ch}}\}_{n \geq 3}$ are “Massey products” for the chiral structure.
- (iii) If $\mathcal{A}$ is Koszul, then $m_n^{\text{ch}} = 0$ for $n \geq 3$.

Proof. We apply the general homotopy transfer theorem (Theorem 9.2.1) to the E_1 -chiral operad.

Step 1 (D-module compatibility). Since $\mathcal{A}$ is a chiral algebra, it carries a $\mathcal{D}_X$ -module structure. The SDR maps (p, ι, h) must be morphisms of $\mathcal{D}_X$ -modules (i.e., commute with the action of $\mathcal{D}_X$). This holds because chiral homology $H = H_*^{\text{ch}}(\mathcal{A})$ is defined as a derived functor in the category of $\mathcal{D}_X$ -modules, so p and ι are automatically $\mathcal{D}_X$ -linear, and h can be chosen $\mathcal{D}_X$ -linearly by the splitting argument of Lemma 9.2.3(i) applied within the $\mathcal{D}_X$ -module category (which is abelian with enough projectives over a smooth curve X).

Step 2 (Transferred binary operation). The transferred product is $\tilde{m}_2 = p \circ \mu^{\text{ch}} \circ (\iota \otimes \iota)$, exactly as in Construction 9.3.1. Since μ^{ch} is a chiral product (defined via the $j_* j^*$ functor on $X \times X$), $\tilde{m}_2$ inherits $\mathcal{D}_X$ -linearity from Step 1.

Step 3 (Higher operations via trees). The transferred operations $\tilde{m}_n^{\text{ch}}$ for $n \geq 3$ are sums over planar rooted trees with n leaves (as in Construction 9.3.1), where each internal edge contributes a factor of h and each internal vertex contributes the chiral product μ^{ch} . Since only tree-level graphs contribute (no loops; cf. Remark 9.3.3), each $\tilde{m}_n^{\text{ch}}$ is a finite sum.

Step 4 (A_∞ -relations). The transferred operations $\{\tilde{m}_n^{\text{ch}}\}$ satisfy the A_∞ -relations by the same algebraic argument as in the general theorem: the identity $\sum_{r+s+t=n} (-1)^{rs+t} \tilde{m}_{r+1+t}(\text{id}^{\otimes r} \otimes \tilde{m}_s \otimes \text{id}^{\otimes t}) = 0$ follows from substituting the tree formulas and using the E_1 -relations on $\mathcal{A}$ together with the SDR identities $p\iota = \text{id}$, $\text{id} - \iota p = dh + hd$, $h^2 = 0$.

Koszulness (iii). If $\mathcal{A}$ is Koszul, the bar spectral sequence degenerates at E_2 with E_∞ concentrated on the Koszul line $q = 0$ (Proposition J.3.4). This means $\text{Ext}_{\mathcal{A}}^{p,q}(k, k) = 0$ for $q \neq 0$: the bar resolution is minimal. One may therefore choose the SDR for $\bar{B}(\mathcal{A}) \rightarrow H^*(\bar{B}(\mathcal{A}))$ compatible with the bigrading, so that the homotopy h preserves bar degree and shifts internal degree. Every tree contributing to $\tilde{m}_n^{\text{ch}}$ for $n \geq 3$ would produce an operation of bar-degree shift incompatible with the Koszul line concentration, forcing $\tilde{m}_n^{\text{ch}} = 0$. Equivalently, for a minimal resolution all Massey products vanish. $\square$

Example 9.6.2 (Kac–Moody minimal model). For the affine Kac–Moody algebra $\hat{\mathfrak{g}}_k$ at level k and a smooth projective curve X of genus g :

- (i) The chiral homology $H_*^{\text{ch}}(X, \hat{\mathfrak{g}}_k)$ depends on both k and g .
- (ii) At generic k (irrational, or more precisely not a non-negative integer and not equal to $-h^\vee$): the higher chiral homology $H_i^{\text{ch}}(X, \hat{\mathfrak{g}}_k) = 0$ for $i > 0$, while $H_0^{\text{ch}}(X, \hat{\mathfrak{g}}_k)$ reduces to the space of conformal blocks, which is one-dimensional for the vacuum module [40].
- (iii) At non-negative integral k : the chiral homology $H_*^{\text{ch}}(X, \hat{\mathfrak{g}}_k)$ is related to spaces of conformal blocks for integrable representations, and the minimal model encodes this representation theory.
- (iv) The transferred higher operations $\tilde{m}_n^{\text{ch}}$ for $n \geq 3$ vanish by Koszulness of $\hat{\mathfrak{g}}_k$ (at non-critical level $k \neq -h^\vee$).

PROPOSITION 9.6.3 (*Transferred structure and bar complex [299];*). The homotopy transfer of chiral structures is compatible with the bar construction:

$$\bar{B}^{\text{geom}}(H, \{\tilde{m}_n\}) \simeq \bar{B}^{\text{geom}}(\mathcal{A}, \{m_n\})$$

as geometric bar complexes. The quasi-isomorphism is induced by the SDR data.

Proof. The bar construction is functorial for A_∞ -morphisms [299]: an A_∞ -quasi-isomorphism $f : A \xrightarrow{\sim} B$ induces a quasi-isomorphism $\bar{B}(f) : \bar{B}(A) \xrightarrow{\sim} \bar{B}(B)$ of bar complexes. (The functoriality of $\bar{B}$ for A_∞ -morphisms is the bar-cobar adjunction as a quantum L_∞ functor.) Since the SDR maps (ι, p) extend to A_∞ -quasi-isomorphisms by Theorem 9.2.1, the bar complexes $\bar{B}(\mathcal{A})$ and $\bar{B}(H, \{\tilde{m}_n\})$ are quasi-isomorphic. The geometric realization is compatible because $\bar{B}^{\text{geom}}$ is computed as the factorization homology of $\bar{B}$, and factorization homology preserves quasi-isomorphisms between factorization algebras on X . $\square$

9.7 HOMOTOPY TRANSFER AND THE MAIN THEOREMS

The homotopy transfer theorem *is* the mechanism by which classical Koszul duality acquires quantum corrections: passing from a chain complex to its cohomology via a deformation retract forces higher operations m_k ($k \geq 3$) on the cohomology, and these are precisely the bar-level quantum corrections that bar-cobar inversion (Theorem B) then re-absorbs.

9.7.1 THE BAR-COBAR COUNIT AS HTT OUTPUT

THEOREM 9.7.1 (*Bar-cobar inversion via homotopy transfer*;). Let $\mathcal{A}$ be a chiral Koszul algebra on a smooth curve X . The bar-cobar counit

$$\psi : \Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$$

of Theorem 11.1.84 is the *canonical* A_∞ -quasi-isomorphism produced by the homotopy transfer theorem (Theorem 9.2.1), applied to the SDR

$$(\Omega(\bar{B}(\mathcal{A})), \mathcal{A}, \psi, \iota_{\text{counit}}, h_{\text{Hodge}})$$

where ι_{counit} is the canonical inclusion and h_{Hodge} is the contracting homotopy from the Hodge decomposition of $\Omega(\bar{B}(\mathcal{A}))$ relative to the bar filtration.

Proof. By construction, the cobar complex $\Omega(\bar{B}(\mathcal{A}))$ is the cofree chiral algebra on $s\bar{\mathcal{A}}^!$ with differential $d_{\text{cobar}} = d_{\text{coop}} + d_{\text{tw}}$, where d_{tw} encodes the twisting morphism $\tau : \bar{B}(\mathcal{A}) \rightarrow \mathcal{A}$.

Step 1 (SDR from bar filtration). The bar filtration $F_p \Omega(\bar{B}(\mathcal{A}))$ gives a spectral sequence with $E_1^{p,q} = H^q(\text{gr}_p^F \Omega(\bar{B}(\mathcal{A})))$. By Koszulness, E_1 is concentrated on $q = 0$ (Proposition J.3.4). The E_1 -degeneration produces an SDR: the projection ψ to $E_\infty \cong \mathcal{A}$ and the inclusion ι from $\mathcal{A}$ back to the cobar complex, with contracting homotopy h lowering the q -degree. The side conditions $\psi\iota = \text{id}$, $h^2 = 0$, $\psi h = 0$, $h\iota = 0$ follow from the bigrading.

Step 2 (HTT produces the same map). Applying Theorem 9.2.1 to the strict E_1 -chiral algebra structure on $\Omega(\bar{B}(\mathcal{A}))$ and the SDR from Step 1 produces transferred operations $\{\tilde{m}_n\}_{n \geq 2}$ on $\mathcal{A}$ and an A_∞ -quasi-isomorphism $f_\infty : \mathcal{A} \rightarrow \Omega(\bar{B}(\mathcal{A}))$. The component $f_1 = \iota$ and the binary product $\tilde{m}_2 = \psi \circ \mu \circ (\iota \otimes \iota) = \mu_{\mathcal{A}}$ (the original product on $\mathcal{A}$, since $\psi\iota = \text{id}$).

Step 3 (Koszulness forces vanishing). For $n \geq 3$, each tree T contributing to $\tilde{m}_n$ (Construction 9.3.1) inserts at least one homotopy h on an internal edge. Since h lowers the filtration degree by 1 and the Koszul-line concentration forces all non-trivial cohomology to live on $q = 0$, the composition $\psi \circ (\text{tree}) \circ \iota^{\otimes n}$ vanishes: the output lives in $q < 0$, which is empty. Therefore $\tilde{m}_n = 0$ for $n \geq 3$, and $f_\infty = \psi$ is a strict quasi-isomorphism of dg algebras, not merely of A_∞ -algebras.

This is the chain-level content of the bar-cobar inversion (Theorem 11.1.84): on the Koszul locus, the bar-cobar counit is the HTT quasi-isomorphism, and Koszulness is the vanishing of all Massey products. $\square$

Remark 9.7.2 (Koszulness as formality). The preceding proof identifies three equivalent conditions (cf. Remark 13.18.9):

- (i) $\mathcal{A}$ is chiral Koszul (bar spectral sequence degenerates at E_2 , Koszul-line concentration).
- (ii) The transferred A_∞ -structure on $H^*(\bar{B}(\mathcal{A}))$ is *formal*: $\tilde{m}_n = 0$ for $n \geq 3$.
- (iii) The bar-cobar counit ψ is a *strict* quasi-isomorphism (not merely A_∞).

The equivalence (i) $\Leftrightarrow$ (ii) is the homotopy-algebraic meaning of Koszulness: a Koszul algebra is one whose derived structure contains no hidden higher information beyond the binary product. Condition (iii) is the geometric meaning: the configuration space integrals computing ψ collapse to residue extraction alone, with no contributions from higher-codimension boundary strata.

9.7.2 TREES AND BOUNDARY STRATA: THE GEOMETRIC HTT

The tree formula of Theorem 9.3.2 has a direct geometric realization via the Fulton–MacPherson compactification.

PROPOSITION 9.7.3 (*Trees as boundary strata*;). Let T be a planar rooted tree with n leaves contributing to the transferred operation $\tilde{m}_n$ (Construction 9.3.1). The corresponding term in the tree formula equals the integral

$$\tilde{m}_n^T(a_1, \dots, a_n) = \int_{\partial_T \bar{C}_n(X)} \text{ev}^*(\bar{a}_1 \otimes \cdots \otimes \bar{a}_n) \wedge \bigwedge_{e \in E_{\text{int}}(T)} \omega_e,$$

where:

- (i) $\partial_T \bar{C}_n(X) \hookrightarrow \bar{C}_n(X)$ is the boundary stratum of the Fulton–MacPherson compactification indexed by T : the locus where the points cluster according to the vertex structure of T ;
- (ii) $\omega_e = d \log(z_{s(e)} - z_{t(e)})$ is the logarithmic propagator on the internal edge e with source $s(e)$ and target $t(e)$;
- (iii) the homotopy h of the SDR corresponds to integration over the fiber direction in $\partial_T \bar{C}_n(X) \rightarrow \bar{C}_{|V(T)|}(X)$, i.e., integration over the “infinitesimal screen” at each vertex cluster.

The full transferred operation is the sum over all trees:

$$\tilde{m}_n = \sum_{T \in \text{PRT}_n} \int_{\partial_T \bar{C}_n(X)} \text{ev}^*(\bar{a}_1 \otimes \cdots \otimes \bar{a}_n) \wedge \omega_T.$$

Proof. The Fulton–MacPherson compactification $\bar{C}_n(X) = \text{Bl}_\Delta(X^n)$ has a stratification indexed by planar rooted trees with n leaves: each stratum ∂_T records a pattern of coincidences among the n points (cf. [186]).

The bar differential d_{bar} on $\bar{B}_n^{\text{geom}}(\mathcal{A})$ is the residue along the codimension-1 boundary $\partial_{ij} \bar{C}_n(X)$ where points z_i, z_j collide. This is the contribution from trees with a single internal edge. Higher-codimension strata correspond to multiple simultaneous collisions, i.e., trees with multiple internal edges.

The homotopy h in the SDR integrates “inward” along fibers of the boundary projection $\partial_T \rightarrow \partial_{T/e}$, which contracts an internal edge e of the tree T . This is the geometric content of the formula $h =$

(fiber integral over screen direction): when two points have already collided (codimension-1 stratum), the homotopy h integrates over the residual angular direction to produce a new composite element on the coarser stratum.

Composing: the tree formula $p \circ \prod_v m_{|v|} \circ \prod_e h \circ \iota^{\otimes n}$ places propagators ω_e on internal edges, OPE operations $m_{|v|}$ at vertices, and integrates over the fiber directions via h . The result is precisely the integral over $\partial_T \overline{C}_n(X)$ of the product of logarithmic propagators. $\square$

Remark 9.7.4 (Feynman diagrams as transferred operations). Proposition 9.7.3 establishes the following dictionary between the algebraic HTT and the physical Feynman diagram expansion:

HTT (algebraic)	$\longleftrightarrow$ Feynman (geometric)
Planar rooted tree T	$\longleftrightarrow$ Tree-level Feynman diagram
Internal edge of T	$\longleftrightarrow$ Propagator insertion η_{ij}
Vertex of valence k	$\longleftrightarrow$ k -valent interaction vertex (OPE)
Homotopy h	$\longleftrightarrow$ Propagator (Green's function)
SDR projection p	$\longleftrightarrow$ External state projection
Transferred $\tilde{m}_n$	$\longleftrightarrow$ n -point tree-level amplitude
Massey product $\tilde{m}_3 \neq 0$	$\longleftrightarrow$ Non-trivial 3-point function
Koszulness ($\tilde{m}_n = 0, n \geq 3$)	$\longleftrightarrow$ Formal theory (minimal resolution)

Koszulness means that the *transferred* A_∞ structure on bar cohomology is formal ($\tilde{m}_n = 0$ for $n \geq 3$): the bar complex provides a minimal resolution. This does *not* mean the original theory is free or Gaussian. Affine Kac–Moody algebras and the Virasoro algebra are chirally Koszul (all standard families are, by PBW universality) but have nontrivial OPE structure constants and interaction vertices of arbitrary valence. The formality is a property of the *resolution*, not of the *interactions*.

9.7.3 GENUS CORRECTIONS AS TRANSFERRED OPERATIONS

At genus $g \geq 1$, the fiberwise bar differential acquires curvature $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ (Convention 13.0.2), and the HTT framework extends to the curved setting.

PROPOSITION 9.7.5 (*Genus-1 curvature as m_0*). The genus-1 obstruction $\kappa(\mathcal{A}) \in k$ of Theorem 13.13.16 is the nullary operation m_0 of the curved A_∞ -structure transferred from the genus-1 bar complex:

$$m_0 = \kappa(\mathcal{A}) \cdot [\omega_1] \in H^2(\overline{\mathcal{M}}_{1,1}, \mathbb{Q}).$$

More precisely, let $\bar{B}^{(1)}(\mathcal{A})$ be the genus-1 bar complex with fiberwise differential d_{fib} satisfying $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \lambda_1 \cdot \text{id}$ where λ_1 is the Hodge class. Then the HTT applied to the SDR from the bar filtration produces:

- (i) A nullary operation $m_0 = \kappa(\mathcal{A}) \cdot \lambda_1$, measuring the failure of $d^2 = 0$ at genus 1.
- (ii) A unary operation m_1 with $m_1^2(a) = [m_0, a]$ (the commutator identity for curved A_∞ -algebras).
- (iii) Binary and higher operations m_n ($n \geq 2$) modified by the curvature: m_2 acquires corrections from the Eisenstein propagator on the elliptic curve, and m_3 acquires contributions from the genus-1 Massey product.

Proof. The genus-1 bar complex on an elliptic curve E_τ has differential $d_{\text{fib}} = d^{(0)} + d^{(1)}$ where $d^{(0)}$ is the genus-0 collision differential and $d^{(1)} = \kappa(\mathcal{A}) \cdot \text{tr}$ inserts the trace element (Theorem 13.7.7). Then $(d^{(0)})^2 = 0$ and $\{d^{(0)}, d^{(1)}\} = 0$ by the decomposition of $D_1^2 = 0$ (Theorem 13.7.4).

The SDR from the bar filtration gives $(\bar{B}^{(1)}(\mathcal{A}), H^*(\bar{B}^{(0)}(\mathcal{A})), p, \iota, h)$ at the associated graded level. Applying HTT with the perturbed differential $d^{(1)}$ (the “perturbation lemma” variant [299]), the transferred structure acquires:

- $m_0 = p \circ d^{(1)} \circ \iota(1) = \kappa(\mathcal{A}) \cdot p(\text{tr}) = \kappa(\mathcal{A}) \cdot \lambda_1$ (the trace element projects to the Hodge class),
- $m_1(a) = p \circ d^{(1)} \circ \iota(a) + p \circ d^{(0)} \circ h \circ d^{(1)} \circ \iota(a) + \dots$ (geometric series in $h \circ d^{(1)}$, converging because $d^{(1)}$ raises filtration degree),
- $m_2(a, b) = p \circ \mu \circ (\iota(a) \otimes \iota(b)) + (\text{corrections from } h \circ d^{(1)})$.

The relation $m_1^2(a) = m_2(m_0, a) - m_2(a, m_0) = [m_0, a]$ follows from the general curved A_∞ -identity with $r + s + t = 1$ and $s = 0$. $\square$

Remark 9.7.6 (Higher genus: moduli cohomology as transferred operations). At genus $g \geq 2$, the bar complex $\bar{B}^{(g)}(\mathcal{A})$ is a family over $\bar{\mathcal{M}}_g$ with fiberwise differential d_{fib} satisfying $D_g^2 = 0$ (Theorem 13.7.4). The HTT applied fiberwise produces a curved A_∞ -algebra over $\bar{\mathcal{M}}_g$ whose operations are sections of bundles over moduli space. The key identification is:

The n -ary transferred operation $\tilde{m}_n^{(g)}$ is a section of

$$\text{Hom}(\mathcal{A}^{\boxtimes n}, \mathcal{A}) \otimes H^*(\bar{\mathcal{M}}_{g,n}, \mathbb{Q}).$$

The dependence on $H^(\bar{\mathcal{M}}_{g,n})$ is the “quantum correction” from the genus- g moduli geometry.*

This gives a homotopy-algebraic interpretation of Theorem C (Deformation-Obstruction Complementarity, Theorem 13.15.14): the quantum obstruction $Q_g(\mathcal{A})$ and the dual obstruction $Q_g(\mathcal{A}^1)$ together span $H^*(\bar{\mathcal{M}}_g, Z(\mathcal{A}))$ because they are the complementary components of the transferred A_∞ -structure on $H^*(\bar{B}^{(g)}(\mathcal{A}))$, restricted to the center and projected along the Koszul line and its complement. The complementarity $Q_g(\mathcal{A}) + Q_g(\mathcal{A}^1) = H^*(\bar{\mathcal{M}}_g, Z(\mathcal{A}))$ is the statement that the full transferred structure exhausts the moduli cohomology, with nothing left over.

This interpretation elevates Theorem C from a numerical identity to a structural statement: the bar-cobar machine, viewed through HTT, decomposes moduli-space cohomology into the piece controlled by $\mathcal{A}$ and the piece controlled by $\mathcal{A}^1$, with the Koszul duality functor as the sorting mechanism.

Remark 9.7.7 (Physical content: renormalization vs. homotopy transfer). Homotopy transfer and perturbative renormalization in quantum field theory are analogous, and in the chiral algebra setting they coincide:

- (i) **Tree-level HTT = classical field theory.** The tree formula (Theorem 9.3.2) sums over tree-level Feynman diagrams. The condition $\hbar^2 = 0$ in the SDR (the “no-loop” condition from Remark 9.3.3) ensures that only trees contribute, not graphs with loops. Classical field theory is determined by its tree-level amplitudes.
- (ii) **Genus- g curvature = g -loop quantum corrections.** The curvature $\kappa(\mathcal{A}) \cdot \omega_g$ at genus g is the analogue of the g -loop counterterm in perturbative renormalization. The perturbation lemma that extends HTT to the curved setting (Proposition 9.7.5) corresponds to absorbing the counterterm into the effective action, order by order in $\hbar \sim \kappa(\mathcal{A})$.

- (iii) **Koszulness = absence of anomalies.** A Koszul chiral algebra has $\tilde{m}_n = 0$ for $n \geq 3$ (Theorem 9.6.1(iii)), meaning no higher-point interactions are generated by integrating out degrees of freedom. In physics, this is the statement that the theory is *anomaly-free at the level of OPE structure*: the classical OPE data determine the quantum theory completely, with no need for higher-order counterterms. The genus- g curvature $\kappa(\mathcal{A})$ is the *only* quantum correction, and it is universal (Theorem 13.13.16).

Chapter 10

Non-abelian Poincaré duality and the construction of Koszul dual coalgebras

The MC element $\Theta_{\mathcal{A}}$ lives in a convolution algebra built from the bar coalgebra $\overline{B}(\mathcal{A})$ and the algebra $\mathcal{A}$ itself. Its Verdier dual produces a second algebra: the homotopy Koszul dual $\mathcal{A}_{\infty}^! := \mathbb{D}_{\text{Ran}} \overline{B}(\mathcal{A})$, which is the factorization algebra through which the complementarity theorem (Theorem C) and the modular characteristic (Theorem D) operate. The MC equation for $\Theta_{\mathcal{A}}$ splits genus- g obstructions into $\mathcal{A}$ -visible and $\mathcal{A}^!$ -visible halves; this chapter constructs the $\mathcal{A}^!$ -side of that decomposition.

Concretely, $\overline{B}(\mathcal{A})$ is a factorization coalgebra on $\text{Ran}(X)$. Verdier duality $\mathbb{D}_{\text{Ran}} : D(\mathcal{D}\text{-mod}(\text{Ran}(X))) \rightarrow D(\mathcal{D}\text{-mod}(\text{Ran}(X)))$ exchanges $!$ -tensor and $*$ -tensor, hence factorization coalgebras and factorization algebras. Define

$$\mathcal{A}_{\infty}^! := \mathbb{D}_{\text{Ran}} \overline{B}(\mathcal{A}).$$

This is the *homotopy Koszul dual*, unconditionally a factorization algebra on $\text{Ran}(X)$, carrying an A_{∞} -structure whose operations are:

$$\begin{aligned} \text{bar coproduct } \Delta &\longleftrightarrow \text{chiral product } \mu \text{ of } \mathcal{A}_{\infty}^!, \\ \text{bar differential } d_{\overline{B}} &\longleftrightarrow A_{\infty}\text{-differential of } \mathcal{A}_{\infty}^!, \\ \text{logarithmic forms on } \overline{C}_n(X) &\longleftrightarrow \text{distributional currents on } C_n(X). \end{aligned}$$

No quadratic presentation, no Koszul hypothesis, no classical R^+ is invoked.

Three regimes organize the theory:

- (i) *On the Koszul locus*, $\mathcal{A}_{\infty}^!$ is formal: the bar cohomology $H^*(\overline{B}(\mathcal{A}))$ is concentrated in bar degree 1, the transferred A_{∞} -structure has $m_k = 0$ for $k \geq 3$, and $\mathcal{A}_{\infty}^! \simeq \mathcal{A}^!$ as chiral algebras.
- (ii) *Off the Koszul locus*, $\mathcal{A}_{\infty}^!$ carries genuine higher operations. For $A = k[x]/(x^n)$: $m_{n-1}(a, \dots, a) = b$ is the unique nontrivial Massey product (Example 11.1.30).
- (iii) *At higher genus*, the bar differential acquires curvature $(d_{\text{fb}})^2 = \kappa(\mathcal{A}) \cdot \omega_g$ (Chapter 13), and $\mathcal{A}_{\infty}^!$ becomes a curved A_{∞} -algebra. The modular convolution algebra $\text{Conv}_{\infty}(\overline{B}(\mathcal{A}), \mathcal{A})$ is the natural home: its Maurer–Cartan element $\Theta_{\mathcal{A}}$ (Theorem 13.21.69) encodes the full Koszul duality data at all genera, with the Verdier pairing of logarithmic forms against distributional currents as its chain-level realization.

The classical objects are cohomological shadows:

$$\begin{aligned}\bar{B}(\mathcal{A}) &: \text{ factorization coalgebra, the } \textit{bar side}, \\ \mathcal{A}_\infty^! &= \mathbb{D}_{\text{Ran}} \bar{B}(\mathcal{A}) : \text{ factorization algebra, the } \textit{homotopy dual}, \\ \mathcal{A}^! &= (H^*(\bar{B}(\mathcal{A})))^\vee : \text{ the } \textit{classical dual}, \text{ the cohomological shadow of } \mathcal{A}_\infty^!.\end{aligned}$$

The bar construction does not *compute* the dual; its Verdier dual *is* the dual. The classical $\mathcal{A}_{\text{coal}}^! = H^*(\bar{B}(\mathcal{A}))$ is visible only when $\mathcal{A}$ is Koszul; in general, $\bar{B}(\mathcal{A})$ retains cohomology in all bar degrees, and the correct object is $\mathcal{A}_\infty^!$.

10.1 THE CIRCULARITY PROBLEM

Problem 10.1.1 (Independent construction of Koszul dual). The statement $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_2^!$ is circular as it stands: the dual $\mathcal{A}_2^!$ is “defined” as the Koszul dual coalgebra, but no independent construction of it as a chiral coalgebra exists, and for non-quadratic algebras the classical criterion $R_1 \perp R_2$ does not apply.

Four things are needed: an intrinsic definition of $\mathcal{A}_2^!$ using only $\mathcal{A}_2$; a proof that $\mathcal{A}_2^!$ is inherently a coalgebra; a geometric identification of $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ with this dual; and an extension to non-quadratic and curved cases.

Remark 10.1.2 (NAP duality). Non-abelian Poincaré duality resolves this circularity. For a factorization algebra $\mathcal{A}$ on a manifold M :

$$\int_M \mathcal{A} \xleftrightarrow{\text{NAP}} \mathbb{D} \left(\int_{-M} \mathcal{A}^! \right)$$

where $\int_M$ is factorization homology, $\mathbb{D}$ is Verdier duality, $-M$ is M with opposite orientation, and $\mathcal{A}^!$ is the Koszul dual defined via this duality.

The construction (Kontsevich). Factorization homology is computed as a colimit over Weiss covers:

$$\int_M \mathcal{A} = \text{colim}_{\coprod_i D_i \hookrightarrow M} \bigotimes_i \mathcal{A}(D_i)$$

where the colimit ranges over collections of disjoint disk embeddings $\coprod_i D_i \hookrightarrow M$ (not over arbitrary configuration spaces; cf. the excision property for Weiss covers, Definition 3.10.2).

Verdier duality exchanges integration over $\bar{C}_n(M)$ with distributions on $C_n(M)$, logarithmic forms with delta functions, and residues at collisions with singularity insertions. Construction 10.4.1 makes this precise.

10.2 LOGARITHMIC FORMS AND DISTRIBUTIONAL CURRENTS

Configuration spaces carry a natural duality that resolves the circularity. On $\bar{C}_k(X)$, two dual sheaf complexes coexist; one builds the bar construction, the other the cobar.

The sheaf $\Omega_{\log}^*(\bar{C}_k(X))$ consists of differential forms with at worst logarithmic poles along the boundary divisors $D_I = \{z_i = z_j : i, j \in I\}$. The propagator $\eta_{ij} = d \log(z_i - z_j)$ is the simplest section: it has a simple pole on D_{ij} and is smooth elsewhere. The wedge products $\bigwedge_{e \in E(T)} \eta_e$, indexed by edges of planar trees, are the integrands of the bar construction.

The sheaf $\mathcal{D}_{\text{dist}}^*(C_k(X))$ consists of distributional currents on the open configuration space (more precisely, distributional sections of the dualizing sheaf on $\overline{C}_k(X)$ supported along the boundary strata). The delta current $\delta_{ij} = \delta(z_i - z_j) dz_i \wedge d\bar{z}_j$, supported on the diagonal $\{z_i = z_j\}$ in the ambient space X^k , is the simplest example; the distributional insertions $\prod_{e \in E(T)} \delta_e$ are the integrands of the cobar construction (see Remark 10.3.6 for the precise sheaf-theoretic formulation).

Verdier duality exchanges these two sheaves: there is a canonical perfect pairing

$$\langle \cdot, \cdot \rangle : \Omega_{\log}^*(\overline{C}_k(X)) \otimes \mathcal{D}_{\text{dist}}^*(C_k(X)) \longrightarrow \mathbb{C}$$

given by $\langle \omega, K \rangle = \int_{\overline{C}_k(X)} \omega \wedge \iota^* K$, which identifies residue extraction (bar) with singularity insertion (cobar) as Poincaré–Lefschetz dual operations on $(\overline{C}_k(X), D)$.

Example 10.2.1 (Two points). For $k = 2$ on $X = \mathbb{P}^1$: $\langle \eta_{12}, \delta_{12} \rangle = \text{Res}_{z_1=z_2} \eta_{12} = 1$. The OPE coefficient of the identity channel is the residue of the propagator, paired with the delta current at collision.

Example 10.2.2 (Three points and the Arnold relation). For $k = 3$, the three boundary divisors D_{12}, D_{23}, D_{31} of $\overline{C}_3(\mathbb{P}^1)$ satisfy $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ (Theorem 6.1.31). The pairing with the distributional currents $\delta_{12} \wedge \delta_{23}$, etc., gives the associativity constraint: the signed sum of iterated residues vanishes.

10.3 VERDIER DUALITY ON CONFIGURATION SPACES

Setup 10.3.1 (Configuration space duality). Let X be a smooth curve (or more generally, an n -dimensional manifold). The configuration space of k points is:

$$C_k(X) = \{(z_1, \dots, z_k) \in X^k : z_i \neq z_j \text{ for } i \neq j\}$$

Its Fulton–MacPherson compactification $\overline{C}_k(X)$ is a smooth manifold with corners, with boundary divisors parametrizing collision patterns.

THEOREM 10.3.2 (*Verdier duality for configuration spaces; [250]*). There exists a canonical perfect pairing:

$$\langle \cdot, \cdot \rangle : \Omega_{\log}^*(\overline{C}_k(X)) \otimes \mathcal{D}_{\text{dist}}^*(C_k(X)) \rightarrow \mathbb{C}$$

given by integration:

$$\langle \omega, K \rangle = \int_{\overline{C}_k(X)} \omega \wedge \iota^* K$$

Here $\Omega_{\log}^*(\overline{C}_k(X))$ denotes differential forms with logarithmic poles on boundary divisors, $\mathcal{D}_{\text{dist}}^*(C_k(X))$ denotes distributional currents on the open configuration space, and $\iota : C_k(X) \hookrightarrow \overline{C}_k(X)$ is the inclusion.

Verdier duality.

$$\mathbb{D} : \Omega_{\log}^*(\overline{C}_k(X)) \xrightarrow{\sim} \mathcal{D}_{\text{dist}}^*(C_k(X))[d]$$

where $d = \dim_{\mathbb{R}}(\overline{C}_k(X))$ and the isomorphism is in the derived category $D_c^b(\overline{C}_k(X))$ (not degree-by-degree).

Proof. We apply Verdier duality for constructible sheaves [250] to the specific geometry of configuration spaces.

Step 1. For any constructible complex $\mathcal{F}$ on $\overline{C}_k(X)$:

$$\mathbb{D}(\mathcal{F}) = \mathcal{R}\mathcal{H}\mathcal{I}\mathbb{I}_{\overline{C}_k(X)}(\mathcal{F}, \omega_{\overline{C}_k(X)}[d])$$

Step 2. Since $\overline{C}_k(X)$ is smooth of complex dimension k (for X a smooth curve), the constant sheaf is self-dual up to shift:

$$\mathbb{D}(\mathbb{C}_{\overline{C}_k(X)}) \cong \mathbb{C}_{\overline{C}_k(X)}[2k]$$

For the $j_!$ -extension from the open stratum $C_k(X) \hookrightarrow \overline{C}_k(X)$, Verdier duality exchanges $j_!$ and Rj_* :

$$\mathbb{D}(j_!\mathbb{C}_{C_k(X)}) \cong Rj_*\mathbb{C}_{C_k(X)}[2k]$$

Step 3. Taking hypercohomology with respect to the de Rham complex:

$$\begin{aligned} \mathbb{H}^*(\overline{C}_k(X), \Omega_{\log}^*) &= H_{\mathrm{dR}}^*(\overline{C}_k(X), \log D) \\ \mathbb{H}_{C_k(X)}^*(\Omega_{\mathrm{dist}}^*) &= H_{c, \mathrm{dR}}^*(C_k(X)) \end{aligned}$$

The Verdier duality pairing descends to the de Rham pairing.

Step 4. The explicit pairing is computed by residues:

$$\langle \omega_{\log}, K_{\mathrm{dist}} \rangle = \sum_{\text{strata } S} \int_S \mathrm{Res}_S(\omega_{\log}) \wedge K_{\mathrm{dist}}|_S$$

Verdier duality for constructible complexes on smooth varieties [250] gives perfectness. $\square$

Remark 10.3.3 (Algebraic vs. analytic Verdier duality). Theorem 10.3.2 uses “Verdier duality” in two senses that must be carefully distinguished:

1. *Algebraic ($\mathcal{D}$ -module) Verdier duality.* The functor $\mathbb{D}_{\mathrm{alg}} = \mathcal{R}\mathcal{H}om(-, \omega_{\overline{C}_k}[\dim])$ acts on holonomic $\mathcal{D}$ -modules on $\overline{C}_k(X)$. It exchanges $j_!$ and j_* extensions (Lemma 7.0.13). This is the sense used in Definition 7.0.10 to construct the cobar complex intrinsically.
2. *Analytic (Borel–Moore) Verdier duality.* On the real manifold underlying $C_k(X)$, Poincaré–Lefschetz duality identifies $H^*(\overline{C}_k)$ with $H_c^{d-*}(C_k)$, realized concretely by the integration pairing of logarithmic forms against distributional currents.

The bridge between (1) and (2) is the Riemann–Hilbert correspondence: applying the de Rham functor to holonomic $\mathcal{D}$ -modules produces constructible sheaves, and the algebraic duality $\mathbb{D}_{\mathrm{alg}}$ becomes the topological Verdier duality on constructible complexes [250]. See Theorem 7.0.14 for the analytic realization as a consequence of the algebraic statement.

10.3.1 THE DUAL OPERATIONS

THEOREM 10.3.4 (*Dual differentials*;). Under Verdier duality, the following operations are precisely dual:
Residue vs. delta insertion.

$$\begin{aligned} \text{Bar: } \text{Res}_{D_{ij}} : \Omega_{\log}^*(\overline{C}_k) &\rightarrow \Omega_{\log}^*(\overline{C}_{k-1}) \\ \text{Cobar: } \delta_{ij} : \mathcal{D}_{\text{dist}}^*(C_{k-1}) &\rightarrow \mathcal{D}_{\text{dist}}^*(C_k) \end{aligned}$$

Explicitly:

$$\langle \text{Res}_{D_{ij}}(\omega), K \rangle = \langle \omega, \delta_{ij}(K) \rangle$$

Collapsing vs. splitting.

$$\begin{aligned} \text{Bar: Collapse at } D : C_k &\dashrightarrow C_{k-1} \\ \text{Cobar: Split along diagonal: } C_{k-1} &\rightarrow C_k \end{aligned}$$

Composition product vs. coproduct.

$$\begin{aligned} \text{Bar: } \circ : \Omega_{\log}^*(\overline{C}_k) \times \Omega_{\log}^*(\overline{C}_l) &\rightarrow \Omega_{\log}^*(\overline{C}_{k+l-1}) \\ \text{Cobar: } \Delta : \mathcal{D}_{\text{dist}}^*(C_{k+l-1}) &\rightarrow \mathcal{D}_{\text{dist}}^*(C_k) \otimes \mathcal{D}_{\text{dist}}^*(C_l) \end{aligned}$$

Geometric proof via stratifications. Observation (Serre). Boundary divisors $D \subset \overline{C}_k(X)$ biject with collision patterns (combinatorial data) and with diagonal subspaces in $C_k(X)$ (geometric data).

Residue operation. For a form ω with logarithmic pole along D :

$$\omega = f \cdot \eta_{ij} \wedge \omega' + \text{regular}$$

where $\eta_{ij} = d \log(z_i - z_j)$.

The residue is:

$$\text{Res}_D(\omega) = f|_D \cdot \omega'|_D$$

Delta operation. For a distribution K on $C_{k-1}(X)$, insertion of delta function gives:

$$\delta_{ij}(K)(z_1, \dots, z_k) = K(z_1, \dots, z_{i-1}, z_{i+1}, \dots, z_k) \cdot \delta(z_i - z_j)$$

The duality.

$$\begin{aligned} \langle \omega, \delta_{ij}(K) \rangle &= \int_{\overline{C}_k} (f \cdot \eta_{ij} \wedge \omega') \wedge \delta(z_i - z_j) \cdot K \\ &= \int_D f|_D \cdot \omega'|_D \wedge K|_D \quad (\text{delta function localizes to diagonal}) \\ &= \int_{\overline{C}_{k-1}} \text{Res}_D(f \cdot \eta_{ij} \wedge \omega') \wedge K \\ &= \langle \text{Res}_D(\omega), K \rangle \end{aligned}$$

□

Example 10.3.5 (*Heisenberg specialization*). For the Heisenberg algebra $\mathcal{H}_k$ with generator $J(z)$, Theorem 10.3.4 reduces to: the residue $\text{Res}_{z_1=z_2} J(z_1)J(z_2) d \log(z_1 - z_2) = k$ on the bar side is dual to the delta-function insertion $\delta(z_1 - z_2)$ on the cobar side, recovering the level- k pairing that identifies $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$ in §2.5.

Remark 10.3.6 (Analytic framework). The computation above is formal: the expression $\eta_{ij} \wedge \delta(z_i - z_j)$ is not well-defined as a pointwise product of distributions, since $\eta_{ij} = d \log(z_i - z_j)$ has a singularity precisely at the support of $\delta(z_i - z_j)$. The correct framework is Verdier duality as a functor on constructible sheaves (see [26, Exposé XVIII]): the pairing is defined at the level of the derived category $D_c^b(\overline{C}_k(X))$ via the proper push-forward theorem, not by pointwise multiplication. The formula above is a shorthand for the sheaf-theoretic adjunction, and the passage from line 1 to line 2 is justified by the localization triangle for the pair $(C_k(X), D_{ij})$ rather than by literal integration of a distribution against a singular function.

10.4 FROM VERDIER DUALITY TO COOPERAD STRUCTURE

Construction 10.4.1 (Intrinsic definition of $\mathcal{A}^!$ via Verdier duality). Let $\mathcal{A}$ be a chiral algebra on X . We define the Koszul dual chiral coalgebra $\mathcal{A}^!$ intrinsically as follows. (The Koszul dual algebra $\mathcal{A}^!$ is obtained by linear duality: $\mathcal{A}^! = (\mathcal{A}^!)^{\vee}$; cf. Remark 8.3.3.)

Step 1: Configuration space extension.

The factorization structure of $\mathcal{A}$ extends to configuration spaces:

$$\mathcal{A}^{\otimes k} : C_k(X) \rightarrow \text{Vect}, \quad (z_1, \dots, z_k) \mapsto \mathcal{A}(z_1) \otimes \cdots \otimes \mathcal{A}(z_k).$$

Step 2: Apply Verdier duality.

Define the dual bundle on configuration spaces:

$$(\mathcal{A}^!)^{\boxtimes k} := \mathbb{D}(\mathcal{A}^{\otimes k}) \otimes \omega_{C_k(X)}^{-1}$$

where $\mathbb{D}$ is Verdier duality and we have included an orientation twist.

Step 3: Extract the chiral coalgebra structure.

The factorization structure of $\mathcal{A}$ (composition of insertions) dualizes to a coproduct on $\mathcal{A}^!$ (decomposition of fields), a counit (projection onto the vacuum), and a differential (dual to the chiral product).

Explicit formulas.

Coproduct. For $\phi^* \in \mathcal{A}^!$,

$$\Delta(\phi^*) = \sum_{\text{collision patterns}} \text{Res}_D(\phi^* \cdot \text{propagator}_D)$$

where the sum is over all ways to split points into two groups.

Differential. For $\phi_1^* \otimes \cdots \otimes \phi_k^* \in (\mathcal{A}^!)^{\otimes k}$,

$$d(\phi_1^* \otimes \cdots \otimes \phi_k^*) = \sum_{i < j} \langle \text{OPE}_{ij}, \phi_1^* \otimes \cdots \otimes \phi_k^* \rangle$$

where OPE_{ij} is the operator product expansion of $\mathcal{A}$.

Counit.

$$\epsilon : \mathcal{A}^! \rightarrow \omega_X$$

$$\epsilon(\phi^*) = \langle \phi^*, \mathbb{1}_{\mathcal{A}} \rangle$$

Remark 10.4.2. Construction 10.4.1 uses no bar construction, orthogonal relations, or quadraticity hypothesis. The Koszul dual is defined by the geometry of configuration spaces and Verdier duality alone; the bar construction is then identified with it (Theorem 10.5.1), rather than defining it.

10.4.1 VERIFICATION OF COALGEBRA AXIOMS

THEOREM 10.4.3 (*Coalgebra structure via NAP*;). The construction of $\mathcal{A}^!$ via Verdier duality yields a well-defined conilpotent chiral coalgebra:

1. *Coassociativity*: $(\Delta \otimes \text{id}) \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$.
2. *Counit*: $(\epsilon \otimes \text{id}) \circ \Delta = \text{id} = (\text{id} \otimes \epsilon) \circ \Delta$.
3. *Coderivation (graded)*: $\Delta(d(c)) = \sum d(c_{(1)}) \otimes c_{(2)} + (-1)^{|c_{(1)}|} c_{(1)} \otimes d(c_{(2)})$.
4. *Conilpotency*: For each $\phi^* \in \mathcal{A}^!$, there exists N such that $\Delta^{(N)}(\phi^*) = 0$.

Proof via geometric stratifications. Part 1: Coassociativity.

The coproduct $\Delta : \mathcal{A}^! \rightarrow \mathcal{A}^! \otimes \mathcal{A}^!$ arises from the geometric map:

$$C_k(X) \rightarrow \bigcup_{I \sqcup J = [k]} C_{|I|}(X) \times C_{|J|}(X)$$

that splits points into two groups.

The composition $(\Delta \otimes \text{id}) \circ \Delta$ corresponds to:

$$C_k(X) \rightarrow C_{|I|}(X) \times C_{|J|}(X) \times C_{|K|}(X)$$

for $I \sqcup J \sqcup K = [k]$.

This is manifestly independent of how we bracket the split $(I \sqcup J) \sqcup K$ vs. $I \sqcup (J \sqcup K)$, giving coassociativity.

Part 2: Counit property.

The counit $\epsilon : \mathcal{A}^! \rightarrow \omega_X$ corresponds to the projection:

$$C_k(X) \rightarrow X$$

selecting a single point (say, the first).

The composition $(\epsilon \otimes \text{id}) \circ \Delta$ corresponds to:

$$C_k(X) \xrightarrow{\Delta} C_1(X) \times C_{k-1}(X) \xrightarrow{\epsilon \times \text{id}} X \times C_{k-1}(X) \cong C_{k-1}(X)$$

This is the identity on $C_{k-1}(X)$, verifying the counit axiom.

Part 3: Coderivation property.

The coproduct Δ on $\mathcal{A}^!$ is the Verdier dual of the chiral product on $\mathcal{A}$:

$$\Delta : \mathcal{A}^! \rightarrow \mathcal{A}^! \otimes \mathcal{A}^!$$

Geometrically, this corresponds to:

$$d : C_k(X) \rightarrow \bigcup_{i < j} D_{ij} \times C_{k-2}(X)$$

where D_{ij} is the collision divisor.

The coderivation property:

$$\Delta \circ d = (d \otimes \text{id} + \text{id} \otimes d) \circ \Delta$$

follows from the identity:

$$(\text{split then collide}) = (\text{collide then split on left}) + (\text{collide then split on right})$$

This is the combinatorial identity for configuration space strata, which holds because boundary divisors satisfy:

$$\partial(\overline{C}_k(X)) = \bigcup_{\text{strata}} D_\sigma$$

with compatible orientations.

Part 4: Conilpotency.

The chiral coalgebra $\mathcal{A}^!$ is conilpotent because it inherits a *weight grading* from the conformal weight grading on $\mathcal{A}$. Since $\mathcal{A}$ is graded by conformal weight with finite-dimensional graded pieces, $\mathcal{A}^!$ inherits a dual weight grading. The coproduct on $\mathcal{A}^!$ is dual to the product on $\mathcal{A}$: it maps a linear functional on $\mathcal{A}^{\otimes 1}$ to functionals on $\mathcal{A}^{\otimes 2}$, strictly increasing the number of tensor factors. The iterated coproduct $\Delta^{(N)}$ therefore vanishes on elements of degree $\leq N$.

This perspective is confirmed *a posteriori* by Theorem 10.5.1, which identifies $\mathcal{A}^{!^*} \simeq \bar{B}^{\text{ch}}(\mathcal{A})$: the bar complex is filtered by bar degree and the deconcatenation coproduct strictly increases the number of tensor factors, so $\Delta^{(N)} = 0$ on bar degree $\leq N$. $\square$

10.5 THE BAR CONSTRUCTION COMPUTES THE DUAL COALGEBRA $\mathcal{A}^{!^*}$

THEOREM 10.5.1 (*Bar construction = Verdier dual coalgebra via NAP;*). [Regime: quadratic (Convention 1.10.2).]

Let $\mathcal{A}$ be an augmented chiral algebra on a smooth curve X , valued in holonomic $\mathcal{D}$ -modules (Convention 1.10.1). Assume that the configuration-space pushforwards $\pi_*(\mathcal{A}^{\boxtimes(n+1)} \otimes \omega_{C_{n+1}(X)}^{\log})$ are well-defined in the derived category of holonomic $\mathcal{D}$ -modules on X .

Then there is a canonical quasi-isomorphism of chiral coalgebras:

$$\bar{B}^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}^{!^*}$$

Here $\bar{B}^{\text{ch}}(\mathcal{A})$ is the geometric bar complex (Definition 6.1.15) and $\mathcal{A}^{!^*}$ is the Verdier dual chiral coalgebra (Construction 10.4.1). The Koszul dual algebra is $\mathcal{A}^! = (\mathcal{A}^{!^*})^\vee$.

The isomorphism.

$$\Phi : \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}^!$$

$$\Phi(\phi_1 \otimes \cdots \otimes \phi_k \otimes \omega) = \mathbb{D}(\phi_1 \otimes \cdots \otimes \phi_k) \otimes \iota_*(\omega)$$

with $\mathbb{D}$ the Verdier duality on the factorization algebra and ι_* the direct image along $\iota : C_k(X) \hookrightarrow \overline{C}_k(X)$.

Proof. Step 1: Well-definedness of Φ .

Claim: The map Φ is a morphism of differential graded vector spaces.

Proof of claim: We must verify $\Phi \circ d_{\text{bar}} = d_{\mathcal{A}^!} \circ \Phi$.

The bar differential is:

$$d_{\text{bar}} = d_{\text{int}} + d_{\text{res}} + d_{\text{dR}}$$

The dual differential is:

$$d_{\mathcal{A}^!} = d_{\text{Verdier}}$$

Under Verdier duality:

$$\begin{aligned}\mathbb{D}(d_{\text{int}}) &= d_{\text{int}}^{\text{dual}} \quad (\text{internal differential}) \\ \mathbb{D}(d_{\text{res}}) &= d_{\delta} \quad (\text{delta function insertion}) \\ \mathbb{D}(d_{\text{dR}}) &= d_{\text{dR}}^{\text{dist}} \quad (\text{de Rham on distributions})\end{aligned}$$

These sum to give $d_{\mathcal{A}^\dagger}$, so Φ is a chain map.

Step 2: Φ preserves coalgebra structure.

Claim: Φ is a morphism of coalgebras, i.e., $\Delta_{\mathcal{A}^\dagger} \circ \Phi = (\Phi \otimes \Phi) \circ \Delta_{\bar{B}}$.

Proof of claim: The coproduct on the bar side comes from splitting configurations:

$$\Delta_{\bar{B}} : \bar{C}_k(X) \rightarrow \bigcup_{I \sqcup J} \bar{C}_{|I|}(X) \times \bar{C}_{|J|}(X)$$

Under Verdier duality, this becomes:

$$\mathbb{D}(\Delta_{\bar{B}}) : \mathcal{D}^*(C_k(X)) \rightarrow \mathcal{D}^*(C_{|I|}(X)) \otimes \mathcal{D}^*(C_{|J|}(X))$$

which is precisely $\Delta_{\mathcal{A}^\dagger}$ by construction.

Step 3: Φ is a quasi-isomorphism.

Claim: Φ induces an isomorphism on cohomology.

Proof of claim: By the foundational theorem of Verdier duality (SGA 4, Exposé XVIII):

$$H^*(\mathbb{D}(\mathcal{F})) \cong H^{d-*}(\mathcal{F})^\vee$$

Applying to $\mathcal{F} = \mathcal{A}^{\otimes k}$ as a factorization algebra on configuration spaces:

$$H^*(\mathcal{A}^\dagger) \cong H^{d-*}(\bar{B}^{\text{ch}}(\mathcal{A}))^\vee$$

In general, Φ is a quasi-isomorphism of complexes because Verdier duality is an exact involutive equivalence ($\mathbb{D}^2 \cong \text{id}$) on the bounded derived category of constructible sheaves. When $\mathcal{A}$ is Koszul (Definition 11.1.15), both sides are concentrated in a single degree, and the quasi-isomorphism reduces to a strict isomorphism of coalgebras.

Step 4: Naturality and uniqueness.

The construction is functorial in $\mathcal{A}$ and respects all structure (products, factorization, etc.). Any other natural map $\bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}^\dagger$ must agree with Φ by uniqueness of Verdier duality. $\square$

Example 10.5.2 (Heisenberg specialization). For $\mathcal{A} = \mathcal{H}_k$, Theorem 10.5.1 gives $\bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq \mathcal{H}_k^\dagger$: the bar complex, built from logarithmic forms on $\bar{C}_n(X)$, is quasi-isomorphic to the Verdier dual coalgebra whose linear dual is the Koszul dual algebra $\mathcal{H}_k^\dagger = \text{Sym}^{\text{ch}}(V^*)$. Since $\mathcal{H}_k$ is Koszul, the bar cohomology is concentrated in bar degree 1: $H^*(\bar{B}(\mathcal{H}_k)) \cong \text{Sym}^{\text{ch}}(V^*)$ with graded character $\prod_{n \geq 1} (1 - q^n)^{-1}$ (cf. §2.6).

10.5.1 EXPLICIT COMPUTATION IN LOW DEGREES

COMPUTATION 10.5.3 (*Degree 0 and 1*). We verify the theorem explicitly in low degrees for a quadratic chiral algebra $\mathcal{A} = T_{\text{ch}}(V)/(R)$.

Degree 0.

$$\bar{B}^0(\mathcal{A}) = \mathcal{A}$$

$$(\mathcal{A}^!)^{(0)} = \mathbb{D}(\mathcal{A}) \otimes \omega_X$$

The isomorphism is:

$$\begin{aligned} \Phi_0 : \mathcal{A} &\rightarrow \mathbb{D}(\mathcal{A}) \otimes \omega_X \\ \phi &\mapsto \langle \cdot, \phi \rangle \otimes \omega_X \end{aligned}$$

This is the canonical pairing twisted by the canonical bundle.

Degree 1.

$$\bar{B}^1(\mathcal{A}) = \Gamma(\bar{C}_2(X), \mathcal{A}^{\boxtimes 2} \otimes \eta_{12})$$

The dual is:

$$(\mathcal{A}^!)^{(1)} = \mathcal{D}^*(C_2(X), (\mathcal{A}^!)^{\otimes 2})$$

The isomorphism is:

$$\Phi_1(\phi_1 \otimes \phi_2 \otimes \eta_{12}) = \mathbb{D}(\phi_1 \otimes \phi_2) \otimes \delta(z_1 - z_2)$$

with $\eta_{12} = d \log(z_1 - z_2)$ the logarithmic form and $\delta(z_1 - z_2)$ the delta distribution.

The pairing is given by the residue:

$$\langle \eta_{12}, \delta_{12} \rangle = \text{Res}_{z_1=z_2} d \log(z_1 - z_2) = 1$$

(The pointwise product $\frac{1}{z} \delta(z)$ is not defined in distribution theory; the correct formulation uses the residue pairing between logarithmic forms and delta currents supported on the diagonal.) This is the fundamental Verdier pairing.

Degree 2 (first nontrivial case).

$$\bar{B}^2(\mathcal{A}) = \Gamma(\bar{C}_3(X), \mathcal{A}^{\boxtimes 3} \otimes (\eta_{12} \wedge \eta_{23} + \text{cyc}))$$

The dual is:

$$(\mathcal{A}^!)^{(2)} = \mathcal{D}^*(C_3(X), (\mathcal{A}^!)^{\otimes 3})$$

The isomorphism involves:

$$\Phi_2(\phi_1 \otimes \phi_2 \otimes \phi_3 \otimes \eta_{12} \wedge \eta_{23}) = \mathbb{D}(\phi_1 \otimes \phi_2 \otimes \phi_3) \otimes \delta(z_1 - z_2) \delta(z_2 - z_3)$$

The Arnold relations on the bar side:

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$$

correspond, under Verdier duality, to relations among constructible sheaves supported on the diagonal strata $\{z_i = z_j\}$. The precise formulation requires working with $\mathcal{D}$ -modules or perverse sheaves on $C_3(X)$ rather than literal products of delta distributions (the naive products $\delta(z_1 - z_2) \delta(z_2 - z_3)$, $\delta(z_2 - z_3) \delta(z_3 - z_1)$, $\delta(z_3 - z_1) \delta(z_1 - z_2)$ are each well-defined as distributions on $\mathbb{C}^3$, but they are all supported on the full diagonal $\{z_1 = z_2 = z_3\}$ and sum to $3\delta_{123} \neq 0$, so the Arnold relation is *not* preserved by naive Verdier duality at the level of distributions). The correct dual statement is that the Verdier dual of the Arnold relation, viewed as a relation in $H^2(C_3(X))$, yields the corresponding relation in the homology H_{2n-2} of the Borel–Moore compactification.

10.6 KOSZUL PAIRS AND SYMMETRIC DUALITY

PROPOSITION 10.6.1 (*Chiral Koszul pair via NAP*;). Two chiral algebras $(\mathcal{A}_1, \mathcal{A}_2)$ on X form a chiral Koszul pair (Definition 11.1.15) if and only if there exist quasi-isomorphisms of chiral coalgebras:

$$\begin{aligned}\bar{B}^{\text{ch}}(\mathcal{A}_1) &\xrightarrow{\sim} (\mathcal{A}_2)^! \\ \bar{B}^{\text{ch}}(\mathcal{A}_2) &\xrightarrow{\sim} (\mathcal{A}_1)^!\end{aligned}$$

where $\mathcal{A}_i^!$ is defined via Verdier duality as in Construction 10.4.1.

Equivalent characterization (NAP).

$$\int_X \mathcal{A}_1 \simeq \mathbb{D}\left(\int_{-X} \mathcal{A}_2\right)$$

with $\int_X$ the factorization homology, $-X$ the orientation reversal, and $\mathbb{D}$ Verdier duality.

Proof. By Theorem 10.5.1, the bar construction computes the Verdier-dual coalgebra: $\bar{B}^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}^!$. Construction 10.4.1 defines that coalgebra intrinsically as $\mathbb{D}(\int_{-X} \mathcal{A})$. Therefore the quasi-isomorphism $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq (\mathcal{A}_2)^!$ is equivalent to the NAP statement $\int_X \mathcal{A}_1 \simeq \mathbb{D}(\int_{-X} \mathcal{A}_2)$, and the same argument with the indices reversed gives the second bar quasi-isomorphism. This is exactly the asserted equivalence. $\square$

THEOREM 10.6.2 (*Symmetric Koszul duality*;). [Regime: quadratic on the Koszul locus (Convention 1.10.2).]

If $(\mathcal{A}_1, \mathcal{A}_2)$ is a Koszul pair, then:

$$\begin{aligned}(\mathcal{A}_1)^! &\simeq \bar{B}^{\text{ch}}(\mathcal{A}_2) \quad (\text{bar of } \mathcal{A}_2) \\ (\mathcal{A}_2)^! &\simeq \bar{B}^{\text{ch}}(\mathcal{A}_1) \quad (\text{bar of } \mathcal{A}_1) \\ \Omega^{\text{ch}}((\mathcal{A}_1)^!) &\simeq \mathcal{A}_2 \quad (\text{cobar reconstructs } \mathcal{A}_2) \\ \Omega^{\text{ch}}((\mathcal{A}_2)^!) &\simeq \mathcal{A}_1 \quad (\text{cobar reconstructs } \mathcal{A}_1)\end{aligned}$$

Diagram of mutual duality.

$$\begin{array}{ccc}\mathcal{A}_1 & \xrightarrow{\bar{B}} & (\mathcal{A}_2)^! \\ \Omega^! \downarrow & & \downarrow \simeq \\ \Omega((\mathcal{A}_2)^!) & \xrightarrow{\simeq} & \bar{B}^{\text{ch}}(\mathcal{A}_2)\end{array}$$

Proof. By Theorem 10.5.1, the bar construction computes the Verdier dual: $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq (\mathcal{A}_1)_{\text{Verdier}}^!$. For a Koszul pair $(\mathcal{A}_1, \mathcal{A}_2)$, the defining condition $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq (\mathcal{A}_2)^!$ combined with uniqueness of Verdier duals gives $(\mathcal{A}_2)^! \simeq (\mathcal{A}_1)_{\text{Verdier}}^!$. Applying the involution property of Verdier duality ($\mathbb{D} \circ \mathbb{D} \simeq \text{id}$), we obtain the symmetric statement: $\bar{B}^{\text{ch}}(\mathcal{A}_2) \simeq (\mathcal{A}_1)^!$.

The cobar reconstruction follows from the bar-cobar adjunction (Theorem 7.0.51): since $(\mathcal{A}_1)^! \simeq \bar{B}^{\text{ch}}(\mathcal{A}_2)$, applying the cobar functor gives $\Omega^{\text{ch}}((\mathcal{A}_1)^!) \simeq \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A}_2)) \simeq \mathcal{A}_2$, and symmetrically $\Omega^{\text{ch}}((\mathcal{A}_2)^!) \simeq \mathcal{A}_1$, using the fact that for Koszul algebras the counit $\Omega \circ B \rightarrow \text{id}$ is a quasi-isomorphism. $\square$

Example 10.6.3 (Heisenberg specialization). For the Koszul pair $(\mathcal{H}_k, \text{Sym}^{\text{ch}}(V^*))$, Theorem 10.6.2 gives: $\bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq (\text{Sym}^{\text{ch}}(V^*))^!$ and $\Omega^{\text{ch}}((\mathcal{H}_k)^!) \simeq \text{Sym}^{\text{ch}}(V^*)$. The symmetric diagram specializes to the Lie–Com exchange: the chiral Lie structure of $\mathcal{H}_k$ dualizes to the chiral commutative structure of $\text{Sym}^{\text{ch}}(V^*)$, and vice versa (§2.5).

Remark 10.6.4 (Surface observables via factorization homology). For a closed genus- g surface Σ_g , the factorization homology $H_{\Sigma_g}(\mathcal{A}) := \int_{\Sigma_g} \mathcal{A}$ computes the space of *surface observables* of the chiral algebra $\mathcal{A}$. The Ayala–Francis Poincaré/Koszul duality theorem [30] gives

$$\int_{\Sigma_g} \mathcal{A} \simeq \mathbb{D} \int_{-\Sigma_g} \mathcal{A}^!,$$

which is the topological shadow of the modular bar-cobar story: the left side is factorization homology with $\mathcal{A}$; the right side is factorization cohomology with $\mathcal{A}^!$. At genus 0, this recovers Theorem A. At genus $g \geq 1$, the surface observables are the derived global sections of the bar family over $\overline{\mathcal{M}}_g$: $H_{\Sigma_g}(\mathcal{A}) \simeq R\Gamma(\overline{\mathcal{M}}_g, \bar{B}_g(\mathcal{A}))$. The modular characteristic package extracts numerical invariants from this derived object.

10.7 NON-QUADRATIC CASES AND COMPLETION

Remark 10.7.1 (Necessity of completion). For non-quadratic chiral algebras (W-algebras, Yangians, etc.), the bar construction produces infinitely many generators in each degree:

Problem. The bar complex is not finitely generated, so the Koszul dual $\mathcal{A}^!$ is not a finitely presented coalgebra.

Solution (Beilinson–Drinfeld). Use I-adic completion:

$$\widehat{\bar{B}}(\mathcal{A}) = \varprojlim_n \bar{B}(\mathcal{A})/I^n$$

where $I = \ker(\epsilon : \bar{B}(\mathcal{A}) \rightarrow \mathbb{C})$ is the coaugmentation ideal.

Geometric interpretation. The completion is the inverse limit

$$\widehat{\bar{B}}(\mathcal{A}) = \varprojlim_n \bar{B}(\mathcal{A})/F^n$$

over the conilpotent filtration by bar degree (see Appendix K.7.1), which organizes the bar complex by the number of collision points on $\overline{C}_n(X)$.

Definition 10.7.2 (Completed Koszul dual). For a chiral algebra $\mathcal{A}$, define the *completed Koszul dual* via:

$$\widehat{\mathcal{A}^!} := \varprojlim_n (\mathcal{A}^!)/I^n$$

where I^n is the n -th power of the conilpotent filtration.

Alternatively. Using Verdier duality directly,

$$\widehat{\mathcal{A}^!} = \mathbb{D}(\mathcal{A}) \otimes \widehat{\Omega}_{\text{comp}}^*$$

where $\widehat{\Omega}_{\text{comp}}^*$ are completed differential forms on compactified configuration spaces.

THEOREM 10.7.3 (*Completion and Koszul duality*;). For chiral algebras satisfying:

1. Finite generation over $\mathcal{D}_X$
2. Polynomial growth of structure constants

The completed bar construction:

$$\widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \widehat{\mathcal{A}}^!$$

is a quasi-isomorphism of completed chiral coalgebras.

The cobar construction:

$$\Omega^{\text{ch}}(\widehat{\mathcal{A}}^!) \xrightarrow{\sim} \mathcal{A}$$

recovers the original algebra.

Proof. Step 1: Verdier duality extends to completed sheaves. The bar complex carries a filtration $F_n \bar{B}^{\text{ch}}(\mathcal{A})$ by bar degree $\leq n$. Since $\mathcal{A}$ is finitely generated over $\mathcal{D}_X$ (hypothesis (1)), each $\bar{B}_n^{\text{ch}}(\mathcal{A})$ is a holonomic $\mathcal{D}$ -module on $\bar{C}_n(X)$ (the bar construction at degree n involves n -fold chiral tensor products of $\mathcal{A}$, which are holonomic by closure of holonomic $\mathcal{D}$ -modules under tensor product and proper pushforward). Verdier duality commutes with filtered colimits of holonomic $\mathcal{D}$ -modules and exchanges $\varprojlim$ with $\varinjlim$ by the standard adjunction:

$$\mathbb{D} : \varprojlim_n \mathcal{F}_n \xrightarrow{\sim} \varinjlim_n \mathbb{D}(\mathcal{F}_n).$$

Step 2: Completion filtration is compatible with Verdier duality. The coaugmentation ideal $I = \ker(\epsilon : \bar{B}^{\text{ch}} \rightarrow \mathbb{C})$ defines the I -adic filtration. Each quotient $\bar{B}^{\text{ch}}/I^n$ involves only configuration spaces $C_k(X)$ with $k \leq n$, hence is geometric. The polynomial growth condition (hypothesis (2)) ensures $\dim(I^n/I^{n+1}) \leq C \cdot n^d$ for constants C, d , so the Mittag-Leffler condition holds for the inverse system $\{H^*(\bar{B}^{\text{ch}}/I^n)\}$.

Step 3: Lifting to completions. By Theorem 10.5.1, we have a quasi-isomorphism $\Phi : \bar{B}^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}^!$ at each finite level. The universal property of the inverse limit, together with the Mittag-Leffler condition from Step 2, yields:

$$\widehat{\Phi} : \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) = \varprojlim_n \bar{B}^{\text{ch}}/I^n \xrightarrow{\sim} \varprojlim_n \mathcal{A}^!/I^n = \widehat{\mathcal{A}}^!$$

as a quasi-isomorphism of completed coalgebras.

Step 4: Cobar. By hypothesis (1), each bar component is holonomic (Step 1), so $\dim \text{CH}^n(\mathcal{A}) < \infty$ (de Rham cohomology of holonomic $\mathcal{D}$ -modules is finite-dimensional). Hence the cobar construction $\Omega^{\text{ch}}(\widehat{\mathcal{A}}^!)$ is well-defined and carries a complete filtration compatible with the differential. The bar-cobar adjunction unit $\Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$ (Theorem 7.0.51) is a quasi-isomorphism on the Koszul locus (Theorem 11.1.84). In the completed setting, all operations are continuous with respect to the I -adic topology and the Mittag-Leffler condition (Step 2) ensures $\varprojlim^1 = 0$, so the completed counit $\Omega^{\text{ch}}(\widehat{\mathcal{A}}^!) \rightarrow \mathcal{A}$ is a quasi-isomorphism. $\square$

10.7.1 APPLICATION: $\mathcal{W}$ -ALGEBRAS

Example 10.7.4 ($\mathcal{W}$ -algebra Koszul duality via completion). For the W_3 algebra with generators $T(z) = L(z)$ (weight 2) and $W(z)$ (weight 3):

The composite field.

$$\Lambda = :TT: - \frac{3}{10} \partial^2 T$$

is the quasi-primary composite of weight 4. It does not lie in W_3 itself but appears in $\bar{B}^{\text{ch}}(W_3)$, with OPE coefficient $\frac{16}{22+5c}$ in the W – W channel (Definition H.20.1).

Completed Koszul dual.

$$\widehat{W}_3^! = \text{Free coalgebra}(L^*, W^*, \Lambda^*, (\Lambda^*)^{(2)}, (\Lambda^*)^{(3)}, \dots)$$

where $(\Lambda^*)^{(n)}$ are descendant towers.

Coproduct (computed via Verdier duality).

$$\Delta(L^*) = 0 \quad (\text{primitive})$$

$$\Delta(W^*) = 0 \quad (\text{primitive})$$

$$\Delta(\Lambda^*) = L^* \otimes L^* - \frac{3}{10} (\partial^2 L^* \otimes 1 + 1 \otimes \partial^2 L^*) \quad (\text{composite})$$

The differential. The differential on Λ^* encodes the W – W OPE: since $W(z)W(w) \sim \frac{16}{22+5c} \frac{\Lambda(w)}{(z-w)^2} + \dots$, the bar differential acts by

$$d(\Lambda^*) = \frac{16}{22+5c} W^* \otimes W^*$$

with the remaining terms determined by the full W – W OPE (see Definition H.20.1 and Computation K.7.1 for the explicit structure constants).

Cobar reconstruction.

$$\Omega^{\text{ch}}(\widehat{W}_3^!) = W_3$$

The relation $\Lambda =: T \cdot T: - \frac{3}{10} \partial^2 T$ (with OPE coefficient $\frac{16}{22+5c}$) becomes a Maurer–Cartan element in the cobar complex.

10.8 RESOLUTION OF THE CIRCULARITY

THEOREM 10.8.1 (*Resolution of circularity*;). Construction 10.4.1 defines the Koszul dual coalgebra $\mathcal{A}^!$ intrinsically via Verdier duality on factorization homology, with no reference to bar constructions or orthogonal relations. Theorem 10.5.1 then identifies $\bar{B}^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}^!$ as dg coalgebras (the Koszul dual algebra is $\mathcal{A}^! = (\mathcal{A}^!)^\vee$), and for Koszul pairs $(\mathcal{A}_1, \mathcal{A}_2)$, Theorem 10.6.2 gives the symmetric statement

$$\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq (\mathcal{A}_2)^! \quad \text{and} \quad \bar{B}^{\text{ch}}(\mathcal{A}_2) \simeq (\mathcal{A}_1)^!$$

derived from the NAP identity $\int_X \mathcal{A}_1 \simeq \mathbb{D}(\int_{-X} \mathcal{A}_2)$.

Proof. The intrinsic Koszul dual $\mathcal{A}^! := \mathbb{D}(\int_{-X} \mathcal{A})$ is defined in Definition 7.0.10. The identification $\bar{B}^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}^!$ is Theorem 7.0.36, proved by comparing the geometric bar complex with the Verdier dual via the configuration space model (Theorem 6.1.8). The Koszul pair statement follows from applying this to both $\mathcal{A}_1$ and $\mathcal{A}_2$ and using NAP (Theorem 13.2.13). $\square$

The completed bar construction (Theorem 10.7.3) extends this to non-quadratic algebras. The quantum corrections (curvature from periods on $\bar{\mathcal{M}}_g$) appear in §15.12 and Chapter 13.

Remark 10.8.2 (Downstream dependencies). Theorem 10.8.1 supplies the intrinsic Koszul dual for Theorem A₂ (Theorem 11.1.84); Theorem 7.0.36 supplies the Verdier compatibility input for Theorem C (Theorem 13.15.14); and the explicit NAP computations of Chapter R independently verify Heisenberg, Kac–Moody, and $\beta\gamma/bc$ Koszul pairs.

Chapter II

Chiral Koszul duality

Classical Koszul duality, in the sense of Priddy [359] and Beilinson–Ginzburg–Soergel [41], works for graded algebras over a field: the bar complex is a tensor coalgebra on a finite-dimensional vector space, the cobar functor inverts it when bar cohomology is concentrated in degree one, and the duality exchanges quadratic algebras with quadratic coalgebras. Three features of chiral algebras on algebraic curves defeat this framework simultaneously. First, chiral algebras are *curved*: the bar differential on the genus expansion satisfies $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ rather than $d^2 = 0$, so the classical bar-cobar adjunction, which requires strict nilpotence, does not apply beyond genus zero. Second, chiral algebras live over a curve X , not over a point: the tensor power $V^{\otimes n}$ is replaced by the factorization product $\mathcal{A}^{\boxtimes n}$ over the Fulton–MacPherson compactification $\text{FM}_n(X)$, and the differential is a sum of residues at boundary strata governed by OPE singularities, not a combinatorial sum of face maps. Third, the conformal-weight components are infinite-dimensional, so finite generation hypotheses fail and convergence of spectral sequences becomes a separate problem.

What forces the extension is not a desire for generality but the structure of the objects themselves. The Virasoro algebra has a quartic OPE pole, $\mathcal{W}$ -algebras have poles of arbitrarily high order, Yangians have spectral-parameter relations: none of these admit a quadratic presentation, and the BGS theory does not see them. The Francis–Gaitsgory adjunction $\text{Lie}^{\text{ch}} \dashv \text{Com}^{\text{ch}}$ on $\text{Ran}(X)$ [167] settles Koszul duality of the Lie–Com pair at the operadic level, but it does not determine whether a specific chiral algebra is Koszul: it does not see the genus corrections in the bar complex, and it does not detect the shadow obstruction tower whose depth varies from two to infinity across the standard families.

The bar-cobar adjunction of Theorem A (Theorem II.1.84) is the unique functorial pair that resolves all three obstructions. It is the unique adjunction that (a) inverts on the Koszul locus, producing $\Omega_X(\overline{B}_X(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ (Theorem 8.6.1); (b) intertwines Verdier duality on $\text{Ran}(X)$, connecting $\overline{B}_X(\mathcal{A})$ with the homotopy dual factorization algebra $\mathcal{A}_{\infty}^!$; (c) produces Lagrangian complementarity $Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!) \simeq H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$ (Theorem 13.15.14). No other functorial construction achieves all three: the operadic adjunction achieves (a) but not (b) or (c); Verdier duality alone achieves (b) but has no bar-cobar content; complementarity (c) requires both (a) and (b) as input.

Standing notation for the overview. A chiral twisting datum means a quadruple $(\mathcal{A}, C, \tau, F_{\bullet})$ consisting of an augmented chiral algebra, a conilpotent complete factorization coalgebra, a degree-+1 twisting morphism $\tau: C \rightarrow \mathcal{A}$ satisfying the Maurer–Cartan equation, and a compatible filtration. We write $K_{\tau}^L(\mathcal{A}, C)$ and $K_{\tau}^R(C, \mathcal{A})$ for the corresponding twisted tensor products, and $\Theta_{\mathcal{A}}^{\leq r}$ for the degree- r truncation of the universal Maurer–Cartan element of the modular convolution algebra. A chiral Koszul pair is such a datum on the Koszul locus, so the twisted tensor products are acyclic and the associated graded datum is classically Koszul. Definitions II.1.1, II.1.3, and II.1.15 record the precise versions used below.

Theorem II.1.50 assembles twelve tests and consequences around chiral Koszulness. Nine are unconditional equivalences: E_2 -collapse of the bar spectral sequence, vanishing of transferred A_∞ operations m_k for $k \geq 3$, acyclicity of the twisted tensor product $K_\tau^L(\mathcal{A}, C)$, truncation of the shadow tower $\Theta_{\mathcal{A}}^{\leq r}$, and five others. One (Hochschild duality and concentration in degrees $\{0, 1, 2\}$) is a proved consequence on the Koszul locus. One (the Lagrangian eigenspace decomposition) is conditional on perfectness of the bar-cobar normal complex. One (D-module purity) is a one-directional implication. The count is exact: $9 + 1 + 1 + 1$.

Two distinctions require emphasis. First, the four complexity classes G/L/C/M, with shadow depths $\{2, 3, 4, \infty\}$ (Theorem 13.22.129), record the degree at which the shadow obstruction tower first becomes nontrivial; they do *not* record failure of Koszulness. Every standard chiral algebra is chirally Koszul. The classes separate algebras by the complexity of their higher-genus behaviour, not by the validity of the duality. Second, Koszulness and SC formality are logically independent properties. Koszulness is the condition that bar cohomology is concentrated in degree one; SC formality is the condition $m_k^{\text{SC}} = 0$ for $k \geq 3$ in the Swiss-cheese bar complex. All standard families are Koszul; only class G (Heisenberg and its relatives) is SC-formal (Proposition II.1.60). Confusing the two misidentifies what the shadow tower measures.

On a point, the bar complex $\bar{B}(A) = T^c(s^{-1}\bar{A})$ is built from tensor powers of the augmentation ideal; a classical twisting morphism $\tau: \bar{B}(A) \rightarrow A^1$ is a degree-+1 element in the convolution dg Lie algebra satisfying $d\tau + \tau \star \tau = 0$. On a curve X , the chiral twisting morphism (Definition II.1.1) lives in the chiral convolution algebra, where the star product is mediated by the integration kernel on $X^2 \setminus \Delta$. The acyclicity of the twisted tensor product $K_\tau^L(\mathcal{A}, C)$, the defining property of a chiral Koszul pair, is checked by spectral sequence methods adapted to the PBW filtration by bar degree (Theorem II.1.18).

Three phenomena distinguish the chiral setting from its point-set ancestor, and all three are invisible at genus zero: the modular characteristic $\kappa(\mathcal{A})$, which measures curvature of the genus expansion (Theorem 13.21.44); Lagrangian complementarity between $\mathcal{A}$ and $\mathcal{A}^1$ (Theorem 13.15.14); and the critical discriminant $\Delta = 8\kappa S_4$, whose vanishing controls termination of the shadow obstruction tower (Theorem 13.22.137). At genus zero all three collapse: κ plays no role, complementarity reduces to the genus-0 bar-cobar adjunction, Δ is vacuous. On the formal disk, this further reduces to classical Koszul duality; on the full genus-0 curve $\mathbb{P}^1$, the Fulton–MacPherson compactifications and Arnold relations already refine the classical picture. The present chapter provides the genus-zero input from which the full modular theory is built. The standard families exemplify the four classes: Heisenberg (class G, depth 2, formal), affine Kac–Moody (class L, depth 3, single Massey product), $\beta\gamma$ (class C, depth 4, contact then rigid), Virasoro and $\mathcal{W}_N$ (class M, depth ∞ , intrinsically non-formal). The genus-zero degree-two projection of the universal MC element $\Theta_{\mathcal{A}}$ (Theorem 13.21.69) recovers the classical R -matrix, linking the Koszul pairs of this chapter to the Drinfeld–Kohno bridge of Chapter 12.

The chapter proceeds in three stages. §II.1ff. extracts from the Heisenberg example the general notion of chiral twisting data and formulates the PBW recognition criterion. The chiral Koszul pair (Definition II.1.15) is then defined, and the full bar-cobar adjunction and inversion on the Koszul locus (Theorem A) are proved. The Verdier intertwining that connects $\bar{B}_X(\mathcal{A})$ with the homotopy dual factorization algebra $\mathcal{A}_\infty^!$ completes the genus-zero layer of the duality. The passage to higher genus (Chapter 13), where curvature enters and the fiberwise differential ceases to square to zero, builds on these structures.

II.1 FROM THE HEISENBERG EXAMPLE TO GENERAL TWISTING DATA

The bar complex of $\mathcal{H}_k$ (Chapter 2, Theorem 2.5.1) produces the coalgebra $\bar{B}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*)$, whose cohomology gives the Koszul dual algebra $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$. The bar-cobar counit $\Omega_X(\bar{B}_X(\mathcal{H}_k)) \xrightarrow{\sim} \mathcal{H}_k^!$

$\mathcal{H}_k$ is a quasi-isomorphism (recovering the original algebra, not its dual). Two structural features make this work:

1. The twisted tensor product $K_\tau^L(\mathcal{H}_k, \text{coLie}^{\text{ch}}(V^*))$ is acyclic: the twisting morphism $\tau : \text{coLie}^{\text{ch}}(V^*) \rightarrow \mathcal{H}_k$ solves the Maurer–Cartan equation.
2. The PBW filtration on $\mathcal{H}_k$ produces an associated graded that is quadratic-Koszul in the classical sense.

These two properties (acyclicity of twisted tensor products and classical Koszulness of the associated graded) are the recognition criteria for chiral Koszulness. The point is not that the chiral algebra itself is quadratic (it is not), but that the PBW filtration by bar-length makes the leading-order structure quadratic-Koszul (Theorem 11.1.18). These criteria apply equally to the Virasoro algebra (quartic pole in the TT OPE), $\mathcal{W}$ -algebras (poles of arbitrarily high order), and Yangians (spectral-parameter relations), none of which admit a quadratic presentation.

11.1.1 CONSTRUCTION LAYER: TWISTING DATA

To recognize Koszulness, we need to compare a chiral algebra with its bar coalgebra. The bridge between them is a *twisting morphism*, a degree-+1 map satisfying a Maurer–Cartan equation, and to ensure convergence of the resulting spectral sequences, we need a compatible filtration. The Koszul property is then a *recognition criterion* on these data, not a prerequisite for their existence.

Definition 11.1.1 (Chiral twisting datum). A *chiral twisting datum* on a smooth curve X is a quadruple $(\mathcal{A}, C, \tau, F_\bullet)$ consisting of:

1. an augmented chiral algebra $\mathcal{A} \in \text{Fact}^{\text{aug}}(X)$;
2. a conilpotent complete factorization coalgebra $C \in \text{CoFact}^{\text{conil, comp}}(X)$;
3. a degree +1 morphism $\tau : C \rightarrow \mathcal{A}$ satisfying the Maurer–Cartan equation $d\tau + \tau \star \tau = 0$ in the convolution dg Lie algebra;
4. an exhaustive, complete, bounded-below filtration $F_\bullet$ on $\mathcal{A}, C, \bar{B}_X(\mathcal{A})$, and $\Omega_X(C)$, compatible with all structure maps.

Associated to τ are the *twisted tensor products*

$$K_\tau^L(\mathcal{A}, C) := (\mathcal{A} \otimes C, d_{\mathcal{A}} + d_C + d_\tau^L), \quad K_\tau^R(C, \mathcal{A}) := (C \otimes \mathcal{A}, d_C + d_{\mathcal{A}} + d_\tau^R).$$

Remark 11.1.2 (Explicit twisted differential). The twisting differentials d_τ^L and d_τ^R in Definition 11.1.1 are:

$$d_\tau^L(a \otimes c) = \sum (-1)^{|a|} a \cdot \tau(c_{(1)}) \otimes c_{(2)},$$

$$d_\tau^R(c \otimes a) = \sum (-1)^{|c|} c_{(1)} \otimes \tau(c_{(2)}) \cdot a,$$

where $\Delta(c) = \sum c_{(1)} \otimes c_{(2)}$ is the factorization coproduct. The MC equation $d\tau + \tau \star \tau = 0$ is *equivalent* to $(d_{\mathcal{A}} + d_C + d_\tau^L)^2 = 0$ (cf. [299, Lemma 2.1.4]): the twisting morphism condition is the nilpotence of the twisted differential. In the chiral setting, $\tau(c_{(1)})$ is the OPE extraction: the coproduct $\Delta(c) = \sum c_{(1)} \otimes c_{(2)}$ separates the coalgebra element, and τ evaluates $c_{(1)}$ against the propagator on $\bar{C}_2(X)$ by residue at the collision divisor (Proposition 5.1.24).

Definition II.1.3 (Chiral Koszul morphism). A chiral twisting datum $(\mathcal{A}, C, \tau, F_\bullet)$ is *Koszul* if:

1. both $K_\tau^L(\mathcal{A}, C)$ and $K_\tau^R(C, \mathcal{A})$ are acyclic;
2. the associated graded $(\text{gr } \mathcal{A}, \text{gr } C, \text{gr } \tau)$ is quadratic/Koszul in the ordinary operadic sense;
3. the filtration converges strongly on $\bar{B}_X(\mathcal{A})$ and $\Omega_X(C)$.

Remark II.1.4 (Construction versus resolution). For every augmented chiral algebra $\mathcal{A}$, the bar $\bar{B}_X(\mathcal{A})$ and cobar $\Omega_X(\bar{B}_X(\mathcal{A}))$ exist as constructions. But the counit $\Omega_X(\bar{B}_X(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism *only when τ is a Koszul morphism* (Theorem 8.6.1). Off the Koszul locus, the bar-cobar object persists in the provisional coderived category $D_{\text{prov}}^{\text{co}}(X)$ (Appendix K.7.1), not in the ordinary derived category. This is the chiral/factorization analogue of the fundamental theorem of twisting morphisms [299, Theorem 2.3.1].

The following lemmas make the mapping-cone identifications explicit, as required for Theorem II.1.9.

LEMMA II.1.5 (Left twisted tensor product as mapping cone;). Let $(\mathcal{A}, C, \tau, F_\bullet)$ be a chiral twisting datum. There is a natural identification of chain complexes

$$K_\tau^L(\mathcal{A}, C) \simeq \text{Cone}(\varepsilon_\tau)[-1]$$

where $\varepsilon_\tau: \Omega_X(C) \rightarrow \mathcal{A}$ is the canonical counit. In particular, K_τ^L is acyclic if and only if ε_τ is a quasi-isomorphism.

Proof. Decompose the total differential on $\mathcal{A} \hat{\otimes} C$ as $d_{\mathcal{A}} + d_C + d_\tau^L$. The d_τ^L component acts as the cobar differential on the C -factor and as the ε_τ -induced augmentation on the $\mathcal{A}$ -factor. The resulting complex is exactly the mapping cone of $\varepsilon_\tau: \Omega_X(C) \rightarrow \mathcal{A}$ shifted by $[-1]$: the rows of the double complex are $\mathcal{A} \leftarrow \mathcal{A} \otimes C \leftarrow \mathcal{A} \otimes C^{\otimes 2} \leftarrow \dots$, which is the bar-type resolution of the augmentation map. This is the chiral analogue of [299, Lemma 2.2.5]. $\square$

LEMMA II.1.6 (Right twisted tensor product as mapping cone;). Under the same hypotheses, there is a natural identification

$$K_\tau^R(C, \mathcal{A}) \simeq \text{Cone}(\eta_\tau)[-1]$$

where $\eta_\tau: C \rightarrow \bar{B}_X(\mathcal{A})$ is the canonical unit. In particular, K_τ^R is acyclic if and only if η_τ is a weak equivalence.

Proof. Dual to Lemma II.1.5: the d_τ^R component on $C \hat{\otimes} \mathcal{A}$ acts as the bar differential on the $\mathcal{A}$ -factor and as the η_τ -induced augmentation on the C -factor, identifying K_τ^R with $\text{Cone}(\eta_\tau)[-1]$. $\square$

LEMMA II.1.7 (Filtered comparison;). Let $(\mathcal{A}, C, \tau, F_\bullet)$ be a chiral twisting datum whose filtration is exhaustive, complete, and bounded below. If ε_τ is a quasi-isomorphism, then:

- (a) the associated graded datum $(\text{gr } \mathcal{A}, \text{gr } C, \text{gr } \tau)$ is a classical Koszul datum;
- (b) both twisted tensor products K_τ^L and K_τ^R are acyclic.

Proof. Filter ε_τ by $F_\bullet$. Since the filtration is bounded below and complete, the spectral sequence converges strongly (Eilenberg–Moore). The associated graded $\text{gr } \varepsilon_\tau$ is a quasi-isomorphism between graded objects, which by [299, Theorem 3.2.1] identifies $\text{gr } \tau$ as a classical Koszul morphism. Classical Koszulity gives acyclicity of the associated graded twisted tensor products. Strong convergence then lifts this to acyclicity of K_τ^L and K_τ^R themselves. $\square$

LEMMA 11.1.8 (*Bar-side filtered comparison*;). Let $(\mathcal{A}, C, \tau, F_\bullet)$ be a chiral twisting datum whose filtration is exhaustive, complete, and bounded below. If $\eta_\tau : C \rightarrow \bar{B}_X(\mathcal{A})$ is a weak equivalence, then:

- (a) the associated graded datum $(\text{gr } \mathcal{A}, \text{gr } C, \text{gr } \tau)$ is a classical Koszul datum;
- (b) both twisted tensor products K_τ^L and K_τ^R are acyclic.

Proof. This is the unit-side analogue of Lemma 11.1.7: one replaces the cobar-side filtration on $\Omega_X(C)$ by the induced filtration on the bar coalgebra $\bar{B}_X(\mathcal{A})$. Because $\bar{B}_X(\mathcal{A})$ is the cofree tensor coalgebra on $s^{-1}\mathcal{A}$ and $F_\bullet$ is compatible with the bar structure, the associated graded bar coalgebra is canonically the classical reduced bar construction:

$$\text{gr}_F \bar{B}_X(\mathcal{A}) \cong \bar{B}(\text{gr}_F \mathcal{A}).$$

Filter η_τ by $F_\bullet$. Since the filtration is bounded below and complete, the induced spectral sequence converges strongly, and the associated graded map

$$\text{gr}_F \eta_\tau : \text{gr}_F C \longrightarrow \text{gr}_F \bar{B}_X(\mathcal{A}) \cong \bar{B}(\text{gr}_F \mathcal{A})$$

is a quasi-isomorphism of classical conilpotent coalgebras. By the classical fundamental theorem of twisting morphisms [299, Theorem 2.3.1], the induced twisting morphism $\text{gr}_F \tau$ is classically Koszul, proving (a).

For (b), Lemma 11.1.6 identifies K_τ^R with $\text{Cone}(\eta_\tau)[-1]$, so the weak equivalence of η_τ makes K_τ^R acyclic. Filter K_τ^L by $F_\bullet$; its associated graded complex is the classical left twisted tensor product for $\text{gr}_F \tau$, which is acyclic by (a). Strong convergence then lifts this acyclicity to K_τ^L . $\square$

THEOREM 11.1.9 (*Fundamental theorem of chiral twisting morphisms*;). [Regime: quadratic (Convention 1.10.2).]

This is the chiral analogue of [299, Theorem 2.3.1]. For a chiral twisting datum $(\mathcal{A}, C, \tau, F_\bullet)$ (Definition 11.1.1), the following are equivalent:

- (i) τ is a chiral Koszul morphism (Definition 11.1.3).
- (ii) The canonical counit $\varepsilon_\tau : \Omega_X(C) \rightarrow \mathcal{A}$ is a quasi-isomorphism.
- (iii) The canonical unit $\eta_\tau : C \rightarrow \bar{B}_X(\mathcal{A})$ is a weak equivalence of conilpotent complete factorization coalgebras.
- (iv) Both twisted tensor products $K_\tau^L(\mathcal{A}, C)$ and $K_\tau^R(C, \mathcal{A})$ are acyclic.

Proof. The equivalence follows the same logical structure as the classical case [299, Theorem 2.3.1], adapted to the chiral/factorization setting.

(i) $\Rightarrow$ (iv): By definition (Definition 11.1.3, condition 1).

(iv) $\Rightarrow$ (ii): By Lemma 11.1.5, $K_\tau^L \simeq \text{Cone}(\varepsilon_\tau)[-1]$. Acyclicity of K_τ^L is therefore equivalent to ε_τ being a quasi-isomorphism.

(iv) $\Rightarrow$ (iii): By Lemma 11.1.6, $K_\tau^R \simeq \text{Cone}(\eta_\tau)[-1]$. Acyclicity of K_τ^R is therefore equivalent to η_τ being a weak equivalence.

(ii) $\Rightarrow$ (i): Because the filtration in the twisting datum is exhaustive, complete, and bounded below on both $\Omega_X(C)$ and $\bar{B}_X(\mathcal{A})$, the comparison spectral sequences converge strongly. Lemma 11.1.7 then gives classical Koszulity of the associated graded datum and acyclicity of the twisted tensor products. These are conditions (1) and (2) of Definition 11.1.3; the strong convergence just noted is condition (3).

(iii) $\Rightarrow$ (i): The same completeness and bounded-below hypotheses give strong convergence on the bar-side filtration. Lemma II.1.8 shows that the weak equivalence of η_τ forces the associated graded datum $(\text{gr } \mathcal{A}, \text{gr } C, \text{gr } \tau)$ to be classically Koszul and lifts the acyclicity of the classical twisted tensor products to K_τ^L and K_τ^R . Together with strong convergence, this is exactly Definition II.1.3. $\square$

COROLLARY II.1.10 (*Three bijections for chiral twisting morphisms*;). For a conilpotent complete factorization coalgebra C and an augmented chiral algebra $\mathcal{A}$ on a smooth curve X , there are natural bijections

$$\begin{aligned} \text{Tw}(C, \mathcal{A}) &\cong \text{Hom}_{\text{alg}}(\Omega_X(C), \mathcal{A}) \\ &\cong \text{Hom}_{\text{coalg}}(C, \bar{B}_X(\mathcal{A})) \end{aligned}$$

where $\text{Tw}(C, \mathcal{A})$ is the set of degree +1 morphisms $\tau: C \rightarrow \mathcal{A}$ satisfying the Maurer–Cartan equation $d\tau + \tau \star \tau = 0$.

The *universal twisting morphism* $\tau_{\text{univ}}: \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ (projection to cogenerators) represents the twisting functor: every $\tau \in \text{Tw}(C, \mathcal{A})$ factors uniquely through τ_{univ} . Dually, the *canonical twisting morphism* $\iota: C \rightarrow \Omega_X(C)$ (inclusion of cogenerators) corepresents twisting: every τ factors uniquely through ι .

Proof. The first bijection sends $\tau \in \text{Tw}(C, \mathcal{A})$ to the algebra morphism $g_\tau: \Omega_X(C) \rightarrow \mathcal{A}$ defined on cogenerators by $g_\tau(s^{-1}c) = \tau(c)$; the MC equation for τ is equivalent to g_τ commuting with differentials (the same proof as [299, Theorem 2.2.7]). The second bijection sends τ to the coalgebra morphism $f_\tau: C \rightarrow \bar{B}_X(\mathcal{A})$ defined dually. The universal property of the bar construction as a cofree coalgebra ensures uniqueness of factorization. $\square$

Remark II.1.11 (*Why the MC equation is Stokes’ theorem*). The Maurer–Cartan equation $d\tau + \tau \star \tau = 0$ is not an imposed axiom. It is forced by the geometry of $\bar{C}_2(X)$. The convolution $(\tau \star \tau)(x) = \mu \circ (\tau \otimes \tau) \circ \Delta(x)$ evaluates the two-point OPE: it extracts the residue of the propagator η_{12} at the collision divisor $D_{12} \subset \bar{C}_2(X)$, then multiplies in $\mathcal{A}$. The term $d\tau$ computes the Stokes boundary on $\bar{C}_2(X)$. The MC equation says: *on the compactified two-point configuration space, the propagator residue is exact*. At three points, this becomes the Arnold relation. At n points, $d_{\text{bar}}^2 = 0$.

At genus $g \geq 1$, the propagator acquires monodromy, the Stokes argument picks up a curvature term $\kappa(\mathcal{A}) \cdot \omega_g$, and τ becomes curved (Remark 13.16.14).

Remark II.1.12 (*Theorem A decomposition*). The fundamental theorem of chiral twisting morphisms (Theorem II.1.9) is Theorem A₀ in the decomposition of the main duality theorem:

- A₀ (this theorem): for a single twisting datum, Koszulity $\Leftrightarrow$ counit qi $\Leftrightarrow$ unit we $\Leftrightarrow$ twisted tensor products acyclic.
- A₁: bar concentration (Theorem II.1.25): for a Koszul morphism, $H^i(\bar{B}^{\text{ch}}(\mathcal{A})) = 0$ for $i \neq 0$ and $H^0 \cong C$.
- A₂: geometric bar-cobar duality (Theorem II.1.84): for a chiral dual pair, applying Verdier duality to the bar coalgebra of one side and then reading the result on the post-Verdier side produces the dual factorization algebra of the other.

A₀ is the Koszul recognition theorem; A₁ extracts the dual coalgebra; A₂ links two Koszul data via Verdier geometry.

PROPOSITION II.1.13 (*Universal property of bar construction [299];*). For any augmented chiral algebra $\mathcal{A}$, the bar construction $\overline{B}_X(\mathcal{A})$ together with its canonical twisting morphism $\tau_{\text{can}}: \overline{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ is initial among pairs (C, τ) consisting of a conilpotent chiral coalgebra C and a twisting morphism $\tau: C \rightarrow \mathcal{A}$. Concretely: for any twisting morphism $\alpha: C \rightarrow \mathcal{A}$, there exists a unique coalgebra map $f_\alpha: C \rightarrow \overline{B}_X(\mathcal{A})$ such that $\tau_{\text{can}} \circ f_\alpha = \alpha$. Dually, the cobar construction $\Omega_X(C)$ together with $\iota_{\text{can}}: C \rightarrow \Omega_X(C)$ is terminal among pairs (A, ι) consisting of an augmented chiral algebra A and a twisting morphism $\iota: C \rightarrow A$.

Proof. This is the chiral analogue of [299, Theorem 2.2.8 and Proposition 2.2.7]. The universal property of the bar construction is the statement that $\overline{B}_X(\mathcal{A}) = T_{\text{chiral}}^c(s^{-1}\overline{\mathcal{A}})$ is the cofree conilpotent coalgebra on the desuspended augmentation ideal, equipped with the unique coderivation d whose projection to cogenerators recovers the chiral product. Given $\alpha: C \rightarrow \mathcal{A}$, the map f_α is the unique coalgebra map $C \rightarrow T_{\text{chiral}}^c(s^{-1}\overline{\mathcal{A}})$ whose projection to cogenerators is α ; the MC equation on α ensures f_α is a chain map. The cobar statement is dual. $\square$

THEOREM II.1.14 (*Comparison lemma for chiral twisted products [299, Theorem 2.4.1];*). Let $\alpha, \beta: C \rightarrow \mathcal{A}$ be two chiral twisting morphisms from the same conilpotent coalgebra C to the same algebra $\mathcal{A}$, and let $f: C \rightarrow C$ be a coalgebra quasi-isomorphism such that $\alpha = \beta \circ f$. Then the induced map on twisted tensor products

$$\text{id}_{\mathcal{A}} \otimes f: \mathcal{A} \otimes_\alpha C \xrightarrow{\sim} \mathcal{A} \otimes_\beta C$$

is a quasi-isomorphism. In particular, if $\mathcal{A} \otimes_\alpha C$ is acyclic, then so is $\mathcal{A} \otimes_\beta C$.

This is the chiral analogue of [299, Theorem 2.4.1]. The proof transfers directly: filter both sides by bar degree, observe that $\text{gr}(f)$ is an isomorphism (since f is a quasi-isomorphism of coalgebras), and conclude by spectral sequence comparison.

II.1.2 THE CONCEPT OF CHIRAL KOSZUL PAIRS: PRECISE FORMULATION

To handle non-quadratic examples, we extend the notion of Koszul pairs beyond the quadratic setting. The defining property is a set of *recognition criteria* (checkable conditions on the pair) from which the full bar-cobar identification follows as a theorem. No quasi-isomorphism statement is built into the definition itself.

Definition II.1.15 (*Chiral Koszul pair*). A *chiral Koszul pair* on a smooth projective curve X is a pair of chiral Koszul data (Definition II.1.1, Definition II.1.3)

$$(\mathcal{A}_1, C_1, \tau_1, F_\bullet), \quad (\mathcal{A}_2, C_2, \tau_2, F_\bullet)$$

equipped with Verdier-compatible factorization-algebra identifications

$$\mathbb{D}_{\text{Ran}}(C_1) \simeq \Omega_X(C_2), \quad \mathbb{D}_{\text{Ran}}(C_2) \simeq \Omega_X(C_1),$$

compatible with the twisting morphisms and filtrations. In this situation we write $\mathcal{A}_2 \simeq \mathcal{A}_1^\dagger$ and $\mathcal{A}_1 \simeq \mathcal{A}_2^\dagger$.

These are *antecedent hypotheses*: the twisting data (Definition II.1.1), the Koszulness condition (Definition II.1.3), and Verdier compatibility can all be verified without invoking bar-cobar duality itself. Theorem II.1.84 then *proves* the full bar-cobar identification as a consequence.

Standard construction. For the standard examples, the Koszul pair is constructed as follows: $C_i = \bar{B}_X(\mathcal{A}_i)$ with the canonical twisting morphism, $F_\bullet$ is the PBW filtration (Theorem II.1.18), acyclicity follows from spectral sequence degeneration, and the algebra-level Verdier compatibility

$$\mathbb{D}_{\text{Ran}}(C_1) \simeq \Omega_X(C_2)$$

is supplied by Theorem 7.0.36, which is already a statement about the factorization algebra obtained after applying $\mathbb{D}_{\text{Ran}}$ to the bar coalgebra, together with the counit quasi-isomorphism $\Omega_X(C_2) \xrightarrow{\sim} \mathcal{A}_2$ from Theorem II.1.9. The Heisenberg pair $(\mathcal{H}_k, \text{Sym}^{\text{ch}}(V^*))$ is the prototype (§2.5).

In particular, each algebra $\mathcal{A}_i$ in a chiral Koszul pair is a Koszul chiral algebra in the sense of Definition 3.1.6, and hence lies on the Koszul locus $\text{Kosz}(X)$ (Definition 3.1.7).

Example II.1.16 (Heisenberg specialization). For the Heisenberg algebra $\mathcal{H}_k$ at level $k \neq 0$, Definition II.1.15 yields the Koszul pair $(\mathcal{H}_k, \text{Sym}^{\text{ch}}(V^*))$, where $\mathcal{H}_k$ is Lie^{ch} -type (generated by a single bosonic field $a(z)$ with OPE $a(z)a(w) \sim k/(z-w)^2$) and $\text{Sym}^{\text{ch}}(V^*)$ is Com^{ch} -type: the chiral incarnation of classical Lie–Com duality. The explicit bar computation gives the bar coalgebra $\bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*)$. Applying Theorem II.1.84 to this bar coalgebra identifies its Verdier dual factorization algebra with the Koszul dual algebra $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$: the bar complex $\bar{B}(\mathcal{H}_k)$ was computed degree by degree in §2.1–§2.3, producing exactly the commutative Koszul dual (§2.5). Because $\mathcal{H}_k$ is abelian, the PBW spectral sequence (Theorem II.1.18) is trivial and the Koszul complex $K_\tau(\mathcal{H}_k, \text{Sym}^{\text{ch}}(V^*))$ is manifestly acyclic.

Example II.1.17 (Explicit correspondence: bc ghost system and $\beta\gamma$ system). Consider the chiral Koszul pair $(\mathcal{BC}, \mathcal{BG})$ where:

- $\mathcal{BC}$ is the bc ghost system with fermionic fields $b(z), c(z)$ and OPE $b(z)c(w) \sim \frac{1}{z-w}$
- $\mathcal{BG}$ is the $\beta\gamma$ system with bosonic fields $\beta(z), \gamma(z)$ and OPE $\beta(z)\gamma(w) \sim \frac{1}{z-w}$

The bar-cobar isomorphism manifests as:

Algebra to coalgebra:

$$\begin{aligned} bc \text{ OPE: } b(z)c(w) &\sim \frac{1}{z-w} && (\text{fermionic, } \Lambda^* \text{ structure}) \\ \beta\gamma \text{ OPE: } \beta(z)\gamma(w) &\sim \frac{1}{z-w} && (\text{bosonic, } \text{Sym}^* \text{ structure}) \end{aligned}$$

Generators to Relations (Ext–Sym duality).

- $\mathcal{BC}$: two fermionic generators b, c , with $b^2 = c^2 = 0$ (exterior algebra structure)
- $\mathcal{BG}$: two bosonic generators β, γ , with no nilpotency (symmetric algebra structure)

This is the chiral manifestation of classical $\Lambda^* \leftrightarrow \text{Sym}^*$ Koszul duality.

Geometric picture. The bar complex $\bar{B}^{\text{ch}}(\mathcal{BC})$ involves:

$$\bar{B}^{\text{ch}}(\mathcal{BC})_n = \Gamma\left(\bar{C}_n(X), (b \oplus c)^{\boxtimes n} \otimes \Omega_{\log}^*\right)$$

The residues at collision divisors extract the coproduct structure, which cobar reconstructs into the $\beta\gamma$ algebra.

11.1.3 KOSZULNESS VERIFICATION: THE PBW DEFORMATION METHOD

A systematic method reduces chiral Koszulness to classical Koszulness of the PBW-associated graded via a flat deformation argument.

THEOREM 11.1.18 (*PBW criterion for chiral Koszulness*;). [Regime: filtered-complete (Convention 1.10.2).]

Let $\mathcal{A}$ be a chiral algebra with PBW filtration $F_0 \subset F_1 \subset \cdots \subset \mathcal{A}$ such that the associated graded $\mathrm{gr}_F \mathcal{A}$ is a commutative chiral algebra (equivalently, a vertex Poisson algebra). Suppose:

1. The filtration is *flat*: each F_p/F_{p-1} is a free $\mathcal{O}_X$ -module of finite rank in each conformal weight.
2. The associated graded $\mathrm{gr}_F \mathcal{A}$ is classically Koszul: the Koszul complex $\bar{\mathbf{B}}(\mathrm{gr}_F \mathcal{A}) \otimes_{\tau} \mathrm{gr}_F \mathcal{A}$ is acyclic in positive degrees.
3. For each bar degree n and conformal weight h , the chain group $\bar{\mathbf{B}}_h^n(\mathcal{A})$ is finite-dimensional.

Then $\mathcal{A}$ is chiral Koszul: the Koszul complex $\bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} \mathcal{A}$ is acyclic in positive degrees.

Proof. Equip the Koszul complex $K = \bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} \mathcal{A}$ with the filtration induced by F :

$$F_p K^n = \sum_{i+j=n} F_i \bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} F_j \mathcal{A}.$$

This is a bounded-below, exhaustive filtration compatible with the differential (the bar differential and the twisting morphism τ both respect F since they are defined by the OPE, which respects conformal weight). The resulting spectral sequence has:

$$E_0^{p,q} = \mathrm{gr}_F^p K^{p+q}, \quad d_0 = \mathrm{gr}_F(d_K).$$

By flatness 1, the associated graded of K is the Koszul complex of $\mathrm{gr}_F \mathcal{A}$:

$$\mathrm{gr}_F K \cong \bar{\mathbf{B}}(\mathrm{gr}_F \mathcal{A}) \otimes_{\tau} \mathrm{gr}_F \mathcal{A}.$$

(This uses that the bar construction commutes with taking associated graded for flat filtrations: the residue differential of the associated graded sees only the leading-order OPE terms, i.e., the vertex Poisson bracket.)

By hypothesis 2, the E_1 page is concentrated in degree 0:

$$E_1^{p,q} = H^{p+q}(\mathrm{gr}^p K) = \begin{cases} \mathbb{C} & p = q = 0, \\ 0 & p + q > 0. \end{cases}$$

All higher differentials d_r for $r \geq 1$ are therefore zero (they map between zero groups), so the spectral sequence collapses at E_1 .

By completeness of the filtration and the bounded-below hypothesis, the spectral sequence converges: $E_{\infty} = \mathrm{gr} H^*(K)$. Since E_{∞} is concentrated in degree 0, we conclude $H^n(K) = 0$ for $n > 0$. $\square$

Remark 11.1.19 (*Relation to classical Koszulness*). The PBW criterion reduces chiral Koszulness to the classical statement that $\mathrm{gr}_F \mathcal{A}$ is Koszul. For Kac–Moody and Virasoro algebras, $\mathrm{gr}_F \mathcal{A}$ is a polynomial algebra (Koszul by Priddy’s theorem); semisimplicity of $\mathfrak{g}$ is not required.

THEOREM 11.1.20 (*Affine Kac–Moody algebras are chiral Koszul*;). [Regime: curved-central (Convention 1.10.2).]

For any simple Lie algebra $\mathfrak{g}$ and generic level $k \notin \Sigma(\mathfrak{g})$ (the finite exceptional set of Theorem G.6.9), the affine Kac–Moody vertex algebra $\widehat{\mathfrak{g}}_k$ is chiral Koszul.

Proof. We verify the three hypotheses of Theorem II.1.18.

Hypothesis 1. The PBW filtration on $\widehat{\mathfrak{g}}_k$ is defined by $F_p = \text{span}\{J_{-n_1}^{a_1} \cdots J_{-n_r}^{a_r} | 0\rangle : r \leq p\}$. Each graded piece F_p/F_{p-1} is a direct sum of weight spaces of the symmetric algebra $S^p(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}])$, which is a free $\mathbb{C}$ -module of finite rank in each conformal weight.

Hypothesis 2. The associated graded is:

$$\text{gr}_F \widehat{\mathfrak{g}}_k \cong \text{Sym}(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]).$$

This is a polynomial algebra on the generators $\{J_{-n}^a : a = 1, \dots, \dim \mathfrak{g}, n \geq 1\}$. By Priddy's theorem ([299, Theorem 3.4.5]), polynomial algebras are Koszul, with Koszul dual the exterior coalgebra $\Lambda^c(\mathfrak{g}^* \otimes t\mathbb{C}[t])$. Equivalently, the Koszul complex of $\text{Sym}(V)$ is the de Rham complex of the polynomial ring, which is acyclic in positive degrees (Poincaré lemma for formal power series).

Hypothesis 3. The bar chain group $\bar{\mathbf{B}}_h^n(\widehat{\mathfrak{g}}_k)$ is a subspace of $(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}])^{\otimes n} \otimes \Omega^{n-1}(\bar{C}_n)$ with total conformal weight h . Since the number of monomials of weight h in n tensor factors is bounded by $p(h)^n < \infty$, each chain group is finite-dimensional.

All three hypotheses are verified. By Theorem II.1.18, $\widehat{\mathfrak{g}}_k$ is chiral Koszul. $\square$

THEOREM II.1.21 (*Virasoro chiral Koszulness*;). [Regime: curved-central; Convention 1.10.2.]

For any central charge $c \in \mathbb{C}$, the Virasoro vertex algebra Vir_c is chiral Koszul.

Proof. The PBW filtration on Vir_c is defined by the number of Virasoro mode applications:

$$F_p = \text{span}\{L_{-n_1} \cdots L_{-n_r} | 0\rangle : r \leq p, n_i \geq 2\}.$$

Hypothesis 1. Each $F_p/F_{p-1} \cong S^p(V)$ where $V = \bigoplus_{n \geq 2} \mathbb{C} \cdot L_{-n}$ (the Virasoro generators modulo vacuum), which is free of finite rank in each conformal weight.

Hypothesis 2. $\text{gr}_F \text{Vir}_c \cong \text{Sym}(V)$ is a polynomial algebra (the OPE reduces to a commutative product on the associated graded: the non-linear terms $T_{(0)}T = \partial T$, $T_{(1)}T = 2T$ are lower-order in the PBW filtration, and the quartic pole $T_{(3)}T = c/2$ is a scalar that contributes to the curvature, not the associated graded bracket). By Priddy's theorem, $\text{Sym}(V)$ is Koszul.

Hypothesis 3. Same argument as the Kac–Moody case: the number of partitions of weight h into at most n parts (each ≥ 2) is finite.

By Theorem II.1.18, Vir_c is chiral Koszul. $\square$

COROLLARY II.1.22 (*Bar cohomology computes Koszul dual*;). For a chiral Koszul algebra $\mathcal{A}$ satisfying the hypotheses of Theorem II.1.18, the PBW spectral sequence on $\bar{\mathbf{B}}(\mathcal{A})$ collapses at E_2 , and the bar cohomology dimensions equal the dimensions of the Koszul dual:

$$\dim H^n(\bar{\mathbf{B}}(\mathcal{A})) = \dim(\mathcal{A}^\dagger)_n \quad (\text{identifying } (\mathcal{A}^\dagger)_n = H^n(\bar{\mathbf{B}}(\mathcal{A}))^\vee).$$

In particular:

1. For $\widehat{\mathfrak{g}}_k$ at generic level: $\dim H^n(\bar{\mathbf{B}}(\widehat{\mathfrak{g}}_k)) = \dim(\widehat{\mathfrak{g}}_k^\dagger)_n$ (Theorem G.7.1). The Koszul dual $\widehat{\mathfrak{g}}_k^\dagger$ has the same modular characteristic as $\widehat{\mathfrak{g}}_{-k-2h^\vee}$, but the two are distinct algebras: $\widehat{\mathfrak{g}}_k^\dagger$ is the linear dual of the bar coalgebra, not the affine algebra at the dual level.
2. For Vir_c : $\dim H^n(\bar{\mathbf{B}}(\text{Vir}_c)) = \dim(\text{Vir}_c^\dagger)_n$, the n -th graded piece of the Virasoro Koszul dual coalgebra.

Proof. Step 1: The PBW filtration on the bar complex. Equip $\bar{\mathbf{B}}(\mathcal{A})$ with the filtration inherited from the PBW filtration F on $\mathcal{A}$:

$$F_p \bar{\mathbf{B}}^n(\mathcal{A}) = \{a_1 \otimes \cdots \otimes a_{n+1} \otimes \omega \mid a_i \in F_{p_i} \mathcal{A}, \sum p_i \leq p\}$$

where $\omega \in \Omega_{\log}^n(\bar{C}_{n+1}(X))$. This filtration is exhaustive (every bar element lies in some F_p by finiteness of conformal weight) and compatible with the differential (the bar differential respects conformal weight since the OPE does).

Step 2: The associated graded. The filtration F_p is placed on the algebra factor $\mathcal{A}$ in the bar construction $T^c(s^{-1}\bar{\mathcal{A}})$ underlying $\bar{\mathbf{B}}(\mathcal{A})$; the configuration-space form factor $\Omega_{\log}^\bullet(\bar{C}_\bullet(X))$ carries PBW degree 0. Since T^c is graded cofree and Hypothesis 1 makes each $\text{gr}_F^p \mathcal{A}$ a free graded $\mathcal{O}_X$ -module in each conformal weight, tensor-product flatness gives $\text{gr}_F T^c(s^{-1}\bar{\mathcal{A}}) \cong T^c(s^{-1} \text{gr}_F \bar{\mathcal{A}})$. The bar differential decomposes along the filtration because the OPE respects conformal weight, giving $\text{gr}_F d_{\text{bar}} = d_{\text{bar}, \text{gr}_F \mathcal{A}}$. Therefore:

$$\text{gr}_F \bar{\mathbf{B}}(\mathcal{A}) \cong \bar{\mathbf{B}}(\text{gr}_F \mathcal{A}) = \bar{\mathbf{B}}(\text{Sym}^{\text{ch}}(V)) \quad (\text{II.1})$$

where V is the generating $\mathcal{D}_X$ -module. This identification holds because the bar differential on the associated graded sees only the leading-order OPE terms. For $\widehat{\mathfrak{g}}_k$: the singular OPE $J^a(z)J^b(w) \sim f_c^{ab} J^c(w)/(z-w) + k\kappa^{ab}/(z-w)^2$ reduces on gr_F to the commutative product (the bracket $f_c^{ab} J^c$ and level term $k\kappa^{ab}$ are lower-order in the PBW filtration). For Vir_c : similarly, the Virasoro OPE reduces to a commutative product on the associated graded.

Step 3: Computation of the E_1 page. The E_0 page is $E_0^{p,q} = \text{gr}_F^p \bar{\mathbf{B}}^{p+q}(\mathcal{A})$, with d_0 the associated-graded bar differential. By (II.1), the E_1 page is the bar cohomology of the commutative chiral algebra $\text{Sym}^{\text{ch}}(V)$.

Since $\text{Sym}^{\text{ch}}(V)$ is a free commutative algebra, it is Koszul with Koszul dual the exterior coalgebra $\Lambda^c(V^*)$ (Priddy's theorem applied to the chiral setting, cf. Remark II.1.19). Therefore:

$$E_1^{p,q} = H^{p+q}(\bar{\mathbf{B}}^p(\text{Sym}^{\text{ch}}(V))) = \begin{cases} \Lambda^p(V^*) & \text{if } q = 0, \\ 0 & \text{if } q \neq 0. \end{cases}$$

The E_1 page is concentrated in the row $q = 0$. In particular, for $\widehat{\mathfrak{g}}_k$ with $V = \mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$:

$$E_1^{n,0} = \Lambda^n(\mathfrak{g}^* \otimes t\mathbb{C}[t])$$

is the n -th exterior power of the dual loop algebra generators (graded by conformal weight).

Step 4: E_2 collapse. Since $E_1^{p,q} = 0$ for $q \neq 0$, the higher differentials $d_r : E_r^{p,q} \rightarrow E_r^{p+r, q-r+1}$ vanish for $r \geq 2$: the target has second index $q - r + 1 \leq 0 - 2 + 1 = -1 < 0$, placing it in the zero region. The differential $d_1 : E_1^{p,0} \rightarrow E_1^{p+1,0}$ maps *within* the nonzero row $q = 0$ and is generally nonzero: it is the Chevalley–Eilenberg differential of the loop algebra $\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$ acting on $\Lambda^*(\mathfrak{g}^* \otimes t\mathbb{C}[t])$ by bracket contraction (the leading PBW correction to the commutative bar differential). Therefore $E_\infty = E_2$ and:

$$H^n(\bar{\mathbf{B}}(\mathcal{A})) \cong E_\infty^{n,0} = E_2^{n,0} = H_{\text{CE}}^n(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}], \mathbb{C}) = (\mathcal{A}^!)_n.$$

For commutative chiral algebras (e.g. the Heisenberg algebra), the Lie bracket of $\mathfrak{g}$ vanishes, $d_1 = 0$, $E_\infty = E_2 = E_1 = \Lambda(V^*)$, and the bar cohomology reduces to the exterior algebra. For non-abelian algebras (Kac–Moody, Virasoro), $d_1 \neq 0$ and the bar cohomology is computed by the CE cohomology, a proper subquotient of $\Lambda(V^*)$.

Step 5: Verification for $\widehat{\mathfrak{sl}}_2$. $V = \mathbb{C}^3 \otimes t^{-1}\mathbb{C}[t^{-1}]$ (three generators J^+, J^0, J^- , each with modes J_{-n}^a for $n \geq 1$). The E_1 page has $\dim E_{1h}^{n,0} = \dim \Lambda^n(\mathbb{C}^3 \otimes t\mathbb{C}[t])_h$. For example: $\dim E_{11}^{1,0} = 3$ (the three weight-1 generators), $\dim E_{12}^{2,0} = \binom{3}{2} = 3$ (wedge products $J_{+1}^{a*} \wedge J_{+1}^{b*}$, $a < b$). The d_1 differential is the CE differential of $\mathfrak{sl}_2 \otimes t^{-1}\mathbb{C}[t^{-1}]$; the resulting E_2 page gives: $\dim H^1 = 3$ (all at weight $h = 1$; $d_1 = 0$ at this weight since there are no weight-1 chains in degree 0), and $\dim H^2 = 5$ (concentrated at weight $h = 3$: chain groups $\dim \Lambda_3^1 = 3, \dim \Lambda_3^2 = 9, \dim \Lambda_3^3 = 1$; differential ranks 3 and 1; cohomology $(9-1)-3 = 5$). The computation is verified by checking $d_1^2 = 0$ at each weight (Computation K.7.1). $\square$

Remark II.1.23 (CE cohomology vs exterior algebra dimensions). Bar cohomology of a non-abelian chiral Koszul algebra is the CE cohomology of $\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$, not the exterior algebra $\Lambda^n(V^*)$. For $\widehat{\mathfrak{sl}}_2$: E_1 totals $= \prod_{m \geq 1} (1 + q^m)^3$, but $E_\infty = E_2 \neq E_1$ because the d_1 differential is nonzero for non-abelian $\mathfrak{g}$. In particular, $\dim H^2 = 5$ (not $R(5) = 6$; Appendix K.7.1).

Remark II.1.24 (Chevalley–Eilenberg cohomology vs chiral bar cohomology). The Chevalley–Eilenberg cohomology of the negative-mode Lie algebra $\mathfrak{g}_{<0} = \mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$ and the chiral bar cohomology $H^*(\bar{\mathbf{B}}(\mathcal{A}))$ give *different* Betti sequences, though both compute from the same underlying OPE data. For the Witt algebra $\text{Witt} = \text{Der}(\mathbb{C}((t)))$, the negative-mode Lie algebra is the Lie algebra of polynomial vector fields vanishing to order ≥ 2 at the origin, and its CE cohomology has $\dim H_{\text{CE}}^1(\text{Witt}_{<0}) = 3$ (the three independent cocycles $L_{-1}^*, L_{-2}^*, L_{-3}^*$ on $\text{span}\{L_{-1}, L_{-2}, L_{-3}\}$). The chiral bar cohomology of the Virasoro algebra has $\dim H^1(\bar{\mathbf{B}}(\text{Vir})) = 1$ (a single generator T of conformal weight 2). The discrepancy $3 - 1 = 2$ quantifies the Orlik–Solomon form contribution: the chiral bar differential uses the full logarithmic residue $d \log(z_1 - z_2)$ (the Arnold relation on configuration space), which collapses the three CE cocycles to the single chiral primary.

THEOREM II.1.25 (Bar concentration for Koszul pairs;). [Regime: quadratic on the Koszul locus (Convention I.10.2).]

Let $(\mathcal{A}_1, \mathcal{A}_2)$ be a chiral Koszul pair (Definition II.1.15). Then the augmented bar complex $\bar{B}^{\text{ch}}(\mathcal{A}_1)$, equipped with its bigrading by bar degree p and bar-differential cohomological degree q , satisfies:

$$H^{p,q}(\bar{B}^{\text{ch}}(\mathcal{A}_1)) = 0 \quad \text{for } q \neq 0, \quad H^{p,0}(\bar{B}^{\text{ch}}(\mathcal{A}_1)) \cong (\mathcal{A}_2^!)_p.$$

Equivalently, $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_2^!$ in the derived category of graded chiral coalgebras, where $\mathcal{A}_2^!$ carries its internal grading concentrated in bar-differential degree 0. In particular, the natural map $\bar{B}^{\text{ch}}(\mathcal{A}_1) \rightarrow \mathcal{A}_2^!$ is a quasi-isomorphism of graded chiral coalgebras.

Proof. Filter $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ by bar degree. By the PBW criterion (Theorem II.1.18), the associated graded is the classical Koszul complex of $\text{gr}_F \mathcal{A}_1$, which is acyclic in positive degrees by hypothesis. Corollary II.1.22 then gives $\dim H^n = \dim(\mathcal{A}_2^!)_n$. It remains to show that $H^0(\bar{B}^{\text{ch}}(\mathcal{A}_1)) \cong \mathcal{A}_2^!$ as coalgebras, not merely as graded vector spaces. The twisting morphism $\tau: \bar{B}^{\text{ch}}(\mathcal{A}_1) \rightarrow \mathcal{A}_2$ satisfies the Maurer–Cartan equation $\partial(\tau) + \tau \star \tau = 0$ in the chiral convolution algebra $\text{Hom}(\bar{B}^{\text{ch}}(\mathcal{A}_1), \mathcal{A}_2)$ (Definition II.1.3), so the twisted tensor products $K_\tau^L(\mathcal{A}_1, C_1)$ and $K_\tau^R(C_1, \mathcal{A}_1)$ are well-defined chain complexes (twisted differentials square to zero by the MC equation). These are acyclic by hypothesis. Now τ induces a coalgebra map $\tau_*: H^0(\bar{B}^{\text{ch}}(\mathcal{A}_1)) \rightarrow \mathcal{A}_2^!$ that preserves comultiplication: the bar comultiplication $\Delta_{\bar{B}}$ on H^0 is intertwined with the Koszul dual coalgebra structure on $\mathcal{A}_2^!$ via the convolution product defining τ . Acyclicity of K_τ^L and K_τ^R upgrades this map from a graded comparison to a coalgebra isomorphism (the chiral analogue of [299, Theorem 2.3.1]; the identical argument applies because acyclicity of the Koszul complexes is the only input beyond the MC equation, and both hold in the chiral setting by Lemma 7.0.12 and Theorem II.1.9). $\square$

II.1.4 INTRINSIC CHARACTERIZATIONS OF CHIRAL KOSZULNESS

The MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ lives in a modular convolution algebra bigraded by degree and genus. Chiral Koszulness is a *genus-0 formality property*: it says the genus-0 component $\Theta_{\mathcal{A}}^{(0)}$ is determined by its binary part; equivalently, all genus-0 obstruction classes $o_{r+1}^{(0)}(\mathcal{A}) = 0$ vanish for $r \geq 2$. The shadow obstruction tower probes all genera; Koszulness constrains only genus 0. Twelve characterizations of chiral Koszulness (nine proved unconditionally equivalent, one one-way chiral Hochschild consequence on the Koszul locus, one conditional on perfectness/nondegeneracy (K11, the Lagrangian criterion), and one one-directional (D-module purity, forward direction established)), each reading $\Theta_{\mathcal{A}}^{(0)}$ through a different invariant of the convolution algebra.

Remark II.1.26 (One-loop exactness). The PBW spectral sequence (Corollary II.1.22) admits a sharp physics interpretation. The E_0 page is the tree-level bar complex $\bar{\mathbf{B}}(\text{Sym}^{\text{ch}}(V))$, with cohomology $\Lambda^c(V^*)$ by Priddy's theorem. The d_1 differential is the Chevalley–Eilenberg differential extracted from the simple-pole OPE $a_{(0)}b$: a single operator collision. Collapse $E_2 = E_{\infty}$ means that no multi-particle collisions (the higher poles $a_{(n)}b, n \geq 2$, generating d_r for $r \geq 2$) contribute additional cohomology. Chiral Koszulness is therefore *one-loop exactness*: the Lie-algebraic data from the single-pole OPE determines the bar cohomology completely.

PROPOSITION II.1.27 (Formality implies chiral Koszulness;). Let $\mathcal{A}$ be a chiral algebra on a smooth curve X , and let $(m_2, m_3, m_4, \dots)$ denote the transferred A_{∞} -structure on $\mathcal{A}^! = H^*(\bar{\mathbf{B}}_X(\mathcal{A}))^{\vee}$ obtained via a deformation retract

$$\bar{\mathbf{B}}_X(\mathcal{A}) \xrightleftharpoons[p]{i} H^*(\bar{\mathbf{B}}_X(\mathcal{A})) \quad \text{with contracting homotopy } h$$

and the homological perturbation lemma (Kadeishvili [437]; cf. [440]).

If the minimal A_{∞} -structure is *formal* ($m_n = 0$ for all $n \geq 3$), then $\mathcal{A}$ is chirally Koszul.

Proof. Formality of the A_{∞} -structure means the bar complex $\bar{\mathbf{B}}_X(\mathcal{A})$ is formal as a dg coalgebra: the natural map to its cohomology $H^*(\bar{\mathbf{B}}_X(\mathcal{A}))$ is a quasi-isomorphism of A_{∞} -coalgebras. The higher products m_n ($n \geq 3$) are identified with the PBW spectral sequence differentials d_{n-1} via the standard comparison (cf. [440, Theorem 3.4.1]): $m_n = 0$ for $n \geq 3$ is equivalent to $E_2 = E_{\infty}$, which is the PBW collapse criterion of Theorem II.1.18. $\square$

THEOREM II.1.28 (Converse: chiral Koszulness implies formality;). The converse of Proposition II.1.27 holds: $\mathcal{A}$ is chirally Koszul if and only if $m_n = 0$ for all $n \geq 3$.

Proof. Forward: Proposition II.1.27. Converse: if $m_n = 0$ for $n \geq 3$, the minimal A_{∞} -model of $\bar{\mathbf{B}}_X(\mathcal{A})$ is a strict dg algebra with product m_2 . The chiral A_{∞} structure on $H^*(\bar{\mathbf{B}}_X(\mathcal{A}))$ is computed fiberwise on each FM stratum (Proposition I3.22.107). On each fiber, the HPL transfer is an ordinary A_{∞} transfer over a field, to which Keller's classicality theorem applies. The PBW filtration is defined fiberwise and compatible with the FM stratification, so fiberwise E_2 -collapse assembles to global E_2 -collapse: all transferred differentials $d_r = 0$ for $r \geq 2$ because $m_n = 0$. Hence Koszulness. $\square$

Remark II.1.29 (A_{∞} products as genus-0 shadows). The sequence $(m_3, m_4, \dots)$ is the genus-0 analogue of the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq 3}, \Theta_{\mathcal{A}}^{\leq 4}, \dots$ of Theorem I3.21.69: the m_n measure nonlinearity of the bar differential at genus 0, while the shadows $\Theta_{\mathcal{A}}^{\leq r}$ measure it at all genera.

Example II.1.30 (Truncated polynomials: the homotopy Koszul dual off the Koszul locus). Consider $A = k[x]/(x^n)$ for $n \geq 3$ (non-Koszul; the Koszul case $n = 2$ gives the exterior algebra). The bigraded bar cohomology $H^{p,q}(\bar{B}(A))$ has generators

$$a \in H^{1,1}, \quad b \in H^{2,n},$$

and H is *not* concentrated on the diagonal $p = q$, the signature of non-Koszulness (Theorem II.1.28).

The transferred A_∞ -structure on $H^*(\bar{B}(A))^\vee$ carries exactly one nontrivial higher operation:

$$m_2 = \cdots = m_{n-2} = 0 \quad \text{on } a, \quad m_{n-1}(\underbrace{a, \dots, a}_{n-1}) = b.$$

This is the Massey product detecting the off-diagonal class; it is the first and only nontrivial higher operation (Lu–Palmieri–Wu–Zhang [440]). The homotopy Koszul dual $A_\infty^! = (H^*(\bar{B}(A))^\vee, m_2, m_{n-1})$ is a genuine A_∞ -algebra whose non-formality is measured by the single operation m_{n-1} . For $n = 2$ (exterior algebra), $m_{n-1} = m_1 = 0$ on H , recovering formality and hence Koszulness.

The chiral analogue: for a chiral algebra $\mathcal{A}$ whose bar cohomology has off-diagonal bigraded classes, the homotopy Koszul dual $\mathcal{A}_\infty^!$ carries genuine higher chiral operations measuring non-formality. The shadow obstruction tower (Remark II.1.29) is the all-genera lift of this phenomenon.

THEOREM II.1.31 (*Ext diagonal vanishing criterion*;). Define the *chiral Ext algebra* $\text{Ext}_{\mathcal{A}}^{*,*}(\omega_X, \omega_X) = \bigoplus_{p,q} \text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X)$, bigraded by cohomological degree p and conformal weight q . Then $\mathcal{A}$ is chirally Koszul if and only if $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.

Classical precedent. On the formal disk $\hat{D}$, this reduces to the Beilinson–Ginzburg–Soergel criterion for Zhu($\mathcal{A}$) [41]. On $\mathbb{P}^1$, diagonal vanishing follows from PBW since $H^1(\mathbb{P}^1, \mathcal{O}) = 0$. At genus $g \geq 1$, the Hodge-theoretic contributions from $H^0(X, \omega_X)$ produce the exceptional set $\Sigma(\mathfrak{g})$ of Theorem G.6.9 where diagonal vanishing may fail.

Proof. Forward: E_2 -collapse concentrates $H^*(\bar{B}(\mathcal{A}))$ on the diagonal $p = q$; since the bar resolution computes Ext , $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$. Converse: diagonal concentration forces all PBW differentials d_r ($r \geq 2$) to vanish, since a d_r -differential shifts the bigrading by $(r, 1 - r)$, producing off-diagonal classes that contradict $\text{Ext}_{\mathcal{A}}^{p,q} = 0$ for $p \neq q$. Hence E_2 -collapse, hence Koszulness. $\square$

PROPOSITION II.1.32 (*PBW universality*;). A vertex algebra $\mathcal{A}$ is *freely strongly generated* if it admits strong generators $\{a^i\}_{i \in I}$ whose normally ordered monomials $:\partial^{n_1} a^{i_1} \cdots \partial^{n_r} a^{i_r}:$ form a PBW basis; equivalently, $\text{gr}_F \mathcal{A} \cong \text{Sym}^{\text{ch}}(V)$ where V is the $\mathcal{D}_X$ -module spanned by the generators.

Every freely strongly generated vertex algebra is chirally Koszul.

Proof. The three hypotheses of Theorem II.1.18 hold: (1) flatness of $F_p/F_{p-1} \cong S^p(V)$ by the PBW basis; (2) classical Koszulness of $\text{gr}_F \mathcal{A} \cong \text{Sym}^{\text{ch}}(V)$ by Priddy’s theorem; (3) finite-dimensionality of bar chain groups in each bigrading by the partition bound of Theorem II.1.20. $\square$

COROLLARY II.1.33 (*Universal vertex algebras are chirally Koszul*;). The following are chirally Koszul:

1. $V_k(\mathfrak{g})$ at all levels k (including $k = -h^\vee$), since its vacuum module is Verma with no null vectors.
2. Vir_c as the universal vertex algebra at all c , since the vacuum Verma module is freely strongly generated.

3. $\mathcal{W}^k(\mathfrak{g})$ obtained by Drinfeld–Sokolov reduction, by the Feigin–Frenkel theorem (the Miura images freely generate).

The universal vs. simple distinction. The universal algebra $V_k(\mathfrak{g})$ is always chirally Koszul. The simple quotient $L_k(\mathfrak{g}) = V_k(\mathfrak{g})/I_k$ may fail Koszulness at levels where the singular vector lies in the bar-relevant range; the precise criterion is Theorem II.1.35.

Proof. Proposition II.1.32 applies to every freely strongly generated vertex algebra. The universal affine algebra $V_k(\mathfrak{g})$ and the universal Virasoro algebra are freely strongly generated by their current, respectively stress-tensor, fields, so items (1) and (2) follow immediately. For $\mathcal{W}^k(\mathfrak{g})$, the Feigin–Frenkel Miura theorem supplies a free strong generating set by the Miura images, so the same proposition applies. The final paragraph is the earlier universal-versus-simple warning specialized to these families. $\square$

Remark II.1.34 (Critical level: PBW degeneration vs diagonal Ext concentration). At the critical level $k = -h^\vee$, the PBW spectral sequence degenerates at E_2 (the E_2 -collapse mechanism is k -independent, since $\mathrm{gr}_F V_k(\mathfrak{g}) \cong \mathrm{Sym}^{\mathrm{ch}}(\mathfrak{g})$ for all k). However, the E_2 page is *not* diagonally concentrated: the bar cohomology $H^*(\overline{B}(V_{-h^\vee}(\mathfrak{g}))) = \Omega^*(\mathrm{Op}_{\mathfrak{g}^\vee}(D))$ (Theorem .2) has $H^0 = \mathrm{Fun}(\mathrm{Op}) \neq \mathbb{C}$, contributing off-diagonal classes $\mathrm{Ext}^{0,q} \neq 0$ for all even $q \geq 0$. Hence the diagonal criterion of Theorem II.1.18 ($\mathrm{Ext}^{p,q} = 0$ for $p \neq q$) *fails* at $k = -h^\vee$.

At generic level ($\kappa \neq 0$), the curvature of the bar differential forces $H^0(\overline{B}) = \mathbb{C}$ and concentrates bar cohomology on the diagonal. The critical level is the unique point where curvature vanishes, PBW degeneration persists, but diagonal concentration is lost.

Accordingly, the parenthetical “including $k = -h^\vee$ ” in item (1) of Corollary II.1.33 should be understood as: PBW degeneration holds at all k ; the full Koszulness (diagonal Ext concentration) holds at generic k but fails at $k = -h^\vee$. Theorem H (Theorem 14.4.12) requires the diagonal criterion, so it does not apply at critical level. See Remark 17.2.4 for the Beilinson–Drinfeld comparison that replaces Theorem H at critical level.

THEOREM II.1.35 (Kac–Shapovalov criterion for simple quotients;). Let $\mathcal{A}$ be a conformal vertex algebra with Shapovalov form on the vacuum module. The *bar-relevant range* is the set of conformal weights h with $\overline{B}_h^n(\mathcal{A}) \neq 0$ for some $n > 0$. Then $\mathcal{A}$ is chirally Koszul if and only if the Kac–Shapovalov determinant $\det G_h \neq 0$ for all h in the bar-relevant range.

For universal algebras this holds unconditionally (Corollary II.1.33). The genuine content is for simple quotients: $L_k(\mathfrak{g})$ has null vectors at $h = h_{\mathrm{sing}}(k)$ by the Kac–Kazhdan theorem; at admissible levels $k + h^\vee = p/q$, $(p, q) = 1$, these lie in the bar-relevant range and Koszulness may fail. For the Virasoro algebra, the Kac determinant $\det G_h = \prod_{r,s \leq h} (h - h_{r,s}(c))^{p(h-rs)}$ is nonvanishing in the bar-relevant range for the universal algebra, but $L(c_{p,q}, 0)$ may fail at minimal-model values.

Proof. Forward: Koszulness gives E_2 -collapse, hence the PBW filtration on the vacuum module is strict: $\mathrm{gr}_F M_0(\mathcal{A}) \cong \mathrm{Sym}^{\mathrm{ch}}(V)$. Strictness implies the Shapovalov form G_h is non-degenerate in the bar-relevant range (a degenerate G_h would give a null vector in the PBW-associated graded, contradicting strictness).

Converse: $\det G_h \neq 0$ in the bar-relevant range means the PBW-to-bar comparison map $\mathrm{Sym}^{\mathrm{ch}}(V)_h \rightarrow \overline{B}_h(\mathcal{A})$ is injective at every bar-relevant weight. Injectivity forces E_2 -collapse: a nonzero differential d_r with $r \geq 2$ would kill an element that pairs nontrivially with the Shapovalov form (since the element is nonzero in gr_F and G_h is non-degenerate), contradicting the d_r -exactness. $\square$

Remark II.1.36 (Rationality is not, by itself, a Koszul criterion). Rationality, C_2 -cofiniteness, and semisimplicity of the Zhu algebra are strong *finiteness* inputs, but they do not by themselves imply chiral Koszulness in the sense used here. The obstruction is categorical: the ordinary positive-energy module category $V\text{-gmod}$ controls Zhu theory and conformal blocks, whereas Ext groups in the chiral/factorization module setting are computed via the bar complex (Corollary 8.2.22). The manuscript does not identify these two Ext theories for general rational vertex algebras.

Consequently, the implication

$$\text{ordinary semisimplicity} \implies H^{>0}(\bar{\mathbf{B}}(V)) = 0$$

is *not* established here. For simple quotients at admissible level the Kac–Shapovalov route is visibly obstructed by null vectors in the bar-relevant range (Theorem II.1.35), while the rationality route stops at finiteness of the ordinary representation theory.

Remark II.1.37 (Status of admissible simple quotients). For the universal algebra $V_k(\mathfrak{g})$, free strong generation gives chiral Koszulness at every level (Corollary II.1.33). For the simple quotient $L_k(\mathfrak{g})$, null vectors enter the bar-relevant range at admissible levels, so the PBW/Shapovalov criterion no longer applies directly.

What *is* proved for non-degenerate admissible levels is:

- (i) rationality and semisimplicity of the ordinary module category (Theorem G.II.18(ii));
- (ii) finite-page bar and Li–bar spectral sequences in the ordinary-character calculations: the worked $\widehat{\mathfrak{sl}}_2$, $k = -1/2$ bar derivation of the vacuum Kac–Wakimoto character (Theorem G.II.24), together with weightwise finite-page control and the external general-rank Kac–Wakimoto formulas on the broader non-degenerate admissible lane (Proposition G.II.19 and Theorem G.II.26).

These results are compatible with chiral Koszulness, but they do not yet prove bar-cobar inversion or Ext-diagonal purity for the simple quotient in general.

For $\mathfrak{g} = \mathfrak{sl}_2$, admissible Koszulness is settled: the simple quotient $L_k(\mathfrak{sl}_2)$ is chirally Koszul at *every* admissible level $k = -2 + p/q$ ($p \geq 2$, $q \geq 1$, $\gcd(p, q) = 1$). The argument is structural: the null-vector ideal I_k is generated in a single conformal weight, the bar complex of L_k is the quotient bar complex $\bar{B}(V_k)/\bar{B}(I_k)$, and the quotient bar spectral sequence degenerates at E_2 by the Kac–Wakimoto character formula.

For $\mathfrak{g} = \mathfrak{sl}_3$ at denominator $q \geq 3$, admissible Koszulness *fails*. The bar spectral sequence has $E_1^{2,q} = \dim(\mathfrak{g}) = 8$ off-diagonal classes at Tor-weight q . The Poisson differential d_1 acts as a derivation via the Lie bracket and kills all 6 root-generator classes (corresponding to $E_1, E_2, E_3, F_1, F_2, F_3$), but the 2 Cartan classes (corresponding to H_1, H_2) survive to E_∞ : the Cartan subalgebra $\mathfrak{h} \subset \mathfrak{sl}_3$ is abelian, so $d_1(x_{H_i}) = 0$, and the target of all higher differentials d_r ($r \geq 2$) vanishes for degree reasons. Hence $\dim E_\infty^{2,q} = \text{rk}(\mathfrak{g}) = 2 > 0$, and $H^2(\bar{B}(L_k(\mathfrak{sl}_3))) \neq 0$. At denominator $q \leq 2$, the off-diagonal classes lie on the E_1 diagonal where $d_1 = 0$, and no obstruction appears; Koszulness at $q \leq 2$ remains compatible with the evidence.

The mechanism is uniform: for any simple $\mathfrak{g}$ of $\text{rk}(\mathfrak{g}) \geq 2$, the abelian Cartan subalgebra $\mathfrak{h}$ produces $\text{rk}(\mathfrak{g})$ classes in $E_1^{2,q}$ that are annihilated by the Lie-bracket derivation d_1 (since $[\mathfrak{h}, \mathfrak{h}] = 0$) and persist to E_∞ . This yields:

Conjecture II.1.38 (Admissible Koszulness failure at higher rank). For any simple Lie algebra $\mathfrak{g}$ with $\text{rk}(\mathfrak{g}) \geq 2$, the simple quotient $L_k(\mathfrak{g})$ at admissible level with denominator $q \geq 3$ is *not* chirally Koszul, with $\dim H^2(\bar{B}(L_k(\mathfrak{g}))) \geq \text{rk}(\mathfrak{g})$.

Remark 11.1.39 ($W(2)$ at $c = -2$: Koszulness status). The $W(2)$ algebra at $c = -2$ (the triplet algebra at $p = 2$, $\mathbb{Z}/2$ -orbifold of the symplectic fermion algebra SF) has Koszulness status *open*. PBW universality (Proposition 11.1.32) does not apply directly: $W(2)$ is *not* freely strongly generated, since the vacuum module carries a singular vector at conformal weight 5 (Adamović–Milas; Feigin–Gainutdinov–Semikhatov–Tipunin), which lies in the bar-relevant range ($h = 5 \geq 2h_{\min} = 4$). The “null vector at weight 15” reported in earlier analyses is a Virasoro Kac determinant zero, not a $W(2)$ null vector; but the weight-5 singular vector is genuine and obstructs the PBW route.

A potential alternative route uses the Kazhdan filtration: $W(2)$ embeds into the lattice VOA $V_{2\mathbb{Z}}$ as the momentum-zero sector. If the Kazhdan-filtered associated graded of $W(2)$ (not of $V_{2\mathbb{Z}}$) is polynomial, then Koszulness would follow. This requires verifying that the weight-5 singular vector is absorbed by the Kazhdan filtration, which is not established.

Remark 11.1.40 (*Arithmetic shadows: Koszulness as harmonic metric*). The Kac–Shapovalov non-degeneracy criterion is the analytic shadow of a deeper structure: by Theorem S.12.16 (Chapter S), Koszulness of $\mathcal{A}$ is equivalent to the nondegeneracy of the Shapovalov form on the shadow triple $(\Theta_{\mathcal{A}}, M_{\mathcal{A}}, h_{\mathcal{A}})$: the propagator $P = h^{-1}$ mediates between the flat side (MC element) and the Higgs side (spectral curve).

Remark 11.1.41 (*Deformation quantization compatibility*). Let $\mathcal{A}_{\hbar}$ be a flat deformation of a classically Koszul commutative chiral algebra $\mathcal{A}_0$, with $\mathcal{A}_{\hbar}/\hbar\mathcal{A}_{\hbar} \cong \mathcal{A}_0$. Proposition 11.1.32 implies: $\mathcal{A}_{\hbar}$ is chirally Koszul whenever the PBW filtration deforms flatly ($\mathrm{gr}_F \mathcal{A}_{\hbar} \cong \mathcal{A}_0$). All standard families satisfy this: for $V_k(\mathfrak{g})$ with $\hbar = k^{-1}$, the bracket $[J^a, J^b]_{\star} = f_c^{ab} J^c + k\kappa^{ab}$ lies in $F_{\geq 1}$; Virasoro and $\mathcal{W}$ -algebras are analogous with $\hbar = c^{-1}$. Flat PBW deformation is therefore the mechanism producing chirally Koszul algebras from commutative seeds.

11.1.5 THE LI-BAR SPECTRAL SEQUENCE AND GEOMETRIC KOSZULNESS

The Kac–Shapovalov criterion (Theorem 11.1.35) detects Koszulness by non-degeneracy of a bilinear form weight by weight. We now give a geometric refinement: the Li filtration on $\mathcal{A}$ induces a spectral sequence on the bar complex whose E_1 page is the bar complex of a *commutative Poisson algebra*, and Koszulness is controlled by the geometry of the associated variety $X_{\mathcal{A}}$.

Construction 11.1.42 (*Li-bar spectral sequence*). Let V be a vertex algebra with Li filtration $F_p V$ (Definition 15.2.33). The bar complex $\bar{\mathbf{B}}(V) = \bigoplus_n \bar{\mathbf{B}}^n(V)$ inherits a multiplicative filtration

$$F_p \bar{\mathbf{B}}^n(V) = \sum_{p_1 + \dots + p_n = p} F_{p_1} V \otimes \dots \otimes F_{p_n} V \cap \bar{\mathbf{B}}^n(V).$$

The Li filtration is multiplicative with respect to chiral operations: $a_{(m)} b \in F_{p+q}$ when $a \in F_p$, $b \in F_q$, and $m \leq -2$ (the defining condition of F_p), while $a_{(-1)} b \in F_{p+q}$ (product) and $a_{(0)} b \in F_{p+q-1}$ (Poisson bracket lowers filtration by 1). The bar differential $d_{\bar{\mathbf{B}}}$, assembled from the chiral operations μ_n , respects the filtration: $d_{\bar{\mathbf{B}}}(F_p \bar{\mathbf{B}}^n) \subset F_{p-1} \bar{\mathbf{B}}^{n-1}$. This gives rise to a convergent spectral sequence

$$E_1^{p,q} = H^{p+q}(\mathrm{gr}_p^F \bar{\mathbf{B}}(V)) \implies H^{p+q}(\bar{\mathbf{B}}(V)). \quad (11.2)$$

The E_0 page is the bar complex of the associated graded $R_V := \mathrm{gr}^F V$, which is a commutative vertex algebra with Poisson bracket $\{-, -\}$ induced by the 0-product (Definition 15.2.33). The E_0 differential is the bar differential of R_V as a commutative algebra; the d_1 differential arises from the Poisson bracket.

PROPOSITION II.I.43 (*Poisson differential on the Li-bar E_1 page;*). The d_1 differential on the Li-bar spectral sequence (II.2) is determined by the Poisson bracket on $R_V = \text{gr}^F V$:

$$d_1 : E_1^{p,q} \rightarrow E_1^{p-1,q}, \quad d_1 = \sum_{i < j} \{-, -\}_{ij} \circ \text{contract}_{ij}$$

where $\{-, -\}_{ij}$ applies the Poisson bracket to the i -th and j -th tensor factors. In particular:

- (i) When $R_V \cong \text{Sym}(V_0)$ is a polynomial algebra with trivial Poisson bracket, $d_1 = 0$. Any further degeneration beyond E_1 requires separate control of the higher filtration-lowering pieces of the vertex-algebra differential.
- (ii) When $R_V = \mathcal{O}(Y)$ for an affine Poisson variety (Y, π) , the E_1 page is the ordinary commutative bar cohomology $H_{\text{bar}}^*(\mathcal{O}(Y))$, and d_1 is the differential induced there by π . Equivalently, the E_2 page is the homology of this commutative bar-cohomology page with respect to that bracket-induced differential.

Proof. The d_1 differential is the component of $d_{\bar{B}}$ that lowers the Li filtration by exactly 1. In the OPE $a_{(n)}b$ on a vertex algebra, the filtration behavior is: $a_{(-1)}b$ preserves the filtration (giving the commutative product in gr^F), $a_{(0)}b$ lowers it by 1 (giving the Poisson bracket), and $a_{(n)}b$ with $n \geq 1$ lowers it by $n \geq 1$, contributing to d_r with $r \geq 2$.

Thus d_1 on $\text{gr}^F \bar{\mathbf{B}}(V)$ is exactly the component from the 0-th product, which on the associated graded is the Poisson bracket $\{\bar{a}, \bar{b}\} = \overline{a_{(0)}b}$.

For (i): if $\{-, -\} = 0$, then $d_1 = 0$. This removes only the first Poisson correction on the E_1 page; higher filtration-lowering OPE terms can still contribute to later differentials d_r with $r \geq 2$. For the universal VOA $V_k(\mathfrak{g})$, $\text{gr}^F V_k(\mathfrak{g}) \cong \text{Sym}(\mathfrak{g}[t^{-1}]t^{-1})$ with Poisson bracket from the Lie bracket of $\mathfrak{g}$; here d_1 is the Chevalley–Eilenberg differential, which is nonzero but has concentrated cohomology by Whitehead vanishing (for semisimple $\mathfrak{g}$).

For (ii): when $R_V = \mathcal{O}(Y)$ with Y Poisson, the E_0 page is the ordinary commutative bar complex of $\mathcal{O}(Y)$, and the filtration-1 component of the bar differential induces on $E_1 = H_{\text{bar}}^*(\mathcal{O}(Y))$ the differential coming from the Poisson bracket π . This is bar-side Poisson data on the Li-bar spectral sequence, not ordinary Lichnerowicz–Poisson cohomology. $\square$

THEOREM II.I.44 (*Associated-variety criterion for Koszulness;*). Let V be a vertex algebra with Li filtration $F_p V$, associated graded $R_V = \text{gr}^F V$, and associated variety $X_V = \text{Specm}(R_V/\sqrt{0})$. Consider the Li-bar spectral sequence (II.2).

- (i) *Sufficiency from diagonal concentration of the Li-bar E_2 page.* If the Li-bar E_2 page of R_V is concentrated on the diagonal ($H^{p,q}(E_1, d_1) = 0$ for $p \neq q$), then the Li-bar spectral sequence degenerates at E_2 and V is chirally Koszul.
- (ii) *Orbit criterion.* Suppose $R_V \cong \mathcal{O}(\bar{\mathbf{O}})$ for a nilpotent orbit closure $\bar{\mathbf{O}} \subset \mathfrak{g}^*$, equipped with the Kirillov–Kostant Poisson structure. Then the Li-bar E_1 page is the commutative bar cohomology of $\mathcal{O}(\bar{\mathbf{O}})$, and its d_1 differential is induced by that Poisson bracket. In particular, diagonal concentration of the resulting reduced Li-bar $E_2 = H(E_1, d_1)$ page is a sufficient condition for V to be chirally Koszul.

Proof. For (i): diagonal concentration of the E_2 page $H^{p,q}(E_1, d_1)$ forces all higher differentials $d_r: E_r^{p,q} \rightarrow E_r^{p-r, q+r-1}$ to vanish for degree reasons: sources and targets lie on different diagonals. Hence $E_2 = E_\infty$, and the bar cohomology $H^*(\bar{\mathbf{B}}(V))$ inherits diagonal concentration. By Theorem 11.1.18, this is Koszulness.

For (ii): if $R_V \cong O(\bar{\mathbf{O}})$ as Poisson algebras, then Construction 11.1.42 identifies the E_0 page with the commutative bar complex of $O(\bar{\mathbf{O}})$, so the E_1 page is its ordinary commutative bar cohomology. Then Proposition 11.1.43 identifies the induced d_1 differential on that E_1 page with the operator coming from the Kirillov–Kostant Poisson bracket on the reduced Poisson algebra. Thus the Li–bar E_2 page is exactly the homology of that reduced bar-cohomology page under the induced d_1 . Diagonal concentration of this reduced Li–bar E_2 page implies chiral Koszulness by (i). $\square$

Remark 11.1.45 (What this theorem does not identify). Theorem 11.1.44 is a theorem about the Li–bar spectral sequence and its d_1 complex on the commutative bar construction of R_V . It does *not* identify that E_2 page with ordinary Lichnerowicz–Poisson cohomology, nor with $H^*(\bar{\mathbf{O}}, O_{\bar{\mathbf{O}}})$ for a symplectic resolution $\bar{\mathbf{O}} \rightarrow \bar{\mathbf{O}}$. Any such comparison would require extra geometric input and is not part of the proved surface here.

COROLLARY 11.1.46 (*Minimal-orbit levels under reducedness and reduced Li–bar concentration;*). Let $\mathfrak{g}$ be a simple Lie algebra and k an admissible level with $X_{L_k(\mathfrak{g})} = \bar{\mathbf{O}}_{\min}$ (the closure of the minimal nilpotent orbit). Assume in addition that the Li associated graded is reduced:

$$R_{L_k(\mathfrak{g})} = \text{gr}^F L_k(\mathfrak{g}) \cong O(\bar{\mathbf{O}}_{\min})$$

as Poisson algebras, and assume that the resulting reduced Li–bar E_2 page is diagonally concentrated. Then $L_k(\mathfrak{g})$ is chirally Koszul.

Proof. This is exactly the orbit-reduction criterion of Theorem 11.1.44(ii) applied to the reduced Poisson algebra $O(\bar{\mathbf{O}}_{\min})$. $\square$

PROPOSITION 11.1.47 (*Nilradical obstruction at degenerate admissible levels;*). Let k be a degenerate admissible level for $\widehat{\mathfrak{g}}$ with $X_{L_k(\mathfrak{g})} = \bar{\mathbf{O}} \neq \{0\}$. The associated graded $R_{L_k} = \text{gr}^F L_k$ is a Poisson algebra whose reduced quotient gives $O(\bar{\mathbf{O}})$. The Koszulness obstruction at degenerate levels comes from two sources:

- (i) *Reduced Li–bar surface.* The reduced quotient $O(\bar{\mathbf{O}}) = R_{L_k}^{\text{red}}$ controls only the reduced Li–bar E_2 page furnished by Theorem 11.1.44(ii). Any diagonal-concentration statement established on that reduced surface is therefore evidence only for the reduced quotient, not for the full non-reduced algebra R_{L_k} .
- (ii) *Nilradical obstruction.* The nilradical $\mathcal{I} = \sqrt{0} \subset R_{L_k}$ carries additional bar-cohomological data not visible on the associated variety X_{L_k} . When $\mathcal{I} \neq 0$, the quotient $R_{L_k} \twoheadrightarrow O(\bar{\mathbf{O}})$ forgets tensors in the bar complex with at least one nilpotent factor. These extra summands can support differentials and off-diagonal classes invisible on the reduced quotient, so reduced associated-variety data alone do not determine chiral Koszulness of $L_k(\mathfrak{g})$.

Proof. For (i): this is exactly the distinction in Theorem 11.1.44(ii) between the reduced Poisson algebra $O(\bar{\mathbf{O}})$ and the full non-reduced Li graded R_{L_k} .

For (ii): the quotient map $R_{L_k} \twoheadrightarrow \mathcal{O}(\overline{\mathbf{O}})$ induces a surjection of commutative bar complexes, and its kernel contains bar tensors with at least one factor in $\mathcal{I}$. These nilpotent summands are absent from the reduced quotient, so the reduced Li–bar E_2 page cannot by itself determine the full bar-cohomological behavior of R_{L_k} . $\square$

Remark II.1.48 (The orbit hierarchy of Koszulness). Theorem II.1.44 organizes the Koszulness question for simple quotients into a hierarchy indexed by nilpotent orbits, but only after the full Li associated graded R_{L_k} has been identified. The associated variety $X_{L_k} = (\mathrm{Specm} R_{L_k})_{\mathrm{red}}$ records only the reduced geometry, so nilradical contributions remain a separate obstruction. For $\mathfrak{g} = \mathfrak{sl}_N$, the orbits are indexed by partitions $\lambda \vdash N$:

Orbit	Partition	Reduced Li–bar surface	Koszulness
$\{0\}$	(1^N)	finite-dim. reduced quotient	nilradical-dependent
$\mathbf{O}_{\min}$	$(2, 1^{N-2})$	reduced Li–bar concentration assumed	conditional on reducedness and reduced Li–bar concentration
$\mathbf{O}_{\mathrm{subreg}}$	$(N-1, 1)$	reduced Li–bar concentration open	nilradical-dependent
$\mathcal{N}$	(N)	reduced Li–bar concentration open	nilradical-dependent

The reduced orbit geometry can still provide useful input, but the present theorem does not identify the reduced Li–bar E_2 page with ordinary Poisson cohomology or with $H^*(\overline{\mathbf{O}}, \mathcal{O}_{\overline{\mathbf{O}}})$ for a symplectic resolution. What it does show is that any reduced-level diagonal-concentration statement constrains only the reduced Li–bar page and leaves nilradical contributions as a separate obstruction.

A conjectural type-*A* orbit-duality principle (Conjecture 15.2.36) would exchange the associated varieties of L_k and $L_{k'}$: $\overline{\mathbf{O}} \leftrightarrow \overline{d_{\mathrm{BV}}(\mathbf{O})}$. If that principle holds, it imposes a *compatibility constraint*: the Li–bar obstructions for L_k and $L_{k'}$ should be Barbasch–Vogan dual.

Remark II.1.49 (Comparison with the Kac–Shapovalov criterion). Theorem II.1.44 refines Theorem II.1.35 as follows. The Shapovalov form G_h detects null vectors weight by weight. The Li filtration organizes these null vectors *geometrically*: a null vector at weight h in the vacuum module corresponds to a relation in $R_V = \mathrm{gr}^F V$ at Li filtration level p , and the Poisson bracket determines whether this relation propagates to the bar complex via d_1 . The Shapovalov criterion asks: are there null vectors in the bar-relevant range? The Li–bar criterion asks: does the *geometry* of the associated variety X_V force those null vectors to produce off-diagonal bar cohomology?

The gain is maximal when $X_V \neq \{0\}$ and one can separately establish diagonal concentration on the reduced Li–bar page, possibly guided by geometric input from a symplectic resolution. Minimal-orbit levels are the first test case where the reduced geometry suggests concentration, but an unconditional Koszul theorem still requires the extra reducedness and reduced Li–bar concentration hypotheses recorded in Corollary II.1.46.

THEOREM II.1.50 (Equivalences and consequences of chiral Koszulness;). Let $\mathcal{A}$ be a chiral algebra on a smooth projective curve X with PBW filtration $F_\bullet$. Conditions (i)–(vi), (ix)–(x), and the genus-0 clause of condition (vii) below are equivalent. On the uniform-weight lane, condition (vii) strengthens to the all-genera concentration statement recorded there and remains equivalent to them. Condition (viii) is a proved one-way consequence of them on the Koszul locus: it yields chiral Hochschild duality, polynomial Hilbert series, and E_2 -formality, but it does not force the underlying graded-commutative algebra to be free. Under

the additional perfectness and non-degeneracy hypotheses on the ambient tangent complex, condition (xi) is also equivalent to them. Condition (xii) implies condition (x) (Remark 11.1.62); the converse is open.

Unconditional equivalences:

- (i) $\mathcal{A}$ is chirally Koszul (Definition 11.1.3).
- (ii) The PBW spectral sequence on $\bar{\mathbf{B}}(\mathcal{A})$ collapses at E_2 (Theorem 11.1.18).
- (iii) The minimal A_∞ -model of $\bar{\mathbf{B}}(\mathcal{A})$ is formal: $m_n = 0$ for $n \geq 3$ (Proposition 11.1.27 and Theorem 11.1.28).
- (iv) Ext diagonal vanishing: $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.
- (v) The bar-cobar counit $\Omega(\bar{\mathbf{B}}(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism (Theorem 8.6.1).
- (vi) The Barr–Beck–Lurie comparison for the bar-cobar adjunction is an equivalence on the fiber over $\bar{\mathbf{B}}(\mathcal{A})$.
- (vii) Genus-0 factorization homology concentration, with uniform-weight all-genera refinement: $H^k(\int_{\mathbb{P}^1} \mathcal{A}) = 0$ for $k \neq 0$. If $\mathcal{A}$ lies on the uniform-weight lane, then for every smooth projective curve Σ_g of genus $g \geq 0$ one also has $H^k(\int_{\Sigma_g} \mathcal{A}) = 0$ for $k \neq 0$, and for $g \geq 1$ the surviving scalar obstruction class is

$$\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g \quad (\text{UNIFORM-WEIGHT})$$

(UNIFORM-WEIGHT; Theorem 13.13.16).

- (ix) The Kac–Shapovalov determinant $\det G_h \neq 0$ in the bar-relevant range (Theorem 11.1.35).
- (x) The restriction $i_S^! \bar{\mathbf{B}}_n(\mathcal{A})$ to every FM boundary stratum S is acyclic outside degree 0.

One-way chiral Hochschild consequence on the Koszul locus:

- (viii) $\text{ChirHoch}^*(\mathcal{A})$ is concentrated in cohomological degrees $\{0, 1, 2\}$ and satisfies the duality

$$CH^n(\mathcal{A}) \cong CH^{2-n}(\mathcal{A}^!)^\vee \otimes \omega_X$$

with Hochschild–Hilbert series

$$P_{\mathcal{A}}(t) = \dim Z(\mathcal{A}) + \dim CH^1(\mathcal{A}) \cdot t + \dim Z(\mathcal{A}^!) \cdot t^2,$$

and $CH^*(\mathcal{A})$ is formal as an E_2 -algebra: all higher braces and Massey products are cohomologically trivial, but the underlying graded-commutative cup-product algebra need not be free (Theorem H, Theorem 14.4.10, Theorem 14.4.12, Proposition 14.4.18).

Conditional and partial:

- (xi) The Lagrangian criterion: $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ are transverse Lagrangians in the (-1) -shifted symplectic deformation space $\mathcal{M}_{\text{comp}}$.

- (xii) $\mathcal{D}$ -module purity: each $\bar{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module, with characteristic variety aligned to FM boundary strata.

Proof. THE CORE CIRCUIT (i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (iii) $\Leftrightarrow$ (v):

(i) $\Leftrightarrow$ (ii): Koszulness (Definition 11.1.3) is acyclicity of $\bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} \mathcal{A}$ in positive degrees. Theorem 11.1.18 identifies this with E_2 -collapse; the converse is immediate.

(ii) $\Rightarrow$ (v): E_2 -collapse gives bar concentration (Theorem 11.1.25), which is the input for bar-cobar inversion (Theorem 8.6.1).

(v) $\Rightarrow$ (i): Condition (v) is the statement that the canonical counit

$$\varepsilon_{\tau_{\text{univ}}} : \Omega_X(\bar{B}_X(\mathcal{A})) \longrightarrow \mathcal{A}$$

of the universal twisting morphism $\tau_{\text{univ}} : \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ (Corollary 11.1.10) is a quasi-isomorphism. The fundamental theorem of chiral twisting morphisms (Theorem 11.1.9) identifies this directly with τ_{univ} being a chiral Koszul morphism. With the PBW filtration fixed in the statement of the theorem, that is exactly condition (i).

CHIRAL HOCHSCHILD CONSEQUENCE (v) $\Rightarrow$ (viii):

The quasi-isomorphism $\Omega(\bar{\mathbf{B}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ identifies the bar-cobar resolution with the chiral Hochschild complex. On the Koszul locus, Theorem H, Theorem 14.4.10, Theorem 14.4.12, and Proposition 14.4.18 give the stated cohomological concentration, duality, polynomial Hilbert series, and E_2 -formality. The proof of Proposition 14.4.18 uses the formality of the local configuration spaces $\text{FM}_n(\mathbb{C})$, so the higher braces and Massey products on $CH^*(\mathcal{A})$ are cohomologically trivial. This is the full proved content of (viii) at the theorem level: no freeness statement for the underlying graded-commutative cup-product algebra is claimed here. No converse from (viii) to the bar-cobar counit is proved here.

A_{∞} FORMALITY (i) $\Leftrightarrow$ (iii):

(ii) $\Rightarrow$ (iii): E_2 -collapse means all PBW differentials $d_r = 0$ for $r \geq 2$. The A_{∞} products m_n are identified with d_{n-1} under the HPL transfer, so $m_n = 0$ for $n \geq 3$ (Proposition 11.1.27).

(iii) $\Rightarrow$ (ii): If $m_n = 0$ for $n \geq 3$, the minimal A_{∞} -model is strictly associative: $H^*(\bar{\mathbf{B}}(\mathcal{A}))$ is a dg algebra with m_2 as the product and all higher operations trivial. The bar spectral sequence of this formal A_{∞} -algebra collapses at E_2 by the classicality theorem for formal A_{∞} -algebras (Keller). The chiral A_{∞} structure is computed fiberwise on each FM stratum (Proposition 13.22.107); on each fiber the HPL transfer is an ordinary A_{∞} transfer over a field, to which Keller's theorem applies directly. The PBW filtration is defined fiberwise and compatible with the FM stratification, so fiberwise E_2 -collapse assembles to global E_2 -collapse: all transferred differentials $d_r = 0$ for $r \geq 2$. Hence the spectral sequence on $\bar{\mathbf{B}}(\mathcal{A})$ also collapses at E_2 .

FACTORIZATION HOMOLOGY CONCENTRATION (i) $\Leftrightarrow$ (vii) (the equivalence concerns the genus-0 clause; the uniform-weight all-genera statement is a proved refinement. Cf. Remark 11.1.51):

(i) $\Rightarrow$ (vii): The bar complex is factorization homology (Proposition 8.8.4): $\bar{B}_n(\mathcal{A}) = (\int_X \mathcal{A})_n$. At $g = 0$, E_2 -collapse gives $H^k(\int_{\mathbb{P}^1} \mathcal{A}) = 0$ for $k \neq 0$: the Goodwillie filtration of $\int_{\mathbb{P}^1} \mathcal{A}$ has associated graded given by $\bar{B}_n$ contributions, each concentrated in degree 0 by PBW collapse. If $\mathcal{A}$ lies on the uniform-weight lane, the same identification holds for every genus. The loop-order spectral sequence of the higher-genus bar complex collapses on the modular Koszul locus (Theorem 13.14.15), so after the vertexwise genus-0 PBW

collapse every loop-order stratum remains cohomologically concentrated in degree 0. Theorem 13.13.16 then identifies the surviving scalar obstruction class by

$$\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g \quad (g \geq 1)$$

(UNIFORM-WEIGHT). Because no mixed-weight channels exist on that lane, the cross-channel correction $\delta F_g^{\text{cross}}$ is absent, so no positive-degree cohomology reappears. Hence $H^k(\int_{\Sigma_g} \mathcal{A}) = 0$ for $k \neq 0$ for all $g \geq 0$ on the uniform-weight lane.

(vii) $\Rightarrow$ (i): Suppose $H^k(\int_{\mathbb{P}^1} \mathcal{A}) = 0$ for $k \neq 0$ at $g = 0$ (this genus-0 clause is the only input needed for the converse). The factorization homology $\int_{\mathbb{P}^1} \mathcal{A}$ is computed by the bar complex: $\int_{\mathbb{P}^1} \mathcal{A} \simeq |\bar{\mathbf{B}}(\mathcal{A})|$, the geometric realization. Concentration in degree 0 means the bar spectral sequence computing $H^*(\int_{\mathbb{P}^1} \mathcal{A})$ collapses, which by Theorem 11.1.18 is Koszulness.

Remark 11.1.51 (Research remark: all-genera form of condition (vii)). Condition (vii) has a genus-0 equivalence and a higher-genus scalar refinement. The unconditional statement is

$$H^k(\int_{\mathbb{P}^1} \mathcal{A}) = 0 \quad (k \neq 0),$$

and this genus-0 clause is the only input used in the converse (vii) $\Rightarrow$ (i).

On the uniform-weight lane the higher-genus refinement is proved. Proposition 8.8.4 supplies the bar model for factorization homology on every smooth curve Σ_g . On the Koszul locus, the genus-0 PBW collapse forces each vertex contribution to be concentrated in degree 0, and Theorem 13.14.15 prevents the loop-order spectral sequence from reintroducing positive-degree cohomology. Definition 13.21.41 leaves only one channel, so mixed-channel boundary graphs do not occur. The surviving scalar class is then identified by Theorem 13.13.16:

$$\text{obs}_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g \quad (\text{UNIFORM-WEIGHT}).$$

Hence

$$H^k(\int_{\Sigma_g} \mathcal{A}) = 0 \quad (k \neq 0)$$

for every $g \geq 0$ on the uniform-weight lane. This is the all-genera form of condition (vii).

The scalar identity in that argument has an independent proof path. Remark 13.21.48 applies Grothendieck–Riemann–Roch to the family bar complex over the universal curve and recovers the same class $\kappa(\mathcal{A})\lambda_g$ without using the shadow tower, the Maurer–Cartan element, or Theorem 13.13.16. This does not replace the bar/factorization-homology concentration argument above, but it does give a second proof of the scalar part of the all-genera uniform-weight statement.

For multi-weight algebras, the honest higher-genus replacement of the second sentence of condition (vii) is not another concentration equivalence. The correct all-genera reformulation passes to the scalar projection of the genus- g obstruction package: one replaces higher-genus concentration by the diagonal-plus-cross-channel identity

$$F_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g^{\text{FP}} + \delta F_g^{\text{cross}}(\mathcal{A}) \quad (\text{ALL-WEIGHT, with cross-channel correction } \delta F_g^{\text{cross}})$$

for $g \geq 1$, with $\delta F_1^{\text{cross}} = 0$ universally and $\delta F_g^{\text{cross}} = 0$ on the uniform-weight lane (Theorem 13.22.225). In this form, condition (vii) survives at all genera as a statement about the scalar trace rather than about full cohomological concentration. The uniform-weight hypothesis therefore cannot be removed in general: the interacting algebra $\mathcal{W}_3$ leaves the scalar locus already at $g = 2$, while Proposition 13.22.226 identifies the free-field exception where the correction vanishes genus by genus.

Geometrically, $\delta F_g^{\text{cross}}$ is the scalar trace of mixed-channel boundary residues. The edges still carry the universal weight-1 propagator $d \log E(z, w)$; the correction comes from the vertices, where OPE residues couple distinct conformal-weight sectors on stable-graph boundary strata. Construction 13.22.229 makes this precise: $\delta F_g^{\text{cross}}$ is the sum over stable graphs whose edge-labelling $\sigma: E(\Gamma) \rightarrow \{1, \dots, r\}$ uses at least two weights. At genus 1 the unique boundary graph has one edge, hence no mixed assignment and no correction. At genus $g \geq 2$, multi-edge strata admit genuine mixed assignments, and their integrated OPE residues produce $\delta F_g^{\text{cross}}$. In this precise sense, the cross-channel term is the higher-genus shadow of mixed-weight OPE residues.

Remark 11.1.52 (The strongest proved chiral Hochschild consequence). The strengthened form of (viii) stops at duality, polynomial Hilbert series, and E_2 -formality. It does not imply that the underlying graded-commutative algebra $CH^*(\mathcal{A})$ is free. At generic central charge, Theorem 17.2.1 gives

$$CH^*(\text{Vir}_c) \cong \mathbb{C} \oplus \mathbb{C}[-2].$$

The degree-2 class squares to zero because $CH^4(\text{Vir}_c) = 0$, whereas a free graded-commutative algebra on a degree-2 generator would have nonzero degree 4. Thus vanishing of higher braces and Massey products is the strongest proved consequence; ordinary cup-product relations may remain.

FM BOUNDARY ACYCLICITY (i) $\Leftrightarrow$ (x):

(i) $\Rightarrow$ (x): Each FM boundary stratum $S_T \cong \prod_{v \in V(T)} \overline{\text{Conf}}_{|v|}(X_v)$ is indexed by a tree T . The residue component $d_{\text{res}}|_{S_T}$ of the bar differential restricts to the tensor product of lower-degree bar complexes. E_2 -collapse at each vertex degree (Theorem 11.1.18) gives acyclicity: $H^k(i_{S_T}^! \overline{B}_n(\mathcal{A})) = 0$ for $k \neq 0$.

(x) $\Rightarrow$ (i): At the deepest stratum $S = D_{\{1,2\}} \cong X \times \overline{\text{Conf}}_{n-1}(X)$ (binary collision), the restriction $i_S^! \overline{B}_n(\mathcal{A})$ computes the bar-complex contribution from the OPE $a_{(k)}b$ at a single collision point. Acyclicity of $i_S^!$ at all strata forces the residues at every collision to be exact, which is the PBW condition: $d_1(e_i) = 0$ on the associated graded, hence E_2 -collapse.

BARR-BECK-LURIE MONADICITY (i) $\Leftrightarrow$ (vi):

The Barr-Beck-Lurie theorem ([303, Theorem 4.7.3.5]) states that the comparison functor Φ is an equivalence if and only if $\overline{B}_\kappa$ is conservative and preserves totalizations of $\overline{B}_\kappa$ -split cosimplicial objects. Conservativity: $\overline{B}_\kappa$ detects quasi-isomorphisms on the Koszul locus by bar-cobar inversion (v). Totalization preservation: on the Koszul locus, the bar-cobar adjunction is a Quillen equivalence (Theorem 8.2.14). The derived adjunction on the underlying ∞ -categories satisfies the BBL conditions because the Quillen-equivalence comparison functor is an equivalence restricted to the Koszul locus; this is a formal consequence of Quillen equivalences satisfying monadic descent ([303, Proposition 4.7.3.16]). Therefore Φ is an equivalence if and only if (v) holds, i.e., if and only if $\mathcal{A}$ is chirally Koszul.

(vi) $\Rightarrow$ (i): If the BBL comparison functor Φ is an equivalence, then $\overline{B}_\kappa$ is conservative (detecting quasi-isomorphisms). Conservativity of the bar functor forces bar-cobar inversion, which is (v), which is (i).

KAC-SHAPOVALOV DETERMINANT (i) $\Leftrightarrow$ (ix):

(i) $\Rightarrow$ (ix): If $\mathcal{A}$ is chirally Koszul, the PBW filtration on the vacuum module is strict: $\text{gr}_F M_0(\mathcal{A}) \cong \text{Sym}^{\text{ch}}(V)$. Strictness implies the Shapovalov form G_h is non-degenerate in the bar-relevant range.

(ix) $\Rightarrow$ (i): Non-degeneracy $\det G_h \neq 0$ in the bar-relevant range means the PBW-to-bar comparison map $\iota: \text{Sym}^{\text{ch}}(V)_h \rightarrow \overline{B}_h(\mathcal{A})$ is injective at every bar-relevant weight h . Suppose $d_r \neq 0$ for some $r \geq 2$. Then there exists $x \in E_r^{p,q}$ with $d_r(x) \neq 0$, represented by $\tilde{x} \in F^p \overline{B}$ with $d_{\text{bar}}(\tilde{x}) \in F^{p+r} \overline{B}$. If $\tilde{x} \in \text{im}(\iota)$, it represents a nonzero class in $\text{gr}^p(\overline{B}) \cong \text{Sym}^p(V)$, and $d_r(\tilde{x})$ represents a nonzero class in gr^{p+r} . By

PBW strictness (injectivity of ι at all bar-relevant weights), this contradicts the acyclicity of $\text{Sym}(V)$ as a Koszul complex. Hence $d_r = 0$, giving (ii) and hence (i).

EXT DIAGONAL VANISHING (i) $\Leftrightarrow$ (iv):

(i) $\Rightarrow$ (iv): E_2 -collapse places $H^*(\bar{\mathbf{B}}(\mathcal{A}))$ on the diagonal $p = q$; the bar resolution computes Ext , so $\text{Ext}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.

(iv) $\Rightarrow$ (i): Diagonal Ext-vanishing means $\bar{\mathbf{B}}(\mathcal{A})$ has cohomology concentrated on the line $p = q$ in the bigrading. The PBW spectral sequence has $E_1^{p,q} = H^{p+q}(\text{gr}_F^p \bar{\mathbf{B}})$ converging to $H^{p+q}(\bar{\mathbf{B}})$; diagonal concentration of the abutment forces all differentials d_r ($r \geq 2$) to vanish (a d_r -differential moves off-diagonal by $(r, 1-r)$, which would produce off-diagonal classes contradicting (iv)). The PBW spectral sequence converges conditionally in the sense of Boardman: the filtration is Hausdorff and complete (the PBW filtration on a positively graded algebra is bounded below). In characteristic zero with a split filtration (the PBW filtration splits by conformal weight), the extension problem is trivial: $E_\infty = E_2$ as bigraded objects, not merely as filtered objects. Hence E_2 -collapse, hence (i).

LAGRANGIAN CRITERION (i) $\Leftrightarrow$ (xi) (*unconditional for the standard landscape by Proposition 8.6.4; conditional on perfectness in general*):

(i) $\Rightarrow$ (xi): On the Koszul locus, the bar-cobar adjunction provides a free resolution, and the complementarity splitting $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^\dagger) \simeq H^*(\bar{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$ (Theorem C) identifies $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^\dagger}$ as complementary subspaces of $\mathcal{M}_{\text{comp}}$. The shifted-symplectic structure (Theorem 13.19.5) makes these subspaces isotropic; the complementarity splitting gives maximal dimension, hence Lagrangian.

(xi) $\Rightarrow$ (i): If $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^\dagger}$ are transverse Lagrangians, their derived intersection $\mathcal{M}_{\mathcal{A}} \times_{\mathcal{M}_{\text{comp}}}^h \mathcal{M}_{\mathcal{A}^\dagger}$ is discrete (transverse Lagrangian intersection in a (-1) -shifted symplectic space has expected dimension 0). This derived intersection computes the twisted tensor product $K_\tau(\mathcal{A}, \mathcal{A}^\dagger)$; its acyclicity (i.e., discreteness of the intersection) is Koszulness (Definition 11.1.3). $\square$

Remark 11.1.53 (Proofweb redundancy). The proof of Theorem 11.1.50 is not a single chain. Its unconditional core already has several proof lanes that do not route through the same intermediate condition:

- (i) $\Longleftrightarrow$ (v) (universal twisting morphism and bar filtration), (i) $\Longleftrightarrow$ (iii) (A_∞ transfer and Keller classicality),
 (i) $\Longleftrightarrow$ (iv) (Ext diagonal vanishing), (i) $\Longleftrightarrow$ (vii) (the genus-0 clause of factorization homology concentration),
 (i) $\Longleftrightarrow$ (ix) (Kac–Shapovalov non-degeneracy), (i) $\Longleftrightarrow$ (x) (FM boundary acyclicity),

and on the monadic side

$$(i) \Longleftrightarrow (vi) \quad (\text{Barr–Beck–Lurie monadicity}).$$

Three direct cross-links are the load-bearing redundancy.

(v) $\Rightarrow$ (i) is the shortest loop. For the universal twisting morphism $\tau_{\text{univ}}: \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$, condition (v) is the quasi-isomorphism of the counit $\varepsilon_{\tau_{\text{univ}}}$, and Theorem 11.1.9 identifies that directly with τ_{univ} being a chiral Koszul morphism. This uses the universal bar twisting datum and the bar filtration, not the route through (ii) or (iii).

(i) $\Rightarrow$ (viii) is also direct. Theorem 14.4.10, Theorem 14.4.12, and Proposition 14.4.18 start from a chiral Koszul datum and compute $CH^*(\mathcal{A})$ by the bar-cobar Hochschild resolution. This yields duality, polynomial Hilbert growth, and E_2 -formality without routing through (ii)–(vii) inside the meta-theorem.

(iii) $\Rightarrow$ (x) is fiberwise and geometric. For a boundary stratum S_T , the restriction $i_{S_T}^! \overline{B}_n(\mathcal{A})$ decomposes as the tensor product of the vertexwise collision complexes, and Remark 6.1.36 identifies those iterated residues with the transferred A_∞ operations. If $m_k = 0$ for $k \geq 3$, only the strict binary residue survives at each vertex. Fiberwise Keller classicality, exactly as in Theorem 11.1.28, then gives degree-zero concentration for every vertex factor, so the Künneth spectral sequence yields

$$H^k(i_{S_T}^! \overline{B}_n(\mathcal{A})) = 0 \quad (k \neq 0).$$

This reaches (x) without passing through the shadow tower.

The same bookkeeping gives further direct arrows already implicit in the proof:

$$(ii) \Rightarrow (vii), \quad (vii) \Rightarrow (ii), \quad (iv) \Rightarrow (ii), \quad (ix) \Rightarrow (ii), \quad (v) \Longleftrightarrow (vi).$$

Hence the unconditional core

$$\{(i), (ii), (iii), (iv), (v), (vi), (vii), (ix), (x)\}$$

forms a web rather than a chain.

Here (viii) is a satellite consequence, not part of the equivalence core. Within this proof-web discussion, the node (vii) always means its genus-0 clause. The uniform-weight all-genera statement recorded in Theorem 11.1.50(vii) is a proved strengthening, not an extra unconditional equivalence. Let G_{core} be the undirected graph obtained from the displayed core subweb by forgetting arrow directions and deleting the satellite node (viii). Every displayed core edge lies on one of the cycles

$$\begin{aligned} &((i), (ii), (v)), \quad ((i), (ii), (iv)), \quad ((i), (ii), (vii)), \\ &((i), (iii), (x)), \quad ((i), (v), (vi)), \quad ((i), (ii), (ix), (x)). \end{aligned}$$

Therefore G_{core} has no bridges. Equivalently, deleting any one displayed implication still leaves the unconditional core connected: the proof web has no single point of failure.

Remark 11.1.54 (Status of the Lagrangian and purity refinements). Condition (xi) remains conditional on perfectness and non-degeneracy of the ambient tangent complex. Condition (xii) implies condition (x) (via Saito's theory of mixed Hodge modules; see Remark 11.1.62). The converse direction (Koszulness implies D-module purity) is reduced to a single gap (Remark 11.1.62). The converse of (xii) is proved for the affine Kac–Moody lineage (Proposition 11.1.63); the non-affine case (Virasoro, $\mathcal{W}$ -algebras) remains open. Beyond these twelve conditions, Sklyanin–Poisson rigidity (Theorem 11.1.72) provides a Poisson-geometric proof of Koszulness restricted to the affine Kac–Moody subclass.

PROPOSITION 11.1.55 (*Closure of chiral Koszulness under tensor, dualization, and base change*;). The class of chirally Koszul algebras is closed under the three fundamental operations:

- (a) *Chiral tensor product*. If $\mathcal{A}, \mathcal{B}$ are chirally Koszul on the curve X , then $\mathcal{A} \boxtimes \mathcal{B}$ is chirally Koszul, and $(\mathcal{A} \boxtimes \mathcal{B})^! \simeq \mathcal{A}^! \boxtimes \mathcal{B}^!$ as Koszul duals.
- (b) *Koszul dualization* (involutivity). If $\mathcal{A}$ is chirally Koszul, then so is $\mathcal{A}^!$, and $(\mathcal{A}^!)^! \simeq \mathcal{A}$ canonically.
- (c) *Smooth base change*. If $f: Y \rightarrow X$ is a smooth morphism of curves and $\mathcal{A}$ is chirally Koszul on X , then $f^*\mathcal{A}$ is chirally Koszul on Y , and $(f^*\mathcal{A})^! \simeq f^*(\mathcal{A}^!)$.

Proof. (a): Tensor product closure is Proposition 11.10.5, which constructs the quadratic-tensor witnessing datum and verifies strong convergence under $\boxtimes$. The duality identification $(\mathcal{A} \boxtimes \mathcal{B})^! \simeq \mathcal{A}^! \boxtimes \mathcal{B}^!$ follows from the Künneth formula on the bar complex $\overline{B}(\mathcal{A} \boxtimes \mathcal{B}) \simeq \overline{B}(\mathcal{A}) \boxtimes \overline{B}(\mathcal{B})$, combined with the fact that linear duality commutes with tensor product over a field.

(b): Involutivity is a consequence of Theorem 11.1.9 (the bar-cobar adjunction is a Quillen equivalence on the Koszul locus) and the biduality of holonomic D-modules under Verdier duality. Concretely, the bar complex of $\mathcal{A}^!$ is the cobar complex of $\mathcal{A}$ (by construction of $\mathcal{A}^!$), and the cobar of bar is canonically quasi-isomorphic to $\mathcal{A}$ on the Koszul locus (Theorem 8.6.1). Hence $(\mathcal{A}^!)^! = \text{cobar}(\overline{B}(\mathcal{A}^!)) = \text{cobar}(\Omega(\overline{B}(\mathcal{A}))) \simeq \mathcal{A}$. This is the chiral analog of the standard fact $(A^!)^! \simeq A$ for quadratic algebras (Loday–Vallette [299], Theorem 3.4.6), with the additional Beilinson–Drinfeld holonomicity input ensuring chain-level convergence on a smooth projective curve.

(c): Smooth base change uses Lemma 8.6.19 to verify that f^* preserves quasi-isomorphisms of chiral algebras, combined with Theorem 8.6.21 to verify that f^* commutes with bar-cobar. The witnessing datum for chiral Koszulness pulls back along f , and the E_2 -collapse of the PBW spectral sequence is preserved under flat pullback (since smooth morphisms are flat). The duality identification $(f^*\mathcal{A})^! \simeq f^*(\mathcal{A}^!)$ follows from the compatibility of f^* with linear duality on coherent sheaves. $\square$

Remark 11.1.56 (*Closure does not extend to bare quotients*). The closure properties of Proposition 11.1.55 do *not* extend to general quotients $\mathcal{A}/\mathcal{I}$ by chiral ideals: the quotient of a chirally Koszul algebra by a non-Koszul ideal is generically non-Koszul. The W-algebra construction $\mathcal{W}^k(\mathfrak{g}, f)$ via Drinfeld–Sokolov reduction is the principal example where the quotient *does* preserve Koszulness, and this is a substantive theorem of the chapter (Theorem G.8.2), not a corollary of closure.

Remark 11.1.57 (*A_∞ formality and Gaiotto–Kulp–Wu*). The A_∞ formality characterization (item (iii) of Theorem 11.1.50) is the bar-complex statement of the formality theorem of Gaiotto–Kulp–Wu [193]: the transferred operations $m_k = 0$ for $k \geq 3$ on bar cohomology if and only if $\mathcal{A}$ is chirally Koszul. The shadow depth classification $\mathbf{G}/\mathbf{L}/\mathbf{C}/\mathbf{M}$ (Remark 13.22.131) refines their binary formal/non-formal dichotomy into a four-class stratification governed by the discriminant $\Delta = 8\kappa S_4$.

Remark 11.1.58 (*Loop-exactness ordering $G < L < C < M$*). The four shadow-depth classes are ordered by the number of loop corrections needed to determine the full A_∞ structure on $\mathcal{A}_{\text{line}}^!$:

- Class G (Gaussian, $r_{\max} = 2$): tree-level exact.
- Class L (Lie/tree, $r_{\max} = 3$): one-loop exact (DNP non-renormalization, Theorem 16.8.2(iii)).
- Class C (Contact, $r_{\max} = 4$): two-loop exact.
- Class M (Mixed, $r_{\max} = \infty$): requires all-loop resummation.

This ordering refines the Koszulness programme: all four classes are chirally Koszul (bar E_2 -collapse), but they differ in Swiss-cheese formality depth.

PROPOSITION II.I.59 (*Swiss-cheese non-formality by shadow class*;). The Swiss-cheese operations m_k^{SC} on $\mathcal{A}$ itself (not on the bar cohomology $H^*(\overline{B}(\mathcal{A}))$), which is always A_∞ -formal for Koszul algebras by Theorem II.I.50(iii)) are classified by shadow depth as follows.

Class	Families	m_3^{SC}	m_4^{SC}	$m_k^{\text{SC}}, k \geq 5$
G ($r_{\max} = 2$)	Heisenberg, lattice VOA, free fermion	$= 0$	$= 0$	$= 0$
L ($r_{\max} = 3$)	affine KM	$\neq 0$	$= 0$	$= 0$
C ($r_{\max} = 4$)	$\beta\gamma$	$= 0$	$\neq 0$	$= 0$
M ($r_{\max} = \infty$)	Virasoro, $\mathcal{W}_N$	$\neq 0$	$\neq 0$	$\neq 0 \forall k$

Mechanism. For class G : Heisenberg, lattice VOAs, and free fermions are Gaussian/free-field: their ordered bar data is generated by the binary two-point kernel, so every connected genus-0 tree with at least three external legs factors through pairings and carries no primitive higher vertex. Equivalently, the shadow tower truncates at degree 2: $S_r(\mathcal{A}) = 0$ for $r \geq 3$ (Theorem 13.22.129; for lattices see Corollary B.14.4). Under the averaging map $\text{av}(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1), the mixed Swiss-cheese tree of degree r projects to the degree- r shadow. Since there is no primitive tree for $r \geq 3$, all higher mixed-sector operations vanish. For class L : the affine KM OPE has at most a double pole; the three-channel tree sum over $\overline{\mathcal{M}}_{0,4}$ is nonzero ($S_3 = 2h^\vee/(k+h^\vee) \neq 0$) but the tower terminates at depth 3 because $S_r = 0$ for $r \geq 4$. For class C : the cubic shadow vanishes by weight parity of the γ generator (conformal weight 0), while the quartic contact invariant $Q^{\text{contact}} \neq 0$ from the $\beta\gamma\beta\gamma$ self-contraction; rank-one rigidity of the contact stratum kills all m_k^{SC} for $k \geq 5$. For class M : the quartic pole in the Virasoro OPE ($T_{(3)}T = c/2$) produces $S_3 = 2$ (c -independent) and the critical discriminant $\Delta = 8\kappa S_4 \neq 0$ forces all higher operations to be nonzero.

Proof. Class G : for Heisenberg, centrality of the bracket kills all nested tree compositions, so $m_k^{\text{SC}} = 0$ for $k \geq 3$. For lattice VOAs, bosonization reduces connected genus-0 amplitudes to Wick pairings of the underlying Heisenberg field, and Corollary B.14.4 identifies the shadow tower with its weight-2 truncation. For the free fermion, Wick's theorem gives Pfaffian factorization by the basic contraction $\psi(z)\psi^*(w) \sim (z-w)^{-1}$, so again no connected tree with $r \geq 3$ survives after extracting the binary pairings. In all three cases the mixed Swiss-cheese degree- r operation is the open-colored lift of the same genus-0 tree sum whose closed projection is $S_r(\mathcal{A})$; equivalently, $\text{av}(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1). Because class G means $S_r(\mathcal{A}) = 0$ for all $r \geq 3$, the mixed-sector operations vanish: $m_k^{\text{SC}} = 0$ for $k \geq 3$. The weaker condition $\Delta = 0$ is not sufficient: affine Kac–Moody algebras are class L with $\Delta = 0$ but $m_3^{\text{SC}} \neq 0$. Class L : the cubic shadow $S_3 = 2h^\vee/(k+h^\vee)$ is computed from the OPE coefficient ratio (the structure constant divided by the level); the quartic and higher shadows vanish because the Jacobi identity and rank constraints eliminate all $\overline{\mathcal{M}}_{0,r+1}$ tree sums for $r \geq 4$ when the OPE has at most double poles. Class C : the cubic shadow vanishes by the parity obstruction on the weight-0 generator γ ; the quartic contact invariant Q^{contact} is nonzero by the explicit $\beta\gamma\beta\gamma$ channel computation; termination at depth 4 follows from rank-one rigidity (Theorem 13.22.137). Class M : $S_3 = (\text{scalar projection of } T_{(1)}T)/T_{(3)}T = 2\kappa/\kappa = 2$, independent of c ; $S_4 = 10/[c(5c+22)]$ and $\Delta = 8\kappa S_4 = 40/(5c+22) \neq 0$ for generic c , so the Riccati algebraicity theorem forces the tower to be infinite. Computational verification: `theorem_ainfty_nonformality_class_m_engine.py`

(three independent methods for S_3 , quartic shadow S_4 and Q^{contact} , quintic shadow $S_5 = -48/(c^2(5c + 22))$, all four classes verified). $\square$

The four classes exhaust the standard landscape, but the relationship between SC-formality and the classification is sharper than the table suggests. Proposition 11.1.59 already isolates the first nonzero Swiss-cheese operation in each non-Gaussian class and, on the Gaussian locus, identifies the mixed-sector tree formulas with the degree-by-degree shadow tower after averaging. The criterion below packages this as an equivalence between SC-formality and truncation of the shadow tower at degree 2.

PROPOSITION 11.1.60 (*SC-formality characterises class G*;). Let $\mathcal{A}$ be a chiral algebra in the standard landscape. Then $\mathcal{A}$ is Swiss-cheese formal ($m_k^{\text{SC}} = 0$ for all $k \geq 3$) if and only if $\mathcal{A}$ belongs to class G .

Proof. The forward direction (class $G \implies$ SC-formal) is established in Proposition 11.1.59: the class- G row consists of the Gaussian families Heisenberg, lattice VOA, and free fermion, and in each case the genus-0 mixed tree formulas stop at degree 2, so $m_k^{\text{SC}} = 0$ for $k \geq 3$. This uses the same operadic/Wick-factorization argument in all three families and does not appeal to any invariant bilinear form.

For the converse, suppose $\mathcal{A}$ is SC-formal. Then every mixed Swiss-cheese operation of degree $r \geq 3$ vanishes in the Swiss-cheese structure with open colour $\mathcal{A}$. The tree-shadow correspondence is operadic: the degree- r mixed tree and the degree- r shadow are produced by the same genus-0 tree-transfer formula, with the same propagator on internal edges; the only difference is the output colour, and passage to the symmetric closed sector applies the averaging morphism $\text{av}(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1). Hence SC-formality forces $S_r(\mathcal{A}) = 0$ for every $r \geq 3$: there is no higher mixed tree whose closed projection could survive. By Theorem 13.22.108 and Proposition 13.22.III, this is exactly the statement that the shadow/formality tower truncates at degree 2. Theorem 13.22.129 identifies the standard-landscape locus with this property as precisely class G . Hence an SC-formal algebra must belong to class G . $\square$

Remark 11.1.61 (*Operadic alternative proof*). Proposition 11.1.60 admits a second proof path that stays in genus-0 operadic transfer and makes the tree-shadow mechanism explicit.

For the forward direction, class G is the Gaussian locus where the genus-0 transfer is generated by the binary two-point kernel alone. Every connected Swiss-cheese tree of degree $r \geq 3$ therefore factors through binary pairings and carries no primitive higher vertex, so the mixed operations vanish: $m_k^{\text{SC}} = 0$ for all $k \geq 3$. On the closed side this is recorded by the truncation $S_r(\mathcal{A}) = 0$ for every $r \geq 3$ (Theorem 13.22.129).

For the converse, assume that $\mathcal{A}$ is SC-formal. Then the minimal $\text{SC}^{\text{ch, top}}$ -model on the pair $(CH^*(\mathcal{A}, \mathcal{A}), \mathcal{A})$ has no mixed operations of degree $k \geq 3$. If some $S_r(\mathcal{A})$ with $r \geq 3$ were nonzero, then Theorem 13.22.108, Proposition 13.22.III, and the averaging identity $\text{av}(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1) would identify $S_r(\mathcal{A})$ with the closed-color projection of the same transferred genus-0 tree that defines the mixed degree- r operation. A nonzero closed projection cannot come from the zero tree, so that tree would determine a nontrivial mixed degree- r Massey product, contradicting SC-formality. Hence $S_r(\mathcal{A}) = 0$ for every $r \geq 3$.

This is the relevant vanishing criterion. The discriminant alone does not suffice: class L also has $\Delta = 0$ but $S_3 \neq 0$. Among the standard classes, Proposition 11.1.59 rules out L , C , and M by explicit first nonzero operations m_3^{SC} , m_4^{SC} , and the infinite tower, respectively. Only class G remains. This is the argument used on the theorematic surface because it applies uniformly to Heisenberg, lattice VOAs, and free fermions.

Remark 11.1.62 (*D-module purity: reduction to a single gap*). The converse direction of condition (xii) (Koszulness $\implies$ D-module purity of $\mathbf{B}_n(\mathcal{A})$) admits a five-step proof strategy. Steps 1–3 are established; step 4 is the single remaining gap.

- Step 1. The PBW filtration $F_{\bullet}^{\text{PBW}}$ on $\bar{\mathbf{B}}_n(\mathcal{A})$ is a filtration by $\mathcal{D}$ -submodules on $\text{FM}_n(X)$, with associated graded given by the FG bar complex (the bar of the chiral Lie algebra). Proved: the PBW filtration is defined by order of OPE pole, compatible with $\mathcal{D}$ -module structure.
- Step 2. On the Koszul locus, $\text{gr}_{\bullet}^F \bar{\mathbf{B}}_n$ is a direct sum of rank-one $\mathcal{D}$ -modules supported on the strata of the FM boundary, each pure of weight determined by the stratum codimension. Proved: follows from PBW concentration (ii) and the explicit identification of strata.
- Step 3. Purity of the associated graded implies purity of the filtered module if and only if the PBW filtration coincides with the Saito weight filtration from mixed Hodge module theory. Proved: this is a formal consequence of Saito's strictness theorem for filtered $\mathcal{D}$ -modules.
- Step 4. **The PBW filtration on $\bar{\mathbf{B}}_n(\mathcal{A})$ equals the Saito weight filtration from mixed Hodge modules on $\text{FM}_n(X)$.** For affine Kac–Moody algebras, this is proved via chiral localization (relating $\bar{\mathbf{B}}_n$ to $\mathcal{D}$ -modules on the affine Grassmannian) and the Hitchin connection (providing the variation of Hodge structure). For Virasoro and $\mathcal{W}$ -algebras, it is open: the BPZ equations do not carry a known variation of Hodge structure.
- Step 5. Given steps 1–4, purity of $\bar{\mathbf{B}}_n$ in weight n follows by the strictness of the weight filtration. Proved: formal.

Zero counterexamples have been found: across all tested families, null vectors simultaneously create off-diagonal bar cohomology *and* mixed Hodge extensions. For the affine Kac–Moody lineage, the converse of (xii) is a theorem; the open case is the non-affine lineage (Virasoro, $\mathcal{W}$ -algebras), where the key missing ingredient is a Hodge-theoretic interpretation of the BPZ differential equations.

PROPOSITION II.I.63 (*$\mathcal{D}$ -module purity for affine Kac–Moody algebras*). For $\mathcal{A} = V_k(\mathfrak{g})$ at generic level k , $\bar{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module on $\text{FM}_n(X)$. The proof uses chiral localization (Frenkel–Gaitsgory) to identify $\bar{\mathbf{B}}_n$ with a $\mathcal{D}$ -module on the affine Grassmannian, where purity follows from the Hitchin connection and Saito's theory.

Proof. At generic level, Frenkel–Gaitsgory chiral localization identifies the affine Kac–Moody factorization algebra with the corresponding twisted $\mathcal{D}$ -module on the affine Grassmannian. Under this identification, $\bar{\mathbf{B}}_n(\mathcal{A})$ is obtained from the basic localized object by the standard Hecke/factorization operations that insert n marked points. The Hitchin connection transports that family flatly over the curve, so the resulting object is a mixed Hodge module. Saito's purity theorem for intersection complexes, together with purity under proper pushforward, then shows that each bar insertion contributes one unit of weight. Hence $\bar{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n . $\square$

D-MODULE PURITY: REDUCTION AND FAMILY DEPENDENCE

The Kac–Moody case strengthens to a full equivalence. For other families, the two-way implication fails or remains conditional.

PROPOSITION II.I.64 (*Kac–Moody equivalence via Saito–Kashiwara weight filtration*). Let $\mathcal{A} = V_k(\mathfrak{g})$ be the universal affine Kac–Moody vertex algebra at generic level k on a smooth projective curve X . The following are equivalent:

- (a) $\mathcal{A}$ is chirally Koszul (condition (i) of Theorem II.I.50).

(b) The PBW filtration $F_{\bullet}^{\text{PBW}}$ on each $\bar{\mathbf{B}}_n(\mathcal{A})$ is strict and concentrated in PBW-degree n (condition (ii)).

(c) Each $\bar{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module on $\text{FM}_n(X)$ (condition (xii)).

Proof. The implications (a) $\Leftrightarrow$ (b) are part of the core circuit (i) $\Leftrightarrow$ (ii) of Theorem 11.1.50. The implication (c) $\Rightarrow$ (b) is the one-directional part of the meta-theorem ((xii) $\Rightarrow$ (x)): purity of $\bar{\mathbf{B}}_n$ forces Saito strictness on the weight filtration, and Saito strictness gives FM stratum acyclicity, which in turn forces PBW strictness by the Kac–Shapovalov implication (ix) $\Rightarrow$ (ii).

The new content is the converse (b) $\Rightarrow$ (c). Proposition 11.1.63 already supplies (a) $\Rightarrow$ (c) via chiral localization and the Hitchin connection. We strengthen this to an equivalence by the Saito–Kashiwara weight comparison: the PBW filtration on $V_k(\mathfrak{g})$ coincides with the Saito weight filtration on the associated mixed Hodge module on $\text{FM}_n(X)$ after chiral localization to the affine Grassmannian. The comparison proceeds in three steps.

First, Frenkel–Gaitsgory chiral localization identifies $\bar{\mathbf{B}}_n(V_k(\mathfrak{g}))$ with a $\mathcal{D}$ -module on $\text{Gr}_G^{(n)}$ (the n -th Beilinson–Drinfeld Grassmannian), carrying a canonical variation of mixed Hodge structure through the Hitchin connection. Second, the PBW filtration on the vacuum module lifts to a Hodge-theoretic filtration on this variation: the lift is the one identified by Mochizuki in his proof of Saito’s decomposition theorem for pure twistor $\mathcal{D}$ -modules ([492, 493]), where the Kashiwara filtration along a boundary divisor (here, the FM stratification) gives a weight filtration that, in the presence of a polarization, agrees with the Saito weight filtration by strictness. Third, for Kac–Moody the polarization is supplied by the Kac–Shapovalov form (Theorem 11.1.35): G_h is non-degenerate in the bar-relevant range at generic level, providing the positivity data that forces Saito strictness. PBW strictness (b) is then transported, by the identification above, to strictness of the Saito weight filtration, which is equivalent to (c) by Saito’s theorem.

The three ingredients (Frenkel–Gaitsgory localization, Mochizuki–Sabbah twistor strictness, Kac–Shapovalov positivity) are each family-specific: each relies on properties of $V_k(\mathfrak{g})$ that are not shared by Virasoro or $\beta\gamma$. The non-affine case is precisely the open direction recorded in Remark 11.1.62, Step 4. $\square$

Remark 11.1.65 (Family dependence of the $\mathcal{D}$ -module purity equivalence). The Kac–Moody equivalence of Proposition 11.1.64 does not extend to the full standard landscape. The failure mechanism is family-specific, controlled by the shadow class of the algebra.

Virasoro (class $\mathbf{M}$, $r_{\max} = \infty$): Vir_c is chirally Koszul at generic c (Table 11.1), so condition (ii) holds. The shadow depth is infinite: the shadow tower does not terminate, and the higher Massey products $S_r \neq 0$ for all $r \geq 4$ block the variation of Hodge structure on $\bar{\mathbf{B}}_n(\text{Vir}_c)$ from being pure. The BPZ differential equations do not carry a known polarization of twistor type, so Mochizuki’s strictness theorem does not apply: condition (xii) is strictly stronger than (ii), and the equivalence fails. Explicitly, PBW concentration holds but $\mathcal{D}$ -module purity has no established proof, and the shadow obstruction tower obstructs any naive weight assignment. This is the *shadow depth* ∞ vs. *PBW concentration* gap.

$\beta\gamma$ (class $\mathbf{C}$, $r_{\max} = 4$): The contact shadow $Q^{\text{contact}} \neq 0$ at degree 4 (Proposition 11.1.59) creates a parity obstruction on the Saito weight: the weight-0 generator γ forces the bar complex to carry a nontrivial quartic Massey product, which is incompatible with purity of the associated $\mathcal{D}$ -module. As for Virasoro, condition (ii) holds but condition (xii) is strictly stronger.

$\mathcal{W}_N$ at principal nilpotent, generic central charge (class $\mathbf{M}$):

Conjecture 11.1.66 (Principal $\mathcal{W}_N$ equivalence on the generic locus;). Let $\mathcal{W}_N^k$ be the universal principal $\mathcal{W}$ -algebra obtained from $V_k(\mathfrak{sl}_N)$ by principal Drinfeld–Sokolov reduction, at generic central charge. On the generic locus of the FM configuration space, condition (ii) of Theorem 11.1.50 is equivalent to condition (xii), conditional on the preservation of Saito weights under principal Drinfeld–Sokolov reduction.

The conditional hypothesis is the conjectured compatibility of the principal nilpotent BRST differential with the Kashiwara filtration of the ambient Kac–Moody mixed Hodge module. Only on the generic locus (away from the FM deep strata where higher shadow products interact) is the equivalence plausible; at the boundary, class **M** behavior reintroduces the Virasoro obstruction.

The upshot is that condition (xii) is family-dependent : it depends on more than $\dim(\mathfrak{g})$ or Euler characteristic data, and the equivalence of (xii) with the Koszulness hierarchy survives only on the affine Kac–Moody lineage. For the non-affine families, the one-way implication (xii) $\Rightarrow$ (x) holds unconditionally (Remark II.1.62, Steps 1–3, 5), but the converse requires family-specific input. Across all tested algebras, condition (xii) refines condition (x) strictly: no counterexample to (xii) has been produced where (x) nevertheless holds, consistent with the hypothesis that the shadow obstruction tower and the mixed-Hodge weight filtration measure the same obstruction through different functors, but a direct bridge is available only for Kac–Moody.

Remark II.1.67 (Computational verification landscape). The nine unconditional equivalences and the Hochschild consequence (viii) have been verified computationally for a landscape of 17 algebras (Table II.1): 13 proved Koszul via equivalences (ii) and (ix), 2 proved not Koszul (Ising minimal model, $L(c_{3,4}, 0)$: Kac–Shapovalov null vector at $h = 6$ in the bar-relevant range, so (ix) fails; $L_k(\mathfrak{sl}_3)$ at admissible $q \geq 3$: $\mathrm{rk}(\mathfrak{g}) = 2$ Cartan classes survive in H^2 , Remark II.1.37), 2 open ($L_1(\mathfrak{sl}_2)$ and triplet $\mathcal{W}(2)$). The principal proof mechanism is PBW universality (Proposition II.1.32), which applies to all freely strongly generated algebras: Heisenberg, $V_k(\mathfrak{g})$ at all levels including critical, Vir_c at all central charges, universal $\mathcal{W}$ -algebras, $\beta\gamma$, free fermion, and the symplectic fermion (Remark F.10.4). Three additional mechanisms are needed: lattice filtration (Theorem B.6.3) for lattice VOAs, MC₄ completion tower (Theorem 8.1.27) for $\mathcal{W}_{1+\infty}$, and Kac–Shapovalov null vector detection for disproving Koszulness of minimal models. Cross-family consistency checks: κ additivity, complementarity consistency, and shadow depth independence from Koszulness (shadow classes G, L, C, M each contain Koszul algebras).

PROPOSITION II.1.68 (*Koszulness as formality of the convolution algebra;*). A chiral algebra $\mathcal{A}$ is chirally Koszul if and only if the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ satisfies:

- (i) The shadow algebra $\mathcal{A}^{\mathrm{sh}} = H_{\bullet}(\mathrm{Def}_{\mathrm{cyc}}^{\mathrm{mod}}(\mathcal{A}))$ is concentrated in degree 2: $\mathcal{A}_{r,g}^{\mathrm{sh}} = 0$ for $r \geq 3$, $g = 0$.
- (ii) The bar spectral sequence $E_1^{p,q} = H^q(F^p \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}} / F^{p+1} \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$ degenerates at E_2 .
- (iii) The genus-0 convolution algebra $\mathfrak{g}_{\mathcal{A}}^{(0)}$ is formal as a dg Lie algebra.

These three conditions are equivalent to each other and to the unconditional core consisting of (i)–(vi), the genus-0 clause of (vii), and (ix)–(x) in Theorem II.1.50.

Proof. Condition (i) states $\mathcal{A}_{r,0}^{\mathrm{sh}} = 0$ for $r \geq 3$, i.e. all genus-0 obstruction classes $o_{r+1}^{(0)}(\mathcal{A}) = 0$ for $r \geq 2$. This is the PBW concentration condition (ii) of Theorem II.1.50, establishing (i) $\Leftrightarrow$ (ii). Condition (ii) (bar spectral sequence E_2 -collapse) is the same statement expressed in spectral sequence language. For (i) $\Leftrightarrow$ (iii): a dg Lie algebra is formal if and only if all higher Massey brackets vanish. Proposition 13.22.107 identifies the genus-0 obstruction classes with the transferred L_{∞} brackets $\ell_{r+1}^{(0)}$ at degrees $r = 2, 3, 4$; at each higher degree the same inductive mechanism applies (the obstruction at degree $r+1$ is the next transferred bracket evaluated on the truncated MC element), establishing the identification at all finite degrees. $\square$

Remark 11.1.69 (Two transverse slices of the MC element). The MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ carries two transverse families of invariants. *Koszulness* reads the genus-0 slice: $o_{r+1}^{(0)}(\mathcal{A}) = 0$ for all $r \geq 2$ (the transferred A_{∞} products $m_r = 0$ for $r \geq 3$; Proposition 13.22.107). *Shadow depth* reads the all-genera projection: $r_{\max} := \min\{r : o_{s+1}(\mathcal{A}) = 0 \text{ for all } s > r\}$. These are independent:

Family	Shadow depth $r_{\max}$	Archetype
Heisenberg	2 (finite)	Gaussian
Affine $\widehat{\mathfrak{g}}_k$	3 (finite)	Lie
$\beta\gamma$ system	4 (finite)	Contact
Virasoro Vir_c	∞	Mixed
$\mathcal{W}_N$	∞	Mixed

All five are chirally Koszul (genus-0 slice is formal), yet the Virasoro algebra has infinite shadow depth ($\mathfrak{o}_{\text{Vir}}^{(5)} \neq 0$ at genus ≥ 1). The archetype classification (Theorem 18.5.18) stratifies the Koszul locus by the all-genera termination behavior of $\Theta_{\mathcal{A}}$, a transverse invariant invisible to genus 0.

Remark 11.1.70 (Shadow classes under direct sum). The shadow classes $\{G, L, C, M\}$ form a join-semilattice under the ordering $G < L < C < M$, with the join operation realised by direct sum of chiral algebras. For $\mathcal{A}_1, \mathcal{A}_2$ in the standard landscape, the OPE of $\mathcal{A}_1 \oplus \mathcal{A}_2$ has no mixed singular terms between the two sectors: the $\mathcal{A}_1$ -fields and $\mathcal{A}_2$ -fields are mutually local with regular OPE. The shadow tower of the direct sum therefore decomposes sector by sector, and the shadow depth satisfies

$$r_{\max}(\mathcal{A}_1 \oplus \mathcal{A}_2) = \max(r_{\max}(\mathcal{A}_1), r_{\max}(\mathcal{A}_2)).$$

In particular:

$\mathcal{A}_1$	$\mathcal{A}_2$	$r_{\max}(\mathcal{A}_1 \oplus \mathcal{A}_2)$	Class
G	G	$\max(2, 2) = 2$	G
G	L	$\max(2, 3) = 3$	L
L	L	$\max(3, 3) = 3$	L
G	M	$\max(2, \infty) = \infty$	M
C	M	$\max(4, \infty) = \infty$	M

The entry $L \oplus L = L$ (not C) is the decisive case: two affine Kac–Moody factors at levels k_1, k_2 produce no cross-sector shadow terms at depth 4, because the quartic obstruction S_4 is intrinsic to each factor’s OPE and the mixed channels contribute only regular terms.

This join-semilattice structure is specific to direct sums. Constructions that create new OPE singularities between sectors can raise the shadow class strictly: a quantum Drinfeld–Sokolov reduction of an affine algebra (class L) produces a $\mathcal{W}$ -algebra (class M), and a coset $\mathcal{A}/\mathcal{A}'$ can land in a higher class than either factor. The shadow depth is monotone under direct sum but not under quotient or reduction.

*Remark 11.1.71 (Class **W**: root multiplicities and the Koszul frontier).* The **G/L/C/M** classification (Remark 11.1.69) presupposes chiral Koszulness: E_2 -collapse of the bar spectral sequence (Theorem 11.1.50). Beyond this boundary lies class **W** (wild), where E_2 -collapse fails and the nine unconditional Koszul

equivalences lose force simultaneously, and the chiral Hochschild consequence (viii) no longer follows. The mechanism is controlled by the Kronecker quiver K_m (two vertices, m parallel arrows) and its root multiplicities.

Root multiplicities and higher differentials. The symmetric Euler form of K_m has determinant $4 - m^2$. For $m \leq 2$, this form is positive semi-definite: every positive root has multiplicity 1, the indecomposable representations are classified (finite type for $m = 1$, tame for $m = 2$), and the bar spectral sequence collapses at E_2 by the Kac–Moody concentration argument. For $m \geq 3$, the form is indefinite. The dimension vectors (d_0, d_1) with $d_0^2 + d_1^2 - md_0d_1 < 0$ support *families* of indecomposable representations: the moduli space $\mathcal{M}(d_0, d_1)$ has positive dimension $1 - d_0^2 - d_1^2 + md_0d_1$, and the root multiplicity exceeds 1. These multiple roots produce non-split extensions in the bar complex $\overline{B}(\mathcal{A})$: the $E_2^{p,q}$ page acquires off-diagonal classes supported on the excess moduli, and the higher differentials d_r ($r \geq 2$) act nontrivially between them. The signed Euler series $\prod_{n \geq 1} (1 - t^n)^{m+2}$ acquires negative coefficients at weight 2, confirming the failure of bar concentration.

Why the nine equivalences break. Each of the nine unconditional equivalences (i)–(vii), (ix), (x) in Theorem II.1.50 requires, at its core, that bar cohomology $H^\bullet(\overline{B}(\mathcal{A}))$ be concentrated on the PBW diagonal. In the wild regime, the excess moduli inject off-diagonal classes into H^2 (and higher) that persist to E_∞ : condition (ii) (PBW concentration) fails, and with it the equivalence chain. The conditional Lagrangian criterion (xi) and the one-directional $\mathcal{D}$ -module purity statement (xii) fail *a fortiori*, since both rely on E_2 -collapse as input.

Concrete instances. Three classes of chiral algebras lie in class **W**:

- (i) *Virasoro minimal models.* The simple quotient $L(c_{p,q}, 0)$ is non-Koszul by Proposition II.1.75: the null quotient at weight $w_0 = (p-1)(q-1)$ enlarges $\ker(d: \overline{B}^2 \rightarrow \overline{B}^1)$, producing $H^2 \neq 0$.
- (ii) *Admissible-level simple quotients at higher rank.* For $\mathfrak{g}$ with $\mathrm{rk}(\mathfrak{g}) \geq 2$ and denominator $q \geq 3$, the abelian Cartan subalgebra $\mathfrak{h}$ contributes $\mathrm{rk}(\mathfrak{g})$ classes to $E_1^{2,q}$ that survive to E_∞ (Conjecture II.1.38).
- (iii) *Non-principal $\mathcal{W}$ -algebras at wild nilpotent type.* Quantum Drinfeld–Sokolov reduction at a nilpotent e whose associated Slodowy slice has wild representation type produces a $\mathcal{W}$ -algebra whose Ext quiver has $m \geq 3$ arrows; the resulting bar complex inherits the wild root structure.

The replacement for the shadow obstruction tower in class **W** is the motivic Donaldson–Thomas theory of Kontsevich–Soibelman: the DT invariants $\Omega(d_0, d_1)$ grow exponentially in $\max(d_0, d_1)$ for $m \geq 3$, and their wall-crossing structure encodes the information that the shadow tower would carry in the Koszul world (Remark I3.22.122).

II.1.5.1 Koszulness from Sklyanin Poisson cohomology

The Koszulness meta-theorem (Theorem II.1.50) characterizes chiral Koszulness intrinsically, through the bar complex and its spectral sequences. We now record a Poisson-geometric characterization that applies on the affine Kac–Moody locus and is logically independent of the PBW spectral sequence.

The classical r -matrix $r^{\mathrm{cl}}(z) = k\Omega/z$ of an affine algebra $\mathcal{A} = \widehat{\mathfrak{g}}_k$ defines a Sklyanin–Poisson bracket on $(\mathfrak{g}^1)^*$ via the Semenov–Tian–Shansky construction [383]. The infinitesimal rigidity of this bracket (vanishing of its second Poisson cohomology) turns out to be equivalent to chiral Koszulness for the affine family.

THEOREM II.1.72 (*Koszulness from Sklyanin–Poisson rigidity; for affine KM*). For $\mathcal{A} = \widehat{\mathfrak{g}}_k$ with $\mathfrak{g}$ semisimple, the Sklyanin–Poisson bracket $\{-, -\}_{\mathrm{STS}}$ on $(\mathfrak{g}^1)^*$ determined by the classical r -matrix $r^{\mathrm{cl}}(z) =$

$k\Omega/z$ has vanishing second Poisson cohomology:

$$H_{\pi}^2((\mathfrak{g}^{\dagger})^*, \{-, -\}_{\text{STS}}) = 0.$$

Consequently the Sklyanin bracket is infinitesimally rigid: every first-order Poisson deformation is trivial. This rigidity is equivalent to chiral Koszulness of $\mathcal{A}$ on the affine KM locus, providing a Poisson-geometric proof of E_2 -collapse independent of the PBW spectral sequence.

Proof. The Sklyanin bracket $\pi_{\text{STS}} = \pi_{\text{LP}} + \pi_r$ decomposes as the Lie–Poisson bracket π_{LP} (the Kirillov–Kostant structure on $\mathfrak{g}^*$) plus a constant-coefficient bivector π_r from the symmetric part of the r -matrix. The Lichnerowicz–Poisson complex $(\mathfrak{X}^{\bullet}(\mathfrak{g}^*), \delta_{\pi} = [\pi_{\text{STS}}, -]_{\text{SN}})$ computes the Poisson cohomology $H_{\pi}^{\bullet}$.

Filter the Poisson complex by polynomial degree on $\mathfrak{g}^*$. The E_0 page is the Chevalley–Eilenberg complex $C_{\text{CE}}^{\bullet}(\mathfrak{g}, \text{Sym}^p(\mathfrak{g}^*))$ in each polynomial stratum p ; the constant correction π_r contributes only at the E_0 level. Whitehead’s second lemma gives $H_{\text{CE}}^2(\mathfrak{g}, M) = 0$ for every finite-dimensional $\mathfrak{g}$ -module M when $\mathfrak{g}$ is semisimple (Weibel [395], Theorem 7.8.10). In particular $H_{\text{CE}}^2(\mathfrak{g}, \text{Sym}^p(\mathfrak{g}^*)) = 0$ for all $p \geq 0$. The spectral sequence degenerates at E_1 and yields $H_{\pi}^2(\mathfrak{g}^*, \pi_{\text{STS}}) = 0$.

The explicit verification for $\mathfrak{g} = \mathfrak{sl}_2$ (the three-dimensional Lichnerowicz complex on $\mathbb{C}^3$, carried out in `compute/lib/theorem_sklyanin_poisson_cohomology_engine.py`; 57 tests, three independent verification paths: direct kernel/image, CE comparison, and polynomial-degree spectral sequence) confirms $H_{\pi}^0 = \mathbb{C}[C_2]$ (Casimir ring), $H_{\pi}^1 = H_{\pi}^2 = H_{\pi}^3 = 0$.

Equivalence with Koszulness: the vanishing $H_{\pi}^2 = 0$ means the Sklyanin bracket on $(\mathfrak{g}^{\dagger})^*$ has no nontrivial infinitesimal deformations. The Koszul dual coalgebra $\bar{\mathbf{B}}(\mathcal{A})^{\dagger}$ carries $(\mathfrak{g}^{\dagger})^*$ as its semiclassical shadow; rigidity of the Sklyanin bracket is the Poisson-geometric avatar of bar E_2 -collapse (condition (ii) of Theorem 11.1.50). For the affine family, the semiclassical limit is faithful: the Poisson complex $(\mathfrak{X}^{\bullet}, \delta_{\pi})$ is the associated graded of the bar differential under the PBW filtration, and E_2 -collapse of the bar spectral sequence is equivalent to acyclicity of this associated graded: precisely $H_{\pi}^2 = 0$. $\square$

Remark 11.1.73 (Scope and the class M obstruction). The Sklyanin rigidity proof applies to affine Kac–Moody algebras (shadow classes G and L), where the classical r -matrix is rational of order 1 and the resulting Poisson bracket is algebraic (polynomial coefficients on $\mathfrak{g}^*$). For class M algebras (Virasoro, $\mathcal{W}_N$), the collision residue has higher-order poles producing *differential* Poisson brackets of order ≥ 2 in the sense of [298]. The Lichnerowicz complex for such brackets lies outside the scope of Whitehead’s lemma: H_{CE}^2 controls only the algebraic (order-0) sector. Extending the Sklyanin rigidity proof to class M requires a theory of differential Poisson cohomology that does not yet exist. This is a 14th characterization of chiral Koszulness, restricted to the affine KM subclass. On this subclass it is logically independent of the PBW spectral sequence and provides a second, Poisson-geometric route to E_2 -collapse.

11.1.6 KOSZULNESS AND THE CONFORMAL BOOTSTRAP

THEOREM 11.1.74 (*Koszulness implies bootstrap closure*;). Let $\mathcal{A}$ be a chirally Koszul chiral algebra. Then:

- (i) The Maurer–Cartan moduli $\text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ is discrete (zero-dimensional): the MC element $\Theta_{\mathcal{A}}$ is the unique solution, determined by the genus-0 OPE data.
- (ii) The shadow depth $r_{\text{max}}(\mathcal{A})$ equals the bootstrap closure order: the number of OPE channels at which the crossing equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ at degree $n = 4$ is satisfied.

- (iii) The shadow depth classification corresponds to bootstrap complexity: class G has no OPE corrections beyond leading order, class L has one cubic correction (the pentagon identity), class C terminates at the quartic, class M requires the infinite tower.

The MC equation at $(g=0, n=4)$ is the crossing equation for the four-point function.

Proof. (i) By A_∞ formality (item (iii) of Theorem II.1.50), the transferred A_∞ operations on $H^*(\overline{B}(\mathcal{A}))$ satisfy $m_k = 0$ for $k \geq 3$ on the Koszul locus. The MC moduli of a formal A_∞ algebra is discrete (Kontsevich's formality implies the Deligne groupoid is contractible). Uniqueness of $\Theta_{\mathcal{A}}$ then follows from the bar-intrinsic construction (Theorem 13.21.69).

(ii) The MC equation projected to degree $r+1$ determines $o_{r+1}(\mathcal{A})$ from $\Theta_{\mathcal{A}}^{\leq r}$ (Lemma 18.15.10). The shadow depth $r_{\max}$ is the smallest r such that $o_{r+1} = 0$ identically. At degree 4, the MC equation is the crossing constraint for the four-point function $\langle TTTT \rangle$: both express the vanishing of the obstruction class in $H^2(\text{Def}_{\text{cyc}}^{\text{mod}})$ at weight 4.

(iii) Class G : $S_3 = S_4 = 0$, so the crossing equation is automatically satisfied (no corrections). Class L : $S_3 \neq 0, S_4 = 0$; one cubic crossing constraint (the pentagon identity on five FM boundary strata of $\overline{\mathcal{M}}_{0,5}$). Class C : $S_4 \neq 0, S_5 = 0$; two crossing levels. Class M : all $S_r \neq 0$; infinite tower. $\square$

PROPOSITION II.1.75 (Minimal model non-Koszulness;). Let $L(c_{p,q}, 0)$ be a non-trivial unitary minimal model with first vacuum singular vector at weight $w_0 = (p-1)(q-1)$. The simple quotient $L(c_{p,q}, 0)$ is not chirally Koszul: the bar cohomology $H^2(\overline{B}(L(c_{p,q}, 0)))_{w_0} \neq 0$.

The mechanism is structural: the null quotient removes a generator from $\overline{B}^1$ at weight w_0 while leaving the domain $\overline{B}^2$ at weight w_0 unchanged (all tensor factors have weight $< w_0$). The differential $d: \overline{B}^2 \rightarrow \overline{B}^1$ therefore acquires a larger kernel, producing new cocycles in H^2 .

Proof. At weight w_0 , the universal Virasoro Verma module has $p(w_0)$ states (unrestricted partitions of w_0 into parts ≥ 2), and the simple quotient removes one null state. Thus $\dim \overline{B}_{w_0}^1(V_c) = p(w_0)$ while $\dim \overline{B}_{w_0}^1(L) = p(w_0) - 1$. The domain $\overline{B}_{w_0}^2$ consists of tensor products $s^{-1}a \otimes s^{-1}b$ with $|a| + |b| = w_0$ and $|a|, |b| \geq 2$, which is determined by weights $< w_0$ and is therefore unaffected by the null quotient. For the Ising model $M(4, 3)$: $w_0 = 6, p(6) = 4, \dim \overline{B}_6^1(L) = 3, \dim \overline{B}_6^2 = 5$, and the Euler characteristic shifts from 0 (universal) to 1 (simple quotient), confirming $H_6^2 \neq 0$. $\square$

II.1.7 COMPLETION KINEMATICS: THE PRIMITIVE CUMULANT SPECTRUM

The shadow obstruction tower probes the *dynamic* axis of the completed bar theory: the OPE structure, curvature, and modular anomaly. The complementary *kinematic* axis depends only on the vacuum character of $\mathcal{A}$. The central objects (the primitive cumulant quotients, their generating series, and the completion entropy) are character-level invariants that control the combinatorial growth of the completed bar coalgebra, independently of any curvature parameter.

Definition II.1.76 (Primitive cumulant quotient;). Let $\mathcal{A} = \mathbf{1} \oplus \overline{\mathcal{A}}$ be a conformal chiral algebra with finite-dimensional weight spaces $\mathcal{A}[h], h \geq 0$. Assume the translation operator $\partial: \mathcal{A}[h-1] \rightarrow \mathcal{A}[h]$ is injective on positive weights (away from null loci, i.e. when $\det G_h \neq 0$ in the Kac–Shapovalov sense of Theorem II.1.35). The *primitive cumulant quotient* at weight h is

$$Q_h(\mathcal{A}) := \mathcal{A}[h] / \partial \mathcal{A}[h-1].$$

These are the quasi-primary (or primitive) cumulant spaces: the new degrees of freedom at each conformal weight that are not descendants of lower-weight fields.

Definition II.1.77 (Primitive generating series;). Let $a_h := \dim \mathcal{A}[h]$ and write the vacuum character as $\chi_{\mathcal{A}}(q) = 1 + \sum_{h \geq 1} a_h q^h$. Set $g_r := \dim Q_{r+1}(\mathcal{A})$. The *primitive generating series* is

$$G_{\mathcal{A}}(t) := \sum_{r \geq 1} g_r t^r = \frac{1-t}{t} (\chi_{\mathcal{A}}(t) - 1).$$

Equivalently, $g_r = a_{r+1} - a_r$ for all $r \geq 1$.

Canonical extraction. The primitive spectrum is read off directly from the vacuum character: $G_{\mathcal{A}}$ depends only on the sequence $(a_1, a_2, a_3, \dots)$ and no further algebraic data.

Definition II.1.78 (Completion Hilbert series;). The *completion Hilbert series* of $\mathcal{A}$ is the associated-graded window series of the completed cumulant bar coalgebra:

$$H_{\mathcal{A}}(t) := \frac{G_{\mathcal{A}}(t)}{1 - G_{\mathcal{A}}(t)} = \sum_{q \geq 1} h_q t^q,$$

where h_q counts exact reduced-weight- q bar words in the ideal cumulant model. This is the nonempty ordered-word series on the primitive alphabet $\{g_1, g_2, g_3, \dots\}$: the coefficient h_q enumerates ordered concatenations of primitive generators whose reduced weights sum to q .

Definition II.1.79 (Primitive defect series;). For a chiral algebra with declared strong generators of conformal weights $d_1, \dots, d_s$, the *primitive defect series* is

$$\Delta_{\mathcal{A}}^{\text{prim}}(t) := G_{\mathcal{A}}(t) - \sum_{i=1}^s t^{d_i-1}.$$

The defect vanishes identically for quadratic (or free-like) behaviour: $\Delta_{\mathcal{A}}^{\text{prim}} = 0$ when the declared generators account for all quasi-primaries at every weight. Nonzero defect detects precisely those weights at which nonquadratic OPEs force new primitive cumulants beyond the declared generators.

Definition II.1.80 (Koszul radius and completion entropy;). Define the *Koszul radius* $\rho_{\mathcal{A}}$ as the smallest positive real root of

$$G_{\mathcal{A}}(\rho_{\mathcal{A}}) = 1.$$

The *completion entropy* is

$$h_K(\mathcal{A}) := \log(\rho_{\mathcal{A}}^{-1}).$$

This is the exponential growth rate of the ideal reduced-weight bar windows: $h_q \sim e^{q \cdot h_K(\mathcal{A})}$ as $q \rightarrow \infty$. The completion entropy is *kinematic*: it depends only on the primitive spectrum $(g_1, g_2, \dots)$, hence only on the vacuum character, and not on curvature parameters such as c or k .

Remark II.1.81 (Kinematics versus dynamics). The completed bar theory separates into two orthogonal axes:

- (i) *Completion kinematics*: $Q(\mathcal{A}), G_{\mathcal{A}}(t), H_{\mathcal{A}}(t), h_K(\mathcal{A})$; depends only on the vacuum character.
- (ii) *Modular dynamics*: $D_{\mathcal{A}}, \kappa(\mathcal{A}), \Theta_{\mathcal{A}}, r_{\mathcal{A}}(z)$; depends on the full OPE structure, curvature, anomaly.

The Virasoro involution $c \mapsto 26 - c$ changes dynamic data (it sends κ_c to κ_{26-c}) but does not alter the completion entropy: $h_K(\text{Vir}_c) = h_K(\text{Vir}_{26-c})$ for all c , since both algebras share the same vacuum character. The same-family shadow Vir_{26-c} lives on the dynamic axis (Remark K.7.1); kinematically, even generic Virasoro has infinitely many primitive cumulants, with $g_r = p(r+1) - p(r)$ growing without bound.

This separation is structurally clean: the primitive spectrum determines *how large* the completed bar coalgebra is (how many words at each reduced weight), while the OPE data determines *what the differential does* on those words. Both axes are needed for the full MC₄ theory (Theorem 8.1.27).

PROPOSITION II.1.82 (*Cumulant-to-window inversion*;). The cumulant law is invertible: from the window counts $(h_1, h_2, \dots)$ one recovers the hidden primitive spectrum $(g_1, g_2, \dots)$ by the recursion

$$g_1 = h_1, \quad g_q = h_q - \sum_{r=1}^{q-1} g_r h_{q-r} \quad (q \geq 2).$$

Proof. The identity $H_{\mathcal{A}} = G_{\mathcal{A}}/(1 - G_{\mathcal{A}})$ is equivalent to $G_{\mathcal{A}} = H_{\mathcal{A}}/(1 + H_{\mathcal{A}})$, or at the level of formal power series,

$$G_{\mathcal{A}}(t) = H_{\mathcal{A}}(t) - G_{\mathcal{A}}(t) H_{\mathcal{A}}(t).$$

Extracting the coefficient of t^q gives $g_q = h_q - \sum_{r=1}^{q-1} g_r h_{q-r} - g_q h_0$; since $h_0 = 0$ (no nonempty words of weight 0), the formula follows by induction on q . $\square$

Remark II.1.83 (*The primitive defect as a Koszulness probe*). For a quadratic chiral algebra $\mathcal{A}$ with generators of weights $d_1, \dots, d_s$, the PBW basis ensures that all quasi-primaries are generated by the declared strong generators, so $\Delta_{\mathcal{A}}^{\text{prim}} = 0$ identically. The Virasoro algebra Vir_c has a single strong generator of weight 2 and $g_r = p(r+1) - p(r)$ for all $r \geq 1$, giving primitive defect $\Delta_{\text{Vir}}^{\text{prim}}(t) = G_{\text{Vir}}(t) - t$, which is nonzero starting at t^3 . This nonvanishing defect is the kinematic signature of nonquadraticity and feeds directly into the MC₄ completion programme (§13.22.4).

II.1.8 GEOMETRIC BAR-COBAR DUALITY (THEOREM A)

The homotopy Koszul dual $\mathcal{A}_{\infty}^! := \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A})$ is unconditionally a factorization algebra (Chapter 10). Theorem A identifies the conditions under which $\mathcal{A}_{\infty}^!$ is *formal*, quasi-isomorphic to the classical dual $\mathcal{A}^!$.

THEOREM II.1.84 (*Geometric bar-cobar duality*;). [Regime: quadratic on the Koszul locus (Convention 1.10.2)]. The unit maps in part (1) are equivalences in the derived category of conilpotent complete factorization coalgebras on $\text{Ran}(X)$. The counit maps in part (1) and all post-Verdier identifications in parts (2)–(3) are equivalences in the derived category $D^b(\text{Fact}^{\text{aug}}(X))$ of augmented factorization algebras on X .

The Heisenberg instance was verified in §2.6. In general:

Let $(\mathcal{A}_1, C_1, \tau_1, F_{\bullet})$ and $(\mathcal{A}_2, C_2, \tau_2, F_{\bullet})$ be a chiral Koszul pair in the sense of Definition II.1.15. Then:

1. the canonical unit maps are weak equivalences of conilpotent complete factorization coalgebras, and the canonical counit maps are quasi-isomorphisms of factorization algebras:

$$C_i \xrightarrow{\sim} \bar{B}_X(\mathcal{A}_i), \quad \Omega_X(C_i) \xrightarrow{\sim} \mathcal{A}_i \quad (i = 1, 2);$$

2. the homotopy Koszul dual factorization algebras are identified with the opposite member of the pair:

$$\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1) \simeq \Omega_X(C_2) \simeq \mathcal{A}_2, \quad \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_2) \simeq \Omega_X(C_1) \simeq \mathcal{A}_1;$$

3. if $\mathcal{A}_2$ is denoted by $\mathcal{A}_1^\dagger$, then

$$(\mathcal{A}_1)_\infty^\dagger := \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1) \simeq \mathcal{A}_1^\dagger, \quad (\mathcal{A}_2)_\infty^\dagger := \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_2) \simeq \mathcal{A}_2^\dagger.$$

Proof. Part (1) is the fundamental theorem of chiral twisting morphisms (Theorem 11.1.9): the Koszulness conditions (Definition 11.1.3) are equivalent to the unit maps being weak equivalences of factorization coalgebras and the counit maps being quasi-isomorphisms of factorization algebras. For part (2), the Verdier compatibility in Definition 11.1.15 identifies the algebra-level Verdier dual $\mathbb{D}_{\text{Ran}}(C_1)$ with the factorization algebra $\Omega_X(C_2)$, and likewise with the indices reversed. In the standard examples, this hypothesis is supplied by Theorem 7.0.36, whose output already lives on the post-Verdier factorization-algebra side rather than on a coalgebra side. Let

$$\eta_i: C_i \xrightarrow{\sim} \bar{B}_X(\mathcal{A}_i), \quad \varepsilon_i: \Omega_X(C_i) \xrightarrow{\sim} \mathcal{A}_i$$

be the unit and counit equivalences from part (1). Applying $\mathbb{D}_{\text{Ran}}$ to η_1 gives an equivalence of factorization algebras

$$\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1) \xrightarrow{\sim} \mathbb{D}_{\text{Ran}}(C_1).$$

Composing this with the Verdier-compatibility identification $\mathbb{D}_{\text{Ran}}(C_1) \simeq \Omega_X(C_2)$ and then with ε_2 yields

$$\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1) \simeq \Omega_X(C_2) \simeq \mathcal{A}_2,$$

and similarly for the other index. Every object after $\mathbb{D}_{\text{Ran}}$ is therefore a factorization algebra, not a coalgebra. Part (3) is the same statement after naming $\mathcal{A}_2$ as the Koszul dual $\mathcal{A}_1^\dagger$. $\square$

Remark 11.1.85 (Alternative proof via derived algebraic geometry). There is a second proof of Theorem 11.1.84 at the H-level of Remark 11.1.90. In the stable presentable ∞ -category of augmented factorization algebras on $\text{Ran}(X)$, the role of the terminal algebra k is played by the unit object ω_X . For an augmentation $\varepsilon: \mathcal{A} \rightarrow \omega_X$, the associated simplicial bar object $\text{Bar}_\bullet(\omega_X, \mathcal{A}, \omega_X)$ is the Čech nerve of ε , and its geometric realization is the bar coalgebra $\bar{B}_X(\mathcal{A})$ [303, Chapter 5, especially §§5.2.2–5.2.4]. Dually, a coaugmented conilpotent coalgebra C has a cosimplicial cobar object obtained from the dual Čech nerve, and its totalization is $\Omega_X(C)$ by the same bar/cobar formalism [303, Chapter 5, especially §§5.2.3–5.2.4]. The general realization/totalization adjunction therefore produces the functor pair

$$\bar{B}_X: \text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X)) : \Omega_X.$$

In this ∞ -categorical formulation, the Koszul locus of the chapter is the locus where these Čech and co-Čech resolutions are effective, so the unit and counit are equivalences there. This proves part (1) without the filtered comparison from the simplicial bar object to the explicit dg model.

For part (2), Serre–Grothendieck duality on the relevant holonomic factorization $\mathcal{D}$ -modules over the derived Ran prestack sends geometric realizations to the totalizations of the dual cosimplicial objects and exchanges the left and right module structures carried by the augmentation object [195, Chapter IV.5]. Applied to $\mathcal{A}_1$, this identifies $\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1)$ with the cobar factorization algebra attached to the Verdier dual datum. For a chiral Koszul pair, Definition 11.1.15 identifies that dual datum with $\Omega_X(C_2)$; composing with the counit equivalence $\Omega_X(C_2) \xrightarrow{\sim} \mathcal{A}_2$ from part (1) gives

$$\mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}_1) \simeq \Omega_X(C_2) \simeq \mathcal{A}_2,$$

and similarly with the indices reversed.

This route is independent of the filtered-comparison lemmas. It therefore heals the theorem-level gap whenever the missing step is the passage from the simplicial bar object to its dg presentation: both the adjunction in part (1) and the Verdier intertwining in part (2) follow at the H-level without that comparison. What remains external is the family-by-family verification that the Verdier-dual datum is represented by the opposite member of the chosen Koszul pair. That verification is not a filtered-comparison issue; it is exactly the role isolated in Theorem 7.0.36.

PROPOSITION II.1.86 (*Relative extension from relative Verdier base change*). Let $\pi : X \rightarrow S$ be a family of smooth projective curves. Suppose given relative factorization data

$$(\mathcal{A}_{1,S}, C_{1,S}, \tau_{1,S}, F_\bullet), \quad (\mathcal{A}_{2,S}, C_{2,S}, \tau_{2,S}, F_\bullet)$$

together with relative algebra-level Verdier identifications, where Ω^{rel} denotes the cobar functor formed over the family π :

$$\mathbb{D}_{\text{Ran}(X/S)}(C_{1,S}) \simeq \Omega^{\text{rel}}(C_{2,S}), \quad \mathbb{D}_{\text{Ran}(X/S)}(C_{2,S}) \simeq \Omega^{\text{rel}}(C_{1,S}),$$

whose geometric fibers are chiral Koszul pairs in the sense of Definition II.1.15. Assume:

- (a) each relative bar component is represented on the relative Fulton–MacPherson spaces by a bounded complex of relative holonomic $\mathcal{D}$ -modules;
- (b) for every geometric point $s \rightarrow S$, the canonical base-change morphism

$$s^* \mathbb{D}_{\text{Ran}(X/S)} \overline{B}_{X/S}(\mathcal{A}_{i,S}) \longrightarrow \mathbb{D}_{\text{Ran}(X_s)} \overline{B}_{X_s}(\mathcal{A}_{i,s})$$

is an isomorphism;

- (c) the unit and counit quasi-isomorphisms of Theorem II.1.84(1) commute with pullback to geometric fibers.

Then the equivalences of Theorem II.1.84 assemble into equivalences of relative factorization algebras over S , functorial under base change in S .

For the universal curve over $\overline{\mathcal{M}}_{g,n}$, the only additional input beyond Theorem II.1.84 is the lift of the displayed relative Verdier identifications and the verification of (a) and (b) on the relative Ran space.

Proof. Hypothesis (c) promotes part (1) of Theorem II.1.84 from a fiberwise statement to a compatible relative unit/counit package. Applying $\mathbb{D}_{\text{Ran}(X/S)}$ to the relative unit map and then pulling back to a geometric fiber X_s gives, by hypothesis (b), the algebra-level Verdier equivalence of Theorem II.1.84(2) on that fiber. The displayed relative Verdier identifications provide the algebra target on the total space, and hypothesis (a) is the exact condition needed to take Verdier duals degreewise in the relative holonomic category. These ingredients glue the fiberwise identifications over S . The specialization $S = \overline{\mathcal{M}}_{g,n}$ is obtained by applying the same argument to the universal curve. $\square$

Remark II.1.87 (*Programme for the modular-family extension*). To prove the full modular-family statement over $\overline{\mathcal{M}}_{g,n}$, one must establish the two relative inputs isolated in Proposition II.1.86:

- (1) construct the relative bar components as bounded holonomic $\mathcal{D}$ -complexes on the relative Fulton–MacPherson spaces;

- (2) prove the relative Verdier/base-change isomorphism on the relative Ran space, lift the algebra-level Verdier-compatible pair identifications, and check compatibility with the factorization gluing maps.

The fixed-curve theorem above is the strongest unconditional result proved in this chapter.

Remark 11.1.88 (Geometric substrate (Volume II)). Volume II reveals that this adjunction is the groupoid comodule-module adjunction for the Lagrangian self-intersection $\mathfrak{S} = \mathcal{L} \times_{\mathcal{M}} \mathcal{L}$: the bar complex $\bar{B}_X(\mathcal{A})$ is the structure sheaf of the derived self-intersection of the boundary Lagrangian inside a (-2) -shifted symplectic stack, and the cobar functor reconstructs the Lagrangian from its groupoid algebra.

Remark 11.1.89 (Twisting morphism content of Theorem A). The unit $\eta_{\tau_i} : C_i \rightarrow \bar{B}_X(\mathcal{A}_i)$ and counit $\varepsilon_{\tau_i} : \Omega_X(C_i) \rightarrow \mathcal{A}_i$ in part (1) are induced by the Koszul morphism τ_i of the underlying twisting datum (Definition 11.1.1). Part (1) says each τ_i is acyclic; part (2) says that after applying Verdier duality to the bar coalgebra of one side one obtains the post-Verdier dual factorization algebra recovered from the other; and Proposition 11.1.86 isolates the extra relative Verdier/base-change input needed to transport these identifications over a base.

Remark 11.1.90 (Elementary model presentation; Convention 1.10.2). *Step A* (H-level): The bar functor $\mathbf{B}_X$ and cobar functor Ω_X form an adjoint pair

$$\mathbf{B}_X : \text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X)) : \Omega_X$$

on the stable ∞ -category of factorization (co)algebras on $\text{Ran}(X)$. On the Koszul locus, the unit and counit are equivalences: $\Omega_X \mathbf{B}_X(\mathcal{A}) \simeq \mathcal{A}$. Verdier duality identifies the bar coalgebra with the homotopy dual factorization algebra via the post-Verdier equivalence $\mathbf{D}_{\text{Ran}} \mathbf{B}_X(\mathcal{A}) \simeq (\mathcal{A})_{\infty}^! \simeq \mathcal{A}^!$ on the Koszul locus. This is the theorem; what follows are presentations.

Step B (M-level): The explicit dg model uses the reduced bar complex $\bar{B}_X(\mathcal{A}) = (T^c(s^{-1}\bar{\mathcal{A}}), d_{\text{bar}})$, with d_{bar} encoded by configuration-space integrals on $\bar{C}_n(X)$. The twisting morphism $\tau : \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}^!$ is the degree-+1 propagator extracted from the log form on $\bar{C}_2(X)$. The proof reduces to showing the unit and counit are quasi-isomorphisms, which follows from the Koszul conditions (Definition 11.1.3).

Reduction B $\rightarrow$ A (M-level $\rightarrow$ H-level): Any two admissible dg presentations of the same factorization object are connected by a contractible space of quasi-isomorphisms (Proposition 6.1.45). The M-level quasi-isomorphisms therefore determine the H-level equivalence up to a contractible ambiguity.

Step C (S-level): The cohomological shadow: the bar coalgebra $\bar{B}_X(\mathcal{A})$ has cohomology concentrated in bar degree 1, and the Koszul dual algebra $\mathcal{A}^!$ is characterized by Verdier intertwining $\mathbf{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \simeq \mathcal{A}_{\infty}^!$ (factorization algebra, not coalgebra; Convention 6.0.2), with dimensions controlled by the spectral discriminant $\Delta_{\mathcal{A}}(x)$.

Reduction B $\rightarrow$ C (M-level $\rightarrow$ S-level): Taking cohomology of the M-level dg model extracts the S-level data. Concretely, the PBW spectral sequence $E_1^{p,q} \Rightarrow H^{p+q}(\bar{B}_X(\mathcal{A}))$ collapses at E_2 on the Koszul locus (Corollary 11.1.22, Step 4), and the resulting Hilbert series $\sum_n \dim H^n(\bar{B}_X(\mathcal{A})) x^n$ equals the Hilbert series of $\mathcal{A}^!$, with radius of convergence determined by $\Delta_{\mathcal{A}}(x)$.

11.2 YANGIANS AND AFFINE YANGIANS: SELF-DUALITY AND KOSZUL THEORY

The Yangian $Y(\mathfrak{g})$ and affine Yangian $Y_h(\widehat{\mathfrak{g}})$ provide examples where Koszul duality manifests as self-duality.

For the RTT definition of $Y(\mathfrak{g})$, its Hopf structure, affine Yangian, connection to quantum groups, and physical interpretation, see Chapter O. We record here only the Koszul-duality-specific results.

II.2.1 SELF-DUALITY

THEOREM II.2.1 (*Yangian quadratic dual*;). In the RTT presentation, the Yangian $Y(\mathfrak{g})$ has *quadratic dual*:

$$Y(\mathfrak{g})^{\text{quad}} \cong Y_{R^{-1}}(\mathfrak{g}) \cong Y(\mathfrak{g})^{\hbar \rightarrow -\hbar}$$

where $Y_{R^{-1}}$ is the RTT algebra with R -matrix replaced by R^{-1} . For the Yang R -matrix, $R^{-1}(u; \hbar) = R(u; -\hbar)$, so the quadratic dual is the Yangian at negative deformation parameter.

For simply-laced $\mathfrak{g}$, since $Y(\mathfrak{g})^{\hbar \rightarrow -\hbar} \cong Y(\mathfrak{g})$ (via the algebra automorphism $T_{ij}^{(r)} \mapsto (-1)^r T_{ij}^{(r)}$), the Yangian is quadratic self-dual:

$$Y(\mathfrak{g})^{\text{quad}} \cong Y(\mathfrak{g}) \quad (\text{simply-laced } \mathfrak{g})$$

The explicit $\mathfrak{sl}_2$ computation is given in Chapter O.

Proof of Theorem II.2.1. Step 1: RTT quadraticity. Recall the RTT (Yang–Baxter) presentation: $Y(\mathfrak{g})$ is generated by a transfer matrix $T(u) = (T_{ij}(u)) \in \text{End}(V) \otimes Y(\mathfrak{g})$ subject to

$$R_{12}(u-v) T_1(u) T_2(v) = T_2(v) T_1(u) R_{12}(u-v),$$

where $R_{12}(u) = 1 - \hbar P_{12}/u$ is the Yang R -matrix and P_{12} is the permutation on $V \otimes V$. This relation is quadratic in T ; since the bar complex of a quadratic algebra is determined by generators and relations (bar degrees ≤ 2), the Koszul dual is computed from the relation space alone.

Step 2: Koszul dual via R -matrix inversion. The quadratic dual has relation space $R^\perp$, the orthogonal complement of the RTT relations under the trace pairing on $\text{End}(V)^{\otimes 2}$. Writing the RTT relation as $\Phi_R(X) = R_{12}X - \sigma(X)R_{12}$ and its dual as $\Phi_{R^{-1}}$, direct computation shows $R^\perp = \text{Im}(\Phi_{R^{-1}})$. Thus the Koszul dual is the RTT algebra for R^{-1} .

For the Yang R -matrix, $R^{-1}(u) = (1 - \hbar P/u)^{-1}$; since $P^2 = \text{id}$, the geometric series gives

$$R^{-1}(u) = \frac{u^2}{u^2 - \hbar^2} I + \frac{\hbar u}{u^2 - \hbar^2} P.$$

At the quadratic level, which is all the Koszul dual sees, the leading approximation $R^{-1}(u) \approx 1 + \hbar P/u = R(u; -\hbar)$ suffices: the higher-order corrections affect only the higher filtration, not the quadratic relations.

More precisely, the RTT relation $R_{12}T_1T_2 = T_2T_1R_{12}$ is quadratic in the generators $T_{ij}(u)$, and the Koszul dual is determined by the quadratic part of the relations, namely the orthogonal complement $R^\perp \subset V^{\otimes 2}$. The matrix $R^{-1}(u)$ enters through the dual RTT relation, but only the leading terms $(1 - \hbar P/u + O(\hbar^2))$ contribute to the quadratic orthogonal complement; higher-order terms in R^{-1} produce relations of degree ≥ 3 in the generators.

Step 3: Self-duality for simply-laced $\mathfrak{g}$. The automorphism $\phi: Y(\mathfrak{g}) \rightarrow Y(\mathfrak{g})$ defined by $T_{ij}^{(r)} \mapsto (-1)^r T_{ij}^{(r)}$ sends $\hbar \rightarrow -\hbar$ in the RTT relation (since the spectral parameter u is not affected, only the mode-graded generators pick up signs). For simply-laced $\mathfrak{g}$, where all roots have the same length, this automorphism is well-defined and gives $Y(\mathfrak{g})^{\hbar \rightarrow -\hbar} \cong Y(\mathfrak{g})$.

Step 4: Consistency. At $\hbar = 0$: $Y(\mathfrak{g})$ degenerates to $U(\mathfrak{g}[t])$, and $R = R^{-1} = 1$, so the Koszul dual is the symmetric algebra $\text{Sym}(V)$, which is self-dual at this degenerate level. At $\hbar \rightarrow \infty$: the R -matrix becomes the permutation P , and the algebra degenerates to the commutative polynomial ring, which is Koszul dual to the exterior algebra (i.e., $\text{Sym}^\perp = \wedge$). Both limits are consistent. $\square$

PROPOSITION II.2.2 (*Yangian Koszulness for all simple $\mathfrak{g}$*). For every simple Lie algebra $\mathfrak{g}$, the Yangian $Y(\mathfrak{g})$ in the RTT presentation is Koszul: the bar spectral sequence degenerates at E_2 and the quadratic dual computed above is the true Koszul dual.

Proof. This follows from the Polishchuk–Positselski PBW criterion [349, Ch. 4] applied to $Y(\mathfrak{g})$. The three hypotheses are verified as follows.

1. *PBW basis.* Molev [326] establishes a PBW basis for $Y(\mathfrak{g})$ in the RTT presentation for every simple $\mathfrak{g}$: ordered monomials in the generators $\{T_{ij}^{(r)}\}$ form a vector space basis, and the associated graded is the polynomial algebra $\text{Sym}(V)$ with $V = \bigoplus_{r \geq 0} \text{End}(\mathbb{C}^N)_r$, $N = \dim V_0$ the dimension of the chosen fundamental representation. This gives a flat deformation from $Y(\mathfrak{g})$ to $\text{Sym}(V)$.
2. *Quadraticity.* The RTT relation (O.1) is quadratic in the generators $T_{ij}^{(r)}$, so $Y(\mathfrak{g})$ is a quadratic algebra in the sense of Polishchuk–Positselski.
3. *Local finiteness.* Each level component $V_r = \text{span}\{T_{ij}^{(r)}\}$ has dimension $N^2 = (\dim V_0)^2$, which is finite and independent of r . Since the RTT relation is homogeneous of degree $r + s$ in the level grading, the quadratic algebra is locally finite in a non-negative connected grading. This holds uniformly for all simple $\mathfrak{g}$; no case-by-case verification is needed.

The Polishchuk–Positselski criterion then gives: the PBW flat deformation from $Y(\mathfrak{g})$ to $\text{Sym}(V)$ transfers acyclicity of the Koszul complex $K(\text{Sym}(V)) = \text{Sym}(V) \otimes \wedge(V^*)$ to acyclicity of $K(Y(\mathfrak{g}))$, proving Koszulness. $\square$

II.3 THE THREE-STAGE CONSTRUCTION: RESOLVING THE CIRCULARITY

II.3.1 THE CIRCULARITY PROBLEM

Problem II.3.1 (*Circularity in Koszul duality*). In stating " $\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_2^!$ ", we face a logical gap:

1. We have not given an *independent definition* of $\mathcal{A}_2^!$ as a chiral coalgebra
2. We have not *proven* that $\mathcal{A}_2^!$ satisfies coalgebra axioms
3. We have not *constructed* the quasi-isomorphism $\bar{B}^{\text{ch}}(\mathcal{A}_1) \xrightarrow{\sim} \mathcal{A}_2^!$

For *quadratic* algebras, the classical orthogonality criterion $R_1 \perp R_2$ suffices. But for *non-quadratic* algebras (Virasoro, W-algebras, affine Yangian), this fails completely.

Remark II.3.2. A chiral coalgebra encodes how fields decompose rather than how they compose. The coproduct $\Delta : C \rightarrow C \boxtimes C$ describes how one insertion splits into two, the inverse of the chiral product.

II.3.2 STAGE I: INDEPENDENT DEFINITION OF $\mathcal{A}_2^!$

Definition II.3.3 (*Koszul dual chiral coalgebra: intrinsic construction*). For the Heisenberg algebra, reading off the Koszul dual from the bar coalgebra was immediate: the bar was $\text{coLie}^{\text{ch}}(V^*)$, so the dual was $\text{Sym}^{\text{ch}}(V^*)$ (§2.5). The following definition extends this to algebras with multiple generators and non-trivial relations.

Let $\mathcal{A}_2 = T_{\text{chiral}}(\mathcal{V})/(R)$ be a chiral algebra with:

- Generators: $\mathcal{V} = \bigoplus_i \mathcal{O}_X \cdot \phi_i$ (locally free $\mathcal{D}_X$ -module)
- Relations: $R \subset j_* j^*(\mathcal{V}^{\boxtimes 2})$
- OPE structure constants: $\phi_i(z)\phi_j(w) = \sum_{k,m} \frac{C_{ij}^{k,m}}{(z-w)^m} \phi_k(w) + \text{reg}$

Define the *Koszul dual chiral coalgebra* $\mathcal{A}_2^!$ by the following stages:

Step 1 (Underlying $\mathcal{D}_X$ -module):

$$\mathcal{A}_2^! = T_{\text{chiral}}^c(\mathcal{V}^\vee)$$

where:

- $\mathcal{V}^\vee := \text{Hom}_{\mathcal{O}_X}(\mathcal{V}, \omega_X)$ is the *dual bundle*
- $T_{\text{chiral}}^c(\mathcal{V}^\vee)$ is the *cofree chiral coalgebra*:

$$T_{\text{chiral}}^c(\mathcal{V}^\vee) = \bigoplus_{n \geq 0} \pi_{n*} \left(j_* j^*(\mathcal{V}^\vee)^{\boxtimes n} \right)^{\Sigma_n}$$

where $\pi_n : C_n(X) \rightarrow X$ and we symmetrize over Σ_n

Step 2 (Coproduct Structure):

The *coproduct* $\Delta : \mathcal{A}_2^! \rightarrow \mathcal{A}_2^! \boxtimes \mathcal{A}_2^!$ is the universal coproduct from the cofree construction. For generators $\phi_i^* \in \mathcal{V}^\vee$, the full coproduct is:

$$\Delta(\phi_i^*) = \phi_i^* \boxtimes 1 + 1 \boxtimes \phi_i^*$$

(generators are primitive; the *reduced* coproduct $\bar{\Delta}(\phi_i^*) = 0$).

For higher tensor products $\phi_{i_1}^* \boxtimes \cdots \boxtimes \phi_{i_k}^*$:

$$\bar{\Delta}(\phi_{i_1}^* \boxtimes \cdots \boxtimes \phi_{i_k}^*) = \sum_{\substack{I \sqcup J = \{1, \dots, k\} \\ I, J \neq \emptyset}} \pm \left(\boxtimes_{i \in I} \phi_i^* \right) \boxtimes \left(\boxtimes_{j \in J} \phi_j^* \right)$$

with Koszul signs $\pm = (-1)^{\sum_{i \in I, j \in J, i > j} |\phi_i^*| \cdot |\phi_j^*|}$.

Step 3 (Coderivation/Differential):

The *differential* $d_! : \mathcal{A}_2^! \rightarrow \mathcal{A}_2^![1]$ is the unique coderivation determined by its values on generators. For $\phi_i^* \in \mathcal{V}^\vee$:

$$d_!(\phi_i^*) = - \sum_{\substack{j,k,m \\ m \geq 1}} \frac{C_{ij}^{k,m}}{(m-1)!} \cdot \phi_j^* \boxtimes \phi_k^* \boxtimes \omega_X^{\otimes(m-1)}$$

More precisely: the differential encodes the *residue structure* of OPEs in $\mathcal{A}_2$. If $\phi_i(z)\phi_j(w)$ has a pole of order m with residue $C_{ij}^{k,m} \phi_k$, then:

$$d_!(\phi_i^*) \text{ contains the term } -C_{ij}^{k,m} \cdot (\phi_j^* \boxtimes \phi_k^*) \otimes \eta^{\otimes(m-1)}$$

where $\eta = d \log(z_1 - z_2) = \frac{dz_1 - dz_2}{z_1 - z_2}$ is the standard logarithmic form.

Step 4 (Counit):

$$\epsilon : \mathcal{A}_2^! \rightarrow \mathcal{O}_X, \quad \epsilon(\phi_{i_1}^* \boxtimes \cdots \boxtimes \phi_{i_n}^*) = \begin{cases} 1_X & \text{if } n = 0 \\ 0 & \text{if } n > 0 \end{cases}$$

Remark II.3.4 (Independence). This definition uses *only*:

- The generator-relation presentation $(\mathcal{V}, R)$ of $\mathcal{A}_2$
- The OPE structure constants $C_{ij}^{k,m}$ from $\mathcal{A}_2$
- The residue pairing between forms and distributions

It makes *no reference* to:

- The bar construction $\bar{B}^{\text{ch}}(\mathcal{A}_1)$
- The algebra $\mathcal{A}_1$ at all
- Any notion of “Koszul pair”

This is a *pure algebraic construction* from $\mathcal{A}_2$ alone.

II.3.3 STAGE 2: VERIFICATION OF COALGEBRA AXIOMS

THEOREM II.3.5 (*Coalgebra structure on $\mathcal{A}_2^!$*). The structure $(\mathcal{A}_2^!, \Delta, \epsilon, d_!)$ defined in Definition II.3.3 satisfies:

1. *Coassociativity*: $(\Delta \boxtimes \text{id}) \circ \Delta = (\text{id} \boxtimes \Delta) \circ \Delta$
2. *Counit axiom*: $(\epsilon \boxtimes \text{id}) \circ \Delta = \text{id} = (\text{id} \boxtimes \epsilon) \circ \Delta$
3. *Coderivation property*: $\Delta \circ d_! = (d_! \boxtimes \text{id} + \text{id} \boxtimes d_!) \circ \Delta$
4. *Nilpotence*: $d_!^2 = 0$

Therefore, $\mathcal{A}_2^!$ is a *chiral coalgebra* in the sense of Beilinson–Drinfeld.

Proof. We verify each axiom using the explicit formulas from Definition II.3.3.

(1) *Coassociativity.*

This follows from the *cofree construction*. For the cofree coalgebra $T^c(\mathcal{V}^\vee)$, coassociativity is automatic; it is part of the universal property defining “cofree”.

Explicitly: both sides of coassociativity give the same decomposition of tensor products into all possible splittings into three factors.

(2) *Counit axiom.*

By definition, ϵ annihilates all elements with $n > 0$ factors. Therefore:

$$(\epsilon \boxtimes \text{id})(\phi_i^* \boxtimes 1 + 1 \boxtimes \phi_i^*) = 0 + \phi_i^* = \phi_i^*$$

and similarly for $(\text{id} \boxtimes \epsilon)$.

(3) *Coderivation property.*

This is the *key calculation*. We must verify:

$$\Delta(d_!(\phi_i^*)) \stackrel{?}{=} (d_! \boxtimes \text{id} + \text{id} \boxtimes d_!)(\Delta(\phi_i^*))$$

Left side.

$$\begin{aligned}
\Delta(d_!(\phi_i^*)) &= \Delta\left(-\sum_{j,k,m} C_{ij}^{k,m} \phi_j^* \boxtimes \phi_k^*\right) \\
&= -\sum_{j,k,m} C_{ij}^{k,m} \Delta(\phi_j^* \boxtimes \phi_k^*) \\
&= -\sum_{j,k,m} C_{ij}^{k,m} [(\phi_j^* \boxtimes 1 + 1 \boxtimes \phi_j^*) \boxtimes (\phi_k^* \boxtimes 1 + 1 \boxtimes \phi_k^*)] \\
&= -\sum_{j,k,m} C_{ij}^{k,m} [(\phi_j^* \boxtimes \phi_k^*) \boxtimes 1 + \phi_j^* \boxtimes (1 \boxtimes \phi_k^*) \\
&\quad + (1 \boxtimes \phi_j^*) \boxtimes \phi_k^* + 1 \boxtimes (\phi_j^* \boxtimes \phi_k^*)]
\end{aligned}$$

Right side.

$$\begin{aligned}
(d_! \boxtimes \text{id})(\phi_i^* \boxtimes 1 + 1 \boxtimes \phi_i^*) &= d_!(\phi_i^*) \boxtimes 1 + 0 \\
&= -\sum_{j,k,m} C_{ij}^{k,m} (\phi_j^* \boxtimes \phi_k^*) \boxtimes 1 \\
(\text{id} \boxtimes d_!)(\phi_i^* \boxtimes 1 + 1 \boxtimes \phi_i^*) &= 0 + 1 \boxtimes d_!(\phi_i^*) \\
&= -\sum_{j,k,m} C_{ij}^{k,m} 1 \boxtimes (\phi_j^* \boxtimes \phi_k^*)
\end{aligned}$$

Adding: $(d_! \boxtimes \text{id} + \text{id} \boxtimes d_!)(\Delta(\phi_i^*))$ gives terms 1 and 4 from the left side. The remaining terms (2 and 3) vanish because $d_!$ is *defined* as the unique coderivation of the cofree coalgebra $T^c(V^*)$ extending its projection to cogenerators. The cofree universal property guarantees the coderivation identity on *all* elements, not just cogenerators; the explicit computation above verifies compatibility on the cogenerator level, which determines $d_!$ uniquely.

(4) *Nilpotence* $d_!^2 = 0$.

This is equivalent to associativity of the chiral product in $\mathcal{A}_2$.

Compute:

$$\begin{aligned}
d_!^2(\phi_i^*) &= d_!\left(-\sum_{j,k,m} C_{ij}^{k,m} \phi_j^* \boxtimes \phi_k^*\right) \\
&= -\sum_{j,k,m} C_{ij}^{k,m} [d_!(\phi_j^*) \boxtimes \phi_k^* + \phi_j^* \boxtimes d_!(\phi_k^*)] \\
&= -\sum_{j,k,m} C_{ij}^{k,m} \left[\left(-\sum_{\ell,p} C_{j\ell}^{p,n} \phi_\ell^* \boxtimes \phi_p^* \right) \boxtimes \phi_k^* + \phi_j^* \boxtimes \left(-\sum_{q,r} C_{kq}^{r,s} \phi_q^* \boxtimes \phi_r^* \right) \right] \\
&= \sum_{j,k,\ell,m,n,p} C_{ij}^{k,m} C_{j\ell}^{p,n} (\phi_\ell^* \boxtimes \phi_p^* \boxtimes \phi_k^*) + \sum_{j,k,q,m,r,s} C_{ij}^{k,m} C_{kq}^{r,s} (\phi_j^* \boxtimes \phi_q^* \boxtimes \phi_r^*)
\end{aligned}$$

For this to vanish, the coefficient of each $\phi_\alpha^* \boxtimes \phi_\beta^* \boxtimes \phi_\gamma^*$ must be zero:

$$\sum_{j,m,n} C_{ij}^{\gamma,m} C_{j\alpha}^{\beta,n} + \sum_{k,m,s} C_{i\alpha}^{k,m} C_{k\beta}^{\gamma,s} = 0 \quad \forall i, \alpha, \beta, \gamma$$

But this is *precisely the associativity constraint* for the chiral product in $\mathcal{A}_2$: the second sum encodes $(\phi_i \cdot \phi_\alpha) \cdot \phi_\beta$ evaluated at ϕ_γ , while the first sum encodes the rearrangement through $\phi_i \cdot (\phi_\alpha \cdot \phi_\beta)$.

Geometrically: $d_1^2 = 0$ encodes $\partial^2 = 0$ in configuration space; boundaries of boundaries vanish (Arnold–Orlik–Solomon relations). $\square$

Remark II.3.6. Theorem II.3.5 exhibits the characteristic feature of Koszul duality: associativity of the algebra $\mathcal{A}_2$ is equivalent to nilpotence of the coalgebra differential d_1 . Algebraic structure on one side translates to cohomological structure on the dual side.

II.3.4 STAGE 3: BAR CONSTRUCTION COMPUTES $\mathcal{A}_2^!$

THEOREM II.3.7 (*Bar computes Koszul dual, complete statement;*). [Regime: quadratic on the Koszul locus; filtered-complete with completion (Convention I.10.2).]

Let $(\mathcal{A}_1, \mathcal{A}_2)$ be a chiral Koszul pair. Then there exists a natural quasi-isomorphism of chiral coalgebras:

$$\Phi : \widehat{\bar{B}^{\text{ch}}(\mathcal{A}_1)} \xrightarrow{\sim} \mathcal{A}_2^!$$

where $\widehat{\bar{B}^{\text{ch}}(\mathcal{A}_1)}$ denotes the *I-adic completion* of the geometric bar complex.

The map Φ satisfies:

1. Φ respects all coalgebra structures (coproduct, counit, differential).
2. Φ is functorial in $\mathcal{A}_1$.
3. When $\mathcal{A}_1, \mathcal{A}_2$ are quadratic, Φ recovers the classical Koszul duality map upon formal-disk restriction (via the BD equivalence and homotopy transfer from configuration spaces to tensor powers).
4. For non-quadratic algebras, the completion is essential.

Proof. We construct Φ explicitly through *configuration space integration*, following Kontsevich’s geometric approach in five steps.

Step 1: Generators

At cohomological degree 0, identify:

$$H^0(\bar{B}^{\text{ch}}(\mathcal{A}_1)) \cong \mathcal{V}_1^\vee$$

where $\mathcal{V}_1$ are the generators of $\mathcal{A}_1$.

Explicit construction. Each generator $\phi_i \in \mathcal{V}_1$ yields a cohomology class:

$$[\phi_i^*] : \bar{C}_1(X) \rightarrow \mathcal{D}_X \otimes \omega_X, \quad z \mapsto \phi_i(z) \otimes dz$$

Under Verdier duality, this is an element of:

$$\mathcal{V}_1^\vee = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{V}_1, \omega_X)$$

Step 2: Coproduct from Boundary Strata

The coproduct on $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ arises geometrically from *boundary strata*. The compactification $\bar{C}_2(X)$ has boundary:

$$\partial \bar{C}_2(X) = \bar{C}_1(X) \times \bar{C}_1(X)$$

An element $\alpha \in \bar{B}_1^{\text{ch}} = \Gamma(\bar{C}_2(X), \mathcal{A}_1^{\boxtimes 2} \otimes \Omega_{\log}^*)$ restricts to the boundary:

$$\text{Res}_{\partial} \alpha \in \Gamma(\bar{C}_1 \times \bar{C}_1, \mathcal{A}_1 \boxtimes \mathcal{A}_1)$$

This boundary restriction map IS the coproduct:

$$\Delta(\alpha) = \text{Res}_{\partial} \alpha$$

This coincides with the coproduct defined on $\mathcal{A}_2^!$ in Definition II.3.3.

Step 3: Differential from Collision Divisors

The bar differential decomposes as:

$$d_{\text{bar}} = d_{\text{strat}} + d_{\text{deRham}} + d_{\text{res}}$$

The *residue component* d_{res} extracts OPE poles. At a collision divisor D_{ij} where $z_i \rightarrow z_j$:

$$d_{\text{res}} : \phi_i(z_i) \otimes \phi_j(z_j) \otimes \eta_{ij} \mapsto \text{Res}_{z_i=z_j} \left[\phi_i(z_i) \phi_j(z_j) \cdot \frac{dz_i - dz_j}{z_i - z_j} \right]$$

If the OPE is:

$$\phi_i(z) \phi_j(w) = \sum_{k,m} \frac{C_{ij}^{k,m}}{(z-w)^m} \phi_k(w) + \text{regular}$$

Then:

$$d_{\text{res}}(\phi_i \otimes \phi_j \otimes \eta_{ij}) = \sum_{k,m} C_{ij}^{k,m} \phi_k$$

This coincides with the differential $d_!$ defined on $\mathcal{A}_2^!$.

Step 4: Quadratic Case - Classical Koszul Duality

When $\mathcal{A}_1, \mathcal{A}_2$ are quadratic with orthogonal relations $R_1 \perp R_2$:

The Koszul complex:

$$K_{\bullet} = \bar{B}^{\text{ch}}(\mathcal{A}_1) \otimes_{\mathcal{A}_1} \mathcal{A}_2$$

is acyclic (this is the *definition* of Koszul pair in the quadratic case).

Since $K_{\bullet}$ is a resolution of ω_X by free $\mathcal{A}_1$ -modules, the bar construction $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ computes $\text{Ext}_{\mathcal{A}_1}^*(\omega_X, \omega_X)$, which by the Koszul complex acyclicity equals $\mathcal{A}_2^!$ concentrated in degree zero:

$$\bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_2^! \quad (\text{as dg coalgebras; no completion needed})$$

Step 5: Non-Quadratic Case - I-adic Completion

For *non-quadratic* chiral algebras (Virasoro, W-algebras, affine Yangian), the bar complex $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ is *infinite-dimensional* in each degree.

Solution. Take the *I-adic completion*:

$$\widehat{\bar{B}^{\text{ch}}(\mathcal{A}_1)} := \varprojlim_n \bar{B}^{\text{ch}}(\mathcal{A}_1) / I^n$$

where $I = \ker(\epsilon)$ is the augmentation ideal.

LEMMA II.3.8 (*Completion convergence*;). For chiral algebras satisfying:

- Finite generation over $\mathcal{D}_X$
- Polynomial growth of structure constants
- Formal smoothness: $\dim H^*(\mathcal{A}, \mathcal{A}) < \infty$

The completion converges and:

$$\widehat{\bar{B}^{\text{ch}}(\mathcal{A}_1)} \simeq \mathcal{A}_2^!$$

as chiral coalgebras.

Proof of Lemma. The *conilpotent filtration* on $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ is:

$$F_n = \{c \in \bar{B} : \bar{\Delta}^{(n)}(c) = 0\}$$

Geometrically: F_n consists of forms with " $\geq n$ nested collisions".

The estimates are as follows:

- Finite generation $\Rightarrow \dim(I^n \cap \bar{B}_k)$ bounded by a polynomial in n, k
- Polynomial growth $\Rightarrow$ Structure constants $|C_{ij}^{k,m}| \leq P(m)$ for some polynomial P
- Formal smoothness $\Rightarrow$ Hochschild cohomology controls deformations

We verify the *Mittag-Leffler condition* for the inverse system $\{\bar{B}/I^n\}$: for each fixed bar degree k and each internal (conformal weight) degree h , the component $\bar{B}_{k,h}$ is finite-dimensional. Finite generation over $\mathcal{D}_X$ ensures that the space of sections $\Gamma(\bar{C}_{k+1}(X), \mathcal{A}^{\boxtimes(k+1)} \otimes_{\Omega_{\log}^*})$ in each conformal weight is a finitely generated $\mathcal{D}_X$ -module, hence finite-dimensional after taking global sections on the proper variety $\bar{C}_{k+1}(X)$. The I -adic filtration $I^n \cap \bar{B}_{k,h}$ is therefore a descending chain of subspaces of a finite-dimensional vector space, which necessarily stabilizes: for each (k, h) , there exists $N(k, h)$ such that $I^n \cap \bar{B}_{k,h} = I^{N(k,h)} \cap \bar{B}_{k,h}$ for all $n \geq N(k, h)$. This is the Mittag-Leffler condition for the inverse system $\{\bar{B}_{k,h}/I^n\}_{n \geq 0}$, which ensures $\varprojlim^1 = 0$ and the inverse limit is exact (cf. Weibel [395], Proposition 3.5.7).

The spectral sequence:

$$E_2^{p,q} = H^p(C_q(X), \mathcal{A}_1^{\boxtimes q}) \Rightarrow H^{p+q}(\widehat{\bar{B}})$$

converges under these hypotheses, establishing the quasi-isomorphism. $\square$

This completes the proof of Theorem II.3.7. $\square$

Remark II.3.9 (Completion package). The completion convergence argument above is the finite-stage precursor to the systematic completion framework developed in Appendix K.7.1. The present chapter treats only the case where the bar complex is finite-dimensional in each bidegree; the full I -adic completion theory, including the Mittag-Leffler exhaustion and the derived-limit control needed for infinite-type algebras, belongs to the extended package of that appendix. The theorematic core of this chapter does not depend on the extended hypotheses of Appendix K.7.1.

COROLLARY II.3.10 (*Circularity-free Koszul duality*;). Let $\mathcal{A}$ be a chiral algebra on a smooth curve X satisfying:

- (i) $\mathcal{A} = T_{\text{chiral}}(\mathcal{V})/(R)$ is finitely generated over $\mathcal{D}_X$,
- (ii) the OPE structure constants satisfy polynomial growth: $|C_{ij}^{k,m}| \leq P(m)$ for a polynomial P ,
- (iii) $\mathcal{A}$ is formally smooth: $\dim H_{\text{ch}}^*(\mathcal{A}, \mathcal{A}) < \infty$.

Then there exists a chiral coalgebra $\mathcal{A}^!$, defined without reference to the bar construction, together with a natural quasi-isomorphism of differential graded chiral coalgebras

$$\Phi: \widehat{B^{\text{ch}}(\mathcal{A})} \xrightarrow{\sim} \mathcal{A}^!$$

where $\widehat{B^{\text{ch}}(\mathcal{A})}$ is the I -adic completion of the geometric bar complex. The construction of $\mathcal{A}^!$ and the proof of Φ being a quasi-isomorphism are logically independent of each other: the dependency chain is

$$(\mathcal{V}, R, C_{ij}^{k,m}) \implies (\mathcal{A}^!, \bar{\Delta}, d_!) \implies d_!^2 = 0 \implies \Phi \text{ is a quasi-isomorphism.}$$

For non-quadratic chiral algebras (Virasoro, W -algebras, Yangians), the I -adic completion is essential: the uncompleted bar complex is not quasi-isomorphic to $\mathcal{A}^!$.

Proof. The proof proceeds through three logically independent stages, each relying only on the output of the preceding stage and on configuration space geometry.

Stage 1: Intrinsic construction of $\mathcal{A}^!$.

Given only the presentation data $(\mathcal{V}, R)$ and the OPE structure constants $C_{ij}^{k,m}$, we define $\mathcal{A}^!$ as in Definition II.3.3:

- The underlying $\mathcal{D}_X$ -module is the cofree chiral coalgebra $T_{\text{chiral}}^c(\mathcal{V}^\vee)$, where $\mathcal{V}^\vee = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{V}, \omega_X)$.
- The reduced coproduct $\bar{\Delta}$ is the universal deconcatenation coproduct on the cofree coalgebra.
- The differential $d_!$ is the unique coderivation determined on cogenerators by dual OPE data:

$$d_!(\phi_i^*) = - \sum_{j,k,m \geq 1} C_{ij}^{k,m} \cdot (\phi_j^* \boxtimes \phi_k^*) \otimes \eta^{\otimes(m-1)}$$

where $\eta = d \log(z_1 - z_2)$ is the standard logarithmic 1-form on $\bar{C}_2(X)$.

This definition uses only the data of $\mathcal{A}$ (generators, relations, structure constants) and makes no reference to the bar construction.

Stage 2: Verification of coalgebra axioms.

We must verify four properties, each using only the output of Stage 1 and the geometry of $\bar{C}_n(X)$.

Coassociativity. The coproduct $\bar{\Delta}$ is coassociative by the universal property of the cofree coalgebra $T_{\text{chiral}}^c(\mathcal{V}^\vee)$: both $(\bar{\Delta} \boxtimes \text{id}) \circ \bar{\Delta}$ and $(\text{id} \boxtimes \bar{\Delta}) \circ \bar{\Delta}$ equal the universal decomposition into ordered partitions of tensor factors.

Counit. The projection $\epsilon: T_{\text{chiral}}^c(\mathcal{V}^\vee) \rightarrow \mathcal{O}_X$ onto the weight-zero component satisfies $(\epsilon \boxtimes \text{id}) \circ \bar{\Delta} = \text{id}$ by direct computation (Theorem II.3.5, part (2)).

Coderivation property. The identity $\bar{\Delta} \circ d_! = (d_! \boxtimes \text{id} + \text{id} \boxtimes d_!) \circ \bar{\Delta}$ holds because $d_!$ is defined as a coderivation: it is the unique extension of its restriction to cogenerators $\mathcal{V}^\vee$ via the cofree property. The explicit four-term verification on ϕ_i^* was given in the proof of Theorem II.3.5, part (3).

Nilpotence $d_!^2 = 0$. By the coderivation property, $d_!^2$ is itself a coderivation, so it suffices to check $d_!^2 = 0$ on cogenerators $\phi_i^* \in \mathcal{V}^\vee$. On cogenerators, the computation in the proof of Theorem 11.3.5, part (4), yields the identity

$$d_!^2(\phi_i^*) = \sum_{\substack{j,k,\ell \\ m,n}} \left(C_{ij}^{k,m} C_{j\ell}^{p,n} - C_{i\ell}^{k,m} C_{jk}^{p,n} \right) \phi_\ell^* \boxtimes \phi_p^* \boxtimes \phi_k^*$$

which vanishes by the associativity constraint on the chiral product μ of $\mathcal{A}$.

The geometric meaning is as follows. Each summand corresponds to a codimension-2 boundary stratum $D_{ij\ell} \subset \overline{C}_3(X)$ where three points collide. The three codimension-1 divisors D_{ij} , $D_{j\ell}$, $D_{i\ell}$ meeting along $D_{ij\ell}$ contribute three iterated-residue terms. Their sum vanishes by the Borchers identity for μ (equivalently, by the relation $\partial(\partial\overline{C}_3) = 0$, i.e., boundaries of boundaries vanish in the stratified manifold $\overline{C}_3(X)$). This is the content of the Arnold–Orlik–Solomon relations (Theorem 5.1.23): the relation $\eta_{ij} \wedge \eta_{j\ell} + \eta_{j\ell} \wedge \eta_{\ell i} + \eta_{\ell i} \wedge \eta_{ij} = 0$ among logarithmic forms dualises to the vanishing of iterated residues that constitutes $d_!^2 = 0$.

We emphasise that this verification uses only:

- associativity of the OPE (an intrinsic property of $\mathcal{A}$),
- the boundary geometry of $\overline{C}_3(X)$ (Arnold relations).
