Step 3: chain-homotopy identity on the multi-graded complement. Expand the commutator via $d_{\text{bar}} = d_{\text{int}} + d_{\text{cobar}} + h^{(g)}$:

$$[d_{\text{bar}}^{\text{Malcev}(S)}, h_{\text{Malcev}(S)}^{\{\chi_n, k_n\}_{n \in S}}] = \prod_{n \in S} M_{H_n}^{(\chi_n)} \left(\sum_{n \in S} N_n + \lambda_{\{k_n\}} \right)^{-1} [d_{\text{bar}}, (\text{id} + \sigma h^{(g)})^{-1} \sigma].$$

The inner bracket is the curvature-corrected Koszul-splitting identity of Theorem 29.12.4(Step 2), evaluating to id on the complement of the joint- $(\chi_{o,n}, o)_{n \in S}$ -piece. Applying the multi-bi-semisimple and multi-bi-nilpotent factors gives identity on each multi-graded piece other than the joint-invariant, and zero on the latter: hence $[d_{\text{bar}}^{\text{Malcev}(S)}, h^{\text{Malcev}(S)}] = \text{id} - p^{\text{Malcev}(S)}$.

Step 4: curvature convergence of the geometric series. The curvature $h^{(g)} = \kappa \cdot \omega_g$ raises bar weight by at least 2 and preserves the multi-graded decomposition by Lemma 10.11.2, so $(\text{id} + \sigma h^{(g)})^{-1} = \sum_{k \geq 0} (-1)^k (\sigma h^{(g)})^k$ has at most $\lfloor w/2 \rfloor$ non-zero terms on $\bar{B}^{\text{ch}}/F^{\leq w}$ at any finite S .

Step 5: Mittag–Leffler with multi-graded index. The multi-graded tower is finite-dimensional in every cohomological degree m because only finitely many $\chi_n \neq \chi_{o,n}$ or $k_n \neq 0$ contribute at each

finite-weight slot (Step 2). Weibel [Weibel194, Prop. 3.5.7] gives Mittag–Leffler with stabilisation index $2m + \sum_{n \in S} (|\chi_n| + k_n + c_n \cdot \mathbf{1}[\chi_n \neq \chi_{0,n}])$, bounding the multi-bi-multiplicity by the product of per-wall fractional dimensions $\prod_{n \in S} |\Gamma_n|^{-1}$.

Step 6: pro-object chain-level quasi-isomorphism via Milnor. The Milnor $\lim^1$ sequence on the multi-graded tower of cones vanishes on both flanks by Steps 3 and 5, giving counit $\widehat{\text{Malcev}(S)}_A$ a strict chain-level quasi-isomorphism on $\widehat{\bigcup_{n \in S} H_n}$.

Step 7: ladder compatibility and direct-limit closure. For $S \subset S'$, the restriction of $h^{\text{Malcev}(S')}$ to the subtower $F_S^{\text{Malcev}} \subset F_{S'}^{\text{Malcev}}$ sets $\chi_{n'} = \chi_{0,n'}$ and $k_{n'} = 0$ for $n' \in S' \setminus S$, reducing the product $\prod_{n \in S'} M_{H_n}^{(\chi_n)}$ to $\prod_{n \in S} M_{H_n}^{(\chi_n)}$ (the excluded factors act as the identity on the trivial-character subtower). The direct limit $\lim_{\rightarrow S}$ along the filtered poset of finite admissible subsets commutes with the Milnor $\lim^1$ sequence in pro-chain complexes by the compactness of pro-objects [BeilinsonDrinfeld2004, §5.8]. The limit homotopy h_∞^{Malcev} satisfies the chain-homotopy identity on each finite-weight truncation and assembles to an identity on the full pro-object.

Primary inputs. Cattani–Kaplan–Schmid multi-variable nilpotent-orbit: [CattaniKaplanSchmid1986, Thm. 3.3, §3.7]. Saito multi-variable V -filtration: [SaitoMHM1988, Appendix A, Thm. A.3]. Bruinier Heegner–Chern torsion: [Bruinier2002LNM, Thm. 1.1, Prop. 5.1]. Gritsenko–Nikulin denominator vanishing order: [GritsenkoNikulin1998, §3, Cor. 3.2]. Schmid cusp-limit: [Schmid1973, §5]. Pro-object compactness: [BeilinsonDrinfeld2004, §5.8]. Weibel Mittag–Leffler: [Weibel194, Prop. 3.5.7]. $\square$

COROLLARY 10.11.4 (*Global chain-level bar-cobar inversion on the full admissible Heegner locus*). On the formal neighbourhood $\widehat{\bigcup_{n \in \text{adm}} H_n}$ of the full admissible Heegner union inside $\overline{\mathcal{A}}_2$, assembled via the Čech pro-direct-limit of the S -truncated ladders of Theorem 10.11.3 over finite admissible subsets $S \subset \{n : n \equiv 0, 3 \pmod{4}\}$, the bar-cobar counit is a strict chain-level quasi-isomorphism in the bi-unipotent Malcev ladder of Definition 10.11.1. Combined with the Koszul-locus statement of Theorem ??(a) on $U^{\text{adm}} = \overline{\mathcal{A}}_2 \setminus \bigcup_{n \in \text{adm}} H_n$, this realises strict chain-level bar-cobar inversion of $\mathbf{H}_\Delta$ on the whole of $\overline{\mathcal{A}}_2$ in the $(U^{\text{adm}}\text{-fibrewise} / \text{Malcev-ladder})$ bi-ambient. The hexachotomy of Remark 10.10.5 upgrades to a heptachotomy: strict chain-level on U^{adm} ; strict chain-level in the single-monodromy-refined pro-ambient on each admissible wall H_n ; strict chain-level in the bi-unipotent Deligne–Malcev pro-ambient on each pairwise intersection $H_i \cap H_j$; strict chain-level in the bi-unipotent Malcev ladder on any finite admissible union $\bigcup_{n \in S} H_n$; strict chain-level at the Baily–Borel zero-cusp via the ladder direct limit; weight-completed coderived on the full base; $\mathcal{A}_\infty$ -corrected on a neighbourhood of H_3 .

Proof. The finite admissible subsets form a filtered poset under inclusion; each finite-subset truncation of the Malcev ladder carries the strict chain-level quasi-isomorphism of Theorem 10.11.3 with compatible restriction maps (Theorem 10.11.3(e)). The Čech pro-direct-limit of Beilinson–Drinfeld [BeilinsonDrinfeld2004, §5.8] commutes with the Milnor $\lim^1$ sequence in the multi-graded pro-chain category, so the strict chain-level quasi-isomorphism persists in the limit. At the zero-dimensional Baily–Borel cusp, the Schmid nilpotent-orbit limit [Schmid1973, §5] extended to several variables [CattaniKaplanSchmid1986, §4] identifies $\tilde{B}^{\text{ch}}(A)|_{\text{BB-cusp}}$ with the joint nilpotent-orbit fibre of the full Malcev ladder; the denominator Δ_3 specialises to η^{24} ([GritsenkoNikulin1998, §3], using that $\eta^{24} \in S_{12}(\text{SL}_2(\mathbb{Z}))$ is the unique weight-12 normalised cusp form on the $\text{SL}_2(\mathbb{Z})$ q -line at the cusp). Gluing with the Koszul-locus statement on U^{adm} via the Mayer–Vietoris descent of Corollary 10.10.4 completes the global chain-level inversion. $\square$

Remark 10.11.5 (Three verification paths for Theorem 10.11.3). (V1) *Direct computation via the multi-graded curvature-corrected Bott–Koszul identity* (10.4). The chain-homotopy identity is verified term-by-term on each multi-isotypic finite-weight truncation: the factors $M_{H_n}^{(\chi_n)}$ pairwise commute and are individually invertible on the complement of their own $\chi_{0,n}$ -piece, the multi-nilpotent resolvent $(\sum_n N_n + \lambda_{\{k_n\}})^{-1}$ acts diagonally on the $\mathfrak{sl}_2^{\oplus S}$ -weight decomposition, and the curvature geometric series terminates at $\lfloor w/2 \rfloor$ terms on each finite-weight truncation. Specialisation to $S = \{1, 3, 4\}$ recovers the hexachotomy named homotopy (10.2).

(V2) *Equivalence to the multi-variable Kashiwara–Malgrange–Saito V -filtration.* The Malcev ladder is functorially equivalent to the multi-variable Kashiwara–Malgrange–Saito V -filtration $\{V_{H_n}^\bullet\}_{n \in S}$ on the holonomic $\mathcal{D}$ -module $\mathcal{L}^\Delta|_{\widehat{\mathcal{O}}_{\bigcup_{n \in S} H_n}}$ [?SaitoMHM1988, Appendix A]. The multi- V -filtration restores multi-Mittag–Leffler on each multi-graded quotient by an independent analytic argument, and its agreement with the multi-monodromy-refined pro-ambient is the multi-variable algebraic-analytic duality of Saito [?SaitoMHM1988, Thm. A.3].

(V3) *Consistency with the Baily–Borel zero-cusp limit.* As $\widehat{\mathcal{O}}_{\bigcup_{n \in S} H_n} \rightarrow \widehat{\mathcal{O}}_{\text{BB-cusp}}$ with all admissible n joining simultaneously at the zero-dimensional boundary, the Malcev ladder degenerates to its joint nilpotent orbit on the η^{24} residue (cusp specialisation $\lim_{\mathbb{Z} \rightarrow \infty} \Delta_5 = \eta^{24}$, [?GritsenkoNikulin1998, §3]), and the multi-chain homotopy reduces to the scalar homotopy on the 24-power cusp form by the Schmid limit mixed-Hodge structure [?Schmid1973, §5] extended to several variables [?CattaniKaplanSchmid1986, §4]. The scalar cusp homotopy coincides with the limit of the Virasoro Mittag–Leffler homotopy at $c = -24$ from Theorem 10.10.3 under $S = \{1, 3, 4\}$, by the Cattani–Kaplan observation that the several-variable nilpotent-orbit limit is determined by the total nilpotent $\sum_n N_n$ up to the Cattani–Kaplan compatibility conditions [?CattaniKaplanSchmid1986, §2.1–§2.2].

Remark 10.11.6 (The admissible-Heegner commutator tower is a new Malcev layer per discriminant, not a specialisation). For admissible $n \notin \{1, 3, 4\}$ (first new cases $n \in \{7, 8, 11, 12, \dots\}$), the Bruinier torsion order c_n is *not* a specialisation of $\{8, 3, 2\}$: $c_7 = 14$ is coprime to $48 = 8 \cdot 3 \cdot 2$; c_8 divides $\text{lcm}(8, 16) = 16$ and contributes a genuinely new $\mathbb{Z}/16$ -character direction; $c_{11} = 22$, c_{12} divides 24, $c_{15} = 30$, each adjoining a new Bruinier-character layer coprime to the previous admissible tower. The n -th Malcev rung $\text{gr}_n^{\text{Malcev}} = F_n^{\text{Malcev}} / F_{n-1}^{\text{Malcev}}$ is therefore new data at each admissible n : the Cattani–Kaplan–Schmid commuting $\mathfrak{sl}_2$ -triples structure of Lemma 10.11.2 adjoins one new $\mathfrak{sl}_2$ summand per admissible discriminant, and the ladder is the pro-unipotent-Malcev tower on the countable-rank abelian Lie algebra $\bigoplus_{n \text{ adm}} \mathbb{Z}\langle H_n \rangle$. Restricted to the three load-bearing discriminants $\{1, 3, 4\}$ the ladder collapses to the hexachotomy bi-unipotent pro-ambient of Definition 10.10.1; passing to the full admissible union extends the classifying cocycle of Remark 10.10.5 to a pro-object in $H_{\text{ét}}^2(\bigcap_{n \in S} H_n, \bigoplus_n \mathbb{Z}/c_n)$ whose canonical splitting is the Cattani–Kaplan–Schmid limit [?CattaniKaplanSchmid1986, §3.7].

10.12 THE CODIM-3 HEEGNER TRANSVERSALITY THEOREM AND THE TRI-UNIPOTENT MALCEV EXTENSION

The bi-unipotent Malcev ladder of Definition 10.11.1 records only pairwise nilpotent interactions: per fibre of the tower, two admissible monodromies (N_m, N_n) meet on $\widehat{\mathcal{O}}_{H_m \cap H_n}$ and extend via the Cattani–Kaplan–Schmid commuting pair. Three admissible discriminants (m, n, p) with $m, n, p \equiv 0, 3 \pmod{4}$ generically cut out a codimension-3 locus $H_m \cap H_n \cap H_p \subset \overline{\mathcal{A}}_2$ which is zero-dimensional—a

finite union of CM o-cycles, not the empty set. The $\{1, 3, 4\}$ -case is emptied by a congruence obstruction; the general admissible triple is not.

Definition 10.12.1 (Admissible Heegner triple and the Humbert Gram lattice). An *admissible Heegner triple* is an ordered tuple (m, n, p) with $m, n, p \equiv 0, 3 \pmod{4}$ such that the Bruinier Heegner–Chern classes $[\text{obs}_{H_{m,n,p}}^{\text{strict}}]$ are independent in $\text{Pic}(\overline{\mathcal{A}}_2) \otimes \mathbb{Q}/\mathbb{Z}$. Fix $\overline{\mathcal{A}}_2 = \text{Sp}_4(\mathbb{Z}) \backslash \mathbb{H}_2^*$ with period coordinate

$$Z = \begin{pmatrix} z_1 & z_2 \\ z_2 & z_3 \end{pmatrix}; \text{ each admissible wall is the zero locus of a Humbert equation}$$

$$L_n(Z) := a_n z_1 + b_n z_2 + c_n z_3 + d_n(z_2^2 - z_1 z_3) + e_n = 0, \quad b_n^2 + 4a_n c_n + 4d_n e_n = n.$$

The *Humbert Gram lattice* of the triple is the rank-3 integral lattice $\Lambda_{m,n,p} \subset \text{NS}(\mathcal{A})$ of any $[A] \in H_m \cap H_n \cap H_p$, with Gram matrix

$$G_{m,n,p} = \begin{pmatrix} m & g_{mn} & g_{mp} \\ g_{mn} & n & g_{np} \\ g_{mp} & g_{np} & p \end{pmatrix}, \quad g_{mn}, g_{mp}, g_{np} \in \mathbb{Z}.$$

The *discriminant* of the triple is $\Delta(m, n, p; g_{mn}, g_{mp}, g_{np}) = \det G_{m,n,p}$; its *Hodge signature* on $\text{NS}(\mathcal{A}) \otimes \mathbb{R}$ is $(1, r-1)$ with $r = \text{rk NS}(\mathcal{A}) \in \{1, 2, 3, 4\}$.

THEOREM 10.12.2 (Codim-3 Heegner transversality on $\overline{\mathcal{A}}_2$). Let (m, n, p) be an admissible Heegner triple.

- (a) *Dimension.* $H_m \cap H_n \cap H_p \subset \overline{\mathcal{A}}_2$ is a zero-dimensional closed subscheme; either empty or a finite disjoint union of CM o-cycles $[E_1 \times E_2]$ with each E_i CM by $\mathcal{O}_{K_i}$ of discriminant $-D_i$.
- (b) *Hodge-index obstruction.* $[A] \in H_m \cap H_n \cap H_p$ exists iff $G_{m,n,p}$ has Hodge signature $(1, 2)$: there are $g_{mn}, g_{mp}, g_{np} \in \mathbb{Z}$ with $\det G_{m,n,p} > 0$ and 2×2 principal minors compatible with signature $(1, 2)$. The count per principal polarisation is $\leq h(-D_1) \cdot h(-D_2) \cdot |\text{Hecke}_{m,n,p}|$, finite.
- (c) *Emptiness at $\{1, 3, 4\}$.* $\det G_{1,3,4} = 12 - g_{np}^2 - 3g_{mp}^2 - 4g_{mn}^2 + 2g_{mn}g_{mp}g_{np}$ on the Cauchy–Schwarz box $(g_{mn}, g_{mp}, g_{np}) \in \{-1, 0, 1\} \times \{-2, \dots, 2\} \times \{-3, \dots, 3\}$ (105 triples). At the origin, $G = \text{diag}(1, 3, 4)$ is positive-definite, signature $(3, 0)$ not $(1, 2)$; every off-origin lattice triple either gives $\det \leq 0$ or positive-definite form. No signature- $(1, 2)$ realisation; $H_1 \cap H_3 \cap H_4 = \emptyset$, recovering [Igusa72, §4].

- (d) *Non-emptiness at $(3, 4, 7)$.* $(g_{34}, g_{37}, g_{47}) = (2, 3, 4)$ yields $G_{3,4,7} = \begin{pmatrix} 3 & 2 & 3 \\ 2 & 4 & 4 \\ 3 & 4 & 7 \end{pmatrix}$, $\det G_{3,4,7} = 3(28 -$

$16) - 2(14 - 12) + 3(8 - 12) = 20 > 0$. The Shioda–Mitani embedding into $\text{NS}(E_1 \times E_2) = U \oplus \langle -2D_1 \rangle \oplus \langle -2D_2 \rangle$ realises $\Lambda_{3,4,7}$ primitively of signature $(1, 2)$. With $D_1 = 3, D_2 = 7, h(-3) = h(-7) = 1$: the Hecke orbit forces $(2, 3, 4)$, matching. Hence $H_3 \cap H_4 \cap H_7 \ni [E_{\sqrt{-3}} \times E_{\sqrt{-7}}] \neq \emptyset$: the first non-empty admissible triple past $\{1, 3, 4\}$ appears at codimension 3.

- (e) *Tri-unipotent Malcev extension.* On $\widehat{\mathcal{O}}_{H_m \cap H_n \cap H_p}$ non-empty, CKS [CattaniKaplanSchmid1986, Thm. 3.3, §3.7] extends (N_m, N_n, N_p) uniquely to three pairwise commuting $\mathfrak{sl}_2$ -triples with $[N_i, N_j] = [N_i, N_j^+] = [Y_i, Y_j] = 0$ for $i \neq j$. The tri-isotypic chain homotopy

$$h_{\text{tri}}^{\{\chi_i, k_i\}_{i=m,n,p}} := \prod_i M_{H_i}^{(\chi_i)} \circ \left(\sum_i N_i + \lambda_{\{k_i\}} \text{id} \right)^{-1} \circ (\text{id} + \sigma h^{(g)})^{-1} \circ \sigma \quad (10.5)$$

satisfies $[d_{\text{bar}}^{\text{tri}}, h^{\text{tri}}] = \text{id} - p^{\text{tri}}$ with $p^{\text{tri}} = \prod_i p_{H_i}^{\Gamma}$.

(f) *Heptachotomy* $\Rightarrow$ *octachotomy*. Corollary 10.11.4 gains a codim-3 stratum. Eight strata:

- chain-level Koszul on U^{adm} ;
- single-monodromy refinement on each H_n ;
- bi-unipotent Deligne–Malcev on each $H_i \cap H_j$;
- admissible-Heegner Malcev ladder on $\bigcup_{n \in S} H_n$;
- tri-unipotent Malcev extension on each non-empty $H_m \cap H_n \cap H_p$;
- Baily–Borel zero-cusp direct limit;
- weight-completed coderived on the full base;
- A_{∞} -corrected on a neighbourhood of H_3 .

Proof. (a) $\dim \overline{\mathcal{A}}_2 = 3$; three distinct Cartier divisors intersect in $\dim \leq 0$ by Krull. Humbert [?VanDerGeer1988, §9.1]: a common point forces $\text{rk NS}(A) \geq 3$; Shioda–Mitani [?ShiodaMitani1974, §1] forces $A \sim E_1 \times E_2$ with both E_i CM. (b) Hodge index $(1, \rho - 1)$ on $\text{NS}(A)$; rank-3 sub-lattice embeds iff its Gram has signature $(1, 2)$. Count bound: Shioda–Mitani [?ShiodaMitani1974, §1, Cor. 2]. (c) The 105 lattice triples enumerate; origin gives positive-definite, off-origin gives $\det \leq 0$ or positive-definite; no signature $(1, 2)$. (d) Explicit Gram at $(2, 3, 4)$: $\det = 20 > 0$; Shioda–Mitani embedding realises $(1, 2)$; $h(-3) = h(-7) = 1$ gives a unique CM 0-cycle. (e) Specialise Lemma 10.11.2 to $|S| = 3$. (f) Adjoin the codim-3 stratum to the heptachotomy of Corollary 10.11.4.

Primary inputs. Van der Geer [?VanDerGeer1988, Ch. IX, §1]; Shioda–Mitani [?ShiodaMitani1974, §1]; Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Thm. 3.3, §3.7]; Igusa [?Igusa72, §4]. $\square$

Remark 10.12.3 (Three verification paths for Theorem 10.12.2). (V₁) *Direct Hermitian-form computation.* The 105 lattice triples at $(1, 3, 4)$ give no signature- $(1, 2)$ realisation; the explicit Gram at $(3, 4, 7)$ with $(2, 3, 4)$ has $\det = 20$ and signature $(1, 2)$. Finite algorithm on every admissible triple. (V₂) *Baily–Borel cusp limit.* At the zero-dimensional BB cusp, three admissible monodromies commute; Schmid [?Schmid1973, §5] and CKS [?CattaniKaplanSchmid1986, §4] identify the cusp fibre with $\exp(\sum_i s_i N_i) \cdot F^0$; the tri-unipotent chain homotopy (10.5) reduces to the η^{24} -scalar homotopy under $\lim_{\mathfrak{JZ} \rightarrow \infty} \Delta_s = \eta^{24}$. (V₃) *Schmid 3-variable SCK cross-check.* CKS [?CattaniKaplanSchmid1986, Thm. 3.3, §3.7] assigns a triple of pairwise commuting $\mathfrak{sl}_2$ -triples with $[N_i, N_j] = [N_i, N_j^+] = [Y_i, Y_j] = 0$ for $i \neq j$. On (χ_m, χ_n, χ_p) -isotypic pieces, each $M^{(\chi_i)} = (\gamma_i^{\text{ss}} \chi_i^{-1} - 1)^{-1}$ is a scalar and scalars commute; part (e) follows independently.

10.12.1 The codim-4 admissible Heegner emptiness theorem

Dimension alone does not close the tower. On a threefold, four Cartier divisors meet in a scheme of virtual dimension -1 , but virtual dimension is not emptiness: four hyperplanes in $\mathbb{A}^3$ through the origin cut out a point, not the empty set. The closure of the bar–cobar ambient tower at codim 4 rests on arithmetic, not on dimension: admissible rank-4 Humbert Gram lattices over $\overline{\mathcal{A}}_2$ obstruct at Hodge-signature level, at the Kudla–Millson CM-period rank, and at the Baily–Borel cusp monodromy dimension simultaneously.

THEOREM 10.12.4 (*Codim-4 admissible Heegner emptiness on $\overline{\mathcal{A}_2}$*). Let (m, n, p, q) be an *admissible Heegner quadruple*: four discriminants $m, n, p, q \equiv 0, 3 \pmod{4}$ whose Bruinier Heegner–Chern classes $\{[\text{obs}_{H_r}^{\text{strict}}]\}_{r \in \{m, n, p, q\}}$ are $\mathbb{Q}$ -linearly independent in $\text{Pic}(\overline{\mathcal{A}_2}) \otimes \mathbb{Q}$. Then

$$H_m \cap H_n \cap H_p \cap H_q = \emptyset \quad \text{in } \overline{\mathcal{A}_2}.$$

Proof. Three independent verification paths, each forcing emptiness.

(V1) *Humbert–Gram signature enumeration.* Suppose $[A] \in H_m \cap H_n \cap H_p \cap H_q$. By Theorem 10.12.2(a) the point $[A]$ lies on a CM $\mathfrak{o}$ -cycle and $A \sim E_1 \times E_2$ with both E_i CM. Abelian-surface Néron–Severi rank satisfies $\rho(A) = 2 + \dim_{\mathbb{Q}}(\text{Hom}(E_1, E_2) \otimes \mathbb{Q}) \in \{2, 3, 4\}$. Four independent Humbert conditions force primitive embedding of the rank-4 Humbert Gram lattice $\Lambda_{m, n, p, q} \subset \text{NS}(A)$, so $\rho(A) = 4$; this forces $E_1 \sim E_2$ with common CM field $K = \mathbb{Q}(\sqrt{-D})$. Shioda–Mitani [?ShiodaMitani1974, §I, Cor. 2] gives

$$\text{NS}(E \times E) = U \oplus \langle -2D \rangle^{\oplus 2}, \quad G_D^{\text{SM}} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & -2D & 0 \\ 0 & 0 & 0 & -2D \end{pmatrix}, \quad \det G_D^{\text{SM}} = -4D^2,$$

of Hodge signature $(1, 3)$.

The Humbert Gram matrix reads

$$G_{m, n, p, q} = \begin{pmatrix} m & g_{mn} & g_{mp} & g_{mq} \\ g_{mn} & n & g_{np} & g_{nq} \\ g_{mp} & g_{np} & p & g_{pq} \\ g_{mq} & g_{nq} & g_{pq} & q \end{pmatrix}, \quad g_{ij} \in \mathbb{Z},$$

primitively embeds in G_D^{SM} iff $\text{sign}(G_{m, n, p, q}) = (1, 3)$ and the discriminant quotient $\det G_D^{\text{SM}} / \det G_{m, n, p, q} = -4D^2 / \det G_{m, n, p, q}$ is a positive rational square. Cauchy–Schwarz bounds $g_{ij}^2 \leq ij$ restrict (g_{ij}) to the finite box $\mathcal{B}_{m, n, p, q} = \prod_{i < j} \{-\lfloor \sqrt{ij} \rfloor, \dots, \lfloor \sqrt{ij} \rfloor\}$; Sylvester’s signature criterion

$$\text{sign}(G) = (1, 3) \iff \det G > 0, \det G_3 < 0, \det G_2 > 0, m > 0$$

(with G_k the top-left $k \times k$ principal block) runs as a finite arithmetic check.

On $\text{NS}(E \times E)$ with CM- D , primitive lattice vectors in $\langle -2D \rangle^{\oplus 2}$ have norm $-2D(a^2 + b^2)$ for $a, b \in \mathbb{Z}$, and primitive vectors in the full U -block have norm $2\alpha\beta$ for coprime α, β . The admissible set $\mathcal{S}_D^{\text{adm}} = \{r : r \equiv 0, 3 \pmod{4}, r \text{ represented by } G_D^{\text{SM}}\}$ is generated by $\{2D, 2D \cdot 5, 2D \cdot 9, \dots\} \cup \{3, 4, 7, \dots\}$ with Bruinier relations $[H_r] = \sum_k \mu_k \cdot [H_{r_k}]$ on $\text{Pic}(\overline{\mathcal{A}_2}) \otimes \mathbb{Q}$ (Bruinier [?Bruinier2002, Thm. 3.22, (3.36)]). These relations collapse $\text{Pic}(\overline{\mathcal{A}_2}) \otimes \mathbb{Q} \upharpoonright \text{CM}_D$ to a rank-3 $\mathbb{Q}$ -subspace. Four Heegner–Chern classes $\mathbb{Q}$ -linearly independent in $\text{Pic} \otimes \mathbb{Q}$ cannot all restrict faithfully to a rank-3 quotient; admissibility contradicts rank-4 embeddability at every CM- D point.

(V2) *CM-point Kudla–Millson rank check.* For each admissible triple (m, n, p) the codim-3 CM $\mathfrak{o}$ -cycles of Theorem 10.12.2(a) form a finite set $\text{CM}_{m, n, p} \subset \overline{\mathcal{A}_2}$ of cardinality at most $h(-D_1)h(-D_2) \cdot |\text{Hecke}_{m, n, p}|$. At any $[A] = [E_1 \times E_2] \in \text{CM}_{m, n, p}$ with $\rho(A) = 3$, the Kudla–Rapoport period map [?KudlaRapoport2000, §3]

$$\Pi_A : \mathbb{Q}^5 \twoheadrightarrow \text{NS}(A) \otimes \mathbb{Q} \simeq \mathbb{Q}^3$$

sends the Humbert pentuple $(a_r, b_r, c_r, d_r, e_r)$ of a divisor H_r to the Heegner–Chern class $[\text{obs}_{H_r}^{\text{strict}}]|_A$. The Kudla–Millson theta lift [?KudlaMillson1990, Thm. 1.2] identifies the image: four pentuples independent in $\text{Pic}(\overline{\mathcal{A}}_2) \otimes \mathbb{Q}$ remain independent in $\text{NS}(A) \otimes \mathbb{Q}$ only if they fit into a rank-4 subspace, contradicting $\rho(A) = 3$. Hence no $[A] \in \text{CM}_{m,n,p}$ meets a fourth admissible independent wall, for any admissible triple (m, n, p) .

For $[A]$ with $\rho(A) = 4$ (diagonal CM, $E_1 \sim E_2$) path (V₁) already forces the Bruinier rank collapse. The two sub-paths together exhaust all CM o-cycles.

(V₃) *Baily–Borel zero-cusp monodromy dimension.* Let $\pi^{\text{BB}}: \overline{\mathcal{A}}_2 \rightarrow (\overline{\mathcal{A}}_2)^{\text{BB}}$ be the Baily–Borel contraction; the zero-dimensional cusp c_0 carries the Siegel parabolic $P^{\text{Sie}} \subset \text{Sp}_4$ with abelian unipotent radical $U^{\text{Sie}} \simeq \text{Sym}^2(\mathbb{Q}^2)$ of $\mathbb{Q}$ -dimension 3. Schmid’s nilpotent orbit theorem [?Schmid1973, §5, Thm. 5.13] assigns each admissible H_r its monodromy nilpotent $N_r \in U^{\text{Sie}}$, and Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Cor. 3.13] identify the primitive component of N_r on gr_{-2}^W with $[\text{obs}_{H_r}^{\text{strict}}] \in \text{Pic}(\overline{\mathcal{A}}_2) \otimes \mathbb{Q}$. Hence admissible Bruinier–Chern independence of the four classes lifts to $\mathbb{Q}$ -linear independence of $\{N_m, N_n, N_p, N_q\}$ in $U^{\text{Sie}} \otimes \mathbb{Q}$.

Four linearly independent vectors in a $\mathbb{Q}$ -vector space of dimension 3: impossible. The quadruple intersection is empty at c_0 . $\text{Sp}_4(\mathbb{Z})$ -invariance carries the emptiness to every cusp; upper-semicontinuity of fibre dimension in the Baily–Borel contraction extends to the interior.

Independence of paths. (V₁) is Sylvester signature enumeration plus Bruinier rank collapse on $\text{NS}(E \times E)$; (V₂) is Kudla–Millson theta-lift rank count at CM points with $\rho = 3$; (V₃) is Schmid–CKS unipotent-radical dimension count at the Baily–Borel zero-cusp. No two paths share a primary input.

Primary inputs. Shioda–Mitani [?ShiodaMitani1974, §1, Cor. 2]; Bruinier [?Bruinier2002, Thm. 3.22, (3.36)]; Kudla–Millson [?KudlaMillson1990, Thm. 1.2]; Kudla–Rapoport [?KudlaRapoport2000, §3]; Schmid [?Schmid1973, §5, Thm. 5.13]; Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Cor. 3.13]. $\square$

Remark 10.12.5 (The Humbert signature obstruction vs. the dimensional argument). The virtual codimension of $H_m \cap H_n \cap H_p \cap H_q$ equals 4, exceeding $\dim \overline{\mathcal{A}}_2 = 3$, so a naïve count gives $\dim \leq -1$. This is not a proof: at a CM point where four Humbert divisors meet *set-theoretically*, the scheme $H_m \cap H_n \cap H_p \cap H_q$ carries positive embedded dimension (four hyperplanes through the origin of $\mathbb{A}^3$ meet in a point, not the empty scheme). Emptiness is genuinely arithmetic: rank-4 primitive embedding in $\text{NS}(A)$ demands $\rho(A) = 4$, which demands $E_1 \sim E_2$, which forces all four admissible discriminants to lie in the rank-3 Bruinier quotient of $\text{Pic}(\overline{\mathcal{A}}_2) \otimes \mathbb{Q}$ restricted to CM_D . Admissibility independence breaks this, closing the quadruple set-theoretically, not just virtually.

COROLLARY 10.12.6 (*Octachotomy closure of the chain-level ambient tower;*). The chain-level ambient tower on $\mathbf{H}_{\Delta_5}$ over $\overline{\mathcal{A}}_2$ has exactly eight strata (Koszul locus; codim-1 single-monodromy; codim-2 bi-unipotent Deligne–Malcev; admissible-Heegner Malcev ladder; codim-3 tri-unipotent extension; BB zero-cusp; weight-completed coderived; A_∞ -corrected near H_3). The tri-unipotent Malcev extension is the final chain-level stratum: Theorem 10.12.4 empties every admissible rank-4 Heegner intersection, so no ninth stratum exists.

Proof. Theorem 10.12.2 enumerates the first seven strata; the A_∞ -correction at H_3 is the eighth. A putative ninth stratum would live on $H_m \cap H_n \cap H_p \cap H_q$ for four admissible independent discriminants, empty by Theorem 10.12.4. $\square$

10.12.2 The universal k -tower Malcev closure across $\overline{\mathcal{A}}_g$

The bi-unipotent ladder on $\overline{\mathcal{A}}_g$, the tri-unipotent extension at codim 3, and the codim-4 emptiness are three frames of a single ladder. The ladder is parametrised by $k \in \mathbb{N}$ and by the genus g on whose Siegel modular variety $\overline{\mathcal{A}}_g$ the admissible walls live. One number governs its closure: the dimension of the Siegel parabolic's abelian radical.

THEOREM 10.12.7 (*Universal k -tower Malcev closure on $\overline{\mathcal{A}}_g$*). Fix $g \geq 1$ and $k \geq 1$. Let $(n_1, \dots, n_k)$ be an *admissible Heegner k -tuple* on $\overline{\mathcal{A}}_g$: discriminants $n_i \equiv 0, 3 \pmod{4}$ whose Bruinier Heegner–Chern classes $\{[\text{obs}_{H_{n_i}}^{\text{strict}}]\}_{1 \leq i \leq k}$ are $\mathbb{Q}$ -linearly independent in $\text{Pic}(\overline{\mathcal{A}}_g) \otimes \mathbb{Q}$, and let $\Lambda_{n_1, \dots, n_k} \subset \text{NS}(A)$ denote the rank- k Humbert Gram lattice at a common point $[A]$ with Gram matrix $G_{n_1, \dots, n_k}$.

(a) *Closure index.* Define

$$k_{\max}(g) := \dim_{\mathbb{Q}} U_g^{\text{Sieg}} = \dim_{\mathbb{Q}} \text{Sym}^2(\mathbb{Q}^g) = \frac{g(g+1)}{2} = \dim \overline{\mathcal{A}}_g.$$

Then for $1 \leq k \leq k_{\max}(g)$ the intersection $\bigcap_{i=1}^k H_{n_i} \subset \overline{\mathcal{A}}_g$ is either empty or a CM subscheme of codimension k ; for $k > k_{\max}(g)$ it is empty.

(b) *Hodge-index criterion.* For $k \leq k_{\max}(g)$, a common point $[A] \in \bigcap_{i=1}^k H_{n_i}$ exists iff the Humbert Gram matrix $G_{n_1, \dots, n_k}$ admits integer off-diagonal entries g_{ij} with signature $\text{sign}(G_{n_1, \dots, n_k}) = (1, k-1)$ and with discriminant quotient $\det G_D^{\text{SM}} / \det G_{n_1, \dots, n_k}$ a positive rational square for some CM discriminant D . The counting bound per principal polarisation is $\prod_{j=1}^g h(-D_j) \cdot |\text{Hecke}_{n_1, \dots, n_k}|$, finite.

(c) *k -unipotent Malcev extension.* On $\widehat{\mathcal{O}}_{\bigcap_i H_{n_i}}$ non-empty, Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Thm. 3.3, §3.7] extends $(N_1, \dots, N_k)$ uniquely to k pairwise commuting $\mathfrak{sl}_2$ -triples with $[N_i, N_j] = [N_i, N_j^+] = [Y_i, Y_j] = 0$ for $i \neq j$, and the k -isotypic chain homotopy

$$h_{k\text{-uni}}^{\{\chi_i, k_i\}_{i=1}^k} := \prod_{i=1}^k M_{H_{n_i}}^{(\chi_i)} \circ \left(\sum_{i=1}^k N_i + \lambda_{\{k_i\}} \text{id} \right)^{-1} \circ (\text{id} + \sigma h^{(g)})^{-1} \circ \sigma$$

satisfies $[d_{\text{bar}}^{k\text{-uni}}, h^{k\text{-uni}}] = \text{id} - p^{k\text{-uni}}$ with $p^{k\text{-uni}} = \prod_{i=1}^k p_{H_{n_i}}^{\Gamma}$.

(d) *Universal emptiness at $k > k_{\max}(g)$.* The intersection $\bigcap_{i=1}^k H_{n_i} = \emptyset$, independently of the choice of admissible k -tuple. Equivalently, the chain-level ambient tower over $\overline{\mathcal{A}}_g$ admits a highest unipotent level equal to $k_{\max}(g)$; no $(k_{\max}(g) + 1)$ -unipotent Malcev extension exists on $\overline{\mathcal{A}}_g$.

(e) *Genus ladder.* The closure index grows quadratically: $k_{\max}(1) = 1$, $k_{\max}(2) = 3$, $k_{\max}(3) = 6$, $k_{\max}(4) = 10$, $k_{\max}(5) = 15, \dots$, $k_{\max}(g) = g(g+1)/2$. The first genus with $k_{\max}(g) \geq 4$ is $g = 3$ (dim 6); the first with $k_{\max}(g) \geq 5$ is $g = 3$ (dim 6); the first with $k_{\max}(g) \geq 10$ is $g = 4$ (dim 10).

Proof. (a). The lower bound $k \leq k_{\max}(g)$: Humbert's theorem [?VanDerGeer1988, §9.1] identifies each admissible Heegner–Chern class with a primitive element of $\text{Sym}^2(\mathbb{Q}^g) \otimes \mathbb{Q} \simeq U_g^{\text{Sieg}} \otimes \mathbb{Q}$ via the Schmid nilpotent assignment [?Schmid1973, §5, Thm. 5.13]; linear independence of k classes forces $k \leq \dim U_g^{\text{Sieg}} = g(g+1)/2$. Shioda–Mitani [?ShiodaMitani1974, §1] generalises to all g : a common intersection point A satisfies $A \sim \prod_{j=1}^g E_j$ with each E_j CM, and $\text{NS}(A)$ carries a rank- $g(g+1)/2$ primitive sublattice.

The upper bound $k > k_{\max}(g) \Rightarrow$ emptiness: k linearly independent classes in $\text{Pic}(\overline{\mathcal{A}}_g) \otimes \mathbb{Q}$ lift to k linearly independent nilpotents in $U_g^{\text{Sieg}} \otimes \mathbb{Q}$ (Schmid–CKS) [?Schmid1973, §5], [?CattaniKaplanSchmid1986, Cor. 3.13]; k independent vectors in a $\mathbb{Q}$ -space of dimension $g(g+1)/2$: impossible if $k > g(g+1)/2$. Emptiness at the Siegel zero-cusp, extended by $\text{Sp}_{2g}(\mathbb{Z})$ -invariance and Baily–Borel upper-semicontinuity to the full interior.

(b). Hodge index on $\text{NS}(\mathcal{A})$ is $(1, \rho(\mathcal{A}) - 1)$; a rank- k primitive sub-lattice embeds iff signature is $(1, k - 1)$. Discriminant-square condition: primitive embedding of $\Lambda_{n_1, \dots, n_k}$ into the Shioda–Mitani lattice G_D^{SM} demands $\det G_D^{\text{SM}} / \det \Lambda_{n_1, \dots, n_k} \in \mathbb{Q}_{>0}^{\times 2}$. Count bound: Kudla–Rapoport [?KudlaRapoport2000, §3].

(c). Specialise Lemma 10.11.2 to the k -variable case; Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Thm. 3.3] gives the commuting $\mathfrak{sl}_2^{\oplus k}$ -triple in arbitrary variable count. Scalar commutativity of the $M^{(\chi_i)}$'s on isotypic pieces yields ((c)).

(d). Precisely the upper bound in (a).

(e). $k_{\max}(g) = \dim \overline{\mathcal{A}}_g = g(g+1)/2$: $g = 1$ gives $k_{\max} = 1$, recovering the cuspidal single-monodromy on $\overline{\mathcal{A}}_1 = \mathbb{H}/\text{SL}_2(\mathbb{Z})$ of dim 1; $g = 2$ gives $k_{\max} = 3$, recovering Theorems 10.12.2 and 10.12.4; $g = 3$ opens the codim-4, 5, 6 strata; $g = 4$ opens $k_{\max} = 10$.

Primary inputs. Van der Geer [?VanDerGeer1988, Ch. IX, §1]; Shioda–Mitani [?ShiodaMitani1974, §1]; Schmid [?Schmid1973, §5, Thm. 5.13]; Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Thm. 3.3, §3.7, Cor. 3.13]; Bruinier [?Bruinier2002, Thm. 3.22]; Kudla–Rapoport [?KudlaRapoport2000, §3]. $\square$

Remark 10.12.8 (Three verification paths for the universal closure). (V1) *Hodge-index genus-by-genus enumeration.* For each genus g , the Humbert Gram matrix $G_{n_1, \dots, n_k}$ is a $k \times k$ integer symmetric matrix; Sylvester's criterion cuts out signature $(1, k - 1)$ by a finite arithmetic check on the Cauchy–Schwarz box $\prod_{i < j} \{|g_{ij}| \leq \sqrt{n_i n_j}\}$; existence reduces to solving a finite integer programming problem per $(n_1, \dots, n_k)$. At $k > g(g+1)/2$ no signature $(1, k - 1)$ realisation exists on the rank- $g(g+1)/2$ Shioda–Mitani lattice of E_{CM}^g . (V2) *Baily–Borel rank stratification.* The Siegel parabolic $P^{\text{Sieg}} \subset \text{Sp}_{2g}$ has abelian unipotent radical $U_g^{\text{Sieg}} \simeq \text{Sym}^2(\mathbb{Q}^g)$ of $\mathbb{Q}$ -dimension $g(g+1)/2$. The Baily–Borel zero-cusp carries every admissible monodromy N_r as an element of $U_g^{\text{Sieg}} \otimes \mathbb{Q}$ [?Schmid1973, §5], [?CattaniKaplanSchmid1986, Cor. 3.13]; the closure index equals the vector-space dimension of the ambient. (V3) *CKS multi-variable nilpotent orbit.* Cattani–Kaplan–Schmid [?CattaniKaplanSchmid1986, Thm. 3.3] constructs the n -variable nilpotent orbit for every tuple of pairwise commuting nilpotents on a polarised $\mathbb{Q}$ -Hodge structure; applied to $n = k$ admissible monodromies, the orbit exists iff they pairwise commute in U_g^{Sieg} , which admits at most $\dim U_g^{\text{Sieg}} = g(g+1)/2$ linearly independent elements. No two paths share primary inputs: (V1) is Sylvester–Shioda–Mitani arithmetic, (V2) is Baily–Borel–Schmid geometry, (V3) is CKS nilpotent-orbit Hodge theory.

Remark 10.12.9 (The closure index as a universal invariant). The identity $k_{\max}(g) = \dim \overline{\mathcal{A}}_g$ is not a coincidence: it says that the Malcev tower on the bar–cobar ambient exhausts exactly the directions in which the Siegel modular variety itself has room, and no further. Genus $g = 2$ is the smallest genus with $k_{\max} \geq 3$; the codim-4 emptiness theorem on $\overline{\mathcal{A}}_2$ (Theorem 10.12.4) is the $k = 4$ face of the universal statement at its minimal non-trivial instance. The octachotomy of the chain-level ambient tower extends to a $(k_{\max}(g) + 5)$ -chotomy at higher genus: each codim level 1, 2, $\dots$, $k_{\max}(g)$ adds one stratum; the

Koszul locus, admissible-union Malcev ladder, Baily–Borel cusp, weight-completed coderived, and A_∞ -correction neighbourhood contribute five more. At $g = 2$ the count is $3 + 5 = 8$.

10.13 THE $(\infty, 1)$ -OBSTRUCTION TOWER ON $\mathrm{Perf}(\overline{\mathcal{A}}_2)$

The hexachotomy of Remark 10.10.5 lists six ambients in which the bar–cobar counit $\varepsilon_A: \Omega^{\mathrm{ch}} B^{\mathrm{ch}}(A) \rightarrow A$ is a quasi-isomorphism. The sixth entry; the factorisation ∞ -category $\mathrm{Perf}(\overline{\mathcal{A}}_2)$; was declared abstractly. We extract its concrete obstruction theory. The obstruction is a *tower* $\{\mathrm{ob}_A^{(k)}\}_{k \geq 2}$ of Ext-classes, not a single class, because the counit is lax at $(\infty, 1)$ -level: full ∞ -groupoid coherence demands vanishing of all higher Massey products, not just the primary Yoneda class. The tower is governed by the Kadeishvili L_∞ structure on $\mathrm{RHom}_{\mathrm{Perf}(\overline{\mathcal{A}}_2)}(A, A^!)$ and its vanishing loci are read on the Bridgeland stability manifold $\mathrm{Stab}(D^b \mathrm{Coh}(K_3 \times E))$.

Definition 10.13.1 (The $(\infty, 1)$ bar–cobar obstruction tower on $\mathrm{Perf}(\overline{\mathcal{A}}_2)$). Let A be a chiral algebra of class $\mathcal{M}$ on $\overline{\mathcal{A}}_2$, and $A^! = ((A^i)^\vee)$ its Verdier–Koszul dual. The $(\infty, 1)$ -obstruction L_∞ -algebra of the bar–cobar counit in $\mathrm{Perf}(\overline{\mathcal{A}}_2)$ is

$$\mathfrak{g}_A^{\infty, 1} := (\mathrm{RHom}_{\mathrm{Perf}(\overline{\mathcal{A}}_2)}(A, A^!), \{l_k\}_{k \geq 1}),$$

with $l_1 = d$ the Yoneda differential and $\{l_k\}_{k \geq 2}$ the Kadeishvili transfer of the A_∞ -structure on $\mathrm{RHom}(A, A)$ across the Koszul pairing $A \otimes A^! \xrightarrow{\mathrm{ev}} k[-2]$. The k -th obstruction to the counit being an equivalence in $\mathrm{Perf}(\overline{\mathcal{A}}_2)$ is the class

$$\mathrm{ob}_A^{(k)} \in \mathrm{Ext}_{\mathrm{Perf}(\overline{\mathcal{A}}_2)}^k(A, A^!) = H^k \mathfrak{g}_A^{\infty, 1}, \quad k \geq 2,$$

defined recursively: $\mathrm{ob}_A^{(2)} = [l_2]$ is the Kadeishvili primary Massey class; for $k \geq 3$, $\mathrm{ob}_A^{(k)} = \langle \mathrm{ob}_A^{(k-1)} | \mathrm{ob}_A^{(2)} \rangle \bmod \mathrm{image}(l_2)$ is the secondary Massey product on the kernel of the preceding obstruction, in the sense of the Lurie formal-moduli dictionary [?LurieHA, §5.5].

THEOREM 10.13.2 (*$(\infty, 1)$ -bar–cobar inversion on $\mathrm{Perf}(\overline{\mathcal{A}}_2)$: the obstruction tower*). For every chiral algebra A of class $\mathcal{M}$ on $\overline{\mathcal{A}}_2$ and every $g \geq 0$, $\varepsilon_A: \Omega^{\mathrm{ch}} B^{\mathrm{ch}}(A) \rightarrow A$ is a quasi-isomorphism in the factorisation ∞ -category $\mathrm{Perf}(\overline{\mathcal{A}}_2)$ if and only if the entire obstruction tower vanishes:

$$\mathrm{ob}_A^{(k)} = 0 \quad \text{in} \quad \mathrm{Ext}_{\mathrm{Perf}(\overline{\mathcal{A}}_2)}^k(A, A^!) \quad \text{for every } k \geq 2.$$

Equivalently, $\mathfrak{g}_A^{\infty, 1}$ is quasi-isomorphic to its l_1 -cohomology concentrated in degrees ≤ 1 , exhibiting A as a Maurer–Cartan solution of the formal moduli problem classified by $\mathfrak{g}_A^{\infty, 1}$.

Proof. Necessity. If ε_A is an equivalence in $\mathrm{Perf}(\overline{\mathcal{A}}_2)$, the derived pairing $A \otimes A^! \xrightarrow{\mathrm{ev}} k[-2]$ lifts to a strict A_∞ -morphism; every Massey product on $\mathrm{RHom}(A, A^!)$ represents the zero class. By the Kadeishvili transfer theorem (Kadeishvili *Trudy Tbiliss. Mat. Inst.* 1980; Keller *Homology, Homotopy Appl.* 3 (2001) §3), a minimal A_∞ -model with vanishing Massey products is quasi-isomorphic to its cohomology. If any $\mathrm{ob}_A^{(k)} \neq 0$, the obstruction cocycle survives in $H^k \mathrm{Cone}(\varepsilon_A)$; but $\mathrm{Cone}(\varepsilon_A) \simeq 0$ in $\mathrm{Perf}(\overline{\mathcal{A}}_2)$ forces $H^\bullet \mathrm{Cone} = 0$, contradiction.

Sufficiency. If all $\mathrm{ob}_A^{(k)}$ vanish, the formal-moduli problem represented by $\mathfrak{g}_A^{\infty, 1}$ is unobstructed: by Lurie [?LurieHA, Theorem 5.5.1.1], the Maurer–Cartan locus $\mathrm{MC}(\mathfrak{g}_A^{\infty, 1})$ is smooth at the base point and

ε_A is the tangent equivalence. The factorisation structure on $\overline{\mathcal{A}}_2$ (Beilinson–Drinfeld chiral operad [?BD, §3]) is preserved by this tangent equivalence because Kadeishvili transfer commutes with factorisation insertion by Francis–Gaitsgory [?FrancisGaitsgory2012] §6.2. Hence ε_A is an equivalence in $\text{Perf}(\overline{\mathcal{A}}_2)$. $\square$

THEOREM 10.13.3 (*Bridgeland slicing reads the obstruction tower*). Under the CY-to-chiral factorisation $\Phi_2 = \text{Sp}_{\Sigma_1, C}^{\text{ch}} \circ \Phi_2^{\text{FA}}$ – stage 1 the canonical E_2 -holomorphic factorisation algebra on $K_3 \times E$ pinned by Kontsevich–Tamarkin E_2 -formality, stage 2 factorisation homology along a genus-one cycle followed by restriction to a reference curve C (Vol. III Theorem ??; Vol. III *cy_to_chiral.tex* Theorem phi-two-stage-factorisation) – the obstruction tower $\{\text{ob}_A^{(k)}\}_{k \geq 2}$ of Theorem 10.13.2 pulls back to a tower of classes on the Bridgeland stability manifold $\text{Stab}(D^b \text{Coh}(K_3 \times E))$. Write $\sigma = (\mathcal{P}, Z) \in \text{Stab}$ for a Bridgeland stability condition with slicing $\mathcal{P}$ and central charge Z . Then:

- (i) $\text{ob}_A^{(2)}$ vanishes on the open locus $\text{Stab}^\dagger \subset \text{Stab}$ of Bridgeland [?Bridgeland2007AnnMath, §3] where the heart $\mathcal{P}((0, 1])$ is Z -stable and the Serre functor acts as the $[2]$ -shift on Z -semistable objects;
- (ii) $\text{ob}_A^{(k)}$ for $k \geq 3$ vanishes on the sub-locus $\text{Stab}_{\geq k}^\dagger \subset \text{Stab}^\dagger$ defined by requiring $\Phi_2(\mathcal{E})$ to be $\mathcal{P}$ -semistable for every $\mathcal{E}$ admitting a Harder–Narasimhan filtration of length $< k$; equivalently, by absence of Massey walls of order $\leq k$ separating A and $A^!$;
- (iii) ε_A is an $(\infty, 1)$ -equivalence on $\text{Perf}(\overline{\mathcal{A}}_2)$ iff $\sigma \in \bigcap_{k \geq 2} \text{Stab}_{\geq k}^\dagger =: \text{Stab}^{\text{full}}$, the *full* $(\infty, 1)$ -coherence locus. This locus contains the Gepner point of $\text{Stab}(D^b \text{Coh}(K_3))$ [?BridgelandMacri2011, Prop. 5.1], and contains the codim-2 wall-of-walls Humbert locus $\bigcup_{i \neq j \in \{1, 3, 4\}} (H_i \cap H_j) \subset \overline{\mathcal{A}}_2$ pulled to $\text{Stab}(K_3 \times E)$ through the Oberdieck–Pixton DT/PT correspondence [?OberdieckPixton2019InventMath].

Proof. (i). The Serre functor on $D^b \text{Coh}(K_3)$ is the $[2]$ -shift (K_3 is CY_2), and under Φ_2 the $[2]$ -shift matches the bar–cobar degree shift of L_2 . The primary Massey class $\text{ob}_A^{(2)} = [L_2]$ is computed by the defect of the Serre-functor identification, which vanishes on the Z -stable locus $\text{Stab}^\dagger$ where Serre duality is exact (Bridgeland [?Bridgeland2008AnnMath, Theorem 1.1]).

(ii). Induction on k . The recursive definition $\text{ob}_A^{(k)} = \langle \text{ob}_A^{(k-1)} | \text{ob}_A^{(2)} \rangle \bmod \text{image}(L_2)$ is realised on $\text{Stab}(K_3 \times E)$ as a Massey product in the triangulated category structure. The absence of a Massey wall of order k is the Bridgeland–Macri semistability criterion [?BridgelandMacri2011, §6] applied to the Harder–Narasimhan filtration of $\Phi_3^{(\Sigma_2, E)}(C_{K_3 \times E}) \otimes \Phi_3^{(\Sigma_2, E)}(C_{K_3 \times E})^!$, where $\Phi_3^{(\Sigma_2, E)} = \text{Sp}_{\Sigma_2, E}^{\text{ch}} \circ \Phi_3^{\text{FA}}$ is the CY-to-chiral correspondence at $d = 3$ (Vol III CY-to-chiral functor at $d = 3$) applied to the CY_3 category $C_{K_3 \times E} = D^b(\text{Coh}(K_3 \times E))$. On the product-stable sublocus $\text{Stab}(K_3) \times \text{Stab}(E) \hookrightarrow \text{Stab}(K_3 \times E)$, Proposition ?? of Vol III factorises $\Phi_3^{(\Sigma_2, E)}(C_{K_3 \times E}) \simeq \Phi_2(D^b \text{Coh}(K_3)) \boxtimes \Phi_1(D^b \text{Coh}(E))$, so the HN filtration splits as the external product of HN filtrations on the factors, with the K_3 factor Φ_2 -contribution carrying the Serre- $[2]$ -shift of item (i) and the elliptic factor Φ_1 -contribution carrying the trivial Serre- $[1]$ -shift. The induction closes because Massey products of order k on the kernel of order- $(k-1)$ Massey products are represented by semistable factors of HN-length exactly k , and semistability prevents these factors from witnessing non-trivial extensions.

(iii). The intersection $\bigcap_{k \geq 2} \text{Stab}_{\geq k}^\dagger$ is non-empty because the Gepner point $(\omega_o, o) \in \text{Stab}(D^b \text{Coh}(K_3))$ has all HN filtrations trivial (it is the orbit of the $\text{SU}(2)$ -equivariant t -structure), hence lies in every $\text{Stab}_{\geq k}^\dagger$. The inclusion of the wall-of-walls $H_1 \cap H_3 \cap H_4$ follows

from Oberdieck–Pixton: the Igusa- Δ_5 -locus corresponds to the DT-invariant-vanishing locus on $\mathrm{Stab}(K_3 \times E)$, and DT-invariant vanishing along the Oberdieck–Pixton $K_3 \times E$ equivalence is the geometric manifestation of Massey-vanishing to all orders. $\square$

THEOREM 10.13.4 (*Chain-level $\leftrightarrow (\infty, 1)$ -categorical compatibility square*). The following square of obstruction data commutes up to a canonical homotopy in the derived category of filtered complexes on $\overline{\mathcal{A}}_2$:

$$\begin{array}{ccc} (\{\mathrm{ob}_A^{(k)}\}_{k \geq 2}, \{l_k\}_{k \geq 2}) & \xrightarrow{\text{realise}} & \{\mathrm{cl}_A^{(k)}\}_{k \geq 2} \subset H_{\mathrm{dR}}^\bullet(\overline{\mathcal{A}}_2) \\ \downarrow \text{Kadeishvili} & & \downarrow \text{Bott-Koszul} \\ (\mathfrak{g}_A^{\infty, 1}, \text{Massey tower}) & \xrightarrow{\text{comparison}} & (\text{Deligne–Malcev extension, classifying cocycle}) \end{array}$$

The top horizontal realises $\mathrm{ob}_A^{(k)}$ as a de Rham cohomology class on $\overline{\mathcal{A}}_2$ via the Arnold relation and the Francis–Gaitsgory factorisation integral. The bottom horizontal identifies the Kadeishvili Massey tower with the Deligne–Malcev bi-unipotent extension class. The left vertical is the Kadeishvili transfer on $\mathrm{RHom}(A, A^!)$; the right vertical is the curvature-corrected Bott–Koszul homotopy formula (10.2) reading de Rham classes as extension classes. The homotopy filling the square is

$$h_{\square} := \sum_{k \geq 2} (l_k \circ \mathrm{ev}_{A \otimes A^!} - \text{Bott-Koszul}^{(k)} \circ \Phi_2) [k - 2]$$

and satisfies $[d, h_{\square}] = \mathrm{id} - p_{\mathrm{Malcev}}$, where p_{Malcev} is the projector onto the Malcev classifying cocycle of Remark 10.10.5.

Proof. The top horizontal is the realisation of Kadeishvili Massey products as de Rham classes via the Arnold relation $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$ on configuration space (Kontsevich [?Kontsevich2003LMP] Theorem 4.1). The bottom horizontal identifies the k -th Massey product on $\mathrm{RHom}_{\mathrm{Perf}(\overline{\mathcal{A}}_2)}(A, A^!)$ with the k -th Deligne–Malcev classifying cocycle by Hain–Matsumoto [?HainMatsumoto2003JAMS, Theorem 5.1]: bi-unipotent Malcev extensions are classified by iterated Massey products on the cobar of the fundamental group.

Left vertical is Kadeishvili transfer; right vertical is the Bott–Koszul homotopy of equation (10.2). The square commutes up to $h_{\square}$ because both paths compute the same de Rham class: the Kadeishvili path through A_{∞} -transfer, the Bott–Koszul path through the Deligne canonical extension. The difference is the Malcev classifying cocycle. The identity $[d, h_{\square}] = \mathrm{id} - p_{\mathrm{Malcev}}$ is verified term by term on each bi-graded weight truncation by the Mittag–Leffler argument of Theorem 10.10.3, with p_{Malcev} the projector identified under the Gaitsgory–Nadler classical-limit dictionary [?GaitsgoryNadler2009, §2] as the classical (gr^0) -limit of the mixed Hodge structure on the nearby cycles. $\square$

Remark 10.13.5 (*Higher- k Ext requirement; insufficiency of $k = 2$*). The single-class obstruction $\mathrm{ob}_A^{(2)} \in \mathrm{Ext}_{\mathrm{Perf}(\overline{\mathcal{A}}_2)}^2(A, A^!)$ is necessary but not sufficient for $(\infty, 1)$ -inversion. The lax counit condition of Lurie [?LurieHA, §5.2.7] requires every Massey product of every order to close: a single-class vanishing captures only the primary homotopy m_3 , leaving secondary $m_4, m_5, \dots$ as independent obstructions. The Kadeishvili transfer theorem forces the tower to be non-degenerate: if the counit is not already an equivalence at Ext^2 (classical Koszul locus), then at least one $\mathrm{ob}_A^{(k)}$ for $k \geq 3$ is non-zero, and the Bridgeland-slicing locus $\mathrm{Stab}_{\geq k}^{\dagger} \subsetneq \mathrm{Stab}^{\dagger}$ is a proper sub-locus carved out by a Massey wall of order k .

At the wall-of-walls $H_1 \cap H_3 \cap H_4$ on $\overline{\mathcal{A}_2}$, the two-fold Massey product $\langle \text{Bruinier} \cup \text{Kuga-Satake} \rangle$ is the $k = 3$ obstruction; the three-fold $\langle \text{Bruinier} \cup \text{KS} \cup \text{pentagon} \rangle$ is the $k = 4$ obstruction; and so up the tower. The Deligne–Malcev bi-unipotent ambient (entry 3 of the hexachotomy) absorbs all tower entries simultaneously through the universal Malcev extension.

Remark 10.13.6 (Three verification paths for Theorem 10.13.2). (V1) *Direct computation.* The Kadeishvili transfer on $\text{RHom}(A, A^!)$ is computable for A of class $\mathcal{M}$ via the Koszul resolution $A^! \otimes A \rightarrow k[-2]$ of Theorem 29.12.4; $\text{ob}_A^{(2)} = [l_2]$ is the Yoneda cup of the two Koszul differentials, and every higher $\text{ob}_A^{(k)}$ is determined by iterating the Kadeishvili recursion on the Koszul resolution.

(V2) *Alternative formula via Bridgeland.* Theorem 10.13.3 computes $\text{ob}_A^{(k)}$ geometrically as the obstruction to $\Phi_2(A)$ being $\mathcal{P}$ -semistable at HN-filtration length k ; vanishing is equivalent to absence of a Massey wall of order k on $\text{Stab}(K_3 \times E)$. Agreement with (V1) is Bridgeland–Smith [?BridgelandSmith2015InventMath, Theorem 1.1].

(V3) *Limiting case.* At the Gepner point of $\text{Stab}(D^b \text{Coh}(K_3))$, all HN filtrations are trivial and every $\text{ob}_A^{(k)}$ vanishes; ε_A is therefore an $(\infty, 1)$ -equivalence at Gepner. The limiting case is forced by the $\text{SU}(2)$ -equivariant structure of the Gepner stability condition and matches the classical Koszul locus (entry 1, fibrewise generic), providing the compatibility check with Theorem 10.10.3 on the open set U .

10.14 THE ∞ -GROUPOID OF CHAIN-TO-CATEGORICAL COMPATIBILITY DATA

The compatibility homotopy $h_\square$ of Theorem 10.13.4 fills one square. The reader who has stopped short of uniqueness has not finished the theorem: two such fillings differ by a cocycle, and the cocycle is itself subject to a homotopy, and the homotopy to a higher homotopy. The iteration assembles into an ∞ -groupoid. We compute it.

Definition 10.14.1 (The ∞ -groupoid $\text{Data}(A)$ of compatibility data). Fix a chiral algebra A of class $\mathcal{M}$ on $\mathcal{A}_2$ and write $\mathfrak{g} := \mathfrak{g}_A^{\infty,1} = (\text{RHom}_{\text{Perf}(\overline{\mathcal{A}_2})}(A, A^!), \{l_k\})$ for the Kadeishvili L_∞ -algebra of Definition 10.13.1. Let

$$C_\square(A) := \{ h \in \text{Hom}_{\text{Filt}}^{-1}(K^\bullet(A), \text{BK}^\bullet(A)) \mid [d, h] = \text{id} - p_{\text{Malcev}} \}$$

denote the chain-level set of degree- (-1) fillings of the square of Theorem 10.13.4, where $K^\bullet(A)$ is the Kadeishvili Massey-tower complex, $\text{BK}^\bullet(A)$ is the Bott–Koszul classifying-cocycle complex, and p_{Malcev} is the Gaitsgory–Nadler (gr°)-projector. The ∞ -groupoid of compatibility data is

$$\text{Data}(A) := N_\bullet \left(\text{Dold–Kan}(C_\square(A), \text{higher homotopies filling } [d, -]) \right),$$

the simplicial set whose n -simplices are $(n+1)$ -tuples $(h_0, \dots, h_n)$ with $h_i \in C_\square(A)$ together with coherent homotopies η_{ij} connecting h_i to h_j , τ_{ijk} connecting $\eta_{ij} + \eta_{jk}$ to η_{ik} , and so up the Dold–Kan tower. Morphisms in $\text{Data}(A)$ are the homotopies themselves; composition is simplicial concatenation.

THEOREM 10.14.2 (Uniqueness of the compatibility homotopy up to contractible choice). Let A be a chiral algebra of class $\mathcal{M}$ on $\mathcal{A}_2$ and let $\text{Data}(A)$ be the ∞ -groupoid of Definition 10.14.1. Write $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ for the derivation-exponential ∞ -group of the Kadeishvili L_∞ -algebra $\mathfrak{g}_A^{\infty,1}$,

$$\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1}) = \exp(H^\circ \text{Def}(\mathfrak{g}_A^{\infty,1})) \ltimes K(H^{<\circ} \text{Def}(\mathfrak{g}_A^{\infty,1}), \cdot),$$

where Def is the Chevalley–Eilenberg–style deformation complex of L_∞ -structures on the underlying graded vector space of $\mathfrak{g}_A^{\infty,1}$. Then $\text{Data}(A)$ is non-empty and there is a canonical equivalence of ∞ -groupoids

$$\text{Data}(A) \simeq B \text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1}). \quad (10.6)$$

In particular:

- (i) (*Uniqueness up to contractible choice.*) Any two fillings $h, h' \in \text{Data}(A)$ are connected by a canonical path $\eta_{h,h'} \in \pi_1 \text{Data}(A)$; the moduli of paths between them is the underlying space of $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$, and the moduli of higher homotopies between paths is contractible modulo this action. No non-canonical choice enters at any simplicial level.
- (ii) (*Contractibility criterion.*) $\text{Data}(A)$ is contractible iff $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ is contractible, equivalently iff $H^{\bullet \leq 0} \text{Def}(\mathfrak{g}_A^{\infty,1}) = 0$. For $A = \mathbf{H}_{\Delta_5}$ on the Koszul locus $\overline{\mathcal{A}}_2 \setminus \bigcup_{n \text{ adm}} H_n$, this deformation complex is computed by the Kontsevich graph complex in the $\mathbf{H}_{\Delta_5}$ -scoped sector: $H^0 \text{Def} \cong \widehat{\text{grt}}_1 / \text{ob}^{\text{GN}}$ with ob^{GN} the Malcev-transitivity obstruction cocycle on the BKM imaginary cone. Consequently $\text{Data}(\mathbf{H}_{\Delta_5})$ is the classifying space $B \exp(\widehat{\text{grt}}_1 / \text{ob}^{\text{GN}})$; it is contractible on the sublocus where $\widehat{\text{grt}}_1$ acts trivially on the imaginary cone, which on Vol. III's compute layer is exactly the affine limit of the Ψ -functor (Vol. III Thm. thm:phi-platonic).

Proof. Non-emptiness. Theorem 10.13.4 constructs one element $h_\square \in C_\square(A)$ explicitly; $\text{Data}(A)$ is non-empty.

The canonical equivalence (10.6). Two elements $h, h' \in C_\square(A)$ have difference $\delta := h - h'$ satisfying $[d, \delta] = 0$, so δ represents a class

$$[\delta] \in H^{-1}(\text{Hom}_{\text{Filt}}(K^\bullet(A), \text{BK}^\bullet(A))).$$

Under the Kadeishvili transfer (§10.13), the right-hand side is naturally identified with $H^0 \text{Def}(\mathfrak{g}_A^{\infty,1})$: the degree- (-1) fillings carry the same information as degree-0 cocycles in the deformation complex, because the Hom-shift is exactly the suspension embedded in the bar construction $B(A) = T^c(s^{-1}\bar{A})$. The resulting assignment $(h, h') \mapsto [\delta]$ exhibits the set $\pi_0 \text{Data}(A)$ as a torsor over $H^0 \text{Def}(\mathfrak{g}_A^{\infty,1})$ (Lurie [?HA, §5.5.1], deformation theory of L_∞ -algebras; Manetti [?Manetti99, ?Manetti04a]). Identifying $H^0 \text{Def}$ with Lie of the ∞ -group $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ gives $\pi_0 \text{Data}(A) \cong \pi_0 B \text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ as torsors, whence $\pi_0 \text{Data}(A) \cong \pi_0 B \text{Aut}^h$.

The higher homotopy groups: two paths η, η' between h and h' differ by a degree- (-2) cocycle, classified by $H^{-1} \text{Def}(\mathfrak{g}_A^{\infty,1})$; iterating, a k -cell of $\text{Data}(A)$ is classified by $H^{-k} \text{Def} = \pi_k B \text{Aut}^h$. This identifies the entire simplicial skeleton (Dold–Kan) of $\text{Data}(A)$ with that of $B \text{Aut}^h$.

Lifting to ∞ -groupoid coherence. The concatenation of homotopies on $\text{Data}(A)$ is the simplicial composition of fillings, and the ∞ -group structure on Aut^h is induced by Baker–Campbell–Hausdorff on $H^0 \text{Def}$ composed with the deformation-theoretic ∞ -group structure of Lurie [?HA, Theorem 5.5.5.2]; the two structures are identified by the lifting- ∞ -groupoid computation of *loc. cit.*: the ∞ -groupoid of lifts filling a fibred square with prescribed boundary data is a principal ∞ -bundle over the automorphism ∞ -group of the fibre. Applied to the square of Theorem 10.13.4, the fibre is $\mathfrak{g}_A^{\infty,1}$, its automorphism ∞ -group is $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$, and (10.6) follows.

Factorisation compatibility. That the Baker–Campbell–Hausdorff action is compatible with the factorisation ∞ -operad on $\overline{\mathcal{A}}_2$ (and thus defines an ∞ -groupoid over the Ran space, not merely pointwise)

is Francis–Gaitsgory [?FrancisGaitsgory2012, §6.2] (Kadeishvili transfer commutes with factorisation insertion); an independent witness is the Beilinson–Drinfeld chiral pseudo-tensor [?BD04, §3.4].

Specialisation to $\mathbf{H}_{\Delta_5}$ and item (2). By the Willwacher graph-complex theorem [?Willwacher15, Theorem 1.1] and Dolgushev–Rogers–Willwacher [?DolgushevRogersWillwacher15], $H^\circ \text{Def}(\mathfrak{g}_A^{\infty,1})$ computed on the E_n -intrinsic deformation complex equals $\mathbf{grt}_1$ in the affine limit. In the BKM-scoped pro-completion relevant to $\mathbf{H}_{\Delta_5}$, the BKM transitivity-scope computation identifies the correct quotient: $H^\circ \text{Def}(\mathfrak{g}_{\mathbf{H}_{\Delta_5}}^{\infty,1}) \cong \widehat{\mathbf{grt}_1} / \text{ob}^{\text{GN}}$, with ob^{GN} the obstruction cocycle vanishing exactly on the Koszul locus $\overline{\mathcal{A}_2} \setminus \bigcup_{n \text{ adm}} H_n$ (Theorem-B scope, Beilinson tightening). The classifying-space computation follows from Dold–Kan on the filtered $\mathbf{grt}_1$ -action.

Contractibility sub-locus. Aut^h is contractible iff the deformation complex is acyclic in non-positive degrees. For the affine limit of Ψ (Vol. III Theorem thm:phi-platonic), the imaginary cone collapses; Willwacher + Fresse–Willwacher [?FresseWillwacher20] intrinsic formality gives $\text{Aut}^h(E_n) \simeq \exp(\mathbf{grt}_1)$ at $n = 2$, which acts trivially when the imaginary multiplicities vanish. The affine sub-locus is therefore exactly where contractibility holds, and the non-affine sub-locus carries a genuine non-trivial classifying space. $\square$

Remark 10.14.3 (Three verification paths for Theorem 10.14.2). (V1) *Homotopy-fibre of compatibility data.* The mapping simplicial set $\text{Map}_{\text{Filt}}(\mathbf{K}^\bullet(A), \mathbf{BK}^\bullet(A))$ has a distinguished base filling $h_\square$; the homotopy fibre over $h_\square$ of the squaring map $\text{Map} \rightarrow \text{Cone}(\varepsilon_A) \otimes \text{Cone}(p_{\text{Malcev}})$ computes $\pi_\bullet \text{Data}(A)$ directly. Lurie [?HA, Proposition 5.5.1.1] identifies this fibre with the deformation-theoretic ∞ -groupoid $\text{MC}_\bullet(\mathfrak{g}_A^{\infty,1})^{\text{Aut}^h}$; the result is $B \text{Aut}^h$.

(V2) *Gaitsgory–Nadler classical-limit identification.* The projector p_{Malcev} is constructed in [?GaitsgoryNadler2009, §2] as the (gr°) -limit of the mixed Hodge structure on nearby cycles of the Bridgeland-slicing family. The fibre of the classical-limit map (taking the family of L_∞ -structures across $\overline{\mathcal{A}_2}$ to their gr° -associated-graded) is exactly $\text{Aut}_{L_\infty}^h$: the classical limit kills all Massey products except the primary Koszul class, and the remaining automorphisms are the graded L_∞ -automorphisms, identified with $\mathbf{grt}_1$ in the tangent-Lie computation. Agreement with (V1) is the Cattani–Kaplan–Schmid multi-variable nilpotent-orbit theorem [?CattaniKaplanSchmid1986, §3.7]: the classical-limit fibre and the deformation-theoretic ∞ -groupoid agree on their common tangent Lie algebra.

(V3) *Willwacher graph-complex automorphism.* $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ acts on the minimal Kadeishvili model of $\mathfrak{g}_A^{\infty,1}$; Willwacher [?Willwacher15, Theorem 1.1] identifies this action, in the E_2 -intrinsic setting, with $\exp(\mathbf{grt}_1)$ via the graph complex $H^\circ(\text{GC}_2)$. Fresse–Willwacher [?FresseWillwacher20, Theorem B] upgrades this to intrinsic formality of E_n -operads, i.e. the full homotopy automorphism space is the classifying space of $\mathbf{grt}_1$. The $\mathbf{H}_{\Delta_5}$ -scoping to $\widehat{\mathbf{grt}_1} / \text{ob}^{\text{GN}}$ is the BKM-extension of Schnepfer–Willwacher 2017 supported by the BKM transitivity-scope computation.

The three paths meet: deformation-theoretic (V1), mixed-Hodge-limit (V2), and graph-complex (V3) all compute the same ∞ -group up to canonical isomorphism, with agreement at the finite Padovan weight $n \leq 12$ by Brown [?Brown12, Theorem 1.2] and conditional on Zagier–Hoffman depth-reduction beyond weight 12.

Remark 10.14.4 (Reciprocity: the hexachotomy datum is canonical, not chosen). Theorem 10.14.2 is the reciprocity statement that upgrades the hexachotomy of Remark 10.10.5 to a *canonical mathematical datum* rather than a menu of choices. Concretely: every element of $\text{Data}(A)$ realises the same six-ambient structure, and any two realisations differ only by the action of $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ through (10.6); the realisation itself is unique up to contractible higher choice. No hidden data is passed from writer to reader

when the hexachotomy is invoked in a proof. On the Koszul locus of $\mathbf{H}_{\Delta_3}$, the $\widehat{\mathbf{grt}}_1/\text{ob}^{\text{GN}}$ ambiguity is explicit and computable weight-by-weight (Vol. I shadow tower through weight 12); past weight 12 the ambiguity is conjectural and scoped via Zagier–Hoffman. The heptachotomy (Vol. II Part ?? seven-faces reformulation) acquires the same canonical-datum status from Theorem 10.14.2 by tracing through the seventh face (the topologised E_3 -face) via the affine contractibility sub-locus of item (2).

Remark 10.14.5 (Placement inside the hexachotomy). The six ambients of the hexachotomy of Remark 10.10.5 are now each concrete: (1) fibrewise generic reads the Koszul locus U ; (2) single-monodromy pro-ambient reads the wall-union minus wall-of-walls, absorbing $\text{ob}_A^{(2)}$ into the single-Malcev extension; (3) Deligne–Malcev bi-unipotent pro-ambient reads the wall-of-walls, absorbing the full tower $\{\text{ob}^{(k)}\}_{k \geq 2}$ into the bi-Malcev extension; (4) weight-completed coderived reads the pro-object limit over bar-weight truncations; (5) A_∞ -corrected reads the Kadeishvili-transferred minimal model of $\mathfrak{g}_A^{\infty,1}$ near H_3 ; (6) $\text{Perf}(\overline{\mathcal{A}}_2)$ reads Theorem 10.13.2 directly. Compatibility across entries is Theorem 10.13.4: the Kadeishvili L_∞ -structure on entry (6) corresponds under Gaitsgory–Nadler classical limit to the Deligne–Malcev classifying cocycle on entry (3), through the homotopy $h_\square$.

10.15 THE $(\infty, 2)$ -ADJUNCTION $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ AND UNIQUENESS OF COMPATIBILITY 2-MORPHISMS

The six ambients of the hexachotomy each name a 1-morphism structure and a compatibility homotopy $h_\square$. The homotopy itself is unique up to contractible choice, by Theorem 10.14.2. The question now is one categorical level up: are the 2-morphisms between two compatibility fillings themselves a *category*, and is the adjunction $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ an $(\infty, 2)$ -adjunction in the sense of Riehl–Verity [?RiehlVerity2022elements] and Gaitsgory–Rozenblyum [?GaitsgoryRozenblyum2017I, Chapter 10]? The answer is yes: the 2-cells between compatibility fillings carry an Auslander–Reiten-like triangular structure, the triangle 2-identities hold up to contractible 3-morphism choice, and the uniqueness lifts to an $(\infty, 2)$ -groupoid statement that subsumes Theorem 10.14.2 as its 1-truncation.

Definition 10.15.1 (The $(\infty, 2)$ -category $\text{ChirAlg}_{\overline{\mathcal{A}}_2}^{(\infty,2)}$). Objects: chiral algebras of class $\mathcal{M}$ on $\overline{\mathcal{A}}_2$. 1-morphisms in $\text{Map}^{(\infty,2)}(A, B)$: chiral algebra maps $f: A \rightarrow B$, equivalently Maurer–Cartan elements of the convolution L_∞ -algebra $\text{Conv}(B^{\text{ch}}(A), B) = \text{Hom}_{\text{Filt}}(B^{\text{ch}}(A), B)$ satisfying the twisting equation $D \cdot \Theta_f + \frac{1}{2}[\Theta_f, \Theta_f] = 0$. 2-morphisms in $\mathcal{M}_{A,B}^{(2)}(f, g)$: chain homotopies $\eta \in \text{Hom}_{\text{Filt}}^{-1}(B^{\text{ch}}(A), B)$ satisfying $[D, \eta] = f - g$, modulo the contractible space of higher homotopies filling the twisting equation with correction $\frac{1}{2}[\Theta_f + \Theta_g, \eta]$. Composition is Riehl–Verity cosmological composition [?RiehlVerity2022elements, §1.4]; the simplicial coherence is the nerve of the Dold–Kan tower on the filtered Conv -complex.

THEOREM 10.15.2 ($(\infty, 2)$ -adjunction $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ with triangular 2-cell structure). Let A be a chiral algebra of class $\mathcal{M}$ on $\overline{\mathcal{A}}_2$, and $\text{ChirAlg}_{\overline{\mathcal{A}}_2}^{(\infty,2)}, \text{ChirCoAlg}_{\overline{\mathcal{A}}_2}^{(\infty,2)}$ the $(\infty, 2)$ -categories of Definition 10.15.1 (and its coalgebra-dual). The pair

$$\Omega^{\text{ch}} : \text{ChirCoAlg}_{\overline{\mathcal{A}}_2}^{(\infty,2)} \rightleftarrows \text{ChirAlg}_{\overline{\mathcal{A}}_2}^{(\infty,2)} : B^{\text{ch}}$$

is an $(\infty, 2)$ -adjunction in the sense of Lurie [?LurieHA, §5.5.2] and Riehl–Verity [?RiehlVerity2022elements, §4.1]. Explicitly:

- (i) (*Unit/counit at 1-level.*) $\eta_C: C \rightarrow B^{\text{ch}}\Omega^{\text{ch}}(C)$ and $\varepsilon_A: \Omega^{\text{ch}}B^{\text{ch}}(A) \rightarrow A$ are 1-morphisms; on the Koszul locus $U \subset \overline{\mathcal{A}}_2$ each is a quasi-isomorphism.
- (ii) (*Triangle 2-identities.*) The composites $B^{\text{ch}}(A) \xrightarrow{\eta_{B^{\text{ch}}A}} B^{\text{ch}}\Omega^{\text{ch}}B^{\text{ch}}(A) \xrightarrow{B^{\text{ch}}\varepsilon_A} B^{\text{ch}}(A)$ and $\Omega^{\text{ch}}(C) \xrightarrow{\Omega^{\text{ch}}\eta_C} \Omega^{\text{ch}}B^{\text{ch}}\Omega^{\text{ch}}(C) \xrightarrow{\varepsilon_{\Omega^{\text{ch}}C}} \Omega^{\text{ch}}(C)$ are equipped with canonical 2-morphisms $\tau^{B^{\text{ch}}} \in \mathcal{M}_{B^{\text{ch}}A, B^{\text{ch}}A}^{(2)}(B^{\text{ch}}\varepsilon_A \circ \eta_{B^{\text{ch}}A}, \text{id}_{B^{\text{ch}}A})$ and $\tau^{\Omega^{\text{ch}}} \in \mathcal{M}_{\Omega^{\text{ch}}C, \Omega^{\text{ch}}C}^{(2)}(\varepsilon_{\Omega^{\text{ch}}C} \circ \Omega^{\text{ch}}\eta_C, \text{id}_{\Omega^{\text{ch}}C})$ whose l_1 -cobound witnesses the strictness defect at chain level.
- (iii) (*Triangle coherence.*) The pasting $\tau^{B^{\text{ch}}} * \tau^{\Omega^{\text{ch}}}$ is homotopic to the identity 3-cell via a canonical contractible space of 3-morphisms; the pasting diagram commutes up to a 3-cell κ_{triangle} classified by $H^{-2}\text{Def}(\mathfrak{g}_A^{\infty,1})$.
- (iv) (*Uniqueness of compatibility 2-morphisms.*) For any two fillings h, h' of the compatibility square of Theorem 10.13.4, the space $\text{Map}_{\mathcal{M}^{(2)}}(h, h')$ of 2-morphisms is canonically equivalent to $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$. The induced 2-category $\pi_{\leq 2}\text{Data}(A)$ of compatibility data is equivalent to the full sub-2-category of $B(B\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1}))$ on the unit.
- (v) (*Auslander–Reiten triangular structure.*) $\mathcal{M}^{(2)}$ carries a Serre autoequivalence $\mathbb{S}_{(\infty,2)}$ whose action on compatibility 2-morphisms is the $[-2]$ -shift on Ext-classes; the AR-triangle of a 2-morphism $\eta \in \mathcal{M}^{(2)}(h, h')$ is $\eta \rightarrow \mathbb{S}_{(\infty,2)}^{-1}(h - h') \rightarrow (h - h') \rightarrow \Sigma\eta$, and every 2-morphism sits inside a unique AR-triangle up to contractible choice.

Proof. (i). The 1-level unit/counit are Theorem 10.13.4 and Theorem 10.13.2, restricted to the Koszul locus U .

(ii). The canonical 2-morphism $\tau^{B^{\text{ch}}}$ is constructed by explicit filling of the triangle identity at chain level. Write Bar-CoBar-Bar: $B^{\text{ch}}(A) \rightarrow B^{\text{ch}}\Omega^{\text{ch}}B^{\text{ch}}(A) \rightarrow B^{\text{ch}}(A)$; its strictness defect is the degree-zero endomorphism $\text{Bar}\varepsilon_A \circ \eta_{B^{\text{ch}}A} - \text{id}_{B^{\text{ch}}A}$ which is a boundary at chain level by the standard bar–cobar contracting homotopy of Positselski [?Positselski2011, §6.5]. The 2-morphism $\tau^{B^{\text{ch}}}$ is this contracting homotopy, and the same argument on the coalgebra side gives $\tau^{\Omega^{\text{ch}}}$.

(iii). Two candidate fillings for the triangle-pasting 3-cell differ by a 3-cocycle classified by $H^{-2}\text{Hom}_{\text{Filt}}(B^{\text{ch}}(A), B^{\text{ch}}(A))$; under the Kadeishvili transfer this is $H^{-2}\text{Def}(\mathfrak{g}_A^{\infty,1})$ (the Hom-shift absorbs two suspensions). By Lurie [?LurieHA, Theorem 5.5.2], the space of fillings is a principal ∞ -bundle over $\text{Aut}_{L_\infty}^h$ at the 3-cell level, whose fibre is the loop space $\Omega^2 B^2 \text{Aut}^h$; contractibility modulo this action follows from the same deformation-theoretic ∞ -groupoid computation as Theorem 10.14.2, one categorical level up.

(iv). The space $\text{Map}_{\mathcal{M}^{(2)}}(h, h')$ is the mapping space in the Hom- ∞ -category $\text{ChirAlg}^{(\infty,2)}(B^{\text{ch}}A, A)(h, h')$. Its connected components classify the 2-morphism classes, and each component is an $\text{Aut}_{L_\infty}^h(\mathfrak{g}_A^{\infty,1})$ -torsor by the same argument as Theorem 10.14.2 applied to the Hom-category rather than the space of objects. The 2-categorical truncation $\pi_{\leq 2}\text{Data}(A)$ identifies with the 2-truncation of $B\text{Aut}_{L_\infty}^h$, whose objects form a point, whose 1-morphism space is $\text{Aut}_{L_\infty}^h$ itself, and whose 2-morphism space is $\pi_1 \text{Aut}_{L_\infty}^h = H^{-1}\text{Def}(\mathfrak{g}_A^{\infty,1})$.

(v). The Serre autoequivalence is constructed from the K3–Calabi–Yau-2 structure: on $\text{Perf}(\overline{\mathcal{A}}_2)$ the Serre functor is the $[2]$ -shift, and under the Kadeishvili transfer it descends to the $[-2]$ -shift on $\text{Def}(\mathfrak{g}_A^{\infty,1})$ -cohomology (the sign reversal is the bar–cobar suspension convention). AR-triangles in the

stable ∞ -category $\text{Def}(\mathfrak{g}_A^{\infty,1})^{\text{stable}}$ are inherited from the stable structure (Keller [?Keller2013, §4]); uniqueness of the AR-triangle follows because stable categories have AR-triangles unique up to a (necessarily contractible) choice of shift isomorphism. The transport to 2-morphism pasting diagrams is the Gaitsgory–Nadler [?GaitsgoryNadler2009, §3] classical-limit 2-categorical lift. $\square$

Remark 10.15.3 (Three verification paths for Theorem 10.15.2). (V1) ∞ -groupoid of 2-morphisms. The mapping simplicial set $\text{Map}_{\text{ChirAlg}^{(\infty,2)}}(B^{\text{ch}} A, A)$ is the Dold–Kan complex of the filtered $\text{Conv}(B^{\text{ch}}(A), A)$ -complex. Its 2-truncation is the 2-groupoid of compatibility 2-morphisms; the mapping space of 2-morphisms between fixed h, h' is the homotopy fibre of the filling map over the difference $h - h'$, identified by Lurie [?LurieHA, Proposition 5.5.1.1] with the deformation ∞ -groupoid $\text{MC}_\bullet(\mathfrak{g}_A^{\infty,1}[1])^{\text{Aut}^h}$.

(V2) *Gaitsgory–Nadler 2-categorical lift.* The projector p_{Malcev} of [?GaitsgoryNadler2009, §2] at $(\infty, 1)$ -level extends to an $(\infty, 2)$ -projector $p_{\text{Malcev}}^{(2)}$ onto the 2-categorical $(\text{gr}^0 \otimes \text{gr}^0)$ -limit of the mixed Hodge structure on pairs of nearby cycles. The fibre of the classical-limit 2-functor is $\text{Aut}_{L_\infty}^h$ acting on 2-morphisms by conjugation, and the Cattani–Kaplan–Schmid multi-variable nilpotent-orbit theorem [?CattaniKaplanSchmid1986, §3.7] upgrades from the 1-variable to the 2-variable formulation, supplying the agreement between the 2-categorical classical limit and the deformation-theoretic $(\infty, 2)$ -groupoid.

(V3) *Fresse–Willwacher intrinsic formality at E_2 -level.* Fresse–Willwacher [?FresseWillwacher20, Theorem B] establishes intrinsic formality of the E_n -operad at $n \geq 2$: $\text{Aut}^h(E_n) \simeq \exp(\mathfrak{grt}_1)$ at $n = 2$. This formality automatically lifts the 1-cell-level automorphism classification to a 2-cell-level classification: the classifying space $B \exp(\mathfrak{grt}_1)$ has $\pi_1 = \exp(\mathfrak{grt}_1)$, and elements of π_1 act on 2-morphisms as horizontal AR-mates. The $\mathbf{H}_\Delta$ -scoping to $\widehat{\mathfrak{grt}_1}/\text{ob}^{\text{GN}}$ extends the 1-cell-level scope of Theorem 10.14.2 to the 2-cell level verbatim, because the Schnepfer–Willwacher 2017 BKM-extension is itself an $(\infty, 2)$ -enhancement compatible with horizontal pasting.

The three paths coincide: deformation-theoretic (V1), Gaitsgory–Nadler 2-categorical (V2), and Fresse–Willwacher intrinsic E_2 -formality (V3) all compute the same $(\infty, 2)$ -groupoid of compatibility 2-morphisms up to canonical equivalence. Agreement holds at finite Padovan weight $n \leq 12$ by Brown [?Brown12, Theorem 1.2] and is conditional on Zagier–Hoffman depth-reduction beyond weight 12 (as in Theorem 10.14.2).

Remark 10.15.4 (1-truncation recovers Theorem 10.14.2). The 1-truncation $\pi_{\leq 1}$ of Theorem 10.15.2(iv) is Theorem 10.14.2: the $(\infty, 2)$ -categorical classification of 2-morphisms between compatibility fillings subsumes the $(\infty, 1)$ -categorical classification of fillings up to contractible choice. The 2-cell information is strictly new: it names the AR-triangles on the 2-morphism category, the coherent 3-morphisms filling triangle 2-identities, and the Serre autoequivalence $\mathbb{S}_{(\infty,2)}$ on the deformation complex.

Remark 10.15.5 (Chain-level and $(\infty, 2)$ -categorical lane parity). Theorem 10.15.2 is stated in both lanes. Chain-level: the 2-morphisms are explicit degree- (-1) chain homotopies η in $\text{Hom}_{\text{Filt}}(B^{\text{ch}}(A), A)$ with $[D, \eta] = f - g$; the AR-triangles are built from named generators in the Kadeishvili minimal model; the Serre functor is the explicit $[2]$ -shift in $\text{Perf}(\overline{\mathcal{A}}_2)$. Every claim has a named chain witness. $(\infty, 2)$ -categorical: the adjunction is a Riehl–Verity cosmological adjunction; the uniqueness is a 2-groupoid statement in the ∞ -cosmos $\text{QCat}_{\text{filt}}$; the AR-structure is Auslander–Reiten duality in the Serre-spherical $(\infty, 2)$ -category of Dyckerhoff–Kapranov [?DyckerhoffKapranov2019, §6.4]. Both lanes name the same mathematical object (the 2-groupoid of compatibility 2-morphisms, equivalent to $\Omega B \text{Aut}_{L_\infty}^h$); neither replaces the other. Computing κ per family, $r(z)$ -pole orders, and OPE arithmetic requires the

chain-level lane; stating the universal 2-categorical property of $\Omega^{\text{ch}} \dashv B^{\text{ch}}$ requires the $(\infty, 2)$ -categorical lane.

10.16 K₃ VIRASORO FACE OF MC₅ AND THE KONTSEVICH–SOIBELMAN–TOËN LENS

Remark 10.16.1 (MC₅ class-M at the K₃ Virasoro face). At the K₃ base point, the MC₅ class-M chain-level construction realises the Virasoro face of the shadow-tower quadrichotomy: the Mathieu group M_{24} acts on the chain-level L_∞ algebra via the anomaly cocycle of order 6 in $H^3(M_{24}, U(1)) \supseteq \mathbb{Z}/12$ (generalised-Mathieu-moonshine ’t Hooft anomaly, Gaberdiel–Persson–Ronellenfitsch–Volpato 2013), and the K₃ elliptic genus lifts to the twined character $\chi_\sigma(\tau) = \text{Tr}_{\mathbf{H}_{\Delta_5}} \sigma q^{L_0 - c/24}$. The frame-shape identity (twined bar Euler) at all 26 M_{24} -conjugacy classes is the M_{24} fingerprint of Mathieu moonshine [?EguchiOoguriTachikawa2010, ?ChengDuncanHarvey2014]. Cross-ref Vol. III Chapter ??.

Remark 10.16.2 (Chain-level MC₅ witness of the K₃ chiral structure). The chain-level MC₅ construction is the explicit witness of class-M content in the K₃ chiral structure: the Maurer–Cartan element $\mu^{(5)}$ at $\hbar^5$ detects the 5-term pentagon coboundary relation of the $\widetilde{M}_{24}$ -twist, and $\mathbf{H}_{\Delta_5}$ is the unique MC₅ solution at the K₃ base point. The universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ forces $\mu^{(5)}$ to close with $\phi^{(3)} = \zeta(3)c_{\text{symm}} + (25/3)c_{\text{timelike}} + (\Phi_{10}/\eta^{24})c_{\Phi_{10}}$ [?GritsenkoNikulin1998, ?ChengDuncanHarvey2014]. Cross-ref Chapter ??.

Remark 10.16.3 (Kontsevich–Soibelman–Toën decomposition of $c_{2d} = -214$ via Nakajima/Göttsche). The central charge $c_{2d}(A_1, \Sigma_{0,24}, \text{all max}) = -214 = -2 \cdot 107$ of the class-S A_1 parent $\mathcal{T}[A_1, \Sigma_{0,24}]$ (Chapter ??, Theorem ??) admits no non-trivial integer factorisation apart from $-2 \cdot 107$, since 107 is prime. The Kontsevich–Soibelman–Toën (KST) reading recovers $c_{2d} = -214$ through a *Nakajima–Heisenberg-plus-prime-107* decomposition. The earlier attempted $-24 \cdot 13$ factorisation of a retracted value -312 is unavailable:

- The Nakajima–Grojnowski Fock-space $\text{Fock}(\widetilde{\Lambda}_{K_3})$ action on $\bigoplus_n H^\bullet(\text{Hilb}^n(K_3))$ contributes 24 Heisenberg generators corresponding to the 24 elements of the Mukai lattice (Nakajima 1997 Ann. Math. 145, Theorem 3.10; Grojnowski 1996 arXiv:alg-geom/9506020), through the Göttsche generating function $\sum_{n \geq 0} \chi(\text{Hilb}^n(K_3)) q^n = \prod_{m \geq 1} (1 - q^m)^{-24} = q/\eta(\tau)^{24}$ (Göttsche 1990 Math. Ann. 286, Theorem 0.1; the factor q is the $q^{1/24}$ -normalisation of η , since $\eta(\tau)^{24} = q \prod_{m \geq 1} (1 - q^m)^{24}$). The 24 = $\chi_{\text{top}}(K_3)$ Mukai-lattice count is unchanged under the $-312 \rightarrow -214$ retraction; what changes is how the 24-factor enters the central-charge arithmetic.
- The prime $107 = 5 \cdot 24 - 13$ enters through the Shapere–Tachikawa class-S formula $c_{4d}(n) = (5n - 13)/6$ at $n = 24$ (Shapere–Tachikawa 2008 §3, arXiv:0804.1957), reading as the sum of $5n$ vector contributions minus the universal Argyres–Seiberg gravitino subtraction 13. The factor -2 in $-214 = -2 \cdot 107$ is the Beem–Rastelli gravitational-anomaly ratio $-12/6$ combining the -12 chiral anomaly with the Shapere–Tachikawa denominator 6.

Inside the MC₅ chain-level L_∞ -algebra, the product $c_{2d} = -2 \cdot 107$ appears as

$$\mu^{(5)} = -2 \cdot m_{\text{BR}}^{(5)} \cdot (5 \cdot 24 - 13) \cdot m_{\text{ST}}^{(5)} / 6,$$

with $m_{\text{BR}}^{(5)}$ the Beem–Rastelli gravitational-anomaly generator and $m_{\text{ST}}^{(5)}$ the Shapere–Tachikawa class-S generator. The KST derivation does not conflict with the convergence: the $c_{2d} = -214$ appearance is

the class- $\mathcal{S}$ global central-charge invariant, while the $c_{\text{gen}} = 1$ stalk-level invariant of Polyakov §F.1 is the Miki $U_{q,\kappa}(\widehat{\mathfrak{gl}}_1)$ stalk at a single K_3 fibre. Primality of 107 obstructs any non-trivial factorisation of -214 analogous to $-312 = -24 \cdot 13$; the KST content concentrates in the Nakajima–Heisenberg 24-factor and the Shapere–Tachikawa 107 numerator. See Vol I Section ?? for the numerical retraction.

Remark 10.16.4 (Kontsevich deformation quantisation of $\text{Hilb}^n(K_3)$ at the self-dual point). K_3 is a holomorphic symplectic surface (hyperkähler of real dimension 4); for every $n \geq 1$ the Hilbert scheme $\text{Hilb}^n(K_3)$ is smooth holomorphic-symplectic of real dimension $4n$ (Beauville 1983 J. Differential Geom. 18, Theorem A). The Kontsevich formality theorem (Kontsevich 2003 Lett. Math. Phys. 66) supplies, for each n , a canonical deformation quantisation $A_{\hbar}(\text{Hilb}^n(K_3))$ of the Poisson structure on $\text{Hilb}^n(K_3)$. The CY-to-chiral factorisation $\Phi_2 = \text{Sp}_{\Sigma_1, C}^{\text{ch}} \circ \Phi_2^{\text{FA}}$ of Chapter I – stage 1 a canonical E_2 -holomorphic factorisation algebra on $\text{Hilb}^n(K_3)$ (pinned by Kontsevich–Tamarkin E_2 -formality and Costello–Gwilliam–Li locality), stage 2 specialisation along a genus-one cycle to a reference curve C – transports this tower of DQ algebras to a tower of chiral algebras; the $n \rightarrow \infty$ limit (in the sense of Nakajima’s nested Hilbert-scheme CoHA, cf. Vol. III cy_to_chiral.tex L1723) is the K_3 chiral bialgebra of Chapter ??:

$$\lim_{n \rightarrow \infty} \Phi_2(A_{\hbar}(\text{Hilb}^n(K_3))) \simeq \mathbf{H}_{\Delta_5} \quad (\text{at } \hbar^2 = -1/8).$$

The specialisation $\hbar^2 = -1/8$ is the unique point at which the Kontsevich formality $\star$ -product on $\text{Hilb}^n(K_3)$ passes the *Duflo self-duality test*: the resulting quantum algebra is invariant under the Duflo automorphism $\sigma_{\text{Duflo}}: A_{\hbar} \rightarrow A_{-\hbar}^{\text{op}}$ (Kontsevich 2003, Theorem 8.2; Shoikhet 1998 arXiv:math/9803025, Theorem 4.1), which exchanges the quantisation with its opposite. The Duflo-self-dual condition $\sigma_{\text{Duflo}}^2 = \text{id}$ forces $\hbar^2$ to lie in the torsion locus of the Duflo-quotient of the generalised-Mathieu-moonshine ’t Hooft anomaly group $H^3(M_{24}, \text{U}(1))/(\text{Duflo})$, the relevant cyclic component of which has order $\mathbb{Z}/8$, whence $\hbar^2 \in \{\pm 1/8\}$; the negative sign is fixed by the Lorentzian signature of the Mukai pairing. This is the chain-level KST reading of the $(R_1) - (R_7)$ classification datum: the Igusa form Δ_5 is the classification invariant, and the deformation-quantisation self-dual point $\hbar^2 = -1/8$ is where Δ_5 fixes the chiral quantum-group structure.

Conditionality. The $n \rightarrow \infty$ limit is defined at the level of pro-objects in the chain-level category (the pro-ambient of this chapter); the $(\infty, 1)$ -categorical limit in the presentable ∞ -category $\text{ChirAlg}_X^{E_2\text{-ch}}$ is the native home for $\mathbf{H}_{\Delta_5}$ and is unconditional given Theorem CY-A₂ (Vol. III Theorem ??). The passage from the chain-level pro-ambient to the presentable ∞ -category exhibits the adjunction-strictness split of Lurie HA.5.5: a chain-level adjunction requires an explicit splitting witness, whereas the $(\infty, 1)$ -categorical adjunction is strict by construction. Both lanes carry equal status, neither supersedes the other.

Remark 10.16.5 (KST Φ -functor on $D^b\text{Coh}(K_3)$). The Kontsevich–Soibelman–Toën functor statement on K_3 , assembled from Remarks 10.16.1–10.16.4, reads:

$$\Phi_2: (D^b\text{Coh}(K_3), [2]) \longrightarrow (\mathbf{H}_{\Delta_5}, \text{bar-cobar shift } [2])$$

with input the CY-2 category with Serre-duality pairing $\text{Ext}^i(\mathcal{E}, \mathcal{F}) \simeq \text{Ext}^{2-i}(\mathcal{F}, \mathcal{E})^\vee$ and output the K_3 chiral bialgebra of Chapter ??, Definition ??. The structural dictionary:

CY-2 input	Chiral output
Mukai lattice $\widetilde{\Lambda}_{K_3}((4, 20))$	Cartan of rank 24
Euler char $\chi(K_3) = 24$	Affine level = 24 (Göttsche)
Mukai pairing	Bilinear form on chiral Cartan
Serre duality [2]	Koszul shift [2] on bar
Bridgeland wall $\hbar^2 = -1/8$	DQ self-dual point
Humbert H_1 , order 8	$K^{\kappa_{\text{ch}}} = 8$
K ₃ -CoHA (KV 2018)	positive Borel of $\mathbf{H}_{\Delta_5}$
Hilb ⁿ (K ₃) Fock tower	bar-degree- <i>n</i> pages of $B(\mathbf{H}_{\Delta_5})$
Protected index $1/\chi_{10}$	genus-2 supercharacter of $\mathbf{H}_{\Delta_5}$

The bottom three rows are the BKM/Siegel identification: the BKM denominator Δ_5 is the Gritsenko additive lift of the K₃ elliptic genus $\phi_{0,1}$ (Gritsenko 1999 Algebra i Analiz 11) and the Igusa form $\chi_{10} = \Delta_5^2$ is the scalar denominator whose Fourier coefficients give the protected BPS index on $K_3 \times T^2$. Dijkgraaf–Moore–Verlinde–Verlinde [DijkgraafMooreVerlindeVerlinde1997] separate the charge-graded Hilbert-space decomposition from its supertrace in equations (2.19) and (1.2); their product formulae (1.3) and (3.12) give the reciprocal automorphic denominator. For the K₃ elliptic genus this denominator is the weight-10 Igusa form, with the Weyl prefactor carried by (3.12). Thus the Hilbert-scheme Fock tower supplies the state-space object, while $1/\chi_{10}$ is its charge-graded protected supertrace. Cross-reference Chapter ??, Theorem ?? (Oberdieck–Pixton).

10.17 CHIRAL KONTSEVICH FORMALITY ON $\overline{\mathcal{A}}_2 \setminus \bigcup_n H_n$

Kontsevich 1997 (ARXIV:q-alg/9709040, Theorem 4.1) produces, for a smooth Poisson manifold M , an L_∞ -quasi-isomorphism

$$\mathcal{U}_{\text{Kont}} : (T_{\text{poly}}(M), [[-, -]]_{\text{Schouten}}) \xrightarrow{\sim} (C_{\text{Hoch}}^\bullet(\mathcal{O}_M), b, [[-, -]]_{\text{Ger}})$$

between polyvector fields and Hochschild cochains, with Taylor components weighted by admissible-graph integrals on the upper half-plane (Kontsevich *loc. cit.* Equation (2.2)). The three classical inputs are: (a) smoothness of M ; (b) a Poisson bivector $\pi \in \Gamma(\wedge^2 T^*M)$; (c) convergent graph coefficients w_Γ against harmonic angle forms on admissible configurations. A chiral comparison for $\mathbf{H}_{\Delta_5}$ therefore requires four new constructions: a relative dg Lie algebra of factorisation derivations, a chain-level map to chiral Hochschild cochains, compactified configuration integrals compatible with BD factorisation, and a quasi-isomorphism argument. The KZ associator, the Bruinier divisor calculation, and a BV obstruction theory may contribute to these constructions through separately typed comparison maps. The bridge is a chain map carrying all three data into one cohomology complex.

The arithmetic open used below is

$$\mathcal{U}_{\text{Humb}}^c := \overline{\mathcal{A}}_2 \setminus \bigcup_{n \text{ adm}} H_n, \quad n \text{ adm} \iff n \equiv 0, 3 \pmod{4}.$$

Its relation to the K₃ Koszul locus and to bar–cobar inversion is part of the comparison problem.

Definition 10.17.1 (Chiral polyvector fields on $\overline{\mathcal{A}}_2$). Let $\pi: \text{Ran}(E_{24}^{\text{nod,sm}}) \rightarrow \overline{\mathcal{A}}_2$ be the modular projection of Chapter 26. The chiral polyvector fields

$$T_{\text{ch}}^\bullet(\overline{\mathcal{A}}_2, \mathbf{H}_{\Delta_5}) := \text{Der}_{\text{fact}}^\bullet(\pi_* \mathbf{H}_{\Delta_5}, \pi_* \mathbf{H}_{\Delta_5})$$

are the factorisation-algebra derivations of $\mathbf{H}_{\Delta_5}$ as a BD factorisation $\mathcal{D}$ -module on $\text{Ran}(E_{24}^{\text{nod,sm}})$, graded by wedge degree in the super-quasi-Hopf parity and by cohomological degree. The Schouten bracket $[[-, -]]_{\text{Schouten}}^{\text{ch}}$ is the graded commutator of factorisation derivations against the super-quasi-Hopf sign of Remark 26.8.4 in Chapter 26.

Definition 10.17.2 (Humbert chiral-formality package;). The package H_{HCF} for $\mathbf{H}_{\Delta_5}$ consists of:

- (HCF1) a dg Lie model $T_{\text{ch}}^\bullet$ for factorisation derivations on $\mathcal{U}_{\text{Humb}}^c$ and a dg Lie model for $CH^\bullet(\mathbf{H}_{\Delta_5})$;
- (HCF2) compactified relative configuration spaces, propagator forms, and convergent weights w_Γ^{ch} whose boundary factorisation proves the L_∞ identities;
- (HCF3) a filtered quasi-isomorphism argument for the resulting Taylor series $\mathcal{U}_{\text{Kont}}^{\text{ch}}$;
- (HCF4) a comparison morphism from the resulting obstruction complex to cohomology with support on each H_n , together with a degree-correct purity or Gysin map to the arithmetic divisor class;
- (HCF5) a separate Theorem–B hypothesis H_{BC} asserting that the quadratic recognition map for $\mathbf{H}_{\Delta_5}$ is a quasi-isomorphism in the chosen completed presentation.

Each clause is a chain-level construction. The classical Kontsevich theorem, the Bruinier divisor formula, and the general bar–cobar adjunction supply inputs to distinct clauses.

THEOREM 10.17.3 (Chiral Kontsevich formality on the Humbert-free complement). This is an Open-quadrant statement in factorisation presentation at Beilinson level 3. Assume the package H_{HCF} of Definition 10.17.2. Then the Taylor series constructed in (HCF2) defines a chain-level L_∞ -quasi-isomorphism

$$\mathcal{U}_{\text{Kont}}^{\text{ch}}: (T_{\text{ch}}^\bullet(\overline{\mathcal{A}}_2, \mathbf{H}_{\Delta_5})|_{\mathcal{U}_{\text{Humb}}^c}, [[-, -]]_{\text{Schouten}}^{\text{ch}}) \xrightarrow{\sim} (CH^\bullet(\mathbf{H}_{\Delta_5})|_{\mathcal{U}_{\text{Humb}}^c}, d_{CH}, [[-, -]]_{\text{Ger}}^{\text{ch}}) \quad (10.7)$$

The Taylor component of arity k is the compactified graph integral specified in (HCF2), and its quasi-isomorphism property is the filtered comparison of (HCF3). Clause (HCF5) belongs to the bar–cobar lane and yields the separate corollary below.

Proof. Clause (HCF2) gives Taylor maps satisfying the L_∞ identities, because the codimension-one boundary of every compactified configuration integral is, by assumption, the signed sum of operadic compositions. Clause (HCF3) identifies the associated-graded linear term as a quasi-isomorphism and supplies the complete filtration needed to lift this conclusion. The filtered comparison lemma then proves (10.7). The Bruinier and BV data enter through (HCF4) after construction of their comparison morphism; the formal deduction itself uses (HCF2) and (HCF3). $\square$

COROLLARY 10.17.4 (Bar–cobar inversion under its recognition hypothesis). Assume clause (HCF5). On $\mathcal{U}_{\text{Humb}}^c$ the quadratic recognition map for $\mathbf{H}_{\Delta_5}$ yields the chiral bar–cobar counit

$$\widehat{\text{counit}}_{\mathbf{H}_{\Delta_5}}|_{\mathcal{U}_{\text{Humb}}^c}: \Omega^{\text{ch}}(B^{\text{ch}}(\mathbf{H}_{\Delta_5}))|_{\mathcal{U}_{\text{Humb}}^c} \xrightarrow{\sim} \mathbf{H}_{\Delta_5}|_{\mathcal{U}_{\text{Humb}}^c}$$

as a strict chain-level quasi-isomorphism in the completed presentation specified by H_{BC} .

Proof. This is precisely the conclusion of the Theorem–B recognition theorem after imposing H_{BC} . Theorem 10.17.3 concerns the derived-centre lane; it supplies an additional compatible structure through clauses (HCF1)–(HCF3). $\square$

Remark 10.17.5 (Humbert obstruction comparison problem;). Three classes enter with different types: the arithmetic class $c_1(\mathcal{L}^{\Delta_3}|_{H_n}) \in H^2(H_n)$, a BV obstruction in the cohomology of local functionals for a specified quantum field theory, and a Malcev extension class in the cohomology of its classifying Lie algebra. Clause (HCF4) asks for chain maps from the latter two complexes to one degree-correct local-cohomology group supported on H_n . Equality may then be formulated after all three classes inhabit that common group. The same construction on $H_i \cap H_j$ must include the excess-intersection and Gysin maps; ordinary multiplication of two scalar readouts supplies only the arithmetic target.

Remark 10.17.6 (Three-fold reading of bar–cobar inversion). Three comparison lanes meet on the arithmetic open. The Koszul lane uses the quadratic recognition map q_A of Theorem B. The Malcev lane uses extension classes on formal neighbourhoods of intersections of Humbert divisors. The formality lane uses the L_∞ map of Theorem 10.17.3. Pairwise agreement is a theorem only after constructing comparison morphisms between their source complexes. Package H_{HCF} records the formality-to-arithmetic morphism, while H_{BC} records the Koszul lane. This separation preserves the three ambient categories and makes their common restriction a precise future comparison theorem.

Remark 10.17.7 (Five construction problems for chiral Kontsevich formality;). Package H_{HCF} decomposes into five concrete problems.

- (1) Prove that the chosen arithmetic open supports the relative factorisation objects and compactifications used in (HCF1) and (HCF2).
- (2) Construct the dg Lie bracket on factorisation derivations and the chain map to the Gerstenhaber bracket. A parity convention supplies the signs after this map exists.
- (3) Extend the propagator forms to the compactification, evaluate every boundary residue, and prove convergence uniformly over the base.
- (4) Build an operadic descent functor carrying the classical associator to the selected chiral factorisation operad. The KZ associator is an input; the descent functor and its deformation comparison are the new constructions.
- (5) Construct the local-cohomology comparison maps of (HCF4) and compute them on the first Humbert divisors. The arithmetic divisor multiplicities provide target values for this computation.

Together these constructions produce H_{HCF} ; the theorem then follows by its proof above.

Remark 10.17.8 (Associator and first-divisor comparison problems;). The associator route asks for an operadic functor from the Tamarkin–Hinich setting to the relative chiral factorisation category, together with compatibility between its deformation complex and $T_{ch}^\bullet$. The divisor route begins with the verified Fourier or divisor multiplicities of the automorphic form and asks for actual BV and Malcev cocycles whose images under (HCF4) have those values. Agreement of three integers becomes evidence only after the three chain maps and their normalization conventions have been specified.

Remark 10.17.9 (Architectural place of chiral Kontsevich formality). This theorem belongs to the level-3 derived-centre lane. Theorem H assigns a support set only after the family-specific Hochschild complex has been computed. Theorem D supplies a native deformation class; its comparison package produces

the K-theoretic class, the signed Hodge component, and the graph-evaluated scalar. The formality obstruction, the Theorem–H support, and the Theorem–D Hodge class therefore enter as three typed objects. A K3-modular identification among them is precisely the comparison map required in (HCF₄), with the selected primary line and trace normalization carried as part of the datum.

Definition 10.17.10 (The admissible Humbert complement $U^{\text{adm}} \subset \overline{\mathcal{A}}_2$). The *admissible Humbert complement* is the arithmetic open

$$U^{\text{adm}} := \overline{\mathcal{A}}_2 \setminus \bigcup_{n \text{ adm}} H_n, \quad n \text{ adm} \iff n \equiv 0, 3 \pmod{4},$$

inside the chosen compactification of the principally polarized locus. It is, by notation, $U^{\text{adm}} = \mathcal{U}_{\text{Humb}}^c$ of Theorem 10.17.3. The term “Koszul locus” is reserved for the additional comparison with the quadratic recognition map under H_{BC} .

LEMMA 10.17.11 (Bar–cobar recognition on U^{adm}). Assume H_{BC} from Definition 10.17.2. The restriction of the chiral bar–cobar counit

$$\widehat{\text{counit}}_{\mathbf{H}_{\Delta_5}}|_V : \Omega^{\text{ch}}(B^{\text{ch}}(\mathbf{H}_{\Delta_5}))|_V \longrightarrow \mathbf{H}_{\Delta_5}|_V$$

is a strict chain-level quasi-isomorphism for every open $V \subset U^{\text{adm}}$ in the completed presentation named by that package.

Proof. Apply Corollary 10.17.4 after restriction to V . Exactness and completion compatibility are clauses of H_{BC} . $\square$

Definition 10.17.12 (Finite Humbert-supported obstruction datum;). Let $T_{\text{ch}}^{\text{poly}} := T_{\text{ch}}^{\bullet}(\overline{\mathcal{A}}_2, \mathbf{H}_{\Delta_5})$. For a finite set S of selected Humbert indices write $H_S = \bigcup_{n \in S} H_n$. A finite supported obstruction datum is a compatible family

$$\text{ob}_S^{\text{Kont}} \in H_{H_S}^3(\overline{\mathcal{A}}_2, \text{Sym}^2 T_{\text{ch}}^{\text{poly}}), \quad S \subset S' \implies \text{ob}_{S'}^{\text{Kont}}|_{H_S} = \text{ob}_S^{\text{Kont}}.$$

Its single-wall component is $\text{ob}_{\{n\}}^{\text{Kont}} \in H_{H_n}^3(\overline{\mathcal{A}}_2, \text{Sym}^2 T_{\text{ch}}^{\text{poly}})$. A purity isomorphism, when available, translates this supported class into a class on H_n with the corresponding codimension shift and coefficient twist. Thus the symbol $\text{ob}^{\text{Kont}} = (\text{ob}_S^{\text{Kont}})_S$ denotes a pro-family over finite S . An extension to the full union is an additional completion problem.

THEOREM 10.17.13 (Chiral Kontsevich formality on U^{adm} , unified form). Let $U^{\text{adm}} = \overline{\mathcal{A}}_2 \setminus \bigcup_{n \text{ adm}} H_n$ be the admissible Humbert complement of Definition 10.17.10. Assume H_{HCF} . Assume also that its supported comparison in (HCF₄) carries the formality obstruction to a chosen Malcev class on every finite union H_S . Then:

- (a) *Formality on the arithmetic open.* The chiral Kontsevich map $\mathcal{U}_{\text{Kont}}^{\text{ch}}$ of (10.7) is a chain-level L_{∞} -quasi-isomorphism

$$(T_{\text{ch}}^{\text{poly}}|_{U^{\text{adm}}}, [[-, -]]_{\text{Schouten}}^{\text{ch}}) \xrightarrow{\sim} (CH^{\bullet}(\mathbf{H}_{\Delta_5})|_{U^{\text{adm}}}, d_{CH}, [[-, -]]_{\text{Ger}}^{\text{ch}})$$

in the completed ambient specified by H_{HCF} .

- (b) *Supported comparison on a wall.* For each selected Humbert divisor H_n , clause (HCF₄) gives a common supported cohomology group and identifies the two supplied classes there:

$$\text{ob}_{\{n\}}^{\text{Kont}} = \text{cmp}_n([\text{gr}_n^{\text{Malcev}}]) \in H_{H_n}^3(\overline{\mathcal{A}}_2, \text{Sym}^2 T_{\text{ch}}^{\text{poly}}). \quad (10.8)$$

- (c) *Separation of the three inputs.* The construction retains three distinct source calculations:

- (i) compactified graph integrals produce the formality class;
- (ii) the selected quantum field theory produces a BV class in its local-functional complex;
- (iii) the automorphic line and the Malcev extension produce arithmetic and representation-theoretic classes in their respective cohomology groups.

Their equality is equation (10.8) after applying the comparison maps assumed above.

Proof. Part (a) is Theorem 10.17.3. Part (b) is the single-wall component of the supported comparison assumed in the statement. Part (c) records the domains of the three source classes; equation (10.8) compares their images in one supported cohomology group. Compatibility for finite S is the transition condition of Definition 10.17.12. $\square$

Remark 10.17.14 (Architectural payload of Theorem 10.17.13). The unified theorem is an assembly statement with a visible load-bearing input: H_{HCF} constructs the formality map, while cmp_n compares its supported obstruction with the Malcev class. Theorem H enters after a family-specific computation of the support of $CH^\bullet(\mathbf{H}_{\Delta_j})$. Theorem D enters through its higher Hodge class after the scalar-diagonal package and a map to the supported obstruction complex. These two further comparisons remain named hypotheses and preserve their distinct cohomological degrees.

MC₅: FIVE-POINT SEWING AND GENUS-ONE CLUTCHING

The master conjecture chain $\text{MC}_1 \rightarrow \text{MC}_2 \rightarrow \text{MC}_3 \rightarrow \text{MC}_4$ closes inside genus zero. The four-point function lives on $\overline{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$; its three boundary points are rational nodal degenerations corresponding to the three pairings $\{12|34\}$, $\{13|24\}$, $\{14|23\}$ of the four marked points. No genus-1 stratum appears, and the entire MC_4 sewing closure proceeds inside genus zero.

The five-point function lives on $\overline{\mathcal{M}}_{0,5}$. Its Deligne–Mumford boundary has only rational separating divisors: ten of them, indexed by two-element subsets of the five markings. The first genus-one datum is a different geometric operation. It is the clutching correspondence

$$\text{cl}_T: \overline{\mathcal{M}}_{1,T \cup \{*\}} \times \overline{\mathcal{M}}_{0,T^c \cup \{*\}} \longrightarrow \overline{\mathcal{M}}_{1,5}, \quad |T| = 3,$$

where the node labelled $*$ glues a genus-one component carrying the three markings in T to a residual genus-zero component carrying the remaining two. This correspondence, not an extra divisor of $\overline{\mathcal{M}}_{0,5}$, is the genus-zero/genus-one wall seen by MC_5 .

This chapter inscribes the 5-point sewing theorem in that form. The statement has five clauses: rational separating divisors, genus-one clutching charts, pullback identity from the climax theorem, completed Maurer–Cartan element, and bar-cobar duality. The evaluation-generated-core qualifier is preserved as a mathematical hypothesis and complemented by a full-category conjecture. The chain-level companion (Chapter 10) addresses the ambient-completion question for class $\mathbf{M}$; the present chapter addresses the geometric sewing content.

II.1 SETUP: THE MODULI GEOMETRY OF $\overline{\mathcal{M}}_{0,5}$

Throughout this chapter, X is a smooth projective curve over $\mathbb{C}$, and $\mathcal{A}$ is a strong completion tower (Definition 9.1.26) of finite resonance rank $\rho(\mathcal{A}) < \infty$. The evaluation-generated subcategory $\mathcal{A}^{\text{ec}}$ is defined as in MC_3 (Section 34.1).

Definition II.1.1 (Rational boundary and genus-one clutching). The Deligne–Mumford compactification $\overline{\mathcal{M}}_{0,5}$ of the moduli of 5-pointed genus-zero stable curves has a normal-crossings boundary divisor that decomposes as

$$\partial \overline{\mathcal{M}}_{0,5} = \bigcup_{\substack{S \subset \{1, \dots, 5\} \\ |S|=2}} D_S, \quad D_S = \delta_{0|S, S^c}. \quad (\text{II.1})$$

Here $\delta_{0|S, S^c}$ is the locus of stable curves with two genus-zero components attached at a single node, the markings indexed by S on one component and the markings indexed by S^c on the other. There are $\binom{5}{2} = 10$ such divisors.

For a three-element subset $T \subset \{1, \dots, 5\}$, the genus-one sewing datum is the clutching morphism

$$\text{cl}_T: \overline{\mathcal{M}}_{1,T \cup \{*\}} \times \overline{\mathcal{M}}_{0,T^c \cup \{*\}} \longrightarrow \overline{\mathcal{M}}_{1,5}. \quad (\text{II.2})$$

Stage	Moduli accessed	Genus filter
MC ₁	$\overline{\mathcal{M}}_{0,1}$	$g = 0$
MC ₂	$\overline{\mathcal{M}}_{0,2}$	$g = 0$
MC ₃	$\overline{\mathcal{M}}_{0,3}$	$g = 0$
MC ₄	$\overline{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$	$g = 0$
MC ₅	$\overline{\mathcal{M}}_{0,5}$ plus cl_T for $ T = 3$	$g = 0$ with first $g = 1$ clutching

TABLE 11.1: The MC chain as a stratified arithmetic of point counts. MC₅ is the first stage at which the genus-one clutching datum is visible.

Its image $\Delta_T^{(1)}$ is a boundary divisor of $\overline{\mathcal{M}}_{1,5}$, not of $\overline{\mathcal{M}}_{0,5}$. The elliptic trace in the MC₅ sewing theorem is a compatibility condition along the completed charts of $\Delta_T^{(1)}$.

The decomposition (11.1) contains ten rational divisors. The genus-one charts (11.2) are separate clutching correspondences. The point counts visible to the MC chain at each prior stage are summarised in the following table.

Remark 11.1.2 (The arithmetic of MC₁–MC₅). At MC₁ the moduli is a point, the MC element is the unit-vacuum identification, and no boundary structure appears. At MC₂ the moduli is the line $\overline{\mathcal{M}}_{0,2}$, the MC element is the binary OPE residue at the collision divisor (the chiral classical r -matrix), and the only boundary geometry is the single nodal point. At MC₃ the moduli is $\overline{\mathcal{M}}_{0,3}$, a single point, and the MC element encodes the first associativity homotopy at the level of the bar coderivation $b_2 + b_3$ (see Theorem 34.2.1). At MC₄ the moduli $\overline{\mathcal{M}}_{0,4} \cong \mathbb{P}^1$ has three boundary points, all rational, and the strong-completion-tower closure of Theorem 9.1.28 extends the MC element across them. At MC₅ the moduli $\overline{\mathcal{M}}_{0,5}$ has ten rational separating divisors, and the genus-one trace enters through the clutching maps (11.2).

11.2 THE 5-POINT SEWING THEOREM

The central theorem of the chapter, stated now, is restricted to the evaluation-generated core $\mathcal{A}^{\text{ec}}$ in keeping with the eval-core discipline (thick generation on evaluation-generated representations, not full DK_g) applied throughout MC₃ and MC₄ (see Remark 11.2.2 below for the explicit scope statement).

THEOREM 11.2.1 (*MC₅ 5-point sewing with genus-one clutching*). Let X be a smooth projective curve over $\mathbb{C}$ and let $\mathcal{A}$ be a strong completion tower of finite resonance rank $\rho(\mathcal{A}) < \infty$, restricted to its evaluation-generated core $\mathcal{A}^{\text{ec}}$. For $\xi_1, \dots, \xi_5 \in \mathcal{A}^{\text{ec}}$ and $z_1, \dots, z_5 \in X$ with $z_i \neq z_j$ for $i \neq j$, let

$$\Phi_5^{\text{ec}}(\xi_1, \dots, \xi_5; z_1, \dots, z_5) = \langle \text{vac} \mid V(\xi_1, z_1) \cdots V(\xi_5, z_5) \mid \text{vac} \rangle$$

be the 5-point chiral correlator of $\mathcal{A}^{\text{ec}}$ on X , regarded as a holomorphic section of the conformal-weight line over $\text{Conf}_5^{\text{ord}}(X)$. Then Φ_5^{ec} has a unique rational sewing extension over the completed genus-zero compactification $\widehat{\overline{\mathcal{M}}_{0,5}}(X)$. For each three-element subset $T \subset \{1, \dots, 5\}$ there is also a genus-one sewn block $\widehat{\Phi}_{5,T}^{(1),\text{ec}}$ on the completed clutching chart $\widehat{\Delta}_T^{(1)}$, compatible with the rational nodal factorisation at $q = 0$. The sewing data are:

- (i) **(Genus-o separating divisors.)** For each separating divisor $\delta_{o|S,S^c}$ with $|S| \in \{2, 3\}$, the restriction

$$\bar{\Phi}_5^{\text{ec}}|_{\delta_{o|S,S^c}} = \sum_{a,b} \Phi_{|S|+1}^{\text{ec}}(\xi_S; e_a) \eta^{ab} \Phi_{|S^c|+1}^{\text{ec}}(e_b; \xi_{S^c}) \quad (\text{II.3})$$

agrees with the MC4 (respectively MC3) sewing prediction, where $\{e_a\}$ is a homogeneous basis of the eval-gen-core sectors with parameters a, b ranging over a fixed indexing set, and η^{ab} is the inverse Shapovalov form on the node sector. The sum is convergent and trace-class on the appropriate weighted Hilbert completion.

- (ii) **(Genus-one clutching.)** For each $T = \{i_1, i_2, i_3\}$ with complement $T^c = \{j_1, j_2\}$, along the completed clutching chart $\widehat{\Delta}_T^{(1)}$ parametrised by the bubble nome $q \in \{q \in \mathbb{C} : 0 < |q| < 1\}$, the restriction

$$\bar{\Phi}_{5,T}^{(1),\text{ec}} = \sum_{a,b} \text{Tr}_{\mathcal{A}^{\text{ec}}}^{(1)} \left(V(\xi_{i_1}) V(\xi_{i_2}) V(\xi_{i_3}) e_a q^{L_0 - c/24} \right) \eta^{ab} \Phi_2^{\text{ec}}(\xi_{j_1}, \xi_{j_2}; e_b) \quad (\text{II.4})$$

is the elliptic supertrace of the 3-point function on the genus-one component glued through the node state e_a to the residual 2-point function on the genus-zero component.

- (iii) **(Pullback identity from the climax theorem.)** The bar differential $d_{\text{bar},5}$ of $\bar{B}_{\leq 5}^{\text{ch}}(\mathcal{A}^{\text{ec}})$ is the pullback

$$d_{\text{bar},5} = \text{KZ}^* \left(\nabla_{\text{Arnold}}^{(s)} \right)$$

of the $n = 5$ specialisation of Arnold's universal flat connection on $\text{Conf}_5^{\text{ord}}(X)$ along the KZ functor of Chapter ??, equation (?). The Arnold flatness identity $\nabla_{\text{Arnold}}^{(s)2} = 0$ is, after pullback, the bar squaring-to-zero $d_{\text{bar},5}^2 = 0$.

- (iv) **(Completed Maurer-Cartan element.)** The sewing twisting morphism

$$\tau^{\text{sew},5} \in \text{MC} \left(\text{Conv}(\bar{B}_{\leq 5}^{\text{ch}}(\mathcal{A}^{\text{ec}}), \mathcal{A}^{\text{ec}}) \right)$$

extends the MC4 element $\tau^{\text{sew},4}$, agrees with the genus-o separating prediction (II.3) along each $\delta_{o|S,S^c}$ for $|S| \in \{2, 3\}$, and agrees with the genus-one clutching prediction (II.4) after applying the clutching functor for every T with $|T| = 3$.

- (v) **(Bar-cobar duality.)** The completed counit

$$\widehat{\epsilon}_5 : \widehat{\Omega}^{\text{ch}}(\bar{B}_{\leq 5}^{\text{ch}}(\mathcal{A}^{\text{ec}})) \xrightarrow{\sim} \mathcal{A}_{\leq 5}^{\text{ec}}$$

is a quasi-isomorphism of curved dg chiral algebras at finite stage $N = 5$, and its degree-5 component coincides with the cobar dual of $\tau^{\text{sew},5}$.

Remark II.2.2 (evaluation-generated-core qualifier). Theorem II.2.1 is proved on the evaluation-generated subcategory $\mathcal{A}^{\text{ec}}$, exactly in the sense of MC3 (see item (D1)). The full-category extension to objects outside the eval-gen-core is conjectural for two structural reasons. First, the elliptic supertrace in clause (ii) requires trace-class compactness of the restriction operator on the genus-1 bubble, which is proved by the HS-sewing criterion of Theorem ?? only on eval-gen-core objects: the OPE coefficient growth bound is verified family-by-family for the eval-gen-core, not for arbitrary chiral algebras. Second, the bar-cobar quasi-isomorphism in clause (v) inherits its eval-gen-core restriction from the corresponding MC4 statement (Theorem 9.1.28) via the finite-type bar-cobar comparison. Stating Theorem II.2.1 without

the eval-gen-core qualifier would extend the claim to the full category DK_g , where the OPE-coefficient-growth bound and the MC₄ bar-cobar comparison have not been established; the eval-core discipline (thick generation on evaluation-generated representations) is therefore mandatory throughout the MC chain.

Conjecture 11.2.3 (Full-category MC₅ with genus-one clutching). The conclusions of Theorem 11.2.1 extend to the full subcategory of pronilpotent strong completion towers of finite resonance rank, without the evaluation-generated-core restriction.

Remark 11.2.4 (Higher-stage MC extension is conjectural). The MC chain $\text{MC}_1 \rightarrow \cdots \rightarrow \text{MC}_5$ is closed at MC₅ on the eval-gen-core. Extension to MC₆ and beyond would force additional genus-filter crossings: at $n = 6$ markings, either two disjoint genus-one clutching components appear or the first genus-two clutching component is reached. The corresponding sewing theorems are conjectural; their proofs would require trace-class compactness on the higher-genus component, beyond the HS-sewing criterion currently available on the eval-gen-core (with 11.2.3 the simplest analogue).

11.3 STRATIFIED EXTENSION AND GENUS-ONE CLUTCHING

The proof of Theorem 11.2.1 proceeds by extension across the ten rational boundary divisors of $\overline{\mathcal{M}}_{0,5}$ and by a separate compatibility check on the genus-one clutching charts (11.2). The rational divisors are governed by MC₄ and MC₃; the clutching chart is governed by the genus-one trace formula on the elliptic component.

Proof of Theorem 11.2.1. The proof has four steps corresponding to the four sewing clauses. Throughout, $\mathcal{A}$ is restricted to $\mathcal{A}^{\text{ec}}$ (see Remark 11.2.2).

Step 1: Restriction to rational boundary divisors and clutching charts. The boundary $\partial \overline{\mathcal{M}}_{0,5}$ is decomposed as in (11.1): ten rational separating divisors D_S with $|S| = 2$. The extension $\tilde{\Phi}_5^{\text{ec}}$ is determined by its restriction to these divisors via the standard formal-coordinate factorisation: write $z_i = z_i(t)$ with t the formal parameter normal to the divisor, expand Φ_5^{ec} as a power series in t , and apply the OPE expansion encoded by clause (i). Clause (ii) is not another $\overline{\mathcal{M}}_{0,5}$ boundary condition; it is checked on the completed clutching chart $\widehat{\Delta}_T^{(1)} \subset \overline{\mathcal{M}}_{1,5}$.

Step 2: Compatibility with MC₄ at separating divisors. At each separating divisor $\partial_{0|S,S^c}$ with $|S| = 2$, the curve degenerates into two genus-0 components glued at a single node; the two markings ξ_S live on one component (the bubble), and the three markings ξ_{S^c} live on the other. The factorisation through the node is given by the complete intermediate state sum

$$\Phi_5^{\text{ec}}|_{\partial_{0|S,S^c}} = \sum_{a,b} \Phi_3^{\text{ec}}(\xi_S; e_a) \eta^{ab} \Phi_4^{\text{ec}}(e_b; \xi_{S^c}), \quad (11.5)$$

where the sum runs over the eval-gen-core basis $\{e_a\}$. The right-hand side is exactly the MC₃-MC₄ sewing prediction: the 3-point factor is governed by MC₃ (Theorem 34.2.1), and the 4-point factor is governed by MC₄ (Theorem 9.1.28), both restricted to $\mathcal{A}^{\text{ec}}$ as in Remark 11.2.2.

The case $|S| = 3$ is symmetric: the bubble carries three markings, and the residual sphere carries two. Expanded out,

$$\Phi_5^{\text{ec}}|_{\partial_{0|S,S^c}} = \sum_{a,b} \Phi_4^{\text{ec}}(\xi_S; e_a) \eta^{ab} \Phi_3^{\text{ec}}(e_b; \xi_{S^c}), \quad (11.6)$$

with the symmetric MC₄ closure on the bubble factor and the MC₃ closure on the residual factor.

Convergence and trace-class compactness of the sums in (II.5) and (II.6) follow from the HS-sewing criterion of Theorem ??, applied at $n = 4$ and at $n = 3$ respectively. The strong-completion-tower hypothesis of $\mathcal{A}^{\text{ec}}$ controls the OPE coefficient growth required by the criterion.

Step 3: Compatibility on the genus-one clutching chart. Fix $T = \{i_1, i_2, i_3\}$. The chart $\widehat{\Delta}_T^{(1)}$ is the formal neighbourhood of the image of (II.2) in $\overline{\mathcal{M}}_{1,5}$. Its smoothing parameter is the bubble nome $q = e^{2\pi i \tau}$ with $0 < |q| < 1$; the limit $q \rightarrow 0$ pinches the elliptic component to its nodal degeneration.

On the bubble, the 3-point function is determined by the genus-1 traced 3-point function

$$F_3^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q) = \text{Tr}_{\mathcal{A}^{\text{ec}}} \left(V(\xi_{i_1}) V(\xi_{i_2}) V(\xi_{i_3}) e_a q^{L_0 - c/24} \right),$$

where the trace is over the eval-gen-core sectors. By the factorisation-at-nodes clause of Theorem A (Theorem ??, clause (iv)), the bar differential on a degenerating curve restricts at the node to the ordinary residue OPE, so

$$d_{\text{bar}, T}^{(1|0)} = d_{\text{bar}, 3}^{(1)} \otimes \mathbf{1} + \mathbf{1} \otimes d_{\text{bar}, 2}^{(0)},$$

the formal sum of the genus-1 bar differential on the bubble with the genus-0 bar differential on the residual sphere. The 5-point sewing prediction on the clutching chart is therefore the trace formula

$$\tilde{\Phi}_{5, T}^{(1), \text{ec}} = \sum_{a, b} F_3^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q) \eta^{ab} \Phi_2^{\text{ec}}(\xi_{j_1}, \xi_{j_2}; e_b), \quad (\text{II.7})$$

exactly the right-hand side of clause (ii) of the theorem.

Convergence of (II.7): the sum over the eval-gen-core basis is trace-class for $0 < |q| < 1$ by the HS-sewing criterion applied to the genus-one component. The trace-class property survives the residual genus-0 coupling because the residual 2-point function $\Phi_2^{\text{ec}}(\xi_{j_1}, \xi_{j_2}; e_b)$ is bounded uniformly on compact subsets of the genus-0 residual sphere, controlled by the conformal weight grading on $\mathcal{A}^{\text{ec}}$.

Step 4: Compatibility with the bar differential at non-separating loci. The remaining content is the squaring-to-zero $d_{\text{bar}, 5}^2 = 0$ on the open stratum $\text{Conf}_5^{\text{ord}}(X)$ and its propagation across the boundary. By the climax theorem (Chapter ??, equation (??)), the bar differential is the pullback

$$d_{\text{bar}, 5} = \text{KZ}^*(\nabla_{\text{Arnold}}^{(5)}),$$

and Arnold's three-term relation

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0 \quad \text{on } \text{Conf}_5^{\text{ord}}(X), \quad 1 \leq i < j < k \leq 5, \quad (\text{II.8})$$

gives flatness $\nabla_{\text{Arnold}}^{(5)2} = 0$. Pulling back, $d_{\text{bar}, 5}^2 = 0$. This is clause (iii).

The Maurer-Cartan element $\tau^{\text{sew}, 5}$ is then the universal twisting morphism of the convolution complex $\text{Conv}(\widehat{B}_{\leq 5}^{\text{ch}}(\mathcal{A}^{\text{ec}}), \mathcal{A}^{\text{ec}})$ at degree 5, and clause (iv) asserts that it extends the MC₄ element by construction: each MC₄ sewing prediction at $|S| = 2$ or $|S| = 3$ is a finite-stage truncation of the MC₅ element at ≤ 4 points, and the genus-one clutching prediction on $\widehat{\Delta}_T^{(1)}$ is the extension specified in clause (ii).

Bar-cobar duality on the eval-gen-core. The completed counit $\widehat{e}_5$ is a quasi-isomorphism by the strong-completion-tower closure of MC₄ (Theorem 9.1.28) applied at finite stage $N = 5$, restricted to $\mathcal{A}_{\leq 5}^{\text{ec}}$. The strong completion-tower hypothesis ensures the degree-cutoff lemma (Lemma 9.1.27)

bounds the bar differential by a finite sum at each weight stage, and Mittag-Leffler is automatic on the eval-gen-core (Proposition 9.1.29, clause (iv)). This proves clause (v).

Cross-references. Clause (i) is the Beilinson–Drinfeld factorisation rule at rational separating divisors [?BeilinsonDrinfeld04]. Clause (ii) is the genus-one trace factorisation on the clutching divisor $\Delta_T^{(1)}$, with trace-class convergence supplied by the HS-sewing criterion in the stated eval-gen-core ambient. The two factorisations agree at the nodal limit $q = 0$ because both reduce to the same residue pairing through the node state. $\square$

II.4 THREE CLUTCHING CONSEQUENCES

The 5-point sewing theorem has three concrete instantiations, one for each canonical landscape witness for which the elliptic supertrace in clause (ii) is computable in closed form. We record them as corollaries of Theorem II.2.1, with explicit scope tags.

COROLLARY II.4.1 (*Heisenberg elliptic function at the wall;*). (UNIFORM-WEIGHT.) Let $\mathcal{A} = H_k$ be the Heisenberg vertex algebra at level k , regarded as a class-G chiral algebra in the standard landscape (Chapter ??). The elliptic supertrace in clause (ii) of Theorem II.2.1, applied to $\mathcal{A}^{\text{ec}} = H_k$, is a Fredholm determinant

$$F_3^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q) = \det(1 - T_q)^k \cdot W_3(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q),$$

where T_q is the genus-1 sewing kernel on the reduced Bergman space and W_3 is the Wick-contraction polynomial of the three insertions on the elliptic bubble. Combined with the residual 2-point function on the genus-0 component, the MC₅ sewing reproduces the genus-1 traced 5-point function of the Heisenberg algebra.

Proof. For the Heisenberg algebra, Wick’s theorem reduces the elliptic supertrace to a sum of products of two-point functions on the elliptic bubble. The infinite product structure comes from the bosonic Fock space character, which contributes $\det(1 - T_q)^k$ as the regularised product over oscillator modes. The polynomial factor W_3 collects the connected Wick contractions of the three insertions. This is exactly the genus-one clutching chart of the preceding sewing theorem. $\square$

COROLLARY II.4.2 (*Virasoro class-M shadow corrections at the wall;*). Let $\mathcal{A} = \text{Vir}_c$ be the Virasoro chiral algebra at generic central charge c , regarded as a class-M chiral algebra in the standard landscape (Chapter ??). The elliptic supertrace in clause (ii) of Theorem II.2.1 acquires shadow corrections at order S_r for $r \geq 2$:

$$F_3^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q) = F_3^{(1), \text{cl}}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q) + \sum_{r \geq 2} S_r(\text{Vir}_c) \cdot \delta_3^{(r)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q) + \delta F_2^{\text{cross}}, \quad (\text{II.9})$$

where $S_r(\text{Vir}_c)$ is the r -th Virasoro shadow coefficient and $\delta_3^{(r)}$ is the corresponding r -loop shadow-Feynman correction at the bubble. The term $\delta F_2^{\text{cross}}$ records all-weight cross-channel mixing; it vanishes on the uniform-weight Virasoro stress-tensor line. The genus-one clutching chart is the first MC₅ locus where these class-M corrections are visible in the moduli geometry; the chain-level ambient question for the resulting infinite series is treated in Chapter 10.

Proof. The Virasoro elliptic supertrace at $n = 3$ is computable as a series in the bubble nome q via the Virasoro character formula $\chi_{\text{Vir}_c}(q) = q^{-c/24} / \prod_{n \geq 2} (1 - q^n)$. The shadow corrections $S_r(\text{Vir}_c)$ enter as coefficients of the curvature corrections $m_o^{\lfloor r/2 \rfloor - 1}$ in the bar complex (equation (10.1) of Chapter 10), and

the sum (11.9) is the corresponding shadow-Feynman expansion on the clutching chart. The chain-level convergence of the resulting infinite series in the pro-ambient is the content of Theorem 10.3.1. $\square$

COROLLARY 11.4.3 (*K₃ elliptic genus at the wall;*). Let $\mathcal{A} = \mathcal{A}(K_3)$ be the chiral algebra of the K₃ sigma model at large volume, restricted to its sub-Sugawara stratum $\{k < -h^\vee/2\}$ where the elliptic genus formula of Eguchi–Ooguri–Tachikawa [?EguchiOoguriTachikawa11] is unambiguously defined as a Jacobi form of weight 0 and index 1. On the genus-one component of the clutching chart $\widehat{\Delta}_T^{(1)}$, the elliptic supertrace in clause (ii) of Theorem 11.2.1 acquires the K₃ elliptic genus as the bubble factor:

$$F_3^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q, y) = \chi_{K_3}(q, y) \cdot W_{3, K_3}^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q),$$

up to a normalisation depending on the choice of insertion frames, where $\chi_{K_3}(q, y)$ is the K₃ elliptic genus and $W_{3, K_3}^{(1)}$ is the connected 3-point Wick polynomial on the bubble in the K₃ chiral algebra at the chosen stratum. MC₅ thus produces a chiral-algebraic derivation of the K₃ elliptic genus from the sewing principle, valid on the indicated sub-Sugawara stratum.

Proof. On the sub-Sugawara stratum $\{k < -h^\vee/2\}$, the K₃ chiral algebra admits an $\mathcal{N} = 4$ superconformal structure with $\widehat{c} = 2$, and the elliptic genus

$$\chi_{K_3}(q, y) = \text{Tr}_{\text{RR}}((-1)^F y^{J_0} q^{L_0 - c/24} \bar{q}^{\bar{L}_0 - \bar{c}/24})$$

is a Jacobi form of weight 0 and index 1 in the variables (q, y) (see [?EguchiOoguriTachikawa11]). The elliptic supertrace on the clutching chart specialises to this elliptic genus when the three insertions $(\xi_{i_1}, \xi_{i_2}, \xi_{i_3})$ are chosen in the trivial conformal block at zero left-moving conformal weight; in that case $W_{3, K_3}^{(1)}(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}; e_a; q)$ is a normalisation polynomial controlled by the Wick contractions of the insertions on the elliptic bubble. The detailed identification of the bubble factor with $\chi_{K_3}(q, y)$ uses the Eguchi–Ooguri–Tachikawa decomposition of χ_{K_3} into $\mathcal{N} = 4$ characters, applied to the genus-one bubble trace

$$F_3^{(1)} = \text{Tr}_{\mathcal{A}^{\text{ec}}} \left(V(\xi_{i_1}) V(\xi_{i_2}) V(\xi_{i_3}) e_a q^{L_0 - c/24} \right).$$

The scope is restricted to the sub-Sugawara stratum because the elliptic-genus factorisation through this specific chiral algebra is unambiguous there. The elliptic genus itself is deformation invariant; what is not claimed on the full Sugawara stratum is this MC₅ chiral-algebraic factorisation of the genus-1 bubble trace. $\square$

Remark 11.4.4 (*Sub-Sugawara comparison locus*). Corollary 11.4.3 is deliberately restricted to the sub-Sugawara comparison locus. The K₃ elliptic genus is a fixed weak Jacobi form of weight 0 and index 1; Mathieu moonshine concerns its character decomposition, not a moduli-dependent correction to the genus itself. The sub-Sugawara stratum $\{k < -h^\vee/2\}$ is the regime where the chiral 5-point sewing of MC₅ reduces to the elementary Jacobi-form formula of Eguchi–Ooguri–Tachikawa. Outside this stratum, the same elliptic genus may still be present, but MC₅ does not by itself supply the required chiral trace model. The full-moduli extension is not claimed here.

11.5 THE CLOSED MC_I – MC₅ CHAIN

With Theorem 11.2.1 in place, the MC chain reads as a sequence of sewing theorems for the n -point compactifications. MC₅ adds the first genus-one clutching datum to the rational genus-zero boundary calculus.

- **MC₁**. Augmentation: the MC element at $n = 1$ is the unit-vacuum identification.
- **MC₂**. Binary OPE: at $n = 2$, the MC element is the collision residue $r(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}})$, the chiral classical r -matrix.
- **MC₃**. Associator: at $n = 3$, the MC element on the eval-gen-core encodes the Stasheff pentagon at the level of the bar coderivation $b_2 + b_3$ (Theorem 34.2.1).
- **MC₄**. Quadrilateral sewing: at $n = 4$, the MC element extends across the boundary $\partial \overline{\mathcal{M}}_{0,4}$ via the strong-completion-tower closure on the eval-gen-core (Theorem 9.1.28).
- **MC₅**. Genus-one clutching: at $n = 5$, the MC element extends across the rational separating divisors $\delta_{0|S,S^c}$ (governed by MC₄) and is compatible with the clutching charts $\widehat{\Delta}_T^{(1)}$ (governed by the elliptic 3-point trace on the genus-one component), restricted to the eval-gen-core (Theorem 11.2.1).

Remark 11.5.1 (Climax-theorem integration). Theorem 11.2.1 is the $n = 5$ specialisation of universal KZ sewing (Chapter ??, equation (??)). Pulling back $\nabla_{\text{Arnold}}^{(5)}$ from $\text{Conf}_5^{\text{ord}}(X)$ to its compactification $\widehat{\overline{\mathcal{M}}}_{0,5}(X)$ produces a flat connection on the boundary divisors; the pullback agrees with the chiral bar differential $d_{\text{bar},5}$ by clause (iii), and Arnold's three-term relation (11.8) becomes the squaring-to-zero $d_{\text{bar},5}^2 = 0$.

On the genus-one clutching chart one replaces the rational Arnold forms by the elliptic KZB forms, equivalently by Felder's elliptic r -matrix on the genus-one component. Clause (ii) is the corresponding elliptic trace block, glued to the residual rational two-point block through the node pairing.

The per-family κ conductor of the harmonic discrepancy (Chapter 10, equation (10.1)) is the negative of the ghost charge of any quasi-free BRST resolution by the universal identity of Chapter 25. On the genus-one clutching chart, this κ conductor governs the magnitude of the shadow corrections of Corollary 11.4.2.

By the universality (??), any other 5-point chiral sewing prescription (Drinfeld–Kohno, Verlinde, Borchers, Felder) is a pullback of $\nabla_{\text{Arnold}}^{(5)}$ along the structure functor $\mathcal{A} \rightarrow \text{End}(\bar{B}^{\text{ch}}(\mathcal{A}))$ on the rational genus-zero surface. The theorem applies to those standard landscape objects for which the eval-gen-core and trace-class hypotheses are verified.

11.6 THE CLUTCHING LIMIT

Fix $T = \{i_1, i_2, i_3\}$. The clutching map (11.2) glues a genus-one component carrying the markings in T to a genus-zero component carrying the two remaining markings. The smoothing parameter q belongs to the genus-one component; the nodal limit $q = 0$ recovers the ordinary residue pairing through the gluing state.

Theorem 11.2.1 proves that the genus-zero rational extension and the genus-one clutching block are compatible at that nodal limit. On the rational side, the correlator is the holomorphic 5-point function on $\text{Conf}_5^{\text{ord}}(X)$ extended across the ten divisors of $\overline{\mathcal{M}}_{0,5}$. On the genus-one side, the trace block is the elliptic 3-point function on the genus-one component paired with the residual genus-zero 2-point function. Clause (ii) is exactly this pairing.

Every higher MC stage must impose analogous compatibility along the relevant clutching morphisms. The chain-level companion (Chapter 10) addresses the ambient-completion question for class M chiral algebras in the pro-ambient.

11.7 SUMMARY

The MC₅ statement is the following.

Let X be a smooth projective curve and let $\mathcal{A}$ be a strong completion tower of finite resonance rank, restricted to its evaluation-generated core $\mathcal{A}^{\text{ec}}$. The 5-point chiral correlator of $\mathcal{A}^{\text{ec}}$ on X extends uniquely over the completed genus-zero compactification $\widehat{\mathcal{M}}_{0,5}(X)$ and is compatible with the genus-one clutching charts $\widehat{\Delta}_T^{(1)}$ for $|T| = 3$. The rational extension is governed at the ten separating divisors by the MC_4 sewing prediction. The clutching block is the trace of the genus-one 3-point function against the residual genus-zero 2-point function. The bar differential is the pullback of Arnold's universal flat connection along the KZ functor of Chapter ??; flatness gives squaring-to-zero of the bar differential, and the resulting Maurer-Cartan element extends the MC_4 element. The completed bar-cobar counit at finite stage $N = 5$ is a quasi-isomorphism. The eval-core qualifier restricts the theorem to evaluation-generated representations; full-category extension to DK_g is conjectural (Conjecture 11.2.3).

The MC chain $\text{MC}_1 \rightarrow \text{MC}_2 \rightarrow \text{MC}_3 \rightarrow \text{MC}_4 \rightarrow \text{MC}_5$ thus reaches its first genus-one clutching compatibility, with each MC stage being the sewing theorem at its n -point level. Three concrete consequences (the Heisenberg elliptic Fredholm determinant, the Virasoro class-M shadow corrections, the K_3 elliptic genus on the sub-Sugawara stratum) illustrate the theorem on the canonical landscape witnesses, with the uniform-weight scope made explicit and the sub-Sugawara restriction in the K_3 case.

The MC_5 surface has two components. The geometric 5-point sewing with genus-one clutching is proved on the eval-gen-core (Theorem 11.2.1); the chain-level chain-ambient companion for class M is proved in the pro-ambient (Chapter 10); together they constitute the closed MC_5 statement. Higher-stage extensions are conjectural (Remark 11.2.4).

HOMOTOPY TRANSFER

The homotopy transfer theorem is the mechanism by which classical Koszul duality acquires quantum corrections. Passing from a chain complex to its cohomology via a deformation retract necessarily introduces higher operations m_k for $k \geq 3$; these are precisely the genus-0 quantum corrections of the bar complex (Theorem ??).

PROPOSITION 12.0.1 (*Homotopy transfer as rectification mechanism*). The homotopy transfer theorem is the technical engine of the rectification meta-theorem (Theorem ??): given a deformation retract $V \xrightarrow{p} H \xrightarrow{i} V$ with $pi = \text{id}$ and homotopy h , the transferred A_∞/L_∞ structure on H rectifies to the strict dg structure on V via bar-cobar. The explicit tree formula

$$m_n^{\text{tr}} = p \circ m_n^V \circ (i^{\otimes n}) + \sum_{\text{planar trees } \tau} p \circ m_{\text{val}(\tau)}^V (\text{id}^{\otimes r_1} \otimes h T_{s_1} \otimes \cdots) \circ i^{\otimes n}$$

produces the n -ary brackets that bar-cobar inversion (Theorem B) eliminates.

Proof. The statement has three parts.

- (i) The homotopy transfer theorem (Theorem 12.2.1) endows H with a $\mathcal{P}_\infty$ -structure $\{\tilde{m}_n\}_{n \geq 1}$ such that p and i extend to ∞ -quasi-isomorphisms.
- (ii) The bar-cobar adjunction (Theorem A) produces a strict dg algebra $\Omega(B(H, \{\tilde{m}_n\}))$ from the transferred homotopy data. Bar-cobar inversion (Theorem B) gives a quasi-isomorphism $\Omega(B(H)) \xrightarrow{\sim} H$.
- (iii) Composing: the transferred structure on H rectifies through bar-cobar to a strict model quasi-isomorphic to V , since $H \simeq V$ by the deformation retract. The tree formula for m_n^{tr} is the explicit form of the tensor trick ([?LV12] §10.3), whose summands are indexed by planar trees with internal vertices decorated by the operations m_k^V and internal edges decorated by the homotopy h . Bar-cobar inversion re-absorbs these higher operations into the differential of $\Omega(B(H))$.

□

12.1 HISTORICAL ORIGINS

A_∞ algebras were introduced by Stasheff [?Sta63] to encode the homotopy-coherent associativity of loop space multiplication. The operadic viewpoint identifies them as algebras over the homology of the little intervals operad. For the role of bar-cobar duality in the chiral setting, see Chapter ??.

12.2 THE HOMOTOPY TRANSFER THEOREM

THEOREM 12.2.1 (*Homotopy transfer theorem* [?LV12, ?Kadeishvili80];). Let (V, d_V) and (W, d_W) be chain complexes with:

- (i) A chain map $p : V \rightarrow W$ (projection).
- (ii) A chain map $\iota : W \rightarrow V$ (inclusion).
- (iii) A chain homotopy $h : V \rightarrow V[-1]$ satisfying $\text{id}_V - \iota p = d_V h + h d_V$.
- (iv) The *side conditions* (compatibility of h with p, ι): $p\iota = \text{id}_W$, $h\iota = 0$, $ph = 0$, $h^2 = 0$.

Such data is called a *strong deformation retract* (SDR).

If V carries a $\mathcal{P}_\infty$ -algebra structure (for $\mathcal{P}$ a Koszul operad), then W inherits a $\mathcal{P}_\infty$ -algebra structure such that p and ι extend to ∞ -quasi-isomorphisms of $\mathcal{P}_\infty$ -algebras.

Proof. The transferred structure on W is constructed via the *tensor trick* ([?LV12] §10.3). For an A_∞ -algebra structure on V with operations $m_n : V^{\otimes n} \rightarrow V$, define $T_n : V^{\otimes n} \rightarrow V$ recursively by:

$$T_n = m_n + \sum_{\substack{r+s+t=n \\ s < n}} m_{r+1+t}(\text{id}^{\otimes r} \otimes h T_s \otimes \text{id}^{\otimes t}).$$

This converges since T_s with $s < n$ is already defined and h absorbs the degree. The transferred operations are $\tilde{m}_n := p \circ T_n \circ \iota^{\otimes n}$. Explicitly:

$$\begin{aligned} \tilde{m}_1 &= p d_V \iota = d_W, \\ \tilde{m}_2 &= p m_2 \iota^{\otimes 2}, \\ \tilde{m}_3 &= p m_3 \iota^{\otimes 3} + p m_2(h m_2 \otimes \text{id}) \iota^{\otimes 3} + p m_2(\text{id} \otimes h m_2) \iota^{\otimes 3}. \end{aligned}$$

Verification of A_∞ -relations. The A_∞ -relation at degree n for $\{\tilde{m}_k\}$ requires:

$$\sum_{r+s+t=n} (-1)^{r+s+t} \tilde{m}_{r+1+t}(\text{id}^{\otimes r} \otimes \tilde{m}_s \otimes \text{id}^{\otimes t}) = 0.$$

Substituting $\tilde{m}_k = p \circ T_k \circ \iota^{\otimes k}$ and using the SDR identity $\iota p = \text{id}_V - (d_V h + h d_V)$, each internal composition ιp between an outer T_{r+1+t} and inner T_s decomposes as:

- a term id_V , which together with the A_∞ -relations for $\{m_k\}$ gives cancelling contributions;
- a term $-d_V h - h d_V$, which telescopes by the side conditions $h^2 = 0$, $ph = 0$, $h\iota = 0$.

Concretely, the terms involving id_V reassemble into $p \circ (A_\infty \text{ relation for } \{m_k\}) \circ \iota^{\otimes n} = 0$, while the terms involving $d_V h + h d_V$ cancel pairwise: $h^2 = 0$ prevents double homotopy insertions, and $ph = h\iota = 0$ kill boundary terms. Thus $\{\tilde{m}_n\}$ satisfies the A_∞ -relations.

The maps p and ι extend to ∞ -morphisms $\tilde{p}_n$ and $\tilde{\iota}_n$ by the same tree formula with p (resp. ι) at the root (resp. leaves), and the composite $\tilde{p} \circ \tilde{\iota} = \text{id}_W$ by $p\iota = \text{id}_W$, while $\tilde{\iota} \circ \tilde{p} \sim \text{id}_V$ via the homotopy built from h . $\square$

Definition 12.2.2 (Strong deformation retract data). A *strong deformation retract* (SDR) from V to W is a tuple (V, W, p, ι, h) satisfying the conditions of Theorem 12.2.1. We denote this by:

$$(V, d_V) \xrightleftharpoons[\iota]{p} (W, d_W) \quad h : V \rightarrow V[-1], \quad \text{id} - \iota p = dh + hd.$$

The diagram commutes up to homotopy h .

LEMMA 12.2.3 (Existence of SDR;). If $V \xrightarrow{\sim} W$ is a quasi-isomorphism of chain complexes over a field k , then:

- (i) There exists an SDR from V to $H_*(V) = H_*(W)$.
- (ii) If V and W are both semi-free (or projective as graded modules), there exists an SDR between them.

Proof. (i) Choose a splitting $V = H_*(V) \oplus B \oplus C$ where $d : C \xrightarrow{\sim} B$ is an isomorphism (decomposition into homology, boundaries, and “extra” cycles that become boundaries). Define:

$$\iota : H_*(V) \hookrightarrow V, \quad p : V \twoheadrightarrow H_*(V), \quad h : V \rightarrow V[-1]$$

where h sends B to C via the inverse of $d|_C$, and is zero on $H_*(V) \oplus C$. We verify each condition.

(a) $p \circ \iota = \text{id}_{H_*(V)}$: the inclusion ι maps $H_*(V)$ into V as a direct summand, and p projects back.
(b) $\text{id}_V - \iota \circ p = d \circ h + h \circ d$: we check on each summand. On $H_*(V)$: both d and h vanish, so $dh + hd = 0 = \text{id} - \iota p$. On B : $h|_B = 0$ gives $dh(b) = 0$, while $d(b) \in H_* \oplus C$ and the C -component maps back via $h = (d|_C)^{-1}$, so $hd(b) = b$; since $\iota p(b) = 0$ we get $(dh + hd)(b) = b = (\text{id} - \iota p)(b)$. On C : $h|_C = 0$ gives $dh(c) = 0$, while $d(c) \in B$ and $hd(c) = (d|_C)^{-1}(d(c)) = c$; since $\iota p(c) = 0$ we get $(dh + hd)(c) = c = (\text{id} - \iota p)(c)$. (c) $h^2 = 0$: h maps $B \rightarrow C$ and $h|_C = 0$; $h \circ \iota = 0$: ι lands in $H_*(V)$ and $h|_{H_*} = 0$; $p \circ h = 0$: h maps into C and $p|_C = 0$.

(ii) The Comparison Theorem for projective resolutions provides the maps; standard homological algebra constructs the homotopy. $\square$

12.3 EXPLICIT FORMULAS FOR TRANSFERRED STRUCTURES

Construction 12.3.1 (Transferred A_∞ -structure). Let $(A, \{m_n\})$ be an A_∞ -algebra and (A, H, p, ι, h) an SDR to the homology $H = H_*(A)$. The transferred A_∞ -structure $\{\tilde{m}_n\}$ on H is given by:

$\tilde{m}_1 = 0$. The differential on homology vanishes.

$\tilde{m}_2$. The induced product:

$$\tilde{m}_2(a, b) = p m_2(\iota(a), \iota(b)).$$

$\tilde{m}_3$. The Massey product or A_∞ -associator:

$$\begin{aligned} \tilde{m}_3(a, b, c) &= p m_3(\iota(a), \iota(b), \iota(c)) \\ &\quad + p m_2(h m_2(\iota(a), \iota(b)), \iota(c)) \\ &\quad + (-1)^{|a|} p m_2(\iota(a), h m_2(\iota(b), \iota(c))). \end{aligned}$$

The sign $(-1)^{|a|}$ arises from commuting the homotopy h (degree -1) past $\iota(a)$ (degree $|a|$) via the Koszul sign rule.

$\tilde{m}_n$ (general). Sum over planar rooted trees T with n leaves:

$$\tilde{m}_n = \sum_{T \in \text{PRT}_n} p T(m_\bullet, h, \iota)$$

where $T(m_\bullet, h, \iota)$ places ι at leaves, m_k at vertices of valence k , and h on internal edges.

THEOREM 12.3.2 (Tree formula for transferred operations [?LV12];). The transferred n -ary operation is:

$$\tilde{m}_n = \sum_{T \in \text{PRT}_n} \epsilon(T) \cdot p \circ \prod_{v \in V(T)} m_{|v|} \circ \prod_{e \in E_{\text{int}}(T)} h \circ \iota^{\otimes n}$$

where:

- (i) PRT_n is the set of planar rooted trees with n leaves.
- (ii) $V(T)$ is the set of internal vertices; $|v|$ is the valence of v .
- (iii) $E_{\text{int}}(T)$ is the set of internal edges.
- (iv) $\epsilon(T) \in \{\pm 1\}$ is a sign determined by the Koszul rule.

Remark 12.3.3 (Tree-level only;). Only tree-level graphs contribute to homotopy transfer: the sum in Theorem 12.3.2 runs over trees (acyclic connected graphs), never over graphs with loops. This is because the three side conditions $h^2 = 0$, $ph = 0$, and $h\iota = 0$ together ensure that any graph with a cycle vanishes: $h^2 = 0$ kills paths with consecutive homotopies, $ph = 0$ kills graphs where h appears at the output edge, and $h\iota = 0$ kills graphs where h appears at an input edge. In the chiral algebra setting, this means the transferred operations are algebraic (finite sums), not analytic, and no renormalization issues arise.

Example 12.3.4 (Trees for $\hat{m}_4$). The trees contributing to $\hat{m}_4$ are:

- (1) One vertex of valence 4:

$$\begin{array}{c} \bullet \\ \diagup \\ 1 \quad 2 \quad 3 \quad 4 \end{array} \rightsquigarrow p m_4 \iota^{\otimes 4}$$

- (2) One vertex of valence 3, one of valence 2 (5 configurations: the binary vertex can be a child of the ternary in 3 ways, or the ternary can be a child of the binary in 2 ways):

$$p m_3(h m_2 \otimes \text{id} \otimes \text{id}) \iota^{\otimes 4}, \quad p m_2(h m_3 \otimes \text{id}) \iota^{\otimes 4}, \quad \dots$$

- (3) Three vertices of valence 2 (5 configurations: the Catalan number $C_3 = 5$ binary trees with 4 leaves).

Total: $1 + 5 + 5 = 11$ planar rooted trees with 4 leaves and all internal vertices of degree ≥ 2 .

PROPOSITION 12.3.5 (*Sign computation* [?LV12];). The sign $\epsilon(T)$ in the tree formula is:

$$\epsilon(T) = (-1)^{\sum_{e \in E_{\text{int}}(T)} (|e|_{\text{left}} + 1)}$$

where $|e|_{\text{left}}$ is the sum of degrees of inputs to the left of edge e (counting the edge as separating left from right at its source vertex).

12.4 APPLICATIONS TO MINIMAL MODELS

Definition 12.4.1 (*Minimal model*). A *minimal model* of a dg-algebra A is an A_∞ -algebra M with:

- (i) M has zero differential: $m_1 = 0$.
- (ii) There is an A_∞ -quasi-isomorphism $M \xrightarrow{\sim} A$.

A minimal model is unique up to A_∞ -isomorphism.

THEOREM 12.4.2 (*Existence of minimal models* [?Kadeishvili80];). Every A_∞ -algebra over a field admits a minimal model. Explicitly, if A is an A_∞ -algebra:

- (i) Take $M = H_*(A)$ as a graded vector space.
- (ii) Choose an SDR $(A, H_*(A), p, \iota, h)$.
- (iii) Apply the homotopy transfer theorem to get $\{m_n\}_{n \geq 2}$ on M .
- (iv) The resulting $(M, 0, m_2, m_3, \dots)$ is the minimal model.

COROLLARY 12.4.3 (*Formality* [?DGMS75, ?Kon99];). An A_∞ -algebra A is *formal* if its minimal model has $m_n = 0$ for all $n \geq 3$, i.e., the minimal model is a graded associative algebra with trivial differential and no higher operations.

Equivalently, A is formal if $A \simeq H_*(A)$ as A_∞ -algebras, where $H_*(A)$ has the trivial A_∞ -structure from its product.

Example 12.4.4 (Minimal model of de Rham complex). For $X = S^1$ (circle), the de Rham complex is:

$$(\Omega^*(S^1), d) = (k \xrightarrow{0} k, \quad 1 \mapsto 0, \quad d\theta \mapsto 0)$$

with cohomology $H^* = k \oplus k[-1]$.

The minimal model has:

- (i) $M = k \cdot 1 \oplus k \cdot x$ with $|1| = 0, |x| = 1$.
- (ii) $m_2(1, 1) = 1, m_2(1, x) = m_2(x, 1) = x, m_2(x, x) = 0$.
- (iii) $m_n = 0$ for $n \geq 3$ (the circle is formal).

Application 12.4.5 (Minimal model for chiral algebras). For a chiral algebra $\mathcal{A}$, the homotopy transfer theorem provides:

- (i) A minimal A_∞ -chiral structure on $H_*^{\text{ch}}(\mathcal{A})$.
- (ii) The higher operations $\{m_n\}_{n \geq 3}$ encode obstructions to formality.
- (iii) For Koszul chiral algebras, the minimal model simplifies (higher operations vanish).

For the Heisenberg algebra $\mathcal{H}$:

$$H_*^{\text{ch}}(\mathcal{H}) = k$$

is 1-dimensional (Koszul), and the minimal model is the ground field with trivial structure.

THEOREM 12.4.6 (*Homotopy transfer for operadic algebras* [?LV12];). Let $\mathcal{P}$ be a Koszul operad and (A, W, p, ι, h) an SDR with A a $\mathcal{P}$ -algebra. The transferred $\mathcal{P}_\infty$ -structure on W satisfies:

- (i) The $\mathcal{P}_\infty$ -relations hold strictly (not just up to homotopy).
- (ii) The maps ι and p extend to ∞ -morphisms.
- (iii) If A is already $\mathcal{P}_\infty$ (not just $\mathcal{P}$), the transfer still works.

12.5 EXTENDED FORMULAS AND COMPUTATIONAL TECHNIQUES

Extended formulas for homotopy transfer essential for explicit computations in chiral Koszul duality follow.

Construction 12.5.1 (Homotopy transfer for L_∞ -algebras). Let $(\mathfrak{g}, \{l_n\})$ be an L_∞ -algebra and $(\mathfrak{g}, H, p, \iota, h)$ an SDR. The transferred L_∞ -structure on H has brackets:

$\tilde{l}_1 = 0$. Differential vanishes on homology.

$\tilde{l}_2$. The induced Lie bracket:

$$\tilde{l}_2(a, b) = p l_2(\iota(a), \iota(b)).$$

$\tilde{l}_3$. The *Massey–Lie bracket* or Jacobiator:

$$\begin{aligned}\tilde{l}_3(a, b, c) &= p l_3(\iota(a), \iota(b), \iota(c)) \\ &\quad + p l_2(h l_2(\iota(a), \iota(b)), \iota(c)) \\ &\quad + (-1)^{|b||c|} p l_2(h l_2(\iota(a), \iota(c)), \iota(b)) \\ &\quad + (-1)^{|a|(|b|+|c|)} p l_2(h l_2(\iota(b), \iota(c)), \iota(a)).\end{aligned}$$

The signs arise from the graded antisymmetry of the Lie bracket.

PROPOSITION 12.5.2 (*L_∞ -relations for transferred structure* [?LV12];). The transferred brackets $\{\tilde{l}_n\}$ satisfy the L_∞ -relations:

$$\sum_{i+j=n+1} \sum_{\sigma \in \text{Sh}(i, n-i)} \epsilon(\sigma) \tilde{l}_j(\tilde{l}_i(x_{\sigma(1)}, \dots, x_{\sigma(i)}), x_{\sigma(i+1)}, \dots, x_{\sigma(n)}) = 0$$

where $\text{Sh}(i, n-i)$ denotes $(i, n-i)$ -unshuffles and $\epsilon(\sigma)$ is the Koszul sign.

COMPUTATION 12.5.3 (*Explicit $\tilde{l}_4$ formula*). The 4-ary transferred bracket is:

$$\begin{aligned}\tilde{l}_4(a, b, c, d) &= p l_4(\iota a, \iota b, \iota c, \iota d) \\ &\quad + \sum_{\sigma \in S_4} \epsilon_\sigma p l_3(h l_2(\iota x_{\sigma_1}, \iota x_{\sigma_2}), \iota x_{\sigma_3}, \iota x_{\sigma_4}) \\ &\quad + \sum_{\text{pairings}} \epsilon p l_2(h l_2(\iota a, \iota b), h l_2(\iota c, \iota d)) \\ &\quad + \sum_{\sigma} \epsilon_\sigma p l_2(h l_3(\iota x_{\sigma_1}, \iota x_{\sigma_2}, \iota x_{\sigma_3}), \iota x_{\sigma_4}) \\ &\quad + (\text{trees with two internal edges})\end{aligned}$$

The full formula involves 25 terms corresponding to trees with 4 leaves.

THEOREM 12.5.4 (*Uniqueness of minimal L_∞ -model* [?LV12];). If $(\mathfrak{g}, \{l_n\})$ is an L_∞ -algebra over a field:

- (i) A minimal L_∞ -model $(H, \{\tilde{l}_n\})$ exists with $\tilde{l}_1 = 0$.
- (ii) Any two minimal L_∞ -models are L_∞ -isomorphic.
- (iii) The isomorphism is unique up to L_∞ -homotopy.

CONSTRUCTION 12.5.5 (*Homotopy transfer for coalgebras*). For a dg-coalgebra (C, Δ, d) and SDR (C, H, p, ι, h) , the transferred A_∞ -coalgebra structure on H has coproducts:

$\tilde{\Delta}_1 = 0$. No differential on homology.

$\tilde{\Delta}_2$. The induced coproduct:

$$\tilde{\Delta}_2(c) = (p \otimes p) \Delta(\iota(c)).$$

$\tilde{\Delta}_n$ for $n \geq 3$. Higher coproducts from trees:

$$\tilde{\Delta}_n = \sum_{T \in \text{Trees}_n} \epsilon(T) \cdot (p^{\otimes n}) \circ T(\Delta, h) \circ \iota$$

where trees now have edges “pointing down” (toward outputs) rather than up.

Example 12.5.6 (Transfer for symmetric coalgebra). Let $C = S^c(V)$ be the symmetric coalgebra on a chain complex (V, d_V) . The coproduct is deconcatenation:

$$\Delta(v_1 \cdots v_n) = \sum_{I \sqcup J = [n]} v_I \otimes v_J$$

where $v_I = \prod_{i \in I} v_i$ (in order).

If $V \xrightarrow{p} H_*(V) =: W$ is a deformation retract:

- (i) $\tilde{\Delta}_2$ on $S^c(W)$ is the standard deconcatenation (symmetric coalgebra).
- (ii) $\tilde{\Delta}_3$ involves Massey products: corrections arise when d_V is nontrivial.
- (iii) If V is formal (quasi-isomorphic to $H_*(V)$ with zero differential), then $\tilde{\Delta}_n = 0$ for $n \geq 3$.

12.6 APPLICATIONS TO CHIRAL ALGEBRAS

THEOREM 12.6.1 (*Chiral homotopy transfer;*). Let $\mathcal{A}$ be an E_1 -chiral algebra on a curve X and suppose we have an SDR of the underlying D -module:

$$(\mathcal{A}, H, p, \iota, h) \quad \text{with } H = H_*^{\text{ch}}(\mathcal{A}).$$

Then:

- (i) H inherits an A_∞ -chiral algebra structure.
- (ii) The higher operations $\{m_n^{\text{ch}}\}_{n \geq 3}$ are “Massey products” for the chiral structure.
- (iii) If $\mathcal{A}$ is Koszul, then $m_n^{\text{ch}} = 0$ for $n \geq 3$.

Proof. We apply the general homotopy transfer theorem (Theorem 12.2.1) to the E_1 -chiral operad.

Step 1 (D -module compatibility). Since $\mathcal{A}$ is a chiral algebra, it carries a $\mathcal{D}_X$ -module structure. The SDR maps (p, ι, h) must be morphisms of $\mathcal{D}_X$ -modules (i.e., commute with the action of $\mathcal{D}_X$). This holds because chiral homology $H = H_*^{\text{ch}}(\mathcal{A})$ is defined as a derived functor in the category of $\mathcal{D}_X$ -modules, so p and ι are automatically $\mathcal{D}_X$ -linear, and h can be chosen $\mathcal{D}_X$ -linearly by the splitting argument of Lemma 12.2.3(i) applied within the $\mathcal{D}_X$ -module category (which is abelian with enough projectives over a smooth curve X).

Step 2 (Transferred binary operation). The transferred product is $\tilde{m}_2 = p \circ \mu^{\text{ch}} \circ (\iota \otimes \iota)$, exactly as in Construction 12.3.1. Since μ^{ch} is a chiral product (defined via the $j_* j^*$ functor on $X \times X$), $\tilde{m}_2$ inherits $\mathcal{D}_X$ -linearity from Step 1.

Step 3 (Higher operations via trees). The transferred operations $\tilde{m}_n^{\text{ch}}$ for $n \geq 3$ are sums over planar rooted trees with n leaves (as in Construction 12.3.1), where each internal edge contributes a factor of h and each internal vertex contributes the chiral product μ^{ch} . Since only tree-level graphs contribute (no loops; cf. Remark 12.3.3), each $\tilde{m}_n^{\text{ch}}$ is a finite sum.

Step 4 (A_∞ -relations). The transferred operations $\{\tilde{m}_n^{\text{ch}}\}$ satisfy the A_∞ -relations by the same algebraic argument as in the general theorem: the identity $\sum_{r+s+t=n} (-1)^{r,s+t} \tilde{m}_{r+1+t}(\text{id}^{\otimes r} \otimes \tilde{m}_s \otimes \text{id}^{\otimes t}) = 0$ follows from substituting the tree formulas and using the E_1 -relations on $\mathcal{A}$ together with the SDR identities $p\iota = \text{id}$, $\text{id} - \iota p = dh + hd$, $h^2 = 0$.

Koszulness (iii). If $\mathcal{A}$ is Koszul, the bar spectral sequence degenerates at E_2 with E_∞ concentrated on the Koszul line $q = 0$ (Proposition ??). This means $\text{Ext}_{\mathcal{A}}^{p,q}(k, k) = 0$ for $q \neq 0$: the bar resolution is minimal. One may therefore choose the SDR for $\tilde{B}(\mathcal{A}) \rightarrow H^*(\tilde{B}(\mathcal{A}))$ compatible with the bigrading, so that the homotopy h preserves bar degree and shifts internal degree. Every tree contributing to $\tilde{m}_n^{\text{ch}}$ for

$n \geq 3$ would produce an operation of bar-degree shift incompatible with the Koszul line concentration, forcing $\bar{m}_n^{\text{ch}} = 0$. Equivalently, for a minimal resolution all Massey products vanish. $\square$

Example 12.6.2 (Kac–Moody minimal model). For the affine Kac–Moody algebra $\hat{\mathfrak{g}}_k$ at level k and a smooth projective curve X of genus g :

- (i) The chiral homology $H_*^{\text{ch}}(X, \hat{\mathfrak{g}}_k)$ depends on both k and g .
- (ii) At generic k (irrational, or more precisely not a non-negative integer and not equal to $-h^\vee$): the higher chiral homology $H_i^{\text{ch}}(X, \hat{\mathfrak{g}}_k) = 0$ for $i > 0$, while $H_0^{\text{ch}}(X, \hat{\mathfrak{g}}_k)$ reduces to the space of conformal blocks, which is one-dimensional for the vacuum module [?BD04].
- (iii) At non-negative integral k : the chiral homology $H_*^{\text{ch}}(X, \hat{\mathfrak{g}}_k)$ is related to spaces of conformal blocks for integrable representations, and the minimal model encodes this representation theory.
- (iv) The transferred higher operations m_n^{ch} for $n \geq 3$ vanish by Koszulness of $\hat{\mathfrak{g}}_k$ (at non-critical level $k \neq -h^\vee$).

PROPOSITION 12.6.3 (*Transferred structure and bar complex* [?LV12];). The homotopy transfer of chiral structures is compatible with the bar construction:

$$\bar{B}^{\text{geom}}(H, \{\bar{m}_n\}) \simeq \bar{B}^{\text{geom}}(\mathcal{A}, \{m_n\})$$

as geometric bar complexes. The quasi-isomorphism is induced by the SDR data.

Proof. The bar construction is functorial for A_∞ -morphisms [?LV12]: an A_∞ -quasi-isomorphism $f : A \xrightarrow{\sim} B$ induces a quasi-isomorphism $\bar{B}(f) : \bar{B}(A) \xrightarrow{\sim} \bar{B}(B)$ of bar complexes. (The functoriality of $\bar{B}$ for A_∞ -morphisms is the bar-cobar adjunction as a quantum L_∞ functor.) Since the SDR maps (ι, p) extend to A_∞ -quasi-isomorphisms by Theorem 12.2.1, the bar complexes $\bar{B}(\mathcal{A})$ and $\bar{B}(H, \{\bar{m}_n\})$ are quasi-isomorphic. The geometric realization is compatible because $\bar{B}^{\text{geom}}$ is computed as the factorization homology of $\bar{B}$, and factorization homology preserves quasi-isomorphisms between factorization algebras on X . $\square$

12.7 HOMOTOPY TRANSFER AND THE MAIN THEOREMS

The homotopy transfer theorem *is* the mechanism by which classical Koszul duality acquires quantum corrections: passing from a chain complex to its cohomology via a deformation retract forces higher operations m_k ($k \geq 3$) on the cohomology, and these are precisely the bar-level quantum corrections that bar-cobar inversion (Theorem B) then re-absorbs.

12.7.1 The bar-cobar counit as HTT output

THEOREM 12.7.1 (*Bar-cobar inversion via homotopy transfer*;). Let $\mathcal{A}$ be a chiral Koszul algebra on a smooth curve X . The bar-cobar counit

$$\psi : \Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$$

of Theorem 14.1.103 is the *canonical* A_∞ -quasi-isomorphism produced by the homotopy transfer theorem (Theorem 12.2.1), applied to the SDR

$$(\Omega(\bar{B}(\mathcal{A})), \mathcal{A}, \psi, \iota_{\text{counit}}, h_{\text{Hodge}})$$

where ι_{counit} is the canonical inclusion and h_{Hodge} is the contracting homotopy from the Hodge decomposition of $\Omega(\bar{B}(\mathcal{A}))$ relative to the bar filtration.

Proof. By construction, the cobar complex $\Omega(\bar{B}(\mathcal{A}))$ is the cofree chiral algebra on $s\bar{\mathcal{A}}^1$ with differential $d_{\text{cobar}} = d_{\text{coop}} + d_{\text{tw}}$, where d_{tw} encodes the twisting morphism $\tau: \bar{B}(\mathcal{A}) \rightarrow \mathcal{A}$.

Step 1 (SDR from bar filtration). The bar filtration $F_p\Omega(\bar{B}(\mathcal{A}))$ gives a spectral sequence with $E_1^{p,q} = H^q(\text{gr}_p^F \Omega(\bar{B}(\mathcal{A})))$. By Koszulness, E_1 is concentrated on $q = 0$ (Proposition ??). The E_1 -degeneration produces an SDR: the projection ψ to $E_\infty \cong \mathcal{A}$ and the inclusion ι from $\mathcal{A}$ back to the cobar complex, with contracting homotopy h lowering the q -degree. The side conditions $\psi\iota = \text{id}$, $h^2 = 0$, $\psi h = 0$, $h\iota = 0$ follow from the bigrading.

Step 2 (HTT produces the same map). Applying Theorem 12.2.1 to the strict E_1 -chiral algebra structure on $\Omega(\bar{B}(\mathcal{A}))$ and the SDR from Step 1 produces transferred operations $\{\tilde{m}_n\}_{n \geq 2}$ on $\mathcal{A}$ and an A_∞ -quasi-isomorphism $f_\infty: \mathcal{A} \rightarrow \Omega(\bar{B}(\mathcal{A}))$. The component $f_1 = \iota$ and the binary product $\tilde{m}_2 = \psi \circ \mu \circ (\iota \otimes \iota) = \mu_{\mathcal{A}}$ (the original product on $\mathcal{A}$, since $\psi\iota = \text{id}$).

Step 3 (Koszulness forces vanishing). For $n \geq 3$, each tree T contributing to $\tilde{m}_n$ (Construction 12.3.1) inserts at least one homotopy h on an internal edge. Since h lowers the filtration degree by 1 and the Koszul-line concentration forces all non-trivial cohomology to live on $q = 0$, the composition $\psi \circ (\text{tree}) \circ \iota^{\otimes n}$ vanishes: the output lives in $q < 0$, which is empty. Therefore $\tilde{m}_n = 0$ for $n \geq 3$, and $f_\infty = \psi$ is a strict quasi-isomorphism of dg algebras, not merely of A_∞ -algebras.

This is the chain-level content of the bar-cobar inversion (Theorem 14.1.103): on the Koszul locus, the bar-cobar counit is the HTT quasi-isomorphism, and Koszulness is the vanishing of all Massey products. $\square$

Remark 12.7.2 (Koszulness as formality). The preceding proof identifies three equivalent conditions (cf. Remark ??):

- (i) $\mathcal{A}$ is chiral Koszul (bar spectral sequence degenerates at E_2 , Koszul-line concentration).
- (ii) The transferred A_∞ -structure on $H^*(\bar{B}(\mathcal{A}))$ is *formal*: $\tilde{m}_n = 0$ for $n \geq 3$.
- (iii) The bar-cobar counit ψ is a *strict* quasi-isomorphism (not merely A_∞).

The equivalence (i) $\Leftrightarrow$ (ii) is the homotopy-algebraic meaning of Koszulness: a Koszul algebra is one whose derived structure contains no hidden higher information beyond the binary product. Condition (iii) is the geometric meaning: the configuration space integrals computing ψ collapse to residue extraction alone, with no contributions from higher-codimension boundary strata.

12.7.2 Trees and boundary strata: the geometric HTT

The tree formula of Theorem 12.3.2 has a direct geometric realization via the Fulton–MacPherson compactification.

PROPOSITION 12.7.3 (*Trees as boundary strata*;). Let T be a planar rooted tree with n leaves contributing to the transferred operation $\tilde{m}_n$ (Construction 12.3.1). The corresponding term in the tree formula equals the integral

$$\tilde{m}_n^T(a_1, \dots, a_n) = \int_{\partial_T \bar{C}_n(X)} \text{ev}^*(\bar{a}_1 \otimes \cdots \otimes \bar{a}_n) \wedge \bigwedge_{e \in E_{\text{int}}(T)} \omega_e,$$

where:

- (i) $\partial_T \bar{C}_n(X) \hookrightarrow \bar{C}_n(X)$ is the boundary stratum of the Fulton–MacPherson compactification indexed by T : the locus where the points cluster according to the vertex structure of T ;

- (ii) $\omega_e = d \log(z_{s(e)} - z_{t(e)})$ is the logarithmic propagator on the internal edge e with source $s(e)$ and target $t(e)$;
- (iii) the homotopy h of the SDR corresponds to integration over the fiber direction in $\partial_T \overline{C}_n(X) \rightarrow \overline{C}_{|V(T)|}(X)$, i.e., integration over the “infinitesimal screen” at each vertex cluster.

The full transferred operation is the sum over all trees:

$$\tilde{m}_n = \sum_{T \in \text{PRT}_n} \int_{\partial_T \overline{C}_n(X)} \text{ev}^*(\tilde{a}_1 \otimes \cdots \otimes \tilde{a}_n) \wedge \omega_T.$$

Proof. The Fulton–MacPherson compactification $\overline{C}_n(X) = \text{Bl}_\Delta(X^n)$ has a stratification indexed by planar rooted trees with n leaves: each stratum ∂_T records a pattern of coincidences among the n points (cf. [FM94]).

The bar differential d_{bar} on $\tilde{B}_n^{\text{geom}}(\mathcal{A})$ is the residue along the codimension-1 boundary $\partial_{ij} \overline{C}_n(X)$ where points z_i, z_j collide. This is the contribution from trees with a single internal edge. Higher-codimension strata correspond to multiple simultaneous collisions, i.e., trees with multiple internal edges.

The homotopy h in the SDR integrates “inward” along fibers of the boundary projection $\partial_T \rightarrow \partial_{T|e}$, which contracts an internal edge e of the tree T . This is the geometric content of the formula $h =$ (fiber integral over screen direction): when two points have already collided (codimension-1 stratum), the homotopy h integrates over the residual angular direction to produce a new composite element on the coarser stratum.

Composing: the tree formula $p \circ \prod_v m_{|v|} \circ \prod_e h \circ \iota^{\otimes n}$ places propagators ω_e on internal edges, OPE operations $m_{|v|}$ at vertices, and integrates over the fiber directions via h . The result is precisely the integral over $\partial_T \overline{C}_n(X)$ of the product of logarithmic propagators. $\square$

Remark 12.7.4 (Feynman diagrams as transferred operations). Proposition 12.7.3 establishes the following dictionary between the algebraic HTT and the physical Feynman diagram expansion:

HTT (algebraic)	$\longleftrightarrow$ Feynman (geometric)
Planar rooted tree T	$\longleftrightarrow$ Tree-level Feynman diagram
Internal edge of T	$\longleftrightarrow$ Propagator insertion η_{ij}
Vertex of valence k	$\longleftrightarrow$ k -valent interaction vertex (OPE)
Homotopy h	$\longleftrightarrow$ Propagator (Green’s function)
SDR projection p	$\longleftrightarrow$ External state projection
Transferred $\tilde{m}_n$	$\longleftrightarrow$ n -point tree-level amplitude
Massey product $\tilde{m}_3 \neq 0$	$\longleftrightarrow$ Non-trivial 3-point function
Koszulness ($\tilde{m}_n = 0, n \geq 3$)	$\longleftrightarrow$ Formal theory (minimal resolution)

Koszulness means that the *transferred* A_∞ structure on bar cohomology is formal ($\tilde{m}_n = 0$ for $n \geq 3$): the bar complex provides a minimal resolution. This does *not* mean the original theory is free or Gaussian. Affine Kac–Moody algebras and the Virasoro algebra are chirally Koszul (all standard families are, by PBW universality) but have nontrivial OPE structure constants and interaction vertices of arbitrary valence. The formality is a property of the *resolution*, not of the *interactions*.

12.7.3 Genus corrections as transferred operations

At genus $g \geq 1$, the fiberwise bar differential belongs to a curved A_∞ /CDG package with $m_1^2 = [m_o^{(g)}, -]$, and the scalar diagonal projection of $m_o^{(g)}$ is $\kappa(\mathcal{A}) \cdot \omega_g$ (Convention ??), and the HTT framework extends to the curved setting.

PROPOSITION 12.7.5 (*Genus-1 curvature as m_o*). The genus-1 scalar obstruction $\kappa(\mathcal{A}) \in k$ of Theorem ?? is the nullary operation m_o only after scalar diagonal/Hodge projection of the curved A_∞ -structure transferred from the genus-1 bar complex:

$$m_o = \kappa(\mathcal{A}) \cdot [\omega_1] \in H^2(\overline{\mathcal{M}}_{1,1}, \mathbb{Q}).$$

More precisely, let $\bar{B}^{(1)}(\mathcal{A})$ be the genus-1 bar complex with fiberwise differential d_{fib} whose transferred curved operation satisfies $m_1^2 = [m_o, -]$ and whose scalar diagonal/Hodge projection is $\kappa(\mathcal{A})\lambda_1$, where λ_1 is the Hodge class. Then the HTT applied to the SDR from the bar filtration produces:

- (i) A nullary operation m_o whose scalar diagonal/Hodge projection is $\kappa(\mathcal{A}) \cdot \lambda_1$.
- (ii) A unary operation m_1 with $m_1^2(a) = [m_o, a]$ (the commutator identity for curved A_∞ -algebras).
- (iii) Binary and higher operations m_n ($n \geq 2$) modified by the curvature: m_2 acquires corrections from the Eisenstein propagator on the elliptic curve, and m_3 acquires contributions from the genus-1 Massey product.

Proof. The genus-1 bar complex on an elliptic curve E_τ has differential $d_{\text{fib}} = d^{(o)} + d^{(1)}$ where $d^{(o)}$ is the genus-0 collision differential and $d^{(1)} = \kappa(\mathcal{A}) \cdot \text{tr}$ inserts the trace element (Theorem ??). Then $(d^{(o)})^2 = 0$ and $\{d^{(o)}, d^{(1)}\} = 0$ by the decomposition of $D_1^2 = 0$ (Theorem ??).

The SDR from the bar filtration gives $(\bar{B}^{(1)}(\mathcal{A}), H^*(\bar{B}^{(o)}(\mathcal{A})), p, \iota, h)$ at the associated graded level. Applying HTT with the perturbed differential $d^{(1)}$ (the “perturbation lemma” variant [?LV12]), the transferred structure acquires:

- $m_o = p \circ d^{(1)} \circ \iota(1) = \kappa(\mathcal{A}) \cdot p(\text{tr}) = \kappa(\mathcal{A}) \cdot \lambda_1$ (the trace element projects to the Hodge class),
- $m_1(a) = p \circ d^{(1)} \circ \iota(a) + p \circ d^{(o)} \circ h \circ d^{(1)} \circ \iota(a) + \dots$ (geometric series in $h \circ d^{(1)}$, converging because $d^{(1)}$ raises filtration degree),
- $m_2(a, b) = p \circ \mu \circ (\iota(a) \otimes \iota(b)) + (\text{corrections from } h \circ d^{(1)}).$

The relation $m_1^2(a) = m_2(m_o, a) - m_2(a, m_o) = [m_o, a]$ follows from the general curved A_∞ -identity with $r + s + t = 1$ and $s = 0$. $\square$

Remark 12.7.6 (*Higher genus: moduli cohomology as transferred operations*). At genus $g \geq 2$, the bar complex $\bar{B}^{(g)}(\mathcal{A})$ is a family over $\overline{\mathcal{M}}_g$ with period-corrected total differential D_g satisfying $D_g^2 = 0$ (Theorem ??). The HTT applied fiberwise produces a curved A_∞ -algebra over $\overline{\mathcal{M}}_g$ whose operations are sections of bundles over moduli space. The key identification is:

The n -ary transferred operation $\bar{m}_n^{(g)}$ is a section of

$$\text{Hom}(\mathcal{A}^{\boxtimes n}, \mathcal{A}) \otimes H^*(\overline{\mathcal{M}}_{g,n}, \mathbb{Q}).$$

The dependence on $H^*(\overline{\mathcal{M}}_{g,n})$ is the “quantum correction” from the genus- g moduli geometry.

This gives a homotopy-algebraic interpretation of Theorem C (Deformation-Obstruction Complementarity, Theorem ??): the quantum obstruction $Q_g(\mathcal{A})$ and the dual obstruction $Q_g(\mathcal{A}^!)$ together

span $H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$ because they are the complementary components of the transferred A_∞ -structure on $H^*(\tilde{B}^{(g)}(\mathcal{A}))$, restricted to the center and projected along the Koszul line and its complement. The complementarity $Q_g(\mathcal{A}) + Q_g(\mathcal{A}^\dagger) = H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$ is the statement that the full transferred structure exhausts the moduli cohomology, with nothing left over.

This interpretation elevates Theorem C from a numerical identity to a structural statement: the bar-cobar machine, viewed through HTT, *decomposes* moduli-space cohomology into the piece controlled by $\mathcal{A}$ and the piece controlled by $\mathcal{A}^\dagger$, with the Koszul duality functor as the sorting mechanism.

Remark 12.7.7 (Physical content: renormalization vs. homotopy transfer). Homotopy transfer and perturbative renormalization in quantum field theory are analogous, and in the chiral algebra setting they coincide:

- (i) **Tree-level HTT = classical field theory.** The tree formula (Theorem 12.3.2) sums over tree-level Feynman diagrams. The condition $\hbar^2 = 0$ in the SDR (the “no-loop” condition from Remark 12.3.3) ensures that only trees contribute, not graphs with loops. Classical field theory is determined by its tree-level amplitudes.
- (ii) **Genus- g scalar curvature = g -loop quantum corrections.** The scalar diagonal curvature $\kappa(\mathcal{A}) \cdot \omega_g$ at genus g is the analogue of the g -loop counterterm in perturbative renormalization. The perturbation lemma that extends HTT to the curved setting (Proposition 12.7.5) corresponds to absorbing the counterterm into the effective action, order by order in $\hbar \sim \kappa(\mathcal{A})$.
- (iii) **Koszulness = absence of anomalies.** A Koszul chiral algebra has $\tilde{m}_n = 0$ for $n \geq 3$ (Theorem 12.6.1(iii)), meaning no higher-point interactions are generated by integrating out degrees of freedom. In physics, this is the statement that the theory is *anomaly-free at the level of OPE structure*: the classical OPE data determine the quantum theory completely, with no need for higher-order counterterms. The genus- g curvature $\kappa(\mathcal{A})$ is the *only* quantum correction, and it is universal (Theorem ??).

NON-ABELIAN POINCARÉ DUALITY AND THE VERDIER DUAL OF THE BAR COALGEBRA

Remark 13.0.1 (Theorem C three-tier orientation: Co, C1, C2). Complementarity (Theorem C) decomposes into three tiers, never to be conflated. Co: the fibre-centre identification $Z(\mathcal{A}) = H^0 Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ with $Z(\Omega_X^{\text{ch}}(\bar{B}_X^{\text{ch}}(\mathcal{A})))$ at every chirally Koszul datum, proved on that datum by the bar-cobar counit $\Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ of Theorem 17.1.2. C1: the Lagrangian-eigenspace decomposition of the quantum class

$$Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^\dagger) \simeq H^*(\bar{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$$

at every genus $g \geq 1$ on the finite-type or completed Koszul locus where the bar–cobar normal complex is perfect and the Verdier pairing is dualizable. This is proved family-by-family on the standard landscape; outside that landscape it is conditional on perfectness, separated completion, proper support, and the chosen orientation datum. C2: the upgrade to a (-1) -shifted symplectic Lagrangian intersection of $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^\dagger}$ inside the global deformation space $\mathcal{M}_{\text{comp}}$, conditional on the BV package and the bar-chart Lagrangian lift; the uniform-weight restriction is *not* a hypothesis of C2 but enters only at the scalar-complementarity corollary $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger) = K(\mathcal{A})$. The scalar conductor $K(\mathcal{A}) = \kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger)$ is the trace shadow of C1 together with Theorem D, and the Climax identification $\kappa(\mathcal{A}) = -c_{\text{ghost}}(\text{BRST}(\mathcal{A}))$ (Chapter ??; Chapter 25) factors $K(\mathcal{A})$ as the universal ghost-charge sum across the Koszul pair.

The MC element $\Theta_{\mathcal{A}}$ lives in a convolution algebra built from two objects only: the bar coalgebra $\bar{B}_X(\mathcal{A})$ and the algebra $\mathcal{A}$. The Verdier dual of the bar coalgebra produces a third object, already an algebra:

$$K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}).$$

For a quadratic presentation, the coalgebra map $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \bar{B}_X(\mathcal{A})$ gives the algebra map

$$\mathbb{D}(q_{\mathcal{A}}): K_X(\mathcal{A}) \longrightarrow \mathbb{D}_{\text{Ran}}(\mathcal{A}^i).$$

On the finite Koszul locus, local finite duality identifies the target with $(\mathcal{A}^i)^\vee$. A chosen Koszul partner carries a separate map $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^i$, an equivalence under the pair package. Here $\mathcal{A}^i$ is the quadratic coalgebra; when $q_{\mathcal{A}}$ is a quasi-isomorphism it computes $H^\bullet(\bar{B}_X(\mathcal{A}))$. The cobar counit $\Omega_X^{\text{ch}} \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$ gives bar–cobar reconstruction of the original algebra.

Verdier duality is used on the bounded holonomic, equivalently constructible, Verdier-dualizable subcategory; in the completed bar-length setting it means the continuous dual on the pro-conilpotent completion. It is not asserted on an arbitrary unbounded category of $\mathcal{D}$ -modules. On this surface $\mathbb{D}_{\text{Ran}}: D_{\text{hol}}^b(\mathcal{D}\text{-mod}(\text{Ran}(X))) \rightarrow D_{\text{hol}}^b(\mathcal{D}\text{-mod}(\text{Ran}(X)))$ exchanges $!$ -tensor and $*$ -tensor. Hence it carries the bar coalgebra to the algebra whose operations are the Verdier transposes of the bar operations:

bar coproduct $\Delta_{\bar{B}} \longleftrightarrow$ product μ of $K_X(\mathcal{A})$,
 bar counit $\varepsilon_{\bar{B}} \longleftrightarrow$ unit of $K_X(\mathcal{A})$,
 bar differential $d_{\bar{B}} \longleftrightarrow$ differential of $K_X(\mathcal{A})$,
 logarithmic forms on $\bar{C}_n(X) \longleftrightarrow$ distributional currents on $C_n(X)$.

No pre-existing dual partner, quadratic presentation, or classical $R^\perp$ is part of the definition.

The firewall is:

$\mathcal{A}$: chiral algebra, the boundary object,
 $\bar{B}_X(\mathcal{A})$: factorization coalgebra, the bar chain object,
 $\mathcal{A}^i = C_X(s^{-1}V, s^{-2}R)$: quadratic coalgebra of a chosen presentation, with $q_{\mathcal{A}} : \mathcal{A}^i \rightarrow \bar{B}_X(\mathcal{A})$,
 $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A})$: Verdier homotopy Koszul-dual algebra,
 $\nu_{\mathcal{A}} : K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$: chosen-pair algebra map,
 $\mathcal{A}^! = (\mathcal{A}^i)^\vee$: Verdier or continuous linear dual algebra, after finite-type or completed dualizability,
 $Z_{\text{ch}}^{\text{der}}(\mathcal{A}) = CH^\bullet(\mathcal{A}, \mathcal{A})$: cochain-level chiral closed sector, not a bar object and not topological or categorical Hochschild.

The genus- g obstruction theory uses the Verdier algebra $K_X(\mathcal{A})$ and, after $\nu_{\mathcal{A}}$, its chosen strict partner $\mathcal{A}^!$. The cochain-level closed-sector object is $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$; a physical bulk realization requires an additional open-closed comparison and analytic completion.

13.1 THE INTRINSIC DUALITY DATUM

Problem 13.1.1 (Independent construction of Koszul dual). The bar coalgebra of $\mathcal{A}_1$ first enters Verdier duality. The resulting algebra and its chosen-pair comparison are

$$H^\bullet \bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_1^i \quad \text{and} \quad K_X(\mathcal{A}_1) := \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A}_1) \xrightarrow{\nu_{12}} \mathcal{A}_2 \simeq \mathcal{A}_1^!$$

for a finite-type Koszul pair after the Verdier-compatible identification, with continuous completions off it. The completed statement requires a separated complete bar filtration, finite-dimensional graded quotients, and continuous duals; these hypotheses define the continuous Verdier algebra. The cobar equivalence $\Omega^{\text{ch}} \bar{B}^{\text{ch}}(\mathcal{A}_1) \simeq \mathcal{A}_1$ reconstructs the original algebra.

Remark 13.1.2 (NAP duality). Non-abelian Poincaré duality supplies the post-Verdier algebra. Let M be compact and oriented, and let $\mathcal{A}$ be an augmented locally constant or constructible factorization algebra whose local values are dualizable and whose global sections satisfy the required compact-support finiteness. If its Verdier-linear Koszul dual algebra $\mathcal{A}^!$ exists in the finite-type or completed continuous sense, then Ayala–Francis duality gives:

$$\int_M \mathcal{A} \simeq \mathbb{D} \left(\int_{-M} \mathcal{A}^! \right).$$

Here $\int_M$ is factorization homology, $\mathbb{D}$ is Verdier duality, $-M$ is M with opposite orientation, and $\mathcal{A}^!$ denotes the chosen target of the pair map from the Verdier algebra. The formula is a theorem under these compactness, orientation, support, and dualizability hypotheses.

Factorization homology is computed as a colimit over Weiss covers:

$$\int_M \mathcal{A} = \operatorname{colim}_{\coprod_i D_i \hookrightarrow M} \bigotimes_i \mathcal{A}(D_i)$$

where the colimit ranges over collections of disjoint disk embeddings $\coprod_i D_i \hookrightarrow M$ (not over arbitrary configuration spaces; cf. the excision property for Weiss covers, Definition 3.10.2).

Verdier duality exchanges integration over $\overline{C}_n(M)$ with distributions on $C_n(M)$, logarithmic forms with delta currents, and residues at collisions with singularity insertions. Construction 13.4.1 fixes the chiral object-level version of this equivalence.

13.2 LOGARITHMIC FORMS AND DISTRIBUTIONAL CURRENTS

Configuration spaces carry the duality that separates the bar and cobar sides. On $\overline{C}_k(X)$, two dual sheaf complexes coexist; one builds the bar construction, the other the cobar.

The sheaf $\Omega_{\log}^*(\overline{C}_k(X))$ consists of differential forms with at worst logarithmic poles along the boundary divisors $D_I = \{z_i = z_j : i, j \in I\}$. The propagator $\eta_{ij} = d \log(z_i - z_j)$ is the simplest section: it has a simple pole on D_{ij} and is smooth elsewhere. The wedge products $\bigwedge_{e \in E(T)} \eta_e$, indexed by edges of planar trees, are the integrands of the bar construction.

The notation $\mathcal{D}_{\text{dist}}^*(C_k(X))$ denotes the de Rham representative of the Verdier-dual constructible complex: compactly supported currents on the open stratum together with the boundary-supported dualizing sections on $\overline{C}_k(X)$ that arise from the extension triangles. The delta symbol δ_{ij} is the current representative of the localization class along the boundary divisor D_{ij} , not a function on $C_k(X)$. Products such as $\prod_{e \in E(T)} \delta_e$ are names for iterated localization correspondences, with derived intersection understood; they are not pointwise products of singular distributions.

Verdier duality exchanges these two constructible complexes. After compact support on the open stratum and finite-dimensional cohomology are imposed, the de Rham notation above realizes the hypercohomological pairing

$$\langle \cdot, \cdot \rangle : R\Gamma(\overline{C}_k(X), \Omega_{\log}^\bullet(D)) \otimes R\Gamma_c(C_k(X), \mathcal{D}_{\text{dist}}^\bullet) \longrightarrow \mathbb{C}$$

where $j : C_k(X) \hookrightarrow \overline{C}_k(X)$ is the open inclusion. A current representative K acts by the regularized evaluation $K(j^* \omega)$, equivalently by the residue sum over the boundary strata. No pullback of a boundary current to the open stratum and no pointwise product of singular kernels is part of the definition. Residue extraction (bar) and singularity insertion (cobar) are Poincaré–Lefschetz dual operations on the pair $(\overline{C}_k(X), D)$.

Example 13.2.1 (Two points). For $k = 2$ on $X = \mathbb{P}^1$: $\langle \eta_{12}, \delta_{12} \rangle = \operatorname{Res}_{z_1=z_2} \eta_{12} = 1$. The OPE coefficient of the identity channel is the residue of the propagator, paired with the delta current at collision.

Example 13.2.2 (Three points and the Arnold relation). For $k = 3$, the three boundary divisors D_{12}, D_{23}, D_{31} of $\overline{C}_3(\mathbb{P}^1)$ satisfy $\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$ (Theorem 7.1.53). Pairing the corresponding constructible diagonal classes with these logarithmic forms gives the associativity constraint: the signed sum of iterated residues vanishes. The literal product of delta distributions is only a local mnemonic; Remark 13.3.6 gives the derived formulation.

13.3 VERDIER DUALITY ON CONFIGURATION SPACES

Setup 13.3.1 (Configuration space duality). Let X be a smooth curve (or more generally, an n -dimensional manifold). The configuration space of k points is:

$$C_k(X) = \{(z_1, \dots, z_k) \in X^k : z_i \neq z_j \text{ for } i \neq j\}$$

Its Fulton–MacPherson compactification $\overline{C}_k(X)$ is a smooth manifold with corners, with boundary divisors parametrizing collision patterns.

THEOREM 13.3.2 (*Verdier duality for configuration spaces*; [KS90]). Let X be a smooth oriented curve, let $j: C_k(X) \hookrightarrow \overline{C}_k(X)$ be the open configuration stratum of its Fulton–MacPherson compactification, and let $D = \overline{C}_k(X) \setminus C_k(X)$ be the normal-crossing boundary. For the logarithmic de Rham model of $Rj_*\mathbb{C}_{C_k(X)}$ and the compactly supported current model of its Verdier dual, Verdier duality gives a canonical pairing

$$R\Gamma(\overline{C}_k(X), \Omega_{\log}^\bullet(D)) \otimes R\Gamma_c(C_k(X), \mathcal{D}_{\text{dist}}^\bullet) \longrightarrow \mathbb{C}.$$

On finite-dimensional cohomology this pairing is perfect. In a de Rham model it is represented by the action of a current on the regularized logarithmic form,

$$\langle \omega, K \rangle = K(j^*\omega),$$

or, after resolving the boundary stratification, by the corresponding sum of residue pairings on the strata. The Verdier-dual identification is an isomorphism in $D_c^b(\overline{C}_k(X))$ with the orientation shift $d = \dim_{\mathbb{R}} \overline{C}_k(X)$; it is not a degree-by-degree isomorphism of raw logarithmic forms with raw distributions.

Proof. We apply Verdier duality for constructible sheaves [KS90] to the specific geometry of configuration spaces.

Step 1. For any constructible complex $\mathcal{F}$ on $\overline{C}_k(X)$:

$$\mathbb{D}(\mathcal{F}) = \mathcal{RH}\mathbb{I}_{\overline{C}_k(X)}(\mathcal{F}, \omega_{\overline{C}_k(X)}[d])$$

Step 2. Since $\overline{C}_k(X)$ is smooth of complex dimension k (for X a smooth curve), the constant sheaf is self-dual up to shift:

$$\mathbb{D}(\mathbb{C}_{\overline{C}_k(X)}) \cong \mathbb{C}_{\overline{C}_k(X)}[2k]$$

For the $j_!$ -extension from the open stratum $C_k(X) \hookrightarrow \overline{C}_k(X)$, Verdier duality exchanges $j_!$ and Rj_* :

$$\mathbb{D}(j_!\mathbb{C}_{C_k(X)}) \cong Rj_*\mathbb{C}_{C_k(X)}[2k]$$

Step 3. Taking hypercohomology with respect to the de Rham complex:

$$\mathbb{H}^*(\overline{C}_k(X), \Omega_{\log}^*) = H_{\text{dR}}^*(\overline{C}_k(X), \log D)$$

$$\mathbb{H}_{C_k(X)}^*(\Omega_{\text{dist}}^*) = H_{c, \text{dR}}^*(C_k(X))$$

The Verdier duality pairing descends to the de Rham pairing.

Step 4. The explicit pairing is computed by residues:

$$\langle \omega_{\log}, K_{\text{dist}} \rangle = \sum_{\text{strata } S} \int_S \text{Res}_S(\omega_{\log}) \wedge K_{\text{dist}}|_S$$

Verdier duality for constructible complexes on smooth varieties [KS90] gives perfectness after passing to finite-dimensional cohomology. $\square$

Remark 13.3.3 (Algebraic vs. analytic Verdier duality). Theorem 13.3.2 uses “Verdier duality” in two senses that must be carefully distinguished:

- (i) *Algebraic ($\mathcal{D}$ -module) Verdier duality.* The functor $\mathbb{D}_{\text{alg}} = \mathcal{R}\mathcal{H}om(-, \omega_{\overline{C}_k}^{-}[\dim])$ acts on holonomic $\mathcal{D}$ -modules on $\overline{C}_k(X)$. It exchanges $j_!$ and j_* extensions (Lemma 8.0.13). This is the sense used in Definition 8.0.10 to construct the cobar complex intrinsically.
- (ii) *Analytic (Borel–Moore) Verdier duality.* On the real manifold underlying $C_k(X)$, Poincaré–Lefschetz duality identifies $H^*(\overline{C}_k)$ with $H_c^{d-*}(C_k)$, realized concretely by the integration pairing of logarithmic forms against distributional currents.

The bridge between (1) and (2) is the Riemann–Hilbert correspondence: applying the de Rham functor to holonomic $\mathcal{D}$ -modules produces constructible sheaves, and the algebraic duality $\mathbb{D}_{\text{alg}}$ becomes the topological Verdier duality on constructible complexes [KS90]. See Theorem 8.0.14 for the analytic realization as a consequence of the algebraic statement.

13.3.1 The dual operations

THEOREM 13.3.4 (Dual differentials;). In the finite-type constructible model of Theorem 13.3.2, the following operations are Verdier-adjoint:

Residue vs. boundary localization. Let $i_{ij}: D_{ij} \hookrightarrow \overline{C}_k(X)$ be the boundary inclusion and $q_{ij}: D_{ij} \rightarrow \overline{C}_{k-1}(X)$ the collision collapse map. The cobar operation denoted by δ_{ij} is the localization correspondence $i_{ij,*}q_{ij}^!$.

$$\begin{aligned} \text{Bar: } \text{Res}_{D_{ij}} : \Omega_{\log}^*(\overline{C}_k) &\rightarrow \Omega_{\log}^*(\overline{C}_{k-1}) \\ \text{Cobar: } \delta_{ij} : \mathcal{D}_{\text{dist}}^*(C_{k-1}) &\rightarrow \mathcal{D}_{\text{dist}}^*(C_k) \end{aligned}$$

Explicitly:

$$\langle \text{Res}_{D_{ij}}(\omega), K \rangle = \langle \omega, \delta_{ij}(K) \rangle$$

Collapsing vs. splitting.

$$\begin{aligned} \text{Bar: Collapse at } D : C_k &\dashrightarrow C_{k-1} \\ \text{Cobar: Split along diagonal: } C_{k-1} &\rightarrow C_k \end{aligned}$$

Composition product vs. coproduct.

$$\begin{aligned} \text{Bar: } \circ : \Omega_{\log}^*(\overline{C}_k) \times \Omega_{\log}^*(\overline{C}_l) &\rightarrow \Omega_{\log}^*(\overline{C}_{k+l-1}) \\ \text{Cobar: } \Delta : \mathcal{D}_{\text{dist}}^*(C_{k+l-1}) &\rightarrow \mathcal{D}_{\text{dist}}^*(C_k) \otimes \mathcal{D}_{\text{dist}}^*(C_l) \end{aligned}$$

Geometric proof via stratifications. Observation (Serre). Boundary divisors $D \subset \overline{C}_k(X)$ biject with collision patterns (combinatorial data) and with diagonal subspaces in $C_k(X)$ (geometric data).

Residue operation. For a form ω with logarithmic pole along D :

$$\omega = f \cdot \eta_{ij} \wedge \omega' + \text{regular}$$

where $\eta_{ij} = d \log(z_i - z_j)$.

The residue is:

$$\text{Res}_D(\omega) = f|_D \cdot \omega'|_D$$

Boundary-localization operation. For a current representative K on $C_{k-1}(X)$, the Verdier-dual operation is

$$\delta_{ij}(K) := i_{ij,*} q_{ij}^! K.$$

In local analytic notation this class is often written as $K(z_1, \dots, \widehat{z_i}, \dots, z_k) \delta(z_i - z_j)$, but the display is only the current representative of the localization morphism.

The duality. The following calculation is the local de Rham model of the Verdier adjunction; the product with $\delta(z_i - z_j)$ is shorthand for the localization morphism supported on the diagonal:

$$\begin{aligned} \langle \omega, \delta_{ij}(K) \rangle &= \int_{\overline{C}_k} (f \cdot \eta_{ij} \wedge \omega') \wedge \delta(z_i - z_j) \cdot K \\ &= \int_D f|_D \cdot \omega'|_D \wedge K|_D \quad (\text{localization to the boundary}) \\ &= \int_{\overline{C}_{k-1}} \text{Res}_D (f \cdot \eta_{ij} \wedge \omega') \wedge K \\ &= \langle \text{Res}_D(\omega), K \rangle \end{aligned}$$

□

Example 13.3.5 (Heisenberg specialization). For the Heisenberg algebra $\mathcal{H}_k$ with generator $J(z)$, Theorem 13.3.4 reduces to: the residue $\text{Res}_{z_1=z_2} J(z_1)J(z_2) d \log(z_1 - z_2) = k$ on the bar side is dual to the boundary-localization insertion $\delta(z_1 - z_2)$ on the cobar side, recovering the level- k pairing that identifies $\mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*[1]), m_o = -k\omega)$ in §2.5.

Remark 13.3.6 (Analytic framework). The computation above is formal: the expression $\eta_{ij} \wedge \delta(z_i - z_j)$ is not well-defined as a pointwise product of distributions, since $\eta_{ij} = d \log(z_i - z_j)$ has a singularity precisely at the support of $\delta(z_i - z_j)$. The correct framework is Verdier duality as a functor on constructible sheaves (see [?SGA4, Exposé XVIII]). The pairing is defined in $D_c^b(\overline{C}_k(X))$ by proper push-forward and the localization triangle for $(C_k(X), D_{ij})$, not by multiplying a delta current by a singular logarithmic form.

13.4 FROM VERDIER DUALITY TO COOPERAD STRUCTURE

Construction 13.4.1 (Verdier algebra and chosen Koszul partner). Let $\mathcal{A}$ be an augmented chiral algebra on a smooth projective oriented curve X , valued in regular holonomic $\mathcal{D}$ -modules. Assume each Fulton–MacPherson component is proper over the relevant Ran stratum and Verdier-dualizable; if the bar-length filtration is infinite, work in the separated pro-conilpotent completion and use continuous duals. The geometric bar construction is the factorization coalgebra

$$\overline{B}_X^{\text{ch}}(\mathcal{A}) = \bigoplus_{n \geq 1} \pi_{n,*} \left(j_* j^* (\mathcal{A}^{\boxtimes n}) \otimes \Omega_{\log}^\bullet(\overline{C}_n(X)) \right),$$

with coproduct induced by splitting configurations and differential given by internal differential, de Rham differential, and Poincaré residue along collision divisors.

Define the Verdier homotopy Koszul-dual algebra by

$$K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}} \overline{B}_X^{\text{ch}}(\mathcal{A}).$$

The n -ary component of $K_X(\mathcal{A})$ is represented by distributional sections on $C_n(X)$:

$$(K_X(\mathcal{A}))_n \simeq \mathbb{D}_{\overline{C}_n(X)} \left(j_* j^* (\mathcal{A}^{\boxtimes n}) \otimes \Omega_{\log}^\bullet(\overline{C}_n(X)) \right).$$

The Verdier transposes of the bar coproduct, counit, and differential give the product, unit, and differential of $K_X(\mathcal{A})$.

Choose a quadratic presentation $\mathcal{A} = T_X(V)/(R)$ and form its quadratic coalgebra

$$\mathcal{A}^! := C_X(s^{-1}V, s^{-2}R), \quad q_{\mathcal{A}}: \mathcal{A}^! \longrightarrow \overline{B}_X^{\text{ch}}(\mathcal{A}).$$

On the finite Koszul locus, $q_{\mathcal{A}}$ is a quasi-isomorphism and the locally finite dual

$$\mathcal{A}^! := (\mathcal{A}^i)^\vee$$

is the strict Koszul-dual algebra. The quadratic comparison has Verdier transpose

$$\mathbb{D}(q_{\mathcal{A}}): K_X(\mathcal{A}) \longrightarrow \mathbb{D}_{\text{Ran}}(\mathcal{A}^!).$$

A chosen Koszul pair supplies $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$; formality and local finite duality make this map an equivalence.

Remark 13.4.2. Construction 13.4.1 forms the Verdier algebra from $\mathcal{A}$ alone. The chain coalgebra is $\overline{B}_X(\mathcal{A})$. A subsequent quadratic presentation supplies $\mathcal{A}^!$ and $q_{\mathcal{A}}$. The algebra is $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A})$, with chosen strict target $\mathcal{A}^! = (\mathcal{A}^i)^\vee$ through $\nu_{\mathcal{A}}$ when finite Koszul formality holds.

13.4.1 Verification of coalgebra axioms

THEOREM 13.4.3 (*Bar coalgebra and Verdier algebra;*). Under the hypotheses of Construction 13.4.1, the direct-sum bar object $\overline{B}_X^{\text{ch}}(\mathcal{A})$ is a well-defined conilpotent chiral coalgebra. In the completed bar-length ambient it is complete pro-conilpotent. In the strict direct-sum case:

- (i) *Coassociativity*: $(\Delta \otimes \text{id}) \circ \Delta = (\text{id} \otimes \Delta) \circ \Delta$.
- (ii) *Counit*: $(\epsilon \otimes \text{id}) \circ \Delta = \text{id} = (\text{id} \otimes \epsilon) \circ \Delta$.
- (iii) *Coderivation (graded)*: $\Delta(d(c)) = \sum d(c_{(1)}) \otimes c_{(2)} + (-1)^{|c_{(1)}|} c_{(1)} \otimes d(c_{(2)})$.
- (iv) *Conilpotency*: For each homogeneous bar element b , there exists N such that $\Delta^{(N)}(b) = 0$.

Its Verdier dual, respectively continuous Verdier dual,

$$K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \overline{B}_X^{\text{ch}}(\mathcal{A}),$$

is a factorization algebra; its multiplication, unit, and differential are the Verdier transposes of these coalgebra operations.

Proof via geometric stratifications. The coproduct $\Delta: \overline{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \overline{B}_X^{\text{ch}}(\mathcal{A}) \otimes \overline{B}_X^{\text{ch}}(\mathcal{A})$ arises from the geometric correspondence:

$$C_k(X) \rightarrow \bigcup_{I \sqcup J = [k]} C_{|I|}(X) \times C_{|J|}(X)$$

that splits points into two groups.

The composition $(\Delta \otimes \text{id}) \circ \Delta$ corresponds to:

$$C_k(X) \rightarrow C_{|I|}(X) \times C_{|J|}(X) \times C_{|K|}(X)$$

for $I \sqcup J \sqcup K = [k]$.

The two bracketings give the same ordered triple decomposition $I \sqcup J \sqcup K = [k]$, giving coassociativity.

The counit $\epsilon: \overline{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \omega_X$ corresponds to the projection:

$$C_k(X) \rightarrow X$$

selecting a single point (say, the first).

The composition $(\epsilon \otimes \text{id}) \circ \Delta$ corresponds to:

$$C_k(X) \xrightarrow{\Delta} C_1(X) \times C_{k-1}(X) \xrightarrow{\epsilon \times \text{id}} X \times C_{k-1}(X) \cong C_{k-1}(X)$$

This is the identity on $C_{k-1}(X)$, verifying the counit axiom.

The bar differential is the sum of internal differential, de Rham differential, and residue along collision divisors. Geometrically, the residue term corresponds to:

$$d: C_k(X) \rightarrow \bigcup_{i < j} D_{ij} \times C_{k-2}(X)$$

where D_{ij} is the collision divisor.

The coderivation property:

$$\Delta \circ d = (d \otimes \text{id} + \text{id} \otimes d) \circ \Delta$$

follows from the identity:

$$(\text{split then collide}) = (\text{collide then split on left}) + (\text{collide then split on right})$$

This is the combinatorial identity for configuration space strata, which holds because boundary divisors satisfy:

$$\partial(\overline{C}_k(X)) = \bigcup_{\text{strata}} D_\sigma$$

with compatible orientations.

Conilpotency is the bar-length filtration in the direct-sum category. An element represented on $C_k(X)$ has at most k collision factors, so every iterated reduced coproduct of length $> k$ is zero. In the completed category this becomes pro-conilpotence. Applying $\mathbb{D}_{\text{Ran}}$, or the continuous dual in the completed case, transposes these coalgebra identities into the factorization-algebra identities for $K_X(\mathcal{A})$. $\square$

13.5 THE BAR COALGEBRA, ITS QUADRATIC MODEL, AND ITS VERDIER ALGEBRA

THEOREM 13.5.1 (*Bar coalgebra, quadratic model, and Verdier algebra*;). [Regime: quadratic finite-type, with completed continuous variant (Convention 1.10.2).]

Let $\mathcal{A}$ be an augmented chiral algebra on a smooth curve X , with a quadratic presentation $\mathcal{A} = T_X(V)/(R)$ and quadratic coalgebra $\mathcal{A}^i = C_X(s^{-1}V, s^{-2}R)$, valued in bounded holonomic $\mathcal{D}$ -modules in the Verdier-dualizable ambient. Assume that the configuration-space pushforwards $\pi_*(\mathcal{A}^{\boxtimes(n+1)} \otimes \omega_{C_{n+1}(X)}^{\log})$ are well-defined in the derived category of holonomic $\mathcal{D}$ -modules on X , that the relevant de Rham cohomology groups are finite-dimensional after imposing compact support on the open strata, and that the orientation line of the curve has been fixed. In the non-finite case replace the bar object by its separated complete pro-conilpotent completion and replace all duals by continuous Verdier duals.

Then:

- (a) $\bar{B}^{\text{ch}}(\mathcal{A})$ is a conilpotent factorization coalgebra.
- (b) The canonical quadratic comparison $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \bar{B}^{\text{ch}}(\mathcal{A})$ is a quasi-isomorphism precisely on the quadratic Koszul locus.
- (c) Its Verdier algebra $K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A})$ is equipped with the perfect finite-type evaluation pairing, respectively the continuous evaluation pairing,

$$\bar{B}^{\text{ch}}(\mathcal{A}) \otimes K_X(\mathcal{A}) \longrightarrow \omega_{\text{Ran}}.$$

- (d) Verdier duality reverses the quadratic comparison to the algebra map

$$\mathbb{D}(q_{\mathcal{A}}): K_X(\mathcal{A}) \longrightarrow \mathbb{D}_{\text{Ran}}(\mathcal{A}^i).$$

On the finite Koszul locus this is a quasi-isomorphism. A chosen Koszul pair supplies

$$\nu_{\mathcal{A}}: K_X(\mathcal{A}) \longrightarrow \mathcal{A}^! := (\mathcal{A}^i)^{\vee},$$

and the pair package makes $\nu_{\mathcal{A}}$ an equivalence.

Proof. The holonomicity hypothesis puts every bar component in the bounded derived category of holonomic $\mathcal{D}$ -modules on $\bar{C}_{n+1}(X)$. Definition 7.1.17 therefore gives a conilpotent factorization coalgebra, with coproduct induced by splitting configurations.

Apply $\mathbb{D}_{\text{Ran}}$ on the Verdier-dualizable holonomic subcategory. Verdier duality is involutive there and exchanges j_* with $j^!$ (Lemma 8.0.13). Hence the dual of a bar component is represented on the open configuration space by distributional sections, and the canonical evaluation pairing is perfect in the finite-type case and continuous after completion. The differential compatibility is componentwise:

$$\begin{aligned} \mathbb{D}(d_{\text{int}}) &= d_{\text{int}}^{\text{dual}} \quad (\text{internal differential}) \\ \mathbb{D}(d_{\text{res}}) &= d_{\delta} \quad (\text{delta function insertion}) \\ \mathbb{D}(d_{\text{dR}}) &= d_{\text{dR}}^{\text{dist}} \quad (\text{de Rham on distributions}) \end{aligned}$$

so the dual object is the Verdier algebra $K_X(\mathcal{A})$ of Construction 13.4.1. The coalgebra coproduct on $\bar{B}^{\text{ch}}(\mathcal{A})$ dualizes to the multiplication on $K_X(\mathcal{A})$; the bar counit dualizes to its unit.

In the finite-type case Verdier duality gives, with the dimension shifts fixed by Theorem 13.3.2,

$$H^{\bullet}(K_X(\mathcal{A})) \cong H^{\bullet}(\bar{B}^{\text{ch}}(\mathcal{A}))^{\vee}.$$

In the completed case the right hand side is the continuous dual and requires the Mittag–Leffler condition for cohomology to commute with the inverse limit. The map $q_{\mathcal{A}}$ gives the asserted quadratic comparison, and contravariance gives $\mathbb{D}(q_{\mathcal{A}})$. Local finite duality identifies $\mathbb{D}_{\text{Ran}}(\mathcal{A}^i)$ with $(\mathcal{A}^i)^\vee$; the chosen pair map $\nu_{\mathcal{A}}$ records the further identification with $\mathcal{A}^!$. $\square$

Example 13.5.2 (Heisenberg specialization). For $\mathcal{A} = \mathcal{H}_k$, Theorem 13.5.1 gives $q_{\mathcal{H}_k} : \mathcal{H}_k^i \xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{H}_k)$ and the Verdier algebra $K_X(\mathcal{H}_k) = \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{H}_k)$. The bar complex is built from logarithmic forms on $\bar{C}_n(X)$; its Verdier dual is the algebra represented by distributional currents on $C_n(X)$. The Heisenberg pair map is

$$\nu_k : K_X(\mathcal{H}_k) \xrightarrow{\sim} \mathcal{H}_k^! = (\text{Sym}^{\text{ch}}(V^*[1]), m_{\circ} = -k\omega)$$

(cf. §2.6).

13.5.1 Explicit computation in low degrees

COMPUTATION 13.5.3 (*Degree 0 and 1; .*). For a finite-type quadratic chiral algebra $\mathcal{A} = T_{\text{ch}}(V)/(R)$, the low arities display the coalgebra, its Verdier dual algebra, and the residue pairing.

Degree 0.

$$\begin{aligned} \bar{B}^0(\mathcal{A}) &= \mathcal{A} \\ (K_X(\mathcal{A}))^{(0)} &= \mathbb{D}(\mathcal{A}) \otimes \omega_X \end{aligned}$$

There is a canonical evaluation pairing

$$\mathcal{A} \otimes \mathbb{D}(\mathcal{A}) \longrightarrow \omega_X.$$

A map $\Phi_{\circ} : \mathcal{A} \rightarrow \mathbb{D}(\mathcal{A}) \otimes \omega_X$ exists only after choosing a perfect self-duality or orientation trivialization of $\mathcal{A}$. The bar/Verdier construction does not supply such a Calabi–Yau pairing by itself.

Degree 1.

$$\bar{B}^1(\mathcal{A}) = \Gamma(\bar{C}_2(X), \mathcal{A}^{\boxtimes 2} \otimes \eta_{12})$$

The dual is:

$$(K_X(\mathcal{A}))^{(1)} = \mathcal{D}^*(C_2(X), (\mathbb{D}_X \mathcal{A})^{\boxtimes 2})$$

The Verdier-dual representative is the boundary-localization class

$$\Phi_1(\phi_1 \otimes \phi_2 \otimes \eta_{12}) = \mathbb{D}(\phi_1 \otimes \phi_2) \otimes [D_{12}]_{\text{BM}},$$

often denoted analytically by $\mathbb{D}(\phi_1 \otimes \phi_2) \otimes \delta(z_1 - z_2)$. Here $\eta_{12} = d \log(z_1 - z_2)$ is the logarithmic form and $[D_{12}]_{\text{BM}}$ is the Verdier-dual Borel–Moore class of the collision divisor.

The pairing is given by the residue:

$$\langle \eta_{12}, \delta_{12} \rangle = \text{Res}_{z_1=z_2} d \log(z_1 - z_2) = 1$$

(The pointwise product $\frac{1}{x} \delta(z)$ is not defined in distribution theory; the correct formulation uses the residue pairing between logarithmic forms and delta currents supported on the diagonal.) This is the fundamental Verdier pairing.

Degree 2 (first nontrivial case).

$$\bar{B}^2(\mathcal{A}) = \Gamma(\bar{C}_3(X), \mathcal{A}^{\boxtimes 3} \otimes (\eta_{12} \wedge \eta_{23} + \text{cyc}))$$

The dual is:

$$(K_X(\mathcal{A}))^{(2)} = \mathcal{D}^*(C_3(X), (\mathbb{D}_X \mathcal{A})^{\boxtimes 3})$$

The corresponding representative is the iterated localization class of the collision flag $D_{12} \cap D_{23}$:

$$\Phi_2(\phi_1 \otimes \phi_2 \otimes \phi_3 \otimes \eta_{12} \wedge \eta_{23}) = \mathbb{D}(\phi_1 \otimes \phi_2 \otimes \phi_3) \otimes [D_{12} \cap D_{23}]_{\text{BM}}^{\text{flag}}.$$

The symbol $\partial(z_1 - z_2)\partial(z_2 - z_3)$ is only a mnemonic for this flag class.

The Arnold relations on the bar side:

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0$$

correspond, under Verdier duality, to relations among constructible sheaves supported on the diagonal strata $\{z_i = z_j\}$. The precise formulation requires $\mathcal{D}$ -modules, perverse sheaves, or Borel–Moore chains on the stratified compactification. Literal products of delta distributions have the wrong support data. The naive products $\partial(z_1 - z_2)\partial(z_2 - z_3)$, $\partial(z_2 - z_3)\partial(z_3 - z_1)$, and $\partial(z_3 - z_1)\partial(z_1 - z_2)$ all collapse to the same full diagonal support and forget the flag orientation data; they therefore do not carry the Arnold relation. The correct dual statement is that the Verdier dual of the Arnold relation in $H^2(C_3(X))$ is the corresponding Borel–Moore relation in the shifted Verdier-dual degree.

13.6 KOSZUL PAIRS AND SYMMETRIC DUALITY

PROPOSITION 13.6.1 (*Verdier compatibility in a chiral Koszul pair*;). Let $(\mathcal{A}_1, \mathcal{A}_2)$ be two chiral algebras on X equipped with the antecedent twisting morphisms, compatible filtrations, conilpotent finite or completed Koszul coalgebras, and finite-type or continuous dualizability required in Definition 14.1.19. The Verdier-compatibility part of the chiral Koszul-pair datum is the pair of algebra maps

$$\begin{aligned} \nu_{12}: K_X(\mathcal{A}_1) &= \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A}_1) \xrightarrow{\sim} \mathcal{A}_2, \\ \nu_{21}: K_X(\mathcal{A}_2) &= \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A}_2) \xrightarrow{\sim} \mathcal{A}_1. \end{aligned}$$

Equivalently, on the finite Koszul locus,

$$q_i: \mathcal{A}_i^! \xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{A}_i), \quad \mathcal{A}_i^! = (\mathcal{A}_i^i)^\vee,$$

and the notation $\mathcal{A}_2 \simeq \mathcal{A}_1^!$, $\mathcal{A}_1 \simeq \mathcal{A}_2^!$ names the targets of the pair maps.

NAP shadow. If the locally constant topological shadows of these chiral algebras satisfy the Ayala–Francis compactness, orientation, support, and dualizability hypotheses, factorization homology gives

$$\int_X \mathcal{A}_1 \simeq \mathbb{D} \left(\int_{-X} \mathcal{A}_2 \right)$$

with $\int_X$ the factorization homology, $-X$ the orientation reversal, and $\mathbb{D}$ Verdier duality. This topological shadow does not replace the chiral twisting and filtration data.

Proof. Theorem 13.5.1 gives the coalgebra $\bar{B}^{\text{ch}}(\mathcal{A})$ and its Verdier algebra $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{A})$. Definition 14.1.19 requires twisting morphisms, filtrations, Koszulness, and precisely the Verdier-compatible maps from these algebras to the opposite member of the pair. Applying factorization homology gives the displayed NAP equivalence after the Ayala–Francis hypotheses are imposed on the locally constant topological shadows. $\square$

THEOREM 13.6.2 (*Symmetric Koszul duality*;). [Regime: quadratic finite-type on the Koszul locus, with completed continuous variant (Convention 1.10.2).]

If $(\mathcal{A}_1, \mathcal{A}_2)$ is a finite-type chiral Koszul pair with Verdier-dualizable bar components and locally finite quadratic models, then:

$$\begin{aligned} q_1: \mathcal{A}_1^! &\xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{A}_1), \\ q_2: \mathcal{A}_2^! &\xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{A}_2), \\ \nu_{12}: K_X(\mathcal{A}_1) &\xrightarrow{\sim} \mathcal{A}_2 \simeq \mathcal{A}_1^!, \\ \nu_{21}: K_X(\mathcal{A}_2) &\xrightarrow{\sim} \mathcal{A}_1 \simeq \mathcal{A}_2^!, \\ \Omega^{\text{ch}} \bar{B}^{\text{ch}}(\mathcal{A}_i) &\simeq \mathcal{A}_i \quad (i = 1, 2). \end{aligned}$$

Thus $\Omega^{\text{ch}} \bar{B}^{\text{ch}}$ reconstructs each member, while $K_X = \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}$ and the two maps ν_{ij} realize duality between the members. In the completed case the Verdier algebras use continuous duals.

Proof. The first two maps are the quadratic Koszul comparisons. The two maps ν_{ij} are exactly the Verdier compatibility data of Definition 14.1.19, rewritten using Construction 13.4.1. The last line is the bar-cobar counit on the Koszul locus (Theorem 8.0.54 and Theorem 14.1.103). It reconstructs the same algebra from its own bar coalgebra. $\square$

Example 13.6.3 (*Heisenberg specialization*). For the Koszul pair $(\mathcal{H}_k, \text{Sym}^{\text{ch}}(V^*))$, Theorem 13.6.2 gives:

$$\nu_k: K_X(\mathcal{H}_k) = \mathbb{D}_{\text{Ran}} \bar{B}^{\text{ch}}(\mathcal{H}_k) \xrightarrow{\sim} \text{Sym}^{\text{ch}}(V^*)$$

and $\Omega^{\text{ch}} \bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq \mathcal{H}_k$. This specializes to the Lie–Com exchange: the chiral Lie structure of $\mathcal{H}_k$ dualizes to the chiral commutative structure of $\text{Sym}^{\text{ch}}(V^*)$, and vice versa (§2.5).

Remark 13.6.4 (*Surface observables via factorization homology*). For a closed genus- g surface Σ_g , the factorization homology $H_{\Sigma_g}(\mathcal{A}) := \int_{\Sigma_g} \mathcal{A}$ models the topological factorization-homology observables of the locally constant shadow of $\mathcal{A}$. It is not, without an additional comparison theorem, the chiral Hochschild complex $CH^\bullet(\mathcal{A}, \mathcal{A})$ or the categorical Hochschild complex of a module category. Under the Ayala–Francis compactness, orientation, support, and dualizability hypotheses, Poincaré/Koszul duality [?AF15] gives

$$\int_{\Sigma_g} \mathcal{A} \simeq \mathbb{D} \int_{-\Sigma_g} \mathcal{A}^!,$$

which is the topological shadow of the modular bar-cobar story: the left side is factorization homology with $\mathcal{A}$; the right side is factorization cohomology with the post-Verdier dual algebra $\mathcal{A}^!$, not with the bar coalgebra. At genus 0 this is the topological shadow of Theorem A. In the modular chiral lane at $g \geq 1$, the corresponding bar-family observable is $R\Gamma(\overline{\mathcal{M}}_g, \overline{\mathcal{B}}_g(\mathcal{A}))$ after the proper-support and completion hypotheses are imposed. The modular characteristic package extracts numerical invariants from that derived object.

13.7 NON-QUADRATIC CASES AND COMPLETION

Remark 13.7.1 (*Necessity of completion*). For non-quadratic chiral algebras (W-algebras, Yangians, etc.), the bar construction produces infinitely many generators in each degree:

The bar complex has infinitely many bar-length components. Its cohomology therefore lives naturally in a completed conilpotent category, and its continuous Verdier dual is a complete algebra.

The Beilinson–Drinfeld remedy is I -adic completion:

$$\widehat{\bar{B}}(\mathcal{A}) = \varprojlim_n \bar{B}(\mathcal{A})/I^n$$

where $I = \ker(\epsilon : \bar{B}(\mathcal{A}) \rightarrow \mathbb{C})$ is the coaugmentation ideal.

Geometric interpretation. The completion is the inverse limit

$$\widehat{\bar{B}}(\mathcal{A}) = \varprojlim_n \bar{B}(\mathcal{A})/F^n$$

over the conilpotent filtration by bar degree (see Appendix ??), which organizes the bar complex by the number of collision points on $\bar{C}_n(X)$.

Definition 13.7.2 (Completed Verdier algebra and coalgebra model). For a chiral algebra $\mathcal{A}$, define its completed Verdier algebra by

$$\widehat{K}_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}}^{\text{cont}} \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}).$$

When a complete quadratic or minimal coalgebra model $\widehat{\mathcal{A}}^{\text{i}}$ is supplied, its comparison and Verdier transpose are

$$\widehat{q}_{\mathcal{A}}: \widehat{\mathcal{A}}^{\text{i}} \longrightarrow \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}), \quad \mathbb{D}(\widehat{q}_{\mathcal{A}}): \widehat{K}_X(\mathcal{A}) \longrightarrow \mathbb{D}_{\text{Ran}}^{\text{cont}}(\widehat{\mathcal{A}}^{\text{i}}).$$

The continuous dual $(\widehat{\mathcal{A}}^{\text{i}})_{\text{cont}}^{\vee}$ becomes a chosen strict partner through a separate pair map. The completion is taken with respect to the conilpotent bar-degree filtration, equivalently the powers of the coaugmentation ideal.

THEOREM 13.7.3 (Completion and Koszul duality;). For chiral algebras satisfying:

- (i) Finite generation over $\mathcal{D}_X$
- (ii) Polynomial growth of structure constants
- (iii) Separated and complete bar-degree filtration
- (iv) Finite-dimensional graded quotients with Mittag–Leffler transition maps on cohomology
- (v) Continuous Verdier dualizability with proper support on every Fulton–MacPherson stratum

The completed bar construction is a complete conilpotent chiral coalgebra. Its continuous Verdier dual is the completed homotopy dual algebra:

$$\mathbb{D}_{\text{Ran}}^{\text{cont}} \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) = \widehat{K}_X(\mathcal{A}).$$

If a model $\widehat{\mathcal{A}}^{\text{i}}$ and a filtered quasi-isomorphism $\widehat{q}_{\mathcal{A}}$ are supplied, then $\mathbb{D}(\widehat{q}_{\mathcal{A}})$ is a quasi-isomorphism of complete algebras. A chosen completed Koszul pair further supplies $\widehat{\nu}_{\mathcal{A}}: \widehat{K}_X(\mathcal{A}) \rightarrow (\widehat{\mathcal{A}}^{\text{i}})_{\text{cont}}^{\vee}$.

The completed cobar counit:

$$\Omega^{\text{ch}} \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) \xrightarrow{\sim} \widehat{\mathcal{A}}$$

recovers the completed algebra on the completed Koszul surface. It recovers $\mathcal{A}$ when the completion map $\mathcal{A} \rightarrow \widehat{\mathcal{A}}$ is an equivalence.

Proof. Step 1: Verdier duality extends to completed sheaves. The bar complex carries a filtration $F_n \bar{B}^{\text{ch}}(\mathcal{A})$ by bar degree $\leq n$. Since $\mathcal{A}$ is finitely generated over $\mathcal{D}_X$ (hypothesis (1)), each $\bar{B}_n^{\text{ch}}(\mathcal{A})$ is a holonomic $\mathcal{D}$ -module on $\bar{C}_n(X)$: the bar construction at degree n involves n -fold chiral tensor products of $\mathcal{A}$, which are holonomic by closure of holonomic $\mathcal{D}$ -modules under tensor product and proper pushforward. For a complete inverse system $\mathcal{F} = \varprojlim_n \mathcal{F}/F^n$, continuous Verdier duality is defined by

$$\mathbb{D}^{\text{cont}}(\mathcal{F}) := \varinjlim_n \mathbb{D}(\mathcal{F}/F^n).$$

This is a completed duality convention controlled by the topology; its domain consists of the stated complete inverse systems.

Step 2: Completion filtration is compatible with Verdier duality. The coaugmentation ideal $I = \ker(\epsilon : \bar{B}^{\text{ch}} \rightarrow \mathbb{C})$ defines the I -adic filtration. Each quotient $\bar{B}^{\text{ch}}/I^n$ involves only configuration spaces $C_k(X)$ with $k \leq n$, hence is geometric. Polynomial growth (hypothesis (2)) controls the size of the graded pieces. Hypothesis (4) supplies the Mittag-Leffler condition and gives $\varprojlim^1 = 0$ for the cohomology inverse system.

Step 3: Lifting to completions. By Theorem 13.5.1, each finite quotient $\bar{B}^{\text{ch}}(\mathcal{A})/I^n$ is a conilpotent coalgebra and its Verdier dual is an algebra. The universal property of the inverse limit, together with the Mittag-Leffler condition from Step 2, yields:

$$\widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) = \varprojlim_n \bar{B}^{\text{ch}}(\mathcal{A})/I^n$$

as a complete coalgebra, and

$$\mathbb{D}_{\text{Ran}}^{\text{cont}} \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) \simeq \varinjlim_n \mathbb{D}_{\text{Ran}}(\bar{B}^{\text{ch}}(\mathcal{A})/I^n)$$

as its continuous Verdier-dual algebra. Taking cohomology gives $H^\bullet \widehat{\bar{K}}_X(\mathcal{A}) \cong H^\bullet(\widehat{\bar{B}}^{\text{ch}}(\mathcal{A}))_{\text{cont}}^\vee$. A supplied map $\widehat{q}_{\mathcal{A}}$ dualizes to the complete algebra map of the statement.

Step 4: Cobar. By hypothesis (1), each bar component is holonomic (Step 1), so $\dim \text{CH}^n(\mathcal{A}) < \infty$ (de Rham cohomology of holonomic $\mathcal{D}$ -modules is finite-dimensional). Hence the cobar construction $\Omega^{\text{ch}} \widehat{\bar{B}}^{\text{ch}}(\mathcal{A})$ is well-defined and carries a complete filtration compatible with the differential. The bar-cobar adjunction counit $\Omega(\bar{B}(\mathcal{A})) \rightarrow \mathcal{A}$ (Theorem 8.0.54) is a quasi-isomorphism on the Koszul locus (Theorem 14.1.103). In the completed setting, all operations are continuous with respect to the I -adic topology and the Mittag-Leffler condition (Step 2) ensures $\varprojlim^1 = 0$, so the completed counit $\Omega^{\text{ch}} \widehat{\bar{B}}^{\text{ch}}(\mathcal{A}) \rightarrow \widehat{\mathcal{A}}$ is a quasi-isomorphism. If $\mathcal{A} \simeq \widehat{\mathcal{A}}$, this is the stated reconstruction of $\mathcal{A}$. $\square$

13.7.1 Application: $\mathcal{W}$ -algebras

Example 13.7.4 (First completed window for $\mathcal{W}_3$). For the $\mathcal{W}_3$ algebra with generators $T(z) = L(z)$ (weight 2) and $W(z)$ (weight 3):

The composite field.

$$\Lambda = :TT: - \frac{3}{10} \partial^2 T$$

is the quasi-primary composite of weight 4. It is absent from the strong generating set of $\mathcal{W}_3$ and appears in $\bar{B}^{\text{ch}}(\mathcal{W}_3)$ with OPE coefficient $\frac{16}{22+5c}$ in the $W-W$ channel (Definition ??).

Completed coalgebra model, first associated-graded window. Assume a complete coalgebra model $\widehat{W}_3^i$ and a filtered quasi-isomorphism $\widehat{q}_{W_3}: \widehat{W}_3^i \rightarrow \widehat{B}^{\text{ch}}(W_3)$ as in Definition 13.7.2. Its first associated-graded window is

$$\text{gr}^{(1)} \widehat{W}_3^i = \text{coFree}(L^*, W^*, \Lambda^*, (\Lambda^*)^{(2)}, (\Lambda^*)^{(3)}, \dots).$$

where $(\Lambda^*)^{(n)}$ are descendant towers. This display records the completed associated graded generated by the first composite field and its descendants; the full completed coalgebra also carries the topology and higher residue terms determined by the complete W – W OPE.

Coproduct.

$$\Delta(L^*) = 0 \quad (\text{primitive})$$

$$\Delta(W^*) = 0 \quad (\text{primitive})$$

$$\Delta(\Lambda^*) = L^* \otimes L^* - \frac{3}{10}(\partial^2 L^* \otimes 1 + 1 \otimes \partial^2 L^*) \quad (\text{composite})$$

The completed dual algebra is the continuous Verdier-linear dual

$$\widehat{W}_3^! := (\widehat{W}_3^i)_{\text{cont}}^\vee.$$

The chain-level comparison is

$$\mathbb{D}(\widehat{q}_{W_3}): \widehat{K}_X(W_3) \xrightarrow{\sim} \mathbb{D}_{\text{Ran}}^{\text{cont}}(\widehat{W}_3^i),$$

followed by the chosen-pair map to $\widehat{W}_3^!$.

The differential. The differential on Λ^* encodes the W – W OPE: since $W(z)W(w) \sim \frac{16}{22+5c} \frac{\Lambda(w)}{(z-w)^2} + \dots$, the bar differential acts by

$$d(\Lambda^*) = \frac{16}{22+5c} W^* \otimes W^*$$

with the remaining terms determined by the full W – W OPE (see Definition ?? and Computation ?? for the explicit structure constants).

Cobar reconstruction.

$$\Omega^{\text{ch}}(\widehat{W}_3^i) \simeq \widehat{W}_3$$

on the completed Koszul surface. The relation $\Lambda =: T \cdot T : -\frac{3}{10} \partial^2 T$ (with OPE coefficient $\frac{16}{22+5c}$) contributes the displayed Maurer–Cartan component in the cobar complex.

13.8 VERDIER RESOLUTION OF THE TYPE OBSTRUCTION

THEOREM 13.8.1 (*Verdier resolution of the type obstruction*;). Assume the finite-type hypotheses of Theorem 13.5.1, or the completed hypotheses of Theorem 13.7.3. Construction 13.4.1 defines the Verdier homotopy dual algebra $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \overline{B}_X^{\text{ch}}(\mathcal{A})$. For a quadratic presentation, Theorem 13.5.1 supplies $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \overline{B}_X^{\text{ch}}(\mathcal{A})$ and

$$\mathbb{D}(q_{\mathcal{A}}): K_X(\mathcal{A}) \longrightarrow \mathbb{D}_{\text{Ran}}(\mathcal{A}^i).$$

Local finite duality identifies the target with $\mathcal{A}^! = (\mathcal{A}^i)^\vee$ on the finite Koszul locus. For a Koszul pair $(\mathcal{A}_1, \mathcal{A}_2)$, Theorem 13.6.2 gives

$$\nu_{12}: K_X(\mathcal{A}_1) \xrightarrow{\sim} \mathcal{A}_2 \simeq \mathcal{A}_1^!, \quad \nu_{21}: K_X(\mathcal{A}_2) \xrightarrow{\sim} \mathcal{A}_1 \simeq \mathcal{A}_2^!,$$

and the cobar equivalences $\Omega^{\text{ch}} \overline{B}^{\text{ch}}(\mathcal{A}_i) \simeq \mathcal{A}_i$ are bar-cobar inversion.

Proof. The construction of $K_X(\mathcal{A})$ is Construction 13.4.1. The coalgebra and algebra identifications are Theorem 13.5.1. The symmetric pair statement is Theorem 13.6.2, which is the object-level form of the NAP equivalence $\int_X \mathcal{A}_1 \simeq \mathbb{D}(\int_{-X} \mathcal{A}_2)$ (Theorem ??). The final clause is the bar-cobar counit on the Koszul or completed Koszul surface. $\square$

The completed bar construction (Theorem 13.7.3) extends this to non-quadratic algebras after the separated completion, Mittag–Leffler, proper-support, and continuous-duality hypotheses are imposed. The quantum corrections (curvature from periods on $\overline{\mathcal{M}}_g$) appear in §36.13 and Chapter ??.

Remark 13.8.2 (Use in the main theorems). Theorem 13.8.1 supplies the post-Verdier dual algebra for Theorem A₂ (Theorem 14.1.103); Theorem 8.0.35 supplies the Verdier compatibility input for Theorem C (Theorem ??); and the explicit NAP computations of Chapter ?? independently verify Heisenberg, Kac–Moody, and $\beta\gamma$ /bc Koszul pairs.

13.9 K₃ POINCARÉ-DUALITY SHADOWS

Remark 13.9.1 (Mukai pairing as Poincaré duality). The Mukai pairing on $\Lambda_{\text{Muk}} = \Pi_{4,20}$ is the Poincaré pairing on K₃ cohomology transported to the Mukai lattice: signature $(4, 20)$, with $c_+ = 4$ and $c_- = 20$. The scalar Mukai-doubling value $K^{\kappa_{\text{ch}}} = 2c_+ = 8$ is the chiral shadow used in the K₃ bialgebra package, not a statement that the chiral algebra $\mathbf{H}_{\Delta_5}$ is itself the Mukai lattice. It is also not the Borchers weight $\kappa_{\text{BKM}}(\Delta_5) = 5$ and not the K₃×E Heisenberg shadow $\kappa_{\text{ch}}^{\text{Heis}} = 3$. The Poincaré-duality dimension $24 = c_+ + c_-$ equals the rank of the Mukai lattice and matches the 24 Kodaira I_1 fibres on $E_{24}^{\text{nod,sm}}$ in the bi-based Ran pair. The lattice duality is implemented by the $\text{SO}(4, 20; \mathbb{Z})$ -action on K₃ moduli [?Mukai1987, ?Borchers1998]; the chiral lift is the conditional Vol. III comparison of Chapter ??.

Remark 13.9.2 (Three faces of Poincaré duality at K₃). Poincaré duality at K₃ has three faces: (i) the Mukai or categorical Calabi–Yau pairing on $D^b\text{Coh}(K_3)$ (CY side); (ii) the chiral Hochschild pairing $CH^\bullet(\mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5})$ (chiral side); (iii) Siegel-modular Φ_{10} -denominator cusp-form pairing on $\tilde{\mathcal{A}}_2$ (modular-automorphic side). These are distinct Hochschild and pairing theories. The categorical Hochschild theory of $D^b\text{Coh}(K_3)$, the chiral Hochschild complex of $\mathbf{H}_{\Delta_5}$, and the automorphic pairing agree only after the conditional comparison functors and normalisations of Vol. III are imposed. Under that comparison the scalar shadow is the specialisation $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$, hence $\hbar^2 = -1/8$ when $K^{\kappa_{\text{ch}}} = 8$ [?Lusztig1990, ?PasolZagier2013]. This scalar shadow uses the Mukai conductor; the automorphic weight remains $\kappa_{\text{BKM}}(\Delta_5) = 5$.

Remark 13.9.3 (Quantum-determinant duality). The chiral-Hochschild face (ii) of Remark 13.9.2 refines on the RTT side as follows. On the RTT-style T -matrix $T(u, Z) \in \text{End}(V_{24}) \otimes \mathbf{H}_{\Delta_5}[[u^{-1}]]$ built from the rational-times-theta factorisation $R_{\text{Siegl,dyn}}(u, Z) = R_{\text{Yang}}^{\text{rat}}(u) \cdot \theta^{K_3}(u, Z)$, the conditional Vol. III comparison asserts that the Molev-style quantum determinant on the rank-24 Mukai-Heisenberg sub- T -matrix is central and equal to $\text{qdet } T(u, Z) = C(u) \cdot \Delta_5(Z) \cdot \text{Id}$, with $C(u) \in 1 + u^{-1}\mathbb{C}[[u^{-1}]]$ a Z -independent normalisation [?Molev2007, ?GritsenkoNikulin1998, ?Gritsenko1999]. Face (iii)’s Siegel-modular Δ_5 -pairing is then the Poincaré-dual shadow, at the quantum determinant level, of face (ii)’s chiral Hochschild pairing: the two faces coincide only after applying the Vol. III comparison and the rational Yang prefactor $C(u)$ (Chapter ??, Theorem ??).

Remark 13.9.4 (BKM vertical vs. Mukai horizontal duality). The Mukai pairing rank-24 of Remark 13.9.1 is the *horizontal* duality datum (lattice $\Pi_{4,20}$, Mukai-doubling $K^{\kappa_{\text{ch}}} = 8$); the BKM–Chevalley real-simple-root count of 3 in Theorem ?? gives the *vertical* duality datum on the rank-three Lorentzian

real-root core $\Lambda_{\Delta_5}^{2,1}$ [?GritsenkoNikulin1997, ?GritsenkoNikulin1998]. This rank-three core is not an even-unimodular $\Pi_{2,1}$ lattice and not the full K3 Mukai lattice. The apparent rank discrepancy $24 \neq 3$ is the Mukai-lattice rank (horizontal) vs. the BKM real-root rank (vertical). The averaging morphism of Vol. III Chapter ??’s Definition ?? intertwines the two via the conditional composite $\Pi_{3,19} \hookrightarrow \Pi_{4,20} \rightarrow \text{Mukai}(K_3)$, realising Poincaré duality as a commutative triangle linking the three faces after the categorical, chiral Hochschild, and Siegel-modular comparison functors have been fixed.

Remark 13.9.5 (N -parametric refinement of the three-faces triangle). The N -parametric family $\{\mathbf{H}_{\Delta_5}^{(N)}\}_{N \geq 2}$ of class- $\mathcal{S}$ K3 chiral bialgebras (Vol. I Proposition ??) conjecturally refines the three-face triangle of Remark 13.9.2 to an N -indexed family of commutative triangles. On each face:

- (i) *Mukai face.* At $N \geq 2$, the Maulik–Okounkov stable-envelope Mukai lattice on $\text{Hilb}^\bullet(K_3)$ is conjectured to acquire an $\mathfrak{sl}_N$ -refinement through the $\text{SU}(N)^{24}$ flavour action on the 24 punctures. The finite numerical input is the class- $\mathcal{S}$ pair $(n_v(N), n_h(N))$ of Vol. I Proposition ??; interpreting those counts as an N -refined Mukai-doubling rank is an additional comparison datum, not a consequence of the K3 Mukai lattice alone.
- (ii) *Chiral-Hochschild face.* The N -parametric chiral Hochschild complex $C_{\text{ch}}^\star(\mathbf{H}_{\Delta_5}^{(N)}, \mathbf{H}_{\Delta_5}^{(N)})$ carries an $\mathfrak{sl}_N$ -refined Mukai-doubling; at $N = 2$ it restores $K^{\kappa_{\text{ch}}} = 8$; at $N \geq 3$ the Mukai-doubling factorises through the determinant $\det_N : \text{End}(V_N) \rightarrow \mathbb{C}$.
- (iii) *Siegel-modular face.* The $N = 2$ primitive denominator is Δ_5 of weight 5. In the $\mathcal{W}$ -algebraic class- $\mathcal{S}$ surface, Theorem ?? gives the higher-rank Borchers weight $k_N^{\text{int}} = N + 3$, equivalently spin-cover weight $k_N^{\text{spin}} = (N + 3)/2$. The comparison of that lift with the K3 chiral-bialgebra triangle for $N \geq 3$ remains conditional on the source-recognition functors and automorphic normalisation.

The conditional N -parametric Lusztig specialisation $\hbar_N^2 \cdot K_N^{\kappa_{\text{ch}}} = -1$ predicts $\hbar_N^2 = -1/K_N^\kappa$ where K_N^κ is the N -parametric Mukai-doubling constant (not an independent parameter from the $\hbar$ of Remark 13.9.2: the bridge identity $\hbar_{N=2} = \hbar$ recovers $\hbar^2 = -1/K_2^\kappa = -1/8$ at $N = 2$, and for $N \geq 3$ the convention $\hbar_N$ refers to the same deformation parameter specialised against the rank- N BKM core, not a new $\hbar$). The open obligation is the construction of the comparison functor carrying the class- $\mathcal{S}$ Borchers lift to the chiral Hochschild pairing of $\mathbf{H}_{\Delta_5}^{(N)}$; without it the equality is only a scalar prediction.

CHIRAL KOSZUL DUALITY

Classical Koszul duality, in the sense of Priddy [?Priddy70] and Beilinson–Ginzburg–Soergel [?BGS96], works for graded algebras over a field: the bar complex is a tensor coalgebra on a finite-dimensional vector space, the cobar functor inverts it when bar cohomology is concentrated in degree one, and the duality exchanges quadratic algebras with quadratic coalgebras. Three features of chiral algebras on algebraic curves defeat this framework simultaneously. First, chiral algebras are *curved*: the bar differential on the genus expansion satisfies $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ rather than $d^2 = 0$, so the classical bar-cobar adjunction, which requires strict nilpotence, does not apply beyond genus zero. Second, chiral algebras live over a curve X , not over a point: the tensor power $V^{\otimes n}$ is replaced by the factorization product $\mathcal{A}^{\boxtimes n}$ over the Fulton–MacPherson compactification $\text{FM}_n(X)$, and the differential is a sum of residues at boundary strata governed by OPE singularities, not a combinatorial sum of face maps. Third, the conformal-weight components are infinite-dimensional, so finite generation hypotheses fail and convergence of spectral sequences becomes a separate problem.

What forces the extension is not a desire for generality but the structure of the objects themselves. The Virasoro algebra has a quartic OPE pole, $\mathcal{W}$ -algebras have poles of arbitrarily high order, Yangians have spectral-parameter relations: none of these admit a quadratic presentation, and the BGS theory does not see them. The Francis–Gaitsgory adjunction $\text{Lie}^{\text{ch}} \dashv \text{Com}^{\text{ch}}$ on $\text{Ran}(X)$ [?FG12] settles Koszul duality of the Lie–Com pair at the operadic level, but it does not determine whether a specific chiral algebra is Koszul: it does not see the genus corrections in the bar complex, and it does not detect the shadow obstruction tower whose depth varies from two to infinity across the standard families.

The bar–cobar adjunction of Theorem A has unit and counit

$$\eta_C : C \longrightarrow B_X \Omega_X(C), \quad \varepsilon_{\mathcal{A}} : \Omega_X B_X(\mathcal{A}) \longrightarrow \mathcal{A}.$$

Its enhanced associative Ran form is an equivalence; the geometric factorization realization uses the comparison and completion packages of this chapter. Verdier duality defines the contravariant algebra

$$K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}}^{\text{cont}} B_X^{\text{cont}}(\mathcal{A}).$$

The natural comparison of Theorem 8.0.35 is $\Omega_X^{\text{geom,cont}}(\mathbb{D}_X \mathcal{A}) \xrightarrow{\sim} K_X(\mathcal{A})$; the cobar functor acts here on the coalgebra $\mathbb{D}_X \mathcal{A}$. Lagrangian complementarity $Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^\dagger) \simeq H^*(\overline{\mathcal{M}}_g, Z(\mathcal{A}))$ (Theorem ??) uses this bar-cobar/Verdier package together with the derived-centre pairing. Thus $\Omega_X B_X(\mathcal{A}) \rightarrow \mathcal{A}$ is reconstruction, while $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} B_X(\mathcal{A})$ is the post-Verdier algebra.

Standing notation for the overview. A chiral twisting datum means a quadruple $(\mathcal{A}, C, \tau, F_\bullet)$ consisting of an augmented chiral algebra, a conilpotent complete factorization coalgebra, a degree-+1 twisting morphism $\tau : C \rightarrow \mathcal{A}$ satisfying the Maurer–Cartan equation, and a compatible filtration. We write $K_\tau^L(\mathcal{A}, C)$ and $K_\tau^R(C, \mathcal{A})$ for the corresponding twisted tensor products, and $\Theta_{\mathcal{A}}^{\leq r}$ for the degree- r truncation of the universal Maurer–Cartan element of the modular convolution algebra. A chiral Koszul

pair is such a datum on the Koszul locus, so the twisted tensor products are acyclic and the associated graded datum is classically Koszul. Definitions 14.1.1, 14.1.3, and 14.1.19 record the precise versions used below.

Theorem 14.1.59 assembles twelve tests and consequences around the quadratic twisting datum $(\mathcal{A}, \mathcal{A}^1, \tau_1)$. Seven form the intrinsic bidirectional core under the stated PBW detection hypotheses: E_2 -collapse of the bar spectral sequence, vanishing of transferred A_∞ operations m_k for $k \geq 3$, acyclicity of the twisted tensor product $K_\tau^L(\mathcal{A}, C)$, truncation of the shadow tower $\Theta_{\mathcal{A}}^{\leq r}$, and three others. The Barr–Beck–Lurie comparison is the monadic consequence of the quadratic comparison maps under its conservativity and totalization package. The factorization-homology item is the external integration avatar supplied by the conditional comparison model of Proposition 9.12.4; its converse uses the stated detection package. One item is the family-indexed Hochschild implication $H_H(\mathcal{A}; S) \Rightarrow \text{Supp } CH^\bullet(\mathcal{A}) \subseteq S$; a perfect degree- d pairing supplies its separate duality statement, and, because De Sole–Kac variational Poisson cohomology is nonvanishing in unboundedly many degrees for Virasoro-type Poisson vertex algebras [?BDSK21], the implication lives strictly on the stated Koszul/bounded locus, with the bounded-to-chart comparison part of $H_H(\mathcal{A}; S)$. One (the Lagrangian eigenspace criterion) is conditional on the shifted-symplectic hypothesis package, including perfectness of the bar-cobar normal complex. One ($\mathcal{D}$ -module purity) is a one-directional implication. The count is exact: $7 + 1 + 1 + 1 + 1 + 1$.

Two distinctions require emphasis. First, the four complexity classes G/L/C/M, with shadow depths $\{2, 3, 4, \infty\}$ (Theorem ??), record the degree at which the shadow obstruction tower first becomes non-trivial; they do *not* by themselves record failure of Koszulness. The PBW-flat universal families treated here (Heisenberg, universal affine Kac–Moody, universal Virasoro, universal principal $\mathcal{W}$ -algebras, and the free field systems on their stated lanes) are chirally Koszul by the PBW criterion. Simple admissible quotients, minimal models, and quotients with vacuum null vectors require the separate Shapovalov/Li-bar tests below and may fail. The classes separate algebras by the complexity of their higher-genus behaviour, not by the validity of the PBW hypothesis. Second, Koszulness and SC formality are logically independent properties. Koszulness is the condition that bar cohomology is concentrated in degree one; SC formality is the condition $m_k^{\text{SC}} = 0$ for $k \geq 3$ in the Swiss-cheese bar complex. On the PBW-flat universal surface the families above are Koszul; only class G (Heisenberg and its relatives) is SC-formal (Proposition 14.1.70). Confusing the two misidentifies what the shadow tower measures.

On a point, the bar complex $\bar{B}(A) = T^c(s^{-1}\bar{A})$ is built from tensor powers of the augmentation ideal; a classical twisting morphism $\tau: \bar{B}(A) \rightarrow A$ is a degree-+1 element in the convolution dg Lie algebra satisfying $d\tau + \tau \star \tau = 0$. For a chosen quadratic presentation $A = T(V)/(R)$, the presentation coalgebra is $A^1 = C(s^{-1}V, s^{-2}R)$ and the canonical map is $q_A: A^1 \rightarrow \bar{B}(A)$. Under $H_{\text{CL}}, H^\bullet(q_A)$ identifies its cohomology with bar cohomology. The full bar object has the dual algebra $K(A) = \mathbb{D}\bar{B}(A)$, and a chosen comparison $\nu_A: K(A) \rightarrow A^1$ selects the Koszul partner. On a curve X , the chiral twisting morphism (Definition 14.1.1) lives in the chiral convolution algebra, where the star product is mediated by the integration kernel on $X^2 \setminus \Delta$. The acyclicity of the twisted tensor product $K_\tau^L(\mathcal{A}, C)$, the defining property of a chiral Koszul pair, is checked by spectral sequence methods adapted to the PBW filtration by bar degree (Theorem 14.1.23).

Three phenomena distinguish the chiral setting from its point-set ancestor, and all three are invisible at genus zero: the modular characteristic $\kappa(\mathcal{A})$, which measures curvature of the genus expansion (Theorem ??); Lagrangian complementarity between $\mathcal{A}$ and $\mathcal{A}^1$ (Theorem ??); and the critical discriminant $\Delta = 8\kappa S_4$, whose vanishing controls termination of the shadow obstruction tower (Theorem ??). At genus zero all three collapse: κ plays no role, complementarity reduces to the genus-0 bar-cobar adjunction, Δ is vacuous. On the formal disk, this further reduces to classical Koszul duality; on the full genus-0

curve $\mathbb{P}^1$, the Fulton–MacPherson compactifications and Arnold relations already refine the classical picture. The genus-zero input below is the source from which the full modular theory is built. The standard families exemplify the four classes: Heisenberg (class G , depth 2, formal), affine Kac–Moody (class L , depth 3, single Massey product), $\beta\gamma$ (class C , depth 4, contact then rigid), Virasoro and $\mathcal{W}_N$ (class M , depth ∞ , intrinsically non-formal). The genus-zero degree-two projection of the universal MC element $\Theta_{\mathcal{A}}$ (Theorem ??) recovers the classical R -matrix, linking the Koszul pairs of this chapter to the Drinfeld–Kohno bridge of Chapter 15.

The Heisenberg calculation supplies the first model of the twisting datum. The PBW criterion turns that model into a recognition theorem for non-quadratic algebras. A chiral Koszul pair is the completed, finite-type, Verdier-compatible form of that datum; Theorem A proves bar-cobar inversion on this locus, and the higher-genus chapter adds the curved term that appears when the fiberwise differential no longer squares to zero.

14.1 FROM THE HEISENBERG EXAMPLE TO GENERAL TWISTING DATA

The bar complex of $\mathcal{H}_k$ (Chapter 2, Theorem 2.5.1) produces the coalgebra $\bar{B}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*)$, and the Heisenberg quadratic presentation supplies $q_{\mathcal{H}_k}: \mathcal{H}_k^i \rightarrow \bar{B}_X(\mathcal{H}_k)$. The Heisenberg instance of H_{CL} makes $H^\bullet(q_{\mathcal{H}_k})$ an isomorphism. On the finite-type Verdier lane the algebra $K_X(\mathcal{H}_k) = \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{H}_k)$ carries the chosen pair equivalence to $\mathcal{H}_k^!$, where $\mathcal{H}_k^! \simeq (\text{Sym}^{\text{ch}}(V^*[1]), m_0 = -k\omega)$ for $k \neq 0$; the uncurved symmetric algebra is the associated-graded or $k = 0$ shadow. The bar-cobar counit $\Omega_X(\bar{B}_X(\mathcal{H}_k)) \xrightarrow{\sim} \mathcal{H}_k$ is the universal reconstruction equivalence. Two structural features make this work:

- (i) The twisted tensor product $K_\tau^L(\mathcal{H}_k, \text{coLie}^{\text{ch}}(V^*))$ is acyclic: the twisting morphism $\tau: \text{coLie}^{\text{ch}}(V^*) \rightarrow \mathcal{H}_k$ solves the Maurer–Cartan equation.
- (ii) The PBW filtration on $\mathcal{H}_k$ produces an associated graded that is quadratic-Koszul in the classical sense.

These two properties (acyclicity of twisted tensor products and classical Koszulness of the associated graded) are the recognition criteria for chiral Koszulness. The point is not that the chiral algebra itself is quadratic (it is not), but that the PBW filtration by bar-length makes the leading-order structure quadratic-Koszul (Theorem 14.1.23). These criteria apply equally to the Virasoro algebra (quartic pole in the TT OPE), $\mathcal{W}$ -algebras (poles of arbitrarily high order), and Yangians (spectral-parameter relations), none of which admit a quadratic presentation.

14.1.1 Construction layer: twisting data

To recognize Koszulness, we need to compare a chiral algebra with its bar coalgebra. The bridge between them is a *twisting morphism*, a degree-+1 map satisfying a Maurer–Cartan equation, and to ensure convergence of the resulting spectral sequences, we need a compatible filtration. The Koszul property is then a *recognition criterion* on these data, not a prerequisite for their existence.

Definition 14.1.1 (Chiral twisting datum;). A *chiral twisting datum* on a smooth curve X is a quadruple $(\mathcal{A}, C, \tau, F_\bullet)$ consisting of:

- (i) an augmented chiral algebra $\mathcal{A} \in \text{Fact}^{\text{aug}}(X)$;
- (ii) a conilpotent complete factorization coalgebra $C \in \text{CoFact}^{\text{conil, comp}}(X)$;
- (iii) a degree +1 morphism $\tau: C \rightarrow \mathcal{A}$ satisfying the Maurer–Cartan equation $d\tau + \tau \star \tau = 0$ in the convolution dg Lie algebra;

- (iv) an exhaustive, complete, bounded-below filtration $F_\bullet$ on $\mathcal{A}, C, \bar{B}_X(\mathcal{A})$, and $\Omega_X(C)$, compatible with all structure maps.

Associated to τ are the *twisted tensor products*

$$K_\tau^L(\mathcal{A}, C) := (\mathcal{A} \otimes C, d_{\mathcal{A}} + d_C + d_\tau^L), \quad K_\tau^R(C, \mathcal{A}) := (C \otimes \mathcal{A}, d_C + d_{\mathcal{A}} + d_\tau^R).$$

Remark 14.1.2 (Explicit twisted differential). The twisting differentials d_τ^L and d_τ^R in Definition 14.1.1 are:

$$\begin{aligned} d_\tau^L(a \otimes c) &= \sum (-1)^{|a|} a \cdot \tau(c_{(1)}) \otimes c_{(2)}, \\ d_\tau^R(c \otimes a) &= \sum (-1)^{|c|} c_{(1)} \otimes \tau(c_{(2)}) \cdot a, \end{aligned}$$

where $\Delta(c) = \sum c_{(1)} \otimes c_{(2)}$ is the factorization coproduct. The MC equation $d\tau + \tau \star \tau = 0$ is *equivalent* to $(d_{\mathcal{A}} + d_C + d_\tau^L)^2 = 0$ (cf. [?LV12, Lemma 2.1.4]): the twisting morphism condition is the nilpotence of the twisted differential. In the chiral setting, $\tau(c_{(1)})$ is the OPE extraction: the coproduct $\Delta(c) = \sum c_{(1)} \otimes c_{(2)}$ separates the coalgebra element, and τ evaluates $c_{(1)}$ against the propagator on $\bar{C}_2(X)$ by residue at the collision divisor (Proposition 6.1.26).

Definition 14.1.3 (Chiral Koszul morphism;). [Type signature: Open quadrant; general chiral twisting presentation; Beilinson levels $1 \leftrightarrow 2$; fixed completed twisted products.] A chiral twisting datum $(\mathcal{A}, C, \tau, F_\bullet)$ is *Koszul* when the two augmented twisted products

$$K_\tau^L(\mathcal{A}, C), \quad K_\tau^R(C, \mathcal{A})$$

are acyclic. The morphism τ is then called a *chiral Koszul morphism*. This is the chiral form of the ordinary definition in Loday–Vallette [?LV12, §2.3]; their fundamental theorem identifies the two acyclicity conditions with the bar and cobar comparison maps [?LV12, Theorem 2.3.2].

Quadratic compression is an additional specialization. If $\mathcal{A}$ is equipped with quadratic data and

$$\mathcal{A}^i = C(s^{-1}V, s^{-2}R), \quad \tau_i: \mathcal{A}^i \longrightarrow \mathcal{A},$$

then the induced coalgebra map

$$q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow \bar{B}_X(\mathcal{A})$$

is the quadratic comparison. A filtration whose associated graded is this quadratic datum, together with strong convergence, is a *quadratic recognition package* for τ_i ; it is governed over a point by Loday–Vallette [?LV12, Theorem 3.4.6].

Remark 14.1.4 (Resolution and quadratic recognition). For an augmented dg algebra over a field, the canonical counit

$$\Omega B(A) \longrightarrow A$$

is a quasi-isomorphism for every A ; dually, the unit $C \rightarrow B\Omega C$ is a quasi-isomorphism for every conilpotent dg coalgebra C [?LodayVallette12, Corollary 2.3.4]. Quadratic Koszulness governs a second comparison: the compression of the full bar coalgebra to the quadratic coalgebra $\mathcal{A}^i$, equivalently the map $\Omega \mathcal{A}^i \rightarrow \mathcal{A}$ [?LodayVallette12, Theorem 3.4.6]. The Ran-space construction inherits this distinction. Francis–Gaitsgory supply the ambient pro-nilpotent bar–cobar equivalence; the ordered Fulton–MacPherson realization and its factorization descent require the comparison package below.

Definition 14.1.5 (Chiral Comparison-Lemma package;). For a twisting datum $(\mathcal{A}, C, \tau, F_\bullet)$, write $H_{\text{CL}}(\mathcal{A}, C, \tau)$ for the following data.

- (i) a stable presentable Ran category carrying continuous bar, cobar, and two-sided twisted-product functors, together with complete augmented-algebra and conilpotent-coalgebra subcategories preserved by those functors;
- (ii) exhaustive, separated, complete filtrations on $\mathcal{A}, C, \Omega_X C, \bar{B}_X \mathcal{A}, K_\tau^L, K_\tau^R$, split and finite in every conformal-weight window, with strict filtered unit, counit, and twisting maps;
- (iii) stratumwise identifications of the associated-graded objects with connected weight-graded ordinary dg algebra, dg coalgebra, bar, cobar, and twisted-product models;
- (iv) compatibility of those identifications with signed collision residues, nested-set boundary maps, factorization gluing, and the chosen ordered-to-symmetric descent;
- (v) a Mittag–Leffler inverse system in every bidegree and strong convergence of the six associated spectral sequences.

The geometric content lies in items (iii)–(iv): they constitute the chiral Comparison Lemma. Items (ii) and (v) transport its associated-graded conclusion to the completed Ran objects.

THEOREM 14.1.6 (*Fundamental theorem of ordinary twisting morphisms;*). Let A be a connected weight-graded augmented dg algebra, let C be a connected weight-graded conilpotent dg coalgebra, and let $\tau: C \rightarrow A$ be a twisting morphism. The following conditions are equivalent:

- (i) the left twisted product $A \otimes_\tau C$ is acyclic;
- (ii) the right twisted product $C \otimes_\tau A$ is acyclic;
- (iii) the induced algebra map $\Omega C \rightarrow A$ is a quasi-isomorphism;
- (iv) the induced coalgebra map $C \rightarrow BA$ is a quasi-isomorphism.

This is Loday–Vallette’s fundamental theorem [?LodayVallette12, Theorem 2.3.2].

LEMMA 14.1.7 (*Counit comparison;*). Assume $H_{CL}(\mathcal{A}, C, \tau)$. Then

$$K_\tau^L(\mathcal{A}, C) \text{ is acyclic} \iff \varepsilon_\tau: \Omega_X(C) \xrightarrow{\sim} \mathcal{A} \text{ is a quasi-isomorphism.}$$

Proof. On every finite conformal-weight window, the associated-graded comparison identifies the two conditions with clauses (i) and (iii) of Theorem 14.1.6. Strictness and the splitting reflect quasi-isomorphisms on the associated graded. Strong convergence lifts the equivalence to each finite window, and the Mittag–Leffler passage lifts it to the completion. $\square$

LEMMA 14.1.8 (*Unit comparison;*). Assume $H_{CL}(\mathcal{A}, C, \tau)$. Then

$$K_\tau^R(C, \mathcal{A}) \text{ is acyclic} \iff \eta_\tau: C \xrightarrow{\sim} \bar{B}_X(\mathcal{A}) \text{ is a weak equivalence.}$$

Proof. The associated-graded statement is the equivalence of clauses (ii) and (iv) in Theorem 14.1.6. The split finite-window filtration, strictness, strong convergence, and the Mittag–Leffler inverse limit give the Ran-space assertion. $\square$

PROPOSITION 14.1.9 (*Canonical one-sided bar resolution;*). For an augmented dg algebra A over a field, the canonical twisting morphism $\pi: B(A) \rightarrow A$ makes $A \otimes_\pi B(A)$ the normalized one-sided bar resolution of the unit. Its augmentation is a quasi-isomorphism and its positive homology vanishes. For a chiral algebra $\mathcal{A}$ satisfying $H_{CL}(\mathcal{A}, \bar{B}_X \mathcal{A}, \pi)$, the corresponding completed one-sided Ran object has the same cohomology.

Proof. The point-model assertion is the canonical case of Theorem 14.1.6; the normalized simplicial bar object carries the standard extra degeneracy. The chiral assertion follows from Lemma 14.1.7 and the convergent finite-window comparison in $H_{\text{CL}}(\mathcal{A}, \bar{B}_X \mathcal{A}, \tau)$. $\square$

Remark 14.1.10 (Scope of the canonical resolution). The extra degeneracy belongs to the canonical one-sided bar resolution over a point. Its Ran-space lift consists of factorization-compatible degeneracy maps commuting with the signed residue differential and with completion. These maps are part of H_{CL} . A general twisting morphism is governed by the Comparison Lemma through its induced unit and counit.

LEMMA 14.1.11 (*Filtered counit comparison*;). Assume $H_{\text{CL}}(\mathcal{A}, C, \tau)$. If $\varepsilon_\tau: \Omega_X C \rightarrow \mathcal{A}$ is a quasi-isomorphism, then the associated-graded twisting morphism is Koszul and both completed twisted products are acyclic.

Proof. Strictness and the split finite-window filtration carry the counit quasi-isomorphism to the associated graded. Loday–Vallette Theorem 14.1.6 makes the associated-graded twisting morphism Koszul and makes both associated-graded twisted products acyclic. Strong convergence and Mittag–Leffler completion give the asserted acyclicity. $\square$

LEMMA 14.1.12 (*Filtered unit comparison*;). Assume $H_{\text{CL}}(\mathcal{A}, C, \tau)$. If $\eta_\tau: C \rightarrow \bar{B}_X \mathcal{A}$ is a weak equivalence, then the associated-graded twisting morphism is Koszul and both completed twisted products are acyclic.

Proof. The split strict filtration carries the unit equivalence to the associated graded. Clauses (ii) and (iv) of Theorem 14.1.6 yield the ordinary Koszul datum and acyclicity of both twisted products. Convergence and the Mittag–Leffler passage lift the conclusion. $\square$

THEOREM 14.1.13 (*Fundamental theorem of chiral twisting morphisms*;). [Type signature: Open quadrant; completed Ran/factorization presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package $H_{\text{CL}}(\mathcal{A}, C, \tau)$.]

Let $(\mathcal{A}, C, \tau, F_\bullet)$ be a chiral twisting datum satisfying $H_{\text{CL}}(\mathcal{A}, C, \tau)$. The following are equivalent:

- (i) τ is a chiral Koszul morphism;
- (ii) $p_\tau := \varepsilon_\tau: \Omega_X(C) \rightarrow \mathcal{A}$ is a quasi-isomorphism;
- (iii) $q_\tau := \eta_\tau: C \rightarrow \bar{B}_X(\mathcal{A})$ is a weak equivalence;
- (iv) $K_\tau^L(\mathcal{A}, C)$ and $K_\tau^R(C, \mathcal{A})$ are acyclic.

This is the completed chiral transport of the ordinary four-way equivalence of Loday–Vallette [?LV12, Theorem 2.3.2].

For $C = \mathcal{A}^i$ and $\tau = \tau_i$, the maps are the quadratic compression

$$q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow \bar{B}_X(\mathcal{A}), \quad p_{\mathcal{A}}: \Omega_X(\mathcal{A}^i) \longrightarrow \mathcal{A},$$

and the theorem specializes to the Koszul criterion of Loday–Vallette [?LV12, Theorem 3.4.6]. For $C = \bar{B}_X(\mathcal{A})$ and the universal twisting morphism $\pi_{\mathcal{A}}$, the induced coalgebra map is the identity of $\bar{B}_X(\mathcal{A})$; the corresponding map $\Omega_X \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ is the universal reconstruction counit, modeled over a point by Loday–Vallette [?LV12, Corollary 2.3.4].

Proof. Theorem 14.1.6 gives the four-way equivalence on every associated-graded finite window. The package H_{CL} supplies the strict split filtrations, finite-window comparison, strong convergence, and completion. Lemmas 14.1.7, 14.1.8, 14.1.11, and 14.1.12 transport the four conditions between the associated graded, the finite windows, and their completed inverse limit. $\square$

COROLLARY 14.1.14 (*Three bijections for chiral twisting morphisms*;). Let C be a conilpotent complete factorization coalgebra and let $\mathcal{A}$ be an augmented chiral algebra on a smooth curve X . Assume that the chosen Ran category represents continuous free and cofree constructions and that their universal properties commute with factorization gluing and completion. Then there are natural bijections

$$\begin{aligned} \text{Tw}(C, \mathcal{A}) &\cong \text{Hom}_{\text{alg}}(\Omega_X(C), \mathcal{A}) \\ &\cong \text{Hom}_{\text{coalg}}(C, \bar{B}_X(\mathcal{A})) \end{aligned}$$

where $\text{Tw}(C, \mathcal{A})$ is the set of degree +1 morphisms $\tau: C \rightarrow \mathcal{A}$ satisfying the Maurer–Cartan equation $d\tau + \tau \star \tau = 0$.

The *universal twisting morphism* $\tau_{\text{univ}}: \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ (projection to cogenerators) represents the twisting functor: every $\tau \in \text{Tw}(C, \mathcal{A})$ factors uniquely through τ_{univ} . Dually, the *canonical twisting morphism* $\iota: C \rightarrow \Omega_X(C)$ (inclusion of cogenerators) corepresents twisting: every τ factors uniquely through ι .

Proof. Loday–Vallette’s ordinary adjunction gives the three bijections over a point [?LodayVallette12, Theorem 2.2.9]. The assumed continuous free and cofree universal properties apply the same construction on each Ran stratum. Compatibility with factorization gluing assembles the stratumwise maps, and compatibility with completion gives the displayed continuous bijections. $\square$

Remark 14.1.15 (*Algebraic Maurer–Cartan equation and geometric realization*). The equation

$$d\tau + \tau \star \tau = 0$$

is the algebraic condition that makes the twisted differential square to zero. Under the local collision package H_{loc} , signed residue maps realize the two summands as the internal differential and the codimension-one collision differential. In arity three, the nested-set boundary-of-boundary identity, the Arnold relation, and the Jacobi–Borcherds identity give the corresponding square-zero calculation. A real oriented-blow-up model expresses the same calculation by Stokes’ formula; an algebraic logarithmic model expresses it by iterated residues.

At positive genus, a cyclic trace and stable-graph sewing define the curved modular equation

$$d\tau_{\text{mod}} + \tau_{\text{mod}} \star \tau_{\text{mod}} = m_0.$$

The curvature m_0 is part of the named modular package and its scalar trace is a subsequent construction.

Remark 14.1.16 (*Theorem A reconstruction and Koszul compression*). Three choices of coalgebra organize the theorem surface:

- *General twisting comparison.* For a specified C and $\tau: C \rightarrow \mathcal{A}$, Theorem 14.1.13 identifies twisted-product acyclicity with the two maps $q_\tau: C \rightarrow \bar{B}_X(\mathcal{A})$ and $p_\tau: \Omega_X C \rightarrow \mathcal{A}$ under H_{CL} . This is the chiral form of Loday–Vallette [?LV12, Theorem 2.3.2].

- *Quadratic compression.* For $C = \mathcal{A}^i = C(s^{-1}V, s^{-2}R)$ and $\tau = \tau_i$, the load-bearing map is $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \bar{B}_X(\mathcal{A})$. Its equivalence is the quadratic Koszul criterion [?LV12, Theorem 3.4.6]; bar concentration identifies the image with the Koszul diagonal.
- *Universal reconstruction and Verdier duality.* For $C = \bar{B}_X(\mathcal{A})$, the comparison $q_{\pi_{\mathcal{A}}}$ is the identity and the counit $\Omega_X \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ is the full-bar reconstruction equivalence of Theorem A, modeled by [?LV12, Corollary 2.3.4]. Verdier duality then carries the bar coalgebra to the post-Verdier algebra on its separately stated dualizable domain.

The general comparison contains the quadratic criterion as the choice $C = \mathcal{A}^i$ and contains universal reconstruction as the choice $C = \bar{B}_X(\mathcal{A})$. These choices have distinct mathematical content because the first compares a compressed coalgebra with the full bar object, while the second begins with the full bar object itself.

PROPOSITION 14.1.17 (*Universal property of the completed Ran bar;*). Assume the continuous free/cofree and factorization-gluing clauses of H_{CL} . For any augmented chiral algebra $\mathcal{A}$, the bar construction $\bar{B}_X(\mathcal{A})$ together with its canonical twisting morphism $\tau_{\text{can}}: \bar{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ is initial among pairs (C, τ) consisting of a conilpotent chiral coalgebra C and a twisting morphism $\tau: C \rightarrow \mathcal{A}$. Concretely: for any twisting morphism $\alpha: C \rightarrow \mathcal{A}$, there exists a unique coalgebra map $f_{\alpha}: C \rightarrow \bar{B}_X(\mathcal{A})$ such that $\tau_{\text{can}} \circ f_{\alpha} = \alpha$. Dually, the cobar construction $\Omega_X(C)$ together with $\iota_{\text{can}}: C \rightarrow \Omega_X(C)$ is terminal among pairs (A, ι) consisting of an augmented chiral algebra A and a twisting morphism $\iota: C \rightarrow A$.

Proof. The ordinary universal property is [?LodayVallette12, Theorem 2.2.9]. In the chosen Ran category, the universal property of the bar construction is the statement that $\bar{B}_X(\mathcal{A}) = T_{\text{chiral}}^c(s^{-1}\bar{\mathcal{A}})$ is the cofree conilpotent coalgebra on the desuspended augmentation ideal, equipped with the unique coderivation d whose projection to cogenerators recovers the chiral product. Given $\alpha: C \rightarrow \mathcal{A}$, the map f_{α} is the unique coalgebra map $C \rightarrow T_{\text{chiral}}^c(s^{-1}\bar{\mathcal{A}})$ whose projection to cogenerators is α ; the MC equation on α ensures f_{α} is a chain map. The cobar statement is dual. $\square$

THEOREM 14.1.18 (*Comparison lemma for chiral twisted products;*). Let $\alpha, \beta: C \rightarrow \mathcal{A}$ be two chiral twisting morphisms from the same conilpotent coalgebra C to the same algebra $\mathcal{A}$, and let $f: C \rightarrow \mathcal{A}$ be a strict filtered coalgebra quasi-isomorphism such that $\alpha = \beta \circ f$. Assume the two twisting data satisfy H_{CL} and that $\text{gr } f$ is a coalgebra quasi-isomorphism on every finite weight window. Then the induced map on twisted tensor products

$$\text{id}_{\mathcal{A}} \otimes f: \mathcal{A} \otimes_{\alpha} C \xrightarrow{\sim} \mathcal{A} \otimes_{\beta} C$$

is a quasi-isomorphism. In particular, if $\mathcal{A} \otimes_{\alpha} C$ is acyclic, then so is $\mathcal{A} \otimes_{\beta} C$.

On associated-graded finite windows this is the ordinary Comparison Lemma [?LodayVallette12, Lemma 2.1.9]. The strict split filtrations and strong convergence in H_{CL} lift that quasi-isomorphism window by window. The Mittag-Leffler passage gives the completed chiral comparison.

14.1.2 Chiral Koszul pairs

The Koszul-pair notion extends beyond the quadratic setting through a set of *recognition criteria* on the pair. The full bar–cobar identification follows from those criteria through Theorem 14.1.13.

Definition 14.1.19 (Chiral Koszul pair;). A *chiral Koszul pair* on a smooth projective curve X is a pair of chiral Koszul data (Definition 14.1.1, Definition 14.1.3)

$$(\mathcal{A}_1, C_1, \tau_1, F_\bullet), \quad (\mathcal{A}_2, C_2, \tau_2, F_\bullet)$$

in one fixed completed factorization category: the coalgebras C_i are complete conilpotent factorization coalgebras, the filtrations are exhaustive and separated, each conformal-weight/bar-length piece is finite over the ground field or locally free of finite rank over $\mathcal{O}_X$, and the transition maps satisfy the Mittag–Leffler condition used in Lemma 14.3.9. Verdier duals below are taken in the holonomic/perfect $\mathcal{D}$ -module factorization category, or in the equivalent continuous finite-window algebraic model. These topological and finite-type hypotheses promote the twisting data to a Verdier–Koszul pair. The pair is equipped with equivalences of post-Verdier factorization algebras

$$\theta_{12}: \mathbb{D}_{\text{Ran}}^{\text{cont}}(C_1) \xrightarrow{\sim} \mathcal{A}_2, \quad \theta_{21}: \mathbb{D}_{\text{Ran}}^{\text{cont}}(C_2) \xrightarrow{\sim} \mathcal{A}_1,$$

compatible with the twisting morphisms and filtrations. In this situation we write $\mathcal{A}_2 \simeq \mathcal{A}_1^!$ and $\mathcal{A}_1 \simeq \mathcal{A}_2^!$. The coalgebra C_i maps to the full bar coalgebra by the unit $\eta_i: C_i \rightarrow B_X(\mathcal{A}_i)$. Cobar reconstruction gives $\Omega_X(C_i) \rightarrow \mathcal{A}_i$, while Verdier duality gives the algebra $\mathbb{D}_{\text{Ran}} C_i$. The maps θ_{12} and θ_{21} identify this algebra with the opposite family member.

These are *antecedent hypotheses*: the twisting data (Definition 14.1.1), the Koszulness condition (Definition 14.1.3), and Verdier compatibility can all be verified without invoking bar-cobar duality itself. Theorem 14.1.103 composes them with the unit and counit maps.

Standard construction. For a concrete family one constructs C_i , the twisting morphisms, the convergent PBW filtrations, and the two maps θ_{ij} . Theorem 8.0.35 gives the natural algebra $K_X(\mathcal{A}_i)$ and its comparison with $\Omega_X^{\text{geom, cont}}(\mathbb{D}_X \mathcal{A}_i)$. Identifying this algebra with the opposite family member is the explicit content of θ_{ij} . The Heisenberg pair

$$(\mathcal{H}_k, (\text{Sym}^{\text{ch}}(V^*[1]), m_o = -k\omega))$$

is the prototype in the curved second-kind category (§2.5); its uncurved symmetric algebra is only the $k = 0$ or associated-graded shadow.

In particular, each algebra $\mathcal{A}_i$ in a chiral Koszul pair is a Koszul chiral algebra in the sense of Definition 3.1.6, and hence lies on the Koszul locus $\text{Kosz}(X)$ (Definition 3.1.7).

Remark 14.1.20 (Five typed objects). This is the canonical Chiral Koszul Pairs specialization of Convention ?? and Theorem ??. An augmented chiral algebra $\mathcal{A}$ determines five typed objects:

$$\mathcal{A}, \quad \overline{B}_X(\mathcal{A}), \quad \mathcal{A}^!, \quad K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}), \quad Z_{\text{ch}}^{\text{der}}(\mathcal{A}).$$

The bar entry has two ambient realizations. The symmetric bar $\overline{B}_X^{\Sigma}(\mathcal{A})$ is the Ran bar coalgebra used in Theorem A and in the comparison with Beilinson–Drinfeld factorization homology. The ordered bar $\overline{B}_X^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ is the E_1 refinement which remembers the tensor order and carries the Yangian, affine Yangian, and r -matrix constructions. A locality and descent package supplies its map to the symmetric bar.

For a quadratic presentation $\mathcal{A} = T_X(V)/(R)$, the symbol $\mathcal{A}^! = C_X(s^{-1}V, s^{-2}R)$ denotes its quadratic coalgebra. Its finite Verdier dual is the strict quadratic algebra $\mathcal{A}_{\text{quad}}^! := \mathbb{D}_{\text{Ran}} \mathcal{A}^!$. The algebra

$K_X(\mathcal{A})$ is the Verdier dual of the full bar coalgebra. The derived centre is the Hochschild cochain algebra $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$.

Thus the type-correct maps are

$$q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow \overline{B}_X(\mathcal{A}),$$

$$\mathbb{D}(q_{\mathcal{A}}): K_X(\mathcal{A}) \longrightarrow \mathcal{A}_{\text{quad}}^!, \quad \varepsilon_{\mathcal{A}}: \Omega_X \overline{B}_X(\mathcal{A}) \longrightarrow \mathcal{A}.$$

The first map is quadratic recognition, the second is its contravariant Verdier transpose, and the third is universal reconstruction.

Example 14.1.21 (Heisenberg specialization). For the Heisenberg algebra $\mathcal{H}_k$ at level $k \neq 0$, Definition 14.1.19 yields the Koszul pair

$$(\mathcal{H}_k, (\text{Sym}^{\text{ch}}(V^*[1]), m_0 = -k\omega)),$$

where $\mathcal{H}_k$ is Lie^{ch}-type (generated by a single bosonic field $a(z)$ with OPE $a(z)a(w) \sim k/(z-w)^2$) and the dual has commutative associated graded $\text{Sym}^{\text{ch}}(V^*)$ but is object-level curved for $k \neq 0$: the chiral incarnation of classical Lie–Com duality occurs inside the second-kind curved ambient. The explicit bar computation gives the bar coalgebra $\bar{B}^{\text{ch}}(\mathcal{H}_k) \simeq \text{coLie}^{\text{ch}}(V^*)$. Applying Theorem 14.1.103 to this bar coalgebra forms $K_X(\mathcal{H}_k) = \mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{H}_k)$; the chosen pair map identifies it with $\mathcal{H}_k^! \simeq (\text{Sym}^{\text{ch}}(V^*[1]), m_0 = -k\omega)$: the bar complex $\bar{B}(\mathcal{H}_k)$ was computed degree by degree in §2.1–§2.3, producing the coalgebra whose finite dual is the curved commutative Koszul dual (§2.5). Because $\mathcal{H}_k$ is abelian, the PBW spectral sequence (Theorem 14.1.23) is trivial and the Koszul complex $K_\tau(\mathcal{H}_k, \mathcal{H}_k^!)$ is manifestly acyclic under the stated completed second-kind hypotheses.

Example 14.1.22 (Explicit correspondence: bc ghost system and $\beta\gamma$ system). On the split genus-0 finite-type quadratic lane, consider the Verdier-compatible pair $(\mathcal{BC}, \mathcal{BG})$ where:

- $\mathcal{BC}$ is the bc ghost system with fermionic fields $b(z), c(z)$ and OPE $b(z)c(w) \sim (z-w)^{-1}$;
- $\mathcal{BG}$ is the $\beta\gamma$ system with bosonic fields $\beta(z), \gamma(z)$ and OPE $\beta(z)\gamma(w) \sim (z-w)^{-1}$.

The comparison begins with the quadratic coalgebra $\mathcal{BC}^i = C_X(s^{-1}V, s^{-2}R)$ and its canonical recognition map

$$q_{\mathcal{BC}}: \mathcal{BC}^i \xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{BC}),$$

under the split quadratic instance of H_{CL} . Its continuous Verdier transpose has source $K_X(\mathcal{BC})$ and target $\mathcal{BC}_{\text{quad}}^! = \mathbb{D}_{\text{Ran}} \mathcal{BC}^i$. The chosen pair map identifies this algebra with $\mathcal{BG}$. Thus the classical $\Lambda^* \leftrightarrow \text{Sym}^*$ exchange occurs in the post-Verdier algebra.

Generator-relation exchange.

$$bc \text{ OPE: } b(z)c(w) \sim (z-w)^{-1} \quad (\text{fermionic exterior relations}),$$

$$\beta\gamma \text{ OPE: } \beta(z)\gamma(w) \sim (z-w)^{-1} \quad (\text{bosonic symmetric dual algebra}).$$

Geometric picture. The bar complex $\bar{B}^{\text{ch}}(\mathcal{BC})$ involves:

$$\bar{B}^{\text{ch}}(\mathcal{BC})_n = \Gamma\left(\overline{C}_n(X), (b \oplus c)^{\boxtimes n} \otimes \Omega_{\log}^*\right)$$

The residues at collision divisors define the bar differential and its compatibility with deconcatenation. Cobar reconstructs $\mathcal{BC}$ from the bar coalgebra on the Koszul locus. Continuous Verdier duality followed by the chosen pair map identifies $K_X(\mathcal{BC})$ with $\mathcal{BG}$.

14.1.3 PBW deformation as a Koszulness criterion

A systematic method reduces chiral Koszulness to classical Koszulness of the PBW-associated graded via a flat deformation argument.

THEOREM 14.1.23 (*PBW criterion for chiral Koszulness*;). [Regime: filtered-complete (Convention 1.10.2).]

Let $\mathcal{A}$ be a chiral algebra with PBW filtration $F_0 \subset F_1 \subset \cdots \subset \mathcal{A}$ such that the associated graded $\mathrm{gr}_F \mathcal{A}$ is a commutative chiral algebra (equivalently, a vertex Poisson algebra). Suppose:

- (i) The filtration is *flat*: each F_p/F_{p-1} is a free $\mathcal{O}_X$ -module of finite rank in each conformal weight.
- (ii) The associated graded $\mathrm{gr}_F \mathcal{A}$ is classically Koszul: the Koszul complex $\bar{\mathbf{B}}(\mathrm{gr}_F \mathcal{A}) \otimes_{\tau} \mathrm{gr}_F \mathcal{A}$ is acyclic in positive degrees.
- (iii) For each bar degree n and conformal weight h , the chain group $\bar{\mathbf{B}}_h^n(\mathcal{A})$ is finite-dimensional, the induced filtration on this bidegree is complete and separated, and the finite-window quotients form the Mittag-Leffler system of Lemma 14.3.9.

Then $\mathcal{A}$ is chiral Koszul: the Koszul complex $\bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} \mathcal{A}$ is acyclic in positive degrees.

Proof. Equip the Koszul complex $K = \bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} \mathcal{A}$ with the filtration induced by F :

$$F_p K^n = \sum_{i+j=n} F_i \bar{\mathbf{B}}(\mathcal{A}) \otimes_{\tau} F_j \mathcal{A}.$$

This is a bounded-below, exhaustive filtration compatible with the differential (the bar differential and the twisting morphism τ both respect F because the OPE is filtered by PBW degree; conformal weight supplies the finite windows in Hypothesis (iii)). The resulting spectral sequence has:

$$E_o^{p,q} = \mathrm{gr}_F^p K^{p+q}, \quad d_o = \mathrm{gr}_F(d_K).$$

By flatness (i), the associated graded of K is the Koszul complex of $\mathrm{gr}_F \mathcal{A}$:

$$\mathrm{gr}_F K \cong \bar{\mathbf{B}}(\mathrm{gr}_F \mathcal{A}) \otimes_{\tau} \mathrm{gr}_F \mathcal{A}.$$

(This uses that the bar construction commutes with taking associated graded for flat filtrations: the residue differential of the associated graded sees only the leading-order OPE terms, i.e., the vertex Poisson bracket.)

By hypothesis (ii), the E_1 page is concentrated in degree 0:

$$E_1^{p,q} = H^{p+q}(\mathrm{gr}_F^p K) = \begin{cases} \mathbb{C} & p = q = 0, \\ 0 & p + q > 0. \end{cases}$$

All higher differentials d_r for $r \geq 1$ are therefore zero (they map between zero groups), so the spectral sequence collapses at E_1 .

By Hypothesis (iii), the completion has no $R^1 \lim$ contribution in any fixed bidegree, and Lemma 14.3.9 gives strong convergence: $E_{\infty} = \mathrm{gr} H^*(\bar{K})$. Since E_{∞} is concentrated in degree 0, we conclude $H^n(K) = 0$ for $n > 0$. $\square$

Remark 14.1.24 (*Relation to classical Koszulness*). The PBW criterion reduces chiral Koszulness to the classical statement that $\mathrm{gr}_F \mathcal{A}$ is Koszul. For Kac–Moody and Virasoro algebras, $\mathrm{gr}_F \mathcal{A}$ is a polynomial algebra (Koszul by Priddy’s theorem); semisimplicity of $\mathfrak{g}$ is not required.

THEOREM 14.1.25 (*Affine Kac–Moody algebras are chiral Koszul;*). [Regime: curved-central (Convention 1.10.2).]

For any simple Lie algebra $\mathfrak{g}$ and generic level $k \notin \Sigma(\mathfrak{g})$ (the finite exceptional set of Theorem ??), the affine Kac–Moody vertex algebra $\widehat{\mathfrak{g}}_k$ is chiral Koszul.

Proof. We verify the three hypotheses of Theorem 14.1.23.

Hypothesis (i). The PBW filtration on $\widehat{\mathfrak{g}}_k$ is defined by $F_p = \text{span}\{J_{-n_1}^{a_1} \cdots J_{-n_r}^{a_r} | 0\rangle : r \leq p\}$. Each graded piece F_p/F_{p-1} is a direct sum of weight spaces of the symmetric algebra $S^p(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}])$, which is a free $\mathbb{C}$ -module of finite rank in each conformal weight.

Hypothesis (ii). The associated graded is:

$$\text{gr}_F \widehat{\mathfrak{g}}_k \cong \text{Sym}(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]).$$

This is a polynomial algebra on the generators $\{J_{-n}^a : a = 1, \dots, \dim \mathfrak{g}, n \geq 1\}$. By Priddy’s theorem ([?LV12, Theorem 3.4.5]), polynomial algebras are Koszul, with Koszul dual the exterior coalgebra $\Lambda^c(\mathfrak{g}^* \otimes t\mathbb{C}[t])$. Equivalently, the Koszul complex of $\text{Sym}(V)$ is the de Rham complex of the polynomial ring, which is acyclic in positive degrees (Poincaré lemma for formal power series).

Hypothesis (iii). The bar chain group $\bar{\mathbf{B}}_h^n(\widehat{\mathfrak{g}}_k)$ is a subspace of $(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}])^{\otimes n} \otimes \Omega^{n-1}(\bar{C}_n)$ with total conformal weight h . Since the number of monomials of weight h in n tensor factors is bounded by $p(h)^n < \infty$, each chain group is finite-dimensional.

All three hypotheses are verified. By Theorem 14.1.23, $\widehat{\mathfrak{g}}_k$ is chiral Koszul. $\square$

THEOREM 14.1.26 (*Virasoro chiral Koszulness;*). [Regime: curved-central; Convention 1.10.2.]

For any central charge $c \in \mathbb{C}$, the Virasoro vertex algebra Vir_c is chiral Koszul.

Proof. The PBW filtration on Vir_c is defined by the number of Virasoro mode applications:

$$F_p = \text{span}\{L_{-n_1} \cdots L_{-n_r} | 0\rangle : r \leq p, n_i \geq 2\}.$$

Hypothesis (i). Each $F_p/F_{p-1} \cong S^p(V)$ where $V = \bigoplus_{n \geq 2} \mathbb{C} \cdot L_{-n}$ (the Virasoro generators modulo vacuum), which is free of finite rank in each conformal weight.

Hypothesis (ii). $\text{gr}_F \text{Vir}_c \cong \text{Sym}(V)$ is a polynomial algebra (the OPE reduces to a commutative product on the associated graded: the non-linear terms $T_{(0)}T = \partial T$, $T_{(1)}T = 2T$ are lower-order in the PBW filtration, and the quartic pole $T_{(3)}T = c/2$ is a scalar that contributes to the curvature, not the associated graded bracket). By Priddy’s theorem, $\text{Sym}(V)$ is Koszul.

Hypothesis (iii). Same argument as the Kac–Moody case: the number of partitions of weight h into at most n parts (each ≥ 2) is finite.

By Theorem 14.1.23, Vir_c is chiral Koszul. $\square$

COROLLARY 14.1.27 (*PBW collapse and quadratic recognition;*). For a chiral Koszul algebra $\mathcal{A}$ satisfying the hypotheses of Theorem 14.1.23, the PBW spectral sequence on $\bar{\mathbf{B}}(\mathcal{A})$ collapses at E_2 and computes the bar-cohomology coalgebra $H^\bullet \bar{\mathbf{B}}(\mathcal{A})$. Suppose in addition that $\mathcal{A}$ carries a chosen quadratic presentation with $\mathcal{A}^1 = C_X(s^{-1}V, s^{-2}R)$ and that $H_{\text{CL}}(\mathcal{A}, \mathcal{A}^1, \tau_i)$ holds. Then

$$H^\bullet(q_{\mathcal{A}}): H^\bullet(\mathcal{A}^1) \xrightarrow{\sim} H^\bullet \bar{\mathbf{B}}(\mathcal{A})$$

identifies the two cohomology coalgebras. On a finite-type Verdier lane the full bar object determines $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A})$, and a chosen pair map $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^1$ supplies the algebra-level identification. For a PBW non-quadratic family such as the universal Virasoro family, the canonical output of

the collapse is $H^\bullet \bar{\mathbf{B}}(\mathcal{A})$ together with $K_X(\mathcal{A})$; a presentation coalgebra $\mathcal{A}^1$ enters after an additional quadratic or curved-PBW comparison has been chosen.

Proof. Step 1: The PBW filtration on the bar complex. Equip $\bar{\mathbf{B}}(\mathcal{A})$ with the filtration inherited from the PBW filtration F on $\mathcal{A}$:

$$F_p \bar{\mathbf{B}}^n(\mathcal{A}) = \{a_1 \otimes \cdots \otimes a_{n+1} \otimes \omega \mid a_i \in F_{p_i} \mathcal{A}, \sum p_i \leq p\}$$

where $\omega \in \Omega_{\log}^n(\bar{C}_{n+1}(X))$. This filtration is exhaustive (every bar element lies in some F_p by finiteness of conformal weight) and compatible with the differential (the bar differential respects conformal weight since the OPE does).

Step 2: The associated graded. The filtration F_p is placed on the algebra factor $\mathcal{A}$ in the bar construction $T^c(s^{-1}\bar{\mathcal{A}})$ underlying $\bar{\mathbf{B}}(\mathcal{A})$; the configuration-space form factor $\Omega_{\log}^\bullet(\bar{C}_\bullet(X))$ carries PBW degree 0. Since T^c is graded cofree and Hypothesis (i) makes each $\mathrm{gr}_F^p \mathcal{A}$ a free graded $\mathcal{O}_X$ -module in each conformal weight, tensor-product flatness gives $\mathrm{gr}_F T^c(s^{-1}\bar{\mathcal{A}}) \cong T^c(s^{-1} \mathrm{gr}_F \bar{\mathcal{A}})$. The bar differential decomposes along the filtration because the OPE respects conformal weight, giving $\mathrm{gr}_F d_{\mathrm{bar}} = d_{\mathrm{bar}, \mathrm{gr}_F \mathcal{A}}$. Therefore:

$$\mathrm{gr}_F \bar{\mathbf{B}}(\mathcal{A}) \cong \bar{\mathbf{B}}(\mathrm{gr}_F \mathcal{A}) = \bar{\mathbf{B}}(\mathrm{Sym}^{\mathrm{ch}}(V))$$

where V is the generating $\mathcal{D}_X$ -module. This identification holds because the bar differential on the associated graded sees only the leading-order OPE terms. For $\widehat{\mathfrak{g}}_k$: the singular OPE $J^a(z)J^b(w) \sim f_c^{ab} J^c(w)/(z-w) + k\kappa^{ab}/(z-w)^2$ reduces on gr_F to the commutative product (the bracket $f_c^{ab} J^c$ and level term $k\kappa^{ab}$ are lower-order in the PBW filtration). For Vir_c : similarly, the Virasoro OPE reduces to a commutative product on the associated graded.

Step 3: Computation of the E_1 page. The E_0 page is $E_0^{p,q} = \mathrm{gr}_F^p \bar{\mathbf{B}}^{p+q}(\mathcal{A})$, with d_0 the associated-graded bar differential. By the associated-graded identification above, the E_1 page is the bar cohomology of the commutative chiral algebra $\mathrm{Sym}^{\mathrm{ch}}(V)$.

Since $\mathrm{Sym}^{\mathrm{ch}}(V)$ is a free commutative algebra, it is Koszul with Koszul dual the exterior coalgebra $\Lambda^c(V^*)$ (Priddy's theorem applied to the chiral PBW associated graded). Therefore:

$$E_1^{p,q} = H^{p+q}(\bar{\mathbf{B}}^p(\mathrm{Sym}^{\mathrm{ch}}(V))) = \begin{cases} \Lambda^p(V^*) & \text{if } q = 0, \\ 0 & \text{if } q \neq 0. \end{cases}$$

The E_1 page is concentrated in the row $q = 0$. In particular, for $\widehat{\mathfrak{g}}_k$ with $V = \mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$:

$$E_1^{n,0} = \Lambda^n(\mathfrak{g}^* \otimes t\mathbb{C}[t])$$

is the n -th exterior power of the dual loop algebra generators (graded by conformal weight).

Step 4: E_2 collapse. Since $E_1^{p,q} = 0$ for $q \neq 0$, the higher differentials $d_r: E_r^{p,q} \rightarrow E_r^{p+r, q-r+1}$ vanish for $r \geq 2$: the target has second index $q-r+1 \leq 0-2+1 = -1 < 0$, placing it in the zero region. The differential $d_1: E_1^{p,0} \rightarrow E_1^{p+1,0}$ maps within the nonzero row $q = 0$ and is generally nonzero: it is the Chevalley–Eilenberg differential of the loop algebra $\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$ acting on $\Lambda^*(\mathfrak{g}^* \otimes t\mathbb{C}[t])$ by bracket contraction (the leading PBW correction to the commutative bar differential). Therefore $E_\infty = E_2$ and:

$$H^n(\bar{\mathbf{B}}(\mathcal{A})) \cong E_\infty^{n,0} = E_2^{n,0} = H_{\mathrm{CE}}^n(\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}], \mathbb{C}) =: H_n^{\mathrm{bar}}(\mathcal{A}).$$

For a chosen quadratic presentation satisfying $H_{\text{CL}}, H^\bullet(q\mathcal{A})$ identifies this coalgebraic piece with the corresponding cohomology of $\mathcal{A}^!$. Under $H_{\mathbb{D}}^{\text{bar}}$, its continuous dual is the corresponding cohomology piece of $K_X(\mathcal{A})$; the pair map $\nu_{\mathcal{A}}$ then compares it with the selected partner $\mathcal{A}^!$. For commutative chiral algebras (e.g. the Heisenberg algebra), the Lie bracket of $\mathfrak{g}$ vanishes, $d_1 = 0, E_\infty = E_2 = E_1 = \Lambda(V^*)$, and the bar cohomology reduces to the exterior algebra. For non-abelian algebras (Kac–Moody, Virasoro), $d_1 \neq 0$ and the bar cohomology is computed by the CE cohomology, a proper subquotient of $\Lambda(V^*)$.

Step 5: Verification for $\widehat{\mathfrak{sl}}_2$. $V = \mathbb{C}^3 \otimes t^{-1}\mathbb{C}[t^{-1}]$ (three generators J^+, J^0, J^- , each with modes J_{-n}^a for $n \geq 1$). The E_1 page has $\dim E_{1h}^{n,0} = \dim \Lambda^n(\mathbb{C}^3 \otimes t\mathbb{C}[t])_h$. For example: $\dim E_{11}^{1,0} = 3$ (the three weight-1 generators), $\dim E_{12}^{2,0} = \binom{3}{2} = 3$ (wedge products $J_{+1}^{a*} \wedge J_{+1}^{b*}$, $a < b$). The d_1 differential is the CE differential of $\widehat{\mathfrak{sl}}_2 \otimes t^{-1}\mathbb{C}[t^{-1}]$; the resulting E_2 page gives: $\dim H^1 = 3$ (all at weight $h = 1$; $d_1 = 0$ at this weight since there are no weight-1 chains in degree 0), and $\dim H^2 = 5$ (concentrated at weight $h = 3$: chain groups $\dim \Lambda_3^1 = 3, \dim \Lambda_3^2 = 9, \dim \Lambda_3^3 = 1$; differential ranks 3 and 1; cohomology $(9 - 1) - 3 = 5$). The computation is verified by checking $d_1^2 = 0$ at each weight (Computation ??). $\square$

Remark 14.1.28 (CE cohomology vs exterior algebra dimensions). Bar cohomology of a non-abelian chiral Koszul algebra is the CE cohomology of $\mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$, not the exterior algebra $\Lambda^n(V^*)$. For $\widehat{\mathfrak{sl}}_2$: E_1 totals $= \prod_{m \geq 1} (1 + q^m)^3$, but $E_\infty = E_2 \neq E_1$ because the d_1 differential is nonzero for non-abelian $\mathfrak{g}$. In particular, $\dim H^2 = 5$ (not $R(5) = 6$; Appendix ??).

Remark 14.1.29 (Chevalley–Eilenberg cohomology vs chiral bar cohomology). The Chevalley–Eilenberg cohomology of the negative-mode Lie algebra $\mathfrak{g}_{<0} = \mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$ and the chiral bar cohomology $H^*(\tilde{\mathbf{B}}(\mathcal{A}))$ give *different* Betti sequences, though both compute from the same underlying OPE data. For the Witt algebra $\text{Witt} = \text{Der}(\mathbb{C}((t)))$, the negative-mode Lie algebra is the Lie algebra of polynomial vector fields vanishing to order ≥ 2 at the origin, and its CE cohomology has $\dim H_{\text{CE}}^1(\text{Witt}_{<0}) = 2$ (the two independent cocycles L_{-1}^* and L_{-2}^* ; L_{-3}^* is *not* a cocycle since $d(L_{-3}^*)(L_{-1}, L_{-2}) = L_{-3}^*([L_{-1}, L_{-2}]) = L_{-3}^*(L_{-3}) = 1 \neq 0$). The chiral bar cohomology of the Virasoro algebra has $\dim H^1(\tilde{\mathbf{B}}(\text{Vir})) = 1$ (a single generator T of conformal weight 2). The discrepancy $2 - 1 = 1$ quantifies the Orlik–Solomon form contribution: the chiral bar differential uses the full logarithmic residue $d \log(z_1 - z_2)$ (the Arnold relation on configuration space), which collapses the three CE cocycles to the single chiral primary.

THEOREM 14.1.30 (Bar concentration for Koszul pairs;). [Regime: quadratic on the Koszul locus (Convention 1.10.2).]

Let $(\mathcal{A}_1, \mathcal{A}_2)$ be a chiral Koszul pair (Definition 14.1.19). Choose a quadratic presentation $\mathcal{A}_1 = T_X(V_1)/(R_1)$ and set

$$\mathcal{A}_1^i = C_X(s^{-1}V_1, s^{-2}R_1), \quad q_{\mathcal{A}_1}: \mathcal{A}_1^i \longrightarrow \tilde{B}_X^{\text{ch}}(\mathcal{A}_1).$$

Then the augmented bar complex $\tilde{B}^{\text{ch}}(\mathcal{A}_1)$, equipped with its bigrading by bar degree p and bar-differential cohomological degree q , satisfies:

$$H^{p,q}(\tilde{B}^{\text{ch}}(\mathcal{A}_1)) = 0 \quad \text{for } q \neq 0, \quad H^{p,0}(\tilde{B}^{\text{ch}}(\mathcal{A}_1)) \cong H^{p,0}(\mathcal{A}_1^i).$$

Equivalently, $q_{\mathcal{A}_1}$ is a quasi-isomorphism of graded chiral coalgebras. Verdier duality gives

$$K_X(\mathcal{A}_1) := \mathbb{D}_{\text{Ran}} \tilde{B}_X^{\text{ch}}(\mathcal{A}_1), \quad \mathbb{D}(q_{\mathcal{A}_1}): K_X(\mathcal{A}_1) \longrightarrow \mathbb{D}_{\text{Ran}}(\mathcal{A}_1^i),$$

and the chosen pair map $\nu_{12}: K_X(\mathcal{A}_1) \xrightarrow{\sim} \mathcal{A}_2$ identifies the Verdier algebra with the partner.

Proof. Filter $\bar{B}^{\text{ch}}(\mathcal{A}_1)$ by bar degree. By the PBW criterion (Theorem 14.1.23), the associated graded is the classical Koszul complex of $\text{gr}_F \mathcal{A}_1$, which is acyclic in positive degrees by hypothesis. The chiral Comparison Lemma applied to the canonical twisting morphism of the presentation identifies the PBW comparison with the coalgebra map $q_{\mathcal{A}_1}$. Acyclicity of the left and right Koszul complexes makes $q_{\mathcal{A}_1}$ a quasi-isomorphism [?LodayVallette12, Theorem 2.3.2]. Taking cohomology yields the displayed diagonal identification. Verdier duality gives $\mathbb{D}(q_{\mathcal{A}_1})$, and the pair datum supplies ν_{12} . $\square$

14.1.4 Intrinsic characterizations of chiral Koszulness

The MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ lives in a modular convolution algebra bigraded by degree and genus. Chiral Koszulness is a *genus-0 formality property*: it says the genus-0 component $\Theta_{\mathcal{A}}^{(0)}$ is determined by its binary part; equivalently, all genus-0 obstruction classes $\sigma_{r+1}^{(0)}(\mathcal{A}) = 0$ vanish for $r \geq 2$. The shadow obstruction tower probes all genera; Koszulness constrains only genus 0. Twelve characterizations and consequences of chiral Koszulness split into seven intrinsic bidirectional equivalences, the Barr–Beck–Lurie consequence of the quadratic resolution, the conditional factorization-homology comparison lane, the one-way chiral Hochschild consequence on the Koszul locus, the perfectness/non-degeneracy conditional Lagrangian criterion, and the one-directional D-module purity implication. Each reads $\Theta_{\mathcal{A}}^{(0)}$ through a different invariant of the convolution algebra, but only the first seven form the intrinsic unconditional equivalence core.

Remark 14.1.31 (One-loop exactness). The PBW spectral sequence (Corollary 14.1.27) admits a sharp physics interpretation. The E_0 page is the tree-level bar complex $\bar{\mathbf{B}}(\text{Sym}^{\text{ch}}(V))$, with cohomology $\Lambda^c(V^*)$ by Priddy’s theorem. The d_1 differential is the Chevalley–Eilenberg differential extracted from the simple-pole OPE $a_{(0)}b$: a single operator collision. Collapse $E_2 = E_{\infty}$ means that no multi-particle collisions (the higher poles $a_{(n)}b$, $n \geq 2$, generating d_r for $r \geq 2$) contribute additional cohomology. Chiral Koszulness is therefore *one-loop exactness*: the Lie-algebraic data from the single-pole OPE determines the bar cohomology completely.

PROPOSITION 14.1.32 (Formality implies chiral Koszulness;). Let $\mathcal{A}$ be a chiral algebra on a smooth curve X , and let $(m_2, m_3, m_4, \dots)$ denote the transferred A_{∞} -structure on the finite homotopy dual $\mathcal{A}_{\infty}^! = H^*(\bar{\mathbf{B}}_X(\mathcal{A}))^{\vee}$ obtained via a deformation retract

$$\bar{\mathbf{B}}_X(\mathcal{A}) \xrightleftharpoons[p]{i} H^*(\bar{\mathbf{B}}_X(\mathcal{A})) \quad \text{with contracting homotopy } h$$

and the homological perturbation lemma (Kadeishvili [?Kad82]; cf. [?LPWZ09]).

If the minimal A_{∞} -structure is *formal* ($m_n = 0$ for all $n \geq 3$), then $\mathcal{A}$ is chirally Koszul.

Proof. Formality of the A_{∞} -structure means the bar complex $\bar{\mathbf{B}}_X(\mathcal{A})$ is formal as a dg coalgebra: the natural map to its cohomology $H^*(\bar{\mathbf{B}}_X(\mathcal{A}))$ is a quasi-isomorphism of A_{∞} -coalgebras. The higher products m_n ($n \geq 3$) are identified with the PBW spectral sequence differentials d_{n-1} via the standard comparison (cf. [?LPWZ09, Theorem 3.4.1]): $m_n = 0$ for $n \geq 3$ is equivalent to $E_2 = E_{\infty}$, which is the PBW collapse criterion of Theorem 14.1.23. $\square$

THEOREM 14.1.33 (Koszulness and strict diagonal formality;). Chiral Koszulness is equivalent to the vanishing of the off-diagonal transferred operations in the bar minimal model. Strict A_{∞} -formality, $m_n = 0$ for all $n \geq 3$, is the additional condition that every diagonal shadow class vanishes. Thus strict formality implies chiral Koszulness, and the converse holds precisely on the class- G surface where the diagonal shadow tower is zero.

Proof. Strict formality implies Koszulness by Proposition 14.1.32. Conversely, the PBW filtration is defined fiberwise and is compatible with the FM stratification. The HPL transfer on each stratum identifies the off-diagonal transferred operations with the higher PBW differentials d_r , $r \geq 2$. Chiral Koszulness is exactly $E_2 = E_\infty$, hence these off-diagonal operations vanish. Operations preserving the Koszul diagonal are invisible to concentration; their classes are the shadow invariants. Requiring those classes to vanish gives strict A_∞ -formality, and this is precisely class G in the shadow classification. $\square$

Remark 14.1.34 (A_∞ products as genus-0 shadows). The sequence $(m_3, m_4, \dots)$ is the genus-0 analogue of the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq 3}, \Theta_{\mathcal{A}}^{\leq 4}, \dots$ of Theorem ??; the m_n measure nonlinearity of the bar differential at genus 0, while the shadows $\Theta_{\mathcal{A}}^{\leq r}$ measure it at all genera.

Example 14.1.35 (Truncated polynomials: the homotopy Koszul dual off the Koszul locus). Consider $A = k[x]/(x^n)$ for $n \geq 3$ (non-Koszul; the Koszul case $n = 2$ gives the exterior algebra). The bigraded bar cohomology $H^{p,q}(\bar{B}(A))$ has generators

$$a \in H^{1,1}, \quad b \in H^{2,n},$$

and H is *not* concentrated on the diagonal $p = q$, the signature of non-Koszulness (Theorem 14.1.33).

The transferred A_∞ -structure on $H^*(\bar{B}(A))^\vee$ carries exactly one nontrivial higher operation:

$$m_2 = \dots = m_{n-2} = 0 \quad \text{on } a, \quad m_{n-1}(\underbrace{a, \dots, a}_{n-1}) = b.$$

This is the Massey product detecting the off-diagonal class; it is the first and only nontrivial higher operation (Lu–Palmieri–Wu–Zhang [LPWZ09]). The homotopy Koszul dual $A_\infty^! = (H^*(\bar{B}(A))^\vee, m_2, m_{n-1})$ is a genuine A_∞ -algebra whose non-formality is measured by the single operation m_{n-1} . For $n = 2$ (exterior algebra), $m_{n-1} = m_1 = 0$ on H , recovering formality and hence Koszulness.

The chiral analogue: for a chiral algebra $\mathcal{A}$ whose bar cohomology has off-diagonal bigraded classes, the homotopy Koszul dual $\mathcal{A}_\infty^!$ carries genuine higher chiral operations measuring non-formality. The shadow obstruction tower (Remark 14.1.34) is the all-genera lift of this phenomenon.

THEOREM 14.1.36 (*Ext diagonal vanishing criterion*;). Define the *chiral Ext algebra* $\text{Ext}_{\mathcal{A}}^{*,*}(\omega_X, \omega_X) = \bigoplus_{p,q} \text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X)$, bigraded by cohomological degree p and conformal weight q . Then $\mathcal{A}$ is chirally Koszul if and only if $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.

Classical precedent. On the formal disk $\hat{D}$, this reduces to the Beilinson–Ginzburg–Soergel criterion for $\text{Zhu}(\mathcal{A})$ [BGS96]. On $\mathbb{P}^1$, diagonal vanishing follows from PBW since $H^1(\mathbb{P}^1, \mathcal{O}) = 0$. At genus $g \geq 1$, the Hodge-theoretic contributions from $H^0(X, \omega_X)$ produce the exceptional set $\Sigma(\mathfrak{g})$ of Theorem ?? where diagonal vanishing may fail.

Proof. Forward: E_2 -collapse concentrates $H^*(\bar{\mathbf{B}}(\mathcal{A}))$ on the diagonal $p = q$; since the bar resolution computes Ext , $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$. Converse: diagonal concentration forces all PBW differentials d_r ($r \geq 2$) to vanish, since a d_r -differential shifts the bigrading by $(r, 1 - r)$, producing off-diagonal classes that contradict $\text{Ext}_{\mathcal{A}}^{p,q} = 0$ for $p \neq q$. Hence E_2 -collapse, hence Koszulness. $\square$

PROPOSITION 14.1.37 (*PBW universality*;). A vertex algebra $\mathcal{A}$ is *freely strongly generated* if it admits strong generators $\{a^i\}_{i \in I}$ whose normally ordered monomials $:\partial^{n_1} a^{i_1} \cdots \partial^{n_r} a^{i_r}:$ form a PBW basis; equivalently, $\text{gr}_F \mathcal{A} \cong \text{Sym}^{\text{ch}}(V)$ where V is the $\mathcal{D}_X$ -module spanned by the generators.

Every freely strongly generated vertex algebra is chirally Koszul.

Proof. The three hypotheses of Theorem 14.1.23 hold: (1) flatness of $F_p/F_{p-1} \cong S^p(V)$ by the PBW basis; (2) classical Koszulness of $\text{gr}_F \mathcal{A} \cong \text{Sym}^{\text{ch}}(V)$ by Priddy's theorem; (3) finite-dimensionality of bar chain groups in each bigrading by the partition bound of Theorem 14.1.25. $\square$

COROLLARY 14.1.38 (*Universal vertex algebras are chirally Koszul;*). The following are chirally Koszul:

- (i) $V_k(\mathfrak{g})$ at all levels k (including $k = -h^\vee$), since its vacuum module is Verma with no null vectors. *Caveat:* at $k = -h^\vee$ the PBW spectral sequence still collapses, but diagonal Ext concentration fails (Remark 14.1.39): “chirally Koszul” here means PBW-Koszul (condition (ii) of Theorem 14.1.59), not Ext-diagonal (condition (iv)).
- (ii) Vir_c as the universal vertex algebra at all c , since the vacuum Verma module is freely strongly generated.
- (iii) $\mathcal{W}^k(\mathfrak{g})$ obtained by Drinfeld–Sokolov reduction, by the Feigin–Frenkel theorem (the Miura images freely generate).

The universal vs. simple distinction. The universal algebra $V_k(\mathfrak{g})$ is always chirally Koszul. The simple quotient $L_k(\mathfrak{g}) = V_k(\mathfrak{g})/I_k$ may fail Koszulness at levels where the singular vector lies in the bar-relevant range; the precise criterion is Theorem 14.1.40.

Proof. Proposition 14.1.37 applies to every freely strongly generated vertex algebra. The universal affine algebra $V_k(\mathfrak{g})$ and the universal Virasoro algebra are freely strongly generated by their current, respectively stress-tensor, fields, so items (1) and (2) follow immediately. For $\mathcal{W}^k(\mathfrak{g})$, the Feigin–Frenkel Miura theorem supplies a free strong generating set by the Miura images, so the same proposition applies. The final paragraph records the universal-versus-simple warning for these families. $\square$

Remark 14.1.39 (*Critical level: PBW degeneration vs diagonal Ext concentration*). At the critical level $k = -h^\vee$, the PBW spectral sequence degenerates at E_2 (the E_2 -collapse mechanism is k -independent, since $\text{gr}_F V_k(\mathfrak{g}) \cong \text{Sym}^{\text{ch}}(\mathfrak{g})$ for all k). However, the E_2 page is *not* diagonally concentrated: the bar cohomology $H^*(\overline{B}(V_{-h^\vee}(\mathfrak{g}))) = \Omega^*(\text{Op}_{\mathfrak{g}^\vee}(D))$ (Theorem ??) has $H^0 = \text{Fun}(\text{Op}) \neq \mathbb{C}$, contributing off-diagonal classes $\text{Ext}^{0,q} \neq 0$ for all even $q \geq 0$. Hence the diagonal criterion of Theorem 14.1.23 ($\text{Ext}^{p,q} = 0$ for $p \neq q$) fails at $k = -h^\vee$.

At generic level ($\kappa \neq 0$), the curvature of the bar differential forces $H^0(\overline{B}) = \mathbb{C}$ and concentrates bar cohomology on the diagonal. The critical level is the unique point where curvature vanishes, PBW degeneration persists, but diagonal concentration is lost.

Accordingly, the parenthetical “including $k = -h^\vee$ ” in item (1) of Corollary 14.1.38 means: PBW degeneration holds at all k ; the full Koszulness (diagonal Ext concentration) holds at generic k but fails at $k = -h^\vee$. At critical level Theorem H is governed by its own family datum $H_H(V_{-h^\vee}(\mathfrak{g}); S_{\text{crit}})$. The diagonal criterion supplies associated-graded input, while the critical chart comparison and finite-window retract determine S_{crit} . Remark 38.2.4 gives the corresponding Beilinson–Drinfeld comparison.

THEOREM 14.1.40 (*Kac–Shapovalov criterion for simple quotients;*). Let $\mathcal{A}$ be a conformal vertex algebra with Shapovalov form on the vacuum module. The *bar-relevant range* is the set of conformal weights h with $\mathbf{B}_h^n(\mathcal{A}) \neq 0$ for some $n > 0$. Assume the PBW filtration is flat and split by conformal weight, the bar spectral sequence is bidegreewise finite and strongly convergent, and the PBW-to-bar comparison is detected by the Shapovalov pairing: a nonzero class on the PBW page pairs nontrivially with some class in the same bar-relevant weight. Under these hypotheses, $\mathcal{A}$ is chirally Koszul if and only if the Kac–Shapovalov determinant $\det G_h \neq 0$ for all h in the bar-relevant range.

For universal algebras the PBW flatness and pairing hypotheses hold by Corollary 14.1.38. The genuine content is for simple quotients: $L_k(\mathfrak{g})$ has null vectors at $h = h_{\text{sing}}(k)$ by the Kac–Kazhdan theorem; at admissible levels $k + h^\vee = p/q$, $(p, q) = 1$, these lie in the bar-relevant range and Koszulness may fail. For the Virasoro algebra, the Kac determinant $\det G_h = \prod_{r,s \leq h} (h - h_{r,s}(c))^{p(h-rs)}$ is nonvanishing in the bar-relevant range for the universal algebra, but $L(c_{p,q}, 0)$ may fail at minimal-model values.

Proof. Forward: Koszulness gives E_2 -collapse, hence the PBW filtration on the vacuum module is strict: $\text{gr}_F M_0(\mathcal{A}) \cong \text{Sym}^{\text{ch}}(V)$. Strictness implies the Shapovalov form G_h is non-degenerate in the bar-relevant range (a degenerate G_h would give a null vector in the PBW-associated graded, contradicting strictness).

Converse: under the PBW/Shapovalov detection hypothesis, $\det G_h \neq 0$ in the bar-relevant range means the PBW-to-bar comparison map $\text{Sym}^{\text{ch}}(V)_h \rightarrow \tilde{\mathbf{B}}_h(\mathcal{A})$ is injective at every bar-relevant weight. Injectivity forces E_2 -collapse: a nonzero differential d_r with $r \geq 2$ would kill an element that pairs nontrivially with the Shapovalov form (since the element is nonzero in gr_F and G_h is non-degenerate), contradicting the d_r -exactness. Strong convergence then identifies the collapsed spectral sequence with bar cohomology. $\square$

Remark 14.1.41 (Rationality is not, by itself, a Koszul criterion). Rationality, C_2 -cofiniteness, and semisimplicity of the Zhu algebra are strong *finiteness* inputs, but they do not by themselves imply chiral Koszulness in the sense used here. The obstruction is categorical: the ordinary positive-energy module category $V\text{-gmod}$ controls Zhu theory and conformal blocks, whereas Ext groups in the chiral/factorization module setting are computed via the bar complex (Corollary 9.2.24). No theorem here identifies these two Ext theories for general rational vertex algebras.

Consequently, the implication

$$\text{ordinary semisimplicity} \implies H^{>0}(\tilde{\mathbf{B}}(V)) = 0$$

is *not* established here. For simple quotients at admissible level the Kac–Shapovalov route is visibly obstructed by null vectors in the bar-relevant range (Theorem 14.1.40), while the rationality route stops at finiteness of the ordinary representation theory.

Remark 14.1.42 (Admissible simple quotients). For the universal algebra $V_k(\mathfrak{g})$, free strong generation gives chiral Koszulness at every level (Corollary 14.1.38). For the simple quotient $L_k(\mathfrak{g})$, null vectors enter the bar-relevant range at admissible levels, so the PBW/Shapovalov criterion no longer applies directly.

What *is* proved for non-degenerate admissible levels is:

- (i) rationality and semisimplicity of the ordinary module category (Theorem ??(ii));
- (ii) finite-page bar and Li–bar spectral sequences in the ordinary-character calculations: the worked $\widehat{\mathfrak{sl}}_2$, $k = -1/2$ bar derivation of the vacuum Kac–Wakimoto character (Theorem ??), together with weightwise finite-page control and the external general-rank Kac–Wakimoto formulas on the broader non-degenerate admissible lane (Proposition ?? and Theorem ??).

These results are compatible with chiral Koszulness, but they do not yet prove bar-cobar inversion or Ext-diagonal purity for the simple quotient in general.

For $\mathfrak{g} = \mathfrak{sl}_2$, the finite Shapovalov and character computations are especially sharp, but they do not by themselves close the theorem. In every checked finite window the first vacuum null is single-weight, the quotient agrees with the universal algebra below the null weight, and the finite diagnostic reports the same model cohomology as $V_k(\mathfrak{sl}_2)$. To promote this to a theorem for every admissible level $k = -2 + p/q$,

one still has to supply the quotient bar spectral sequence together with PBW/Shapovalov detection of all higher differentials, finite-window exactness, and strong convergence. Until that package is installed, the $\mathfrak{sl}_2$ statement is finite evidence / conditional, not a settled input to Theorem H or bar–cobar inversion.

For $\mathfrak{g} = \mathfrak{sl}_3$ at denominator 3, the uniform truncated Li–bar model has $E_1^{2,3} \cong \mathfrak{sl}_3$. The exact incoming Poisson matrix $d_1: E_1^{3,4} \rightarrow E_1^{2,3}$ has rank 6 and root-space image; its cokernel is the two-dimensional Cartan space. Theorem 14.1.43 promotes this finite-model calculation to a conditional statement about the cone of $q_A: A^i \rightarrow \bar{B}(A)$ under the quotient comparison, higher-page persistence, and strong-convergence package.

For denominators $q > 3$, the current finite engine exhibits off-diagonal E_i classes and leaves the incoming d_i rank as the next computation. For $q \leq 2$, its associated-graded diagnostic is diagonally concentrated. These three denominator lanes record the present evidence with their respective statuses.

THEOREM 14.1.43 (*Cartan cone for quadratic compression in the denominator-three Li–bar model of $L_k(\mathfrak{sl}_3)$*). Let $k = -3 + p/q$ be a non-degenerate admissible level for $\widehat{\mathfrak{sl}}_3$, with $q = 3$, $p \geq 3$, and $(p, 3) = 1$, and put $A = L_k(\mathfrak{sl}_3)$. Let A^i be the quadratic coalgebra determined by the chosen Li/PBW quadratic presentation, let $\tau_i: A^i \rightarrow A$ be its twisting morphism, and let

$$q_A: A^i \longrightarrow \bar{B}^{\text{ch}}(A)$$

be the induced quadratic comparison. Assume $H_{\text{CL}}(A, A^i, \tau_i)$ and the following finite admissible Li–bar package.

- (A1) The quotient bar complex is bidegreewise finite and the Li–bar spectral sequence converges strongly in each conformal weight.
- (A2) In the bar-relevant window the reduced associated graded is the uniform eight-generator model

$$R^{\text{red}} \cong \bigotimes_{a=1}^8 \mathbb{C}[x_a]/(x_a^3),$$

where two generators form a Cartan basis and six are root generators.

- (A3) The d_1 differential on the resulting Li–bar page is the Kirillov–Kostant Poisson differential of Proposition 14.1.50; its exact finite matrix

$$d_1: E_1^{3,4} \longrightarrow E_1^{2,3}$$

has rank 6, its image is the six-dimensional root subspace, and its cokernel is the Cartan span $\mathbb{C}[H_1] \oplus \mathbb{C}[H_2]$.

- (A4) The map q_A is filtered; its quadratic source has $H^{2,3}(A^i) = 0$; the quotient-to-model comparison carries the computed Cartan cokernel to the actual Li–bar page; and the non-reduced extension data and higher differentials preserve those two classes to the abutment.

Then the quadratic comparison has a rank-two Cartan cone. More precisely:

- (i) $\dim H^2(\bar{B}^{\text{ch}}(L_k(\mathfrak{sl}_3))) \geq \text{rk}(\mathfrak{sl}_3) = 2$, and

$$\dim H^{2,3}(\text{Cone}(q_A)) \geq 2.$$

- (ii) The nonzero cohomology of $\text{Cone}(q_A)$ is a quadratic Koszul defect for τ_i . Equivalently, the mapping cone of the quadratic cobar map $p_A: \Omega_X(A^i) \rightarrow A$ and each of the two quadratic twisted products has nonzero cohomology. This is the specialization of Loday–Vallette [?LV12, Theorem 2.3.2 and Theorem 3.4.6].

- (iii) In the twelve-equivalence meta-theorem (Theorem 14.1.59), the quadratic-compression conditions occupy the obstructed branch. The universal full-bar counit $\Omega_X \tilde{B}_X(A) \xrightarrow{\sim} A$ retains its independent reconstruction status from Loday–Vallette [?LV12, Corollary 2.3.4] and Theorem A.

For denominators $q > 3$, the finite engine presently computes off-diagonal classes on the E_1 page. The corresponding incoming d_1 rank and higher-page persistence form the explicit extension problem beyond this denominator-three theorem.

Proof. Step 1 (Finite admissible model). Hypothesis (A1) supplies the finite, strongly convergent Li–bar spectral sequence. Arakawa finite-length results and Finkelberg semisimplification are the standard sources of finite admissible control; the theorem uses them through the explicit finite package stated above.

Step 2 (E_1 page via Künneth on the truncated associated graded). For one factor $\mathbb{C}[x]/(x^3)$, the degree-two periodic resolution contributes a class of internal weight 3. Künneth therefore gives

$$E_1^{2,3} \cong \mathfrak{sl}_3, \quad \dim E_1^{2,3} = 8,$$

with the decomposition into six root coordinates and two Cartan coordinates.

Step 3 (Exact d_1 matrix). By Hypothesis (A3), the incoming Poisson differential

$$d_1: E_1^{3,4} \longrightarrow E_1^{2,3}$$

has rank 6 and image equal to the root subspace. The outgoing target $E_1^{1,2}$ is zero. Consequently

$$H(E_1, d_1)^{2,3} \cong \operatorname{coker}(d_1: E_1^{3,4} \rightarrow E_1^{2,3}) \cong \mathfrak{h},$$

and this group has dimension 2. The exact rational matrix, its rank, its root-space image, and the two Cartan cokernel calculations are recorded in `compute/lib/admissible_sl3_d1_poisson_engine.py` and `compute/tests/test_admissible_sl3_d1_poisson_engine.py`.

Step 4 (Passage from the finite model to the quotient bar). Hypothesis (A4) is the quotient comparison and persistence statement. It carries the computed Cartan cokernel to the actual Li–bar spectral sequence and preserves it through the higher pages. Strong convergence from (A1) therefore gives a two-dimensional subspace of $H^{2,3}(\tilde{B}^{\text{ch}}(A))$.

Step 5 (The quadratic comparison cone). The source clause of (A4) gives $H^{2,3}(A^i) = 0$. The long exact cohomology sequence of $\operatorname{Cone}(q_A)$ places the two Cartan classes in $H^{2,3}(\operatorname{Cone}(q_A))$. This proves (i) and exhibits the nonzero quadratic Koszul defect of q_A . Applying the general twisting theorem to (A, A^i, τ_i) identifies the same defect in p_A and in the two quadratic twisted products, proving (ii).

For the universal twisting morphism $\pi_A: \tilde{B}(A) \rightarrow A$, the induced coalgebra comparison is $\operatorname{id}_{\tilde{B}(A)}$; Loday–Vallette [?LV12, Corollary 2.3.4] supplies the corresponding reconstruction counit. Thus the calculation locates the Cartan class in the compression q_A , which gives (iii). $\square$

Conjecture 14.1.44 (Higher-rank admissible Cartan cone, $\operatorname{rk}(\mathfrak{g}) \geq 3$). For any simple Lie algebra $\mathfrak{g}$ with $\operatorname{rk}(\mathfrak{g}) \geq 3$, the simple quotient $L_k(\mathfrak{g})$ at admissible level with denominator $q \geq 3$ has a Cartan subspace of dimension $\operatorname{rk}(\mathfrak{g})$ in the cohomology of its quadratic-comparison cone, and hence $\dim H^2(\tilde{B}(L_k(\mathfrak{g}))) \geq \operatorname{rk}(\mathfrak{g})$. At rank 2 and denominator 3, Theorem 14.1.43 establishes the corresponding conditional finite-model statement. The extension to $q > 3$ begins with the incoming d_1 matrix, while the higher-rank extension also includes the d_2 contributions from triple-root brackets.

Remark 14.1.45 ($W(2)$ at $c = -2$: Koszulness status). The $W(2)$ algebra at $c = -2$ (the triplet algebra at $p = 2$, $\mathbb{Z}/2$ -orbifold of the symplectic fermion algebra SF) has Koszulness status *open*. PBW universality (Proposition 14.1.37) does not apply directly: $W(2)$ is *not* freely strongly generated, since the vacuum module carries a singular vector at conformal weight 5 (Adamović–Milas; Feigin–Gainutdinov–Semikhatov–Tipunin), which lies in the bar-relevant range ($h = 5 \geq 2h_{\min} = 4$). The Kac-determinant zero at weight 15 is a Virasoro phenomenon, not a $W(2)$ null vector; but the weight-5 singular vector is genuine and obstructs the PBW route.

A potential alternative route uses the Kazhdan filtration: $W(2)$ embeds into the lattice VOA $V_{\mathbb{Z}\mathbb{Z}}$ as the momentum-zero sector. If the Kazhdan-filtered associated graded of $W(2)$ (not of $V_{\mathbb{Z}\mathbb{Z}}$) is polynomial, then Koszulness would follow. This requires verifying that the weight-5 singular vector is absorbed by the Kazhdan filtration, which is not established.

Remark 14.1.46 (*Arithmetic shadows: Koszulness as harmonic metric*). The Kac–Shapovalov non-degeneracy criterion is the analytic shadow of a deeper structure: by Theorem ?? (Chapter ??), Koszulness of $\mathcal{A}$ is equivalent to the nondegeneracy of the Shapovalov form on the shadow triple $(\Theta_{\mathcal{A}}, M_{\mathcal{A}}, h_{\mathcal{A}})$: the propagator $P = h^{-1}$ mediates between the flat side (MC element) and the Higgs side (spectral curve).

Remark 14.1.47 (*Deformation quantization compatibility*). Let $\mathcal{A}_{\hbar}$ be a flat deformation of a classically Koszul commutative chiral algebra $\mathcal{A}_0$, with $\mathcal{A}_{\hbar}/\hbar\mathcal{A}_{\hbar} \cong \mathcal{A}_0$. Proposition 14.1.37 implies: $\mathcal{A}_{\hbar}$ is chirally Koszul whenever the PBW filtration deforms flatly ($\text{gr}_F \mathcal{A}_{\hbar} \cong \mathcal{A}_0$). All standard families satisfy this: for $V_k(\mathfrak{g})$ with $\hbar = k^{-1}$, the bracket $[J^a, J^b]_{\star} = f_c^{ab} J^c + k\kappa^{ab}$ lies in $F_{\geq 1}$; Virasoro and $\mathcal{W}$ -algebras are analogous with $\hbar = c^{-1}$. Flat PBW deformation is therefore the mechanism producing chirally Koszul algebras from commutative seeds.

14.1.5 The Li–bar spectral sequence and geometric Koszulness

The Kac–Shapovalov criterion (Theorem 14.1.40) detects Koszulness by non-degeneracy of a bilinear form weight by weight. A geometric refinement is as follows: the Li filtration on $\mathcal{A}$ induces a spectral sequence on the bar complex whose E_1 page is the bar complex of a *commutative Poisson algebra*, and Koszulness is controlled by the geometry of the associated variety $X_{\mathcal{A}}$.

Construction 14.1.48 (*Li–bar spectral sequence*;). Let V be a vertex algebra with Li filtration $F_p V$ (Definition 36.2.33). The bar complex $\tilde{\mathbf{B}}(V) = \bigoplus_n \tilde{\mathbf{B}}^n(V)$ inherits a multiplicative filtration

$$F_p \tilde{\mathbf{B}}^n(V) = \sum_{p_1 + \dots + p_n = p} F_{p_1} V \otimes \dots \otimes F_{p_n} V \cap \tilde{\mathbf{B}}^n(V).$$

The Li filtration is multiplicative with respect to chiral operations: $a_{(m)} b \in F_{p+q}$ when $a \in F_p, b \in F_q$, and $m \leq -2$ (the defining condition of F_p), while $a_{(-1)} b \in F_{p+q}$ (product) and $a_{(0)} b \in F_{p+q-1}$ (Poisson bracket lowers filtration by 1). The bar differential $d_{\bar{B}}$, assembled from the chiral operations μ_n , respects the filtration: $d_{\bar{B}}(F_p \tilde{\mathbf{B}}^n) \subset F_{p-1} \tilde{\mathbf{B}}^{n-1}$. This gives rise to a convergent spectral sequence

$$E_1^{p,q} = H^{p+q}(\text{gr}_p^F \tilde{\mathbf{B}}(V)) \implies H^{p+q}(\tilde{\mathbf{B}}(V)). \quad (14.1)$$

The E_0 page is the bar complex of the associated graded $R_V := \text{gr}^F V$, which is a commutative vertex algebra with Poisson bracket $\{-, -\}$ induced by the o-product (Definition 36.2.33). The E_0 differential is the bar differential of R_V as a commutative algebra; the d_1 differential arises from the Poisson bracket.

Remark 14.1.49 (Finite-window KZ–Arnold residue realization;). On a genus-zero affine or tangent window with infinitesimal-braid representation, Theorem 20.2.1 constructs the flat connection $\nabla_{\mathcal{A},V,n}^{B,o} = \text{KZ}_{\mathcal{A},V,n}^*(\nabla_{\text{Arnold}})$ on the coefficient bundle over the ordered configuration space. The finite-window KZ–Arnold bar-superconnection identity is the comparison obtained after Fulton–MacPherson residue realisation: signed residues along the boundary divisors assemble into the corresponding component of $d_{\bar{B}}$. Thus the connection and the chain differential retain their distinct types, while the residue-realisation functor provides the map between them. Extension to every weight and every collision stratum belongs to the completion and incidence-compatibility package of the cited theorem.

PROPOSITION 14.1.50 (Poisson differential on the Li–bar E_1 page;). The d_1 differential on the Li–bar spectral sequence (14.1) is determined by the Poisson bracket on $R_V = \text{gr}^F V$:

$$d_1: E_1^{p,q} \rightarrow E_1^{p-1,q}, \quad d_1 = \sum_{i < j} \{-, -\}_{ij} \circ \text{contract}_{ij}$$

where $\{-, -\}_{ij}$ applies the Poisson bracket to the i -th and j -th tensor factors. In particular:

- (i) When $R_V \cong \text{Sym}(V_o)$ is a polynomial algebra with trivial Poisson bracket, $d_1 = 0$. Any further degeneration beyond E_1 requires separate control of the higher filtration-lowering pieces of the vertex-algebra differential.
- (ii) When $R_V = \mathcal{O}(Y)$ for an affine Poisson variety (Y, π) , the E_1 page is the ordinary commutative bar cohomology $H_{\text{bar}}^*(\mathcal{O}(Y))$, and d_1 is the differential induced there by π . Equivalently, the E_2 page is the homology of this commutative bar-cohomology page with respect to that bracket-induced differential.

Proof. The d_1 differential is the component of $d_{\bar{B}}$ that lowers the Li filtration by exactly 1. In the OPE $a_{(n)}b$ on a vertex algebra, the filtration behavior is: $a_{(-1)}b$ preserves the filtration (giving the commutative product in gr^F), $a_{(0)}b$ lowers it by 1 (giving the Poisson bracket), and $a_{(n)}b$ with $n \geq 1$ lowers it by $n \geq 1$, contributing to d_r with $r \geq 2$.

Thus d_1 on $\text{gr}^F \bar{\mathbf{B}}(V)$ is exactly the component from the 0-th product, which on the associated graded is the Poisson bracket $\{\bar{a}, \bar{b}\} = \overline{a_{(0)}b}$.

For (i): if $\{-, -\} = 0$, then $d_1 = 0$. This removes only the first Poisson correction on the E_1 page; higher filtration-lowering OPE terms can still contribute to later differentials d_r with $r \geq 2$. For the universal VOA $V_k(\mathfrak{g})$, $\text{gr}^F V_k(\mathfrak{g}) \cong \text{Sym}(\mathfrak{g}[\tau^{-1}]\tau^{-1})$ with Poisson bracket from the Lie bracket of $\mathfrak{g}$; here d_1 is the Chevalley–Eilenberg differential, which is nonzero but has concentrated cohomology by Whitehead vanishing (for semisimple $\mathfrak{g}$).

For (ii): when $R_V = \mathcal{O}(Y)$ with Y Poisson, the E_0 page is the ordinary commutative bar complex of $\mathcal{O}(Y)$, and the filtration-1 component of the bar differential induces on $E_1 = H_{\text{bar}}^*(\mathcal{O}(Y))$ the differential coming from the Poisson bracket π . This is bar-side Poisson data on the Li–bar spectral sequence, not ordinary Lichnerowicz–Poisson cohomology. $\square$

THEOREM 14.1.51 (Associated-variety criterion for Koszulness;). Let V be a vertex algebra with Li filtration $F_p V$, associated graded $R_V = \text{gr}^F V$, and associated variety $X_V = \text{Specm}(R_V/\sqrt{0})$. Consider the Li–bar spectral sequence (14.1).

- (i) *Sufficiency from diagonal concentration of the Li–bar E_2 page.* If the Li–bar E_2 page of R_V is concentrated on the diagonal ($H^{p,q}(E_2, d_1) = 0$ for $p \neq q$), then the Li–bar spectral sequence degenerates at E_2 and V is chirally Koszul.

- (ii) *Orbit criterion.* Suppose $R_V \cong \mathcal{O}(\overline{\mathbb{O}})$ for a nilpotent orbit closure $\overline{\mathbb{O}} \subset \mathfrak{g}^*$, equipped with the Kirillov–Kostant Poisson structure. Then the Li–bar E_1 page is the commutative bar cohomology of $\mathcal{O}(\overline{\mathbb{O}})$, and its d_1 differential is induced by that Poisson bracket. In particular, diagonal concentration of the resulting reduced Li–bar $E_2 = H(E_1, d_1)$ page is a sufficient condition for V to be chirally Koszul.

Proof. For (i): diagonal concentration of the E_2 page $H^{p,q}(E_1, d_1)$ forces all higher differentials $d_r: E_r^{p,q} \rightarrow E_r^{p-r, q+r-1}$ to vanish for degree reasons: sources and targets lie on different diagonals. Hence $E_2 = E_\infty$, and the bar cohomology $H^*(\mathbf{\bar{B}}(V))$ inherits diagonal concentration. By Theorem 14.1.23, this is Koszulness.

For (ii): if $R_V \cong \mathcal{O}(\overline{\mathbb{O}})$ as Poisson algebras, then Construction 14.1.48 identifies the E_0 page with the commutative bar complex of $\mathcal{O}(\overline{\mathbb{O}})$, so the E_1 page is its ordinary commutative bar cohomology. Then Proposition 14.1.50 identifies the induced d_1 differential on that E_1 page with the operator coming from the Kirillov–Kostant Poisson bracket on the reduced Poisson algebra. Thus the Li–bar E_2 page is exactly the homology of that reduced bar-cohomology page under the induced d_1 . Diagonal concentration of this reduced Li–bar E_2 page implies chiral Koszulness by (i). $\square$

Remark 14.1.52 (What this theorem does not identify). Theorem 14.1.51 is a theorem about the Li–bar spectral sequence and its d_1 complex on the commutative bar construction of R_V . It does *not* identify that E_2 page with ordinary Lichnerowicz–Poisson cohomology, nor with $H^*(\widetilde{\mathbb{O}}, \mathcal{O}_{\widetilde{\mathbb{O}}})$ for a symplectic resolution $\widetilde{\mathbb{O}} \rightarrow \overline{\mathbb{O}}$. Any such comparison would require extra geometric input and is not part of the proved surface here.

COROLLARY 14.1.53 (*Minimal-orbit levels under reducedness and reduced Li–bar concentration;*). Let $\mathfrak{g}$ be a simple Lie algebra and k an admissible level with $X_{L_k(\mathfrak{g})} = \overline{\mathbb{O}}_{\min}$ (the closure of the minimal nilpotent orbit). Assume in addition that the Li associated graded is reduced:

$$R_{L_k(\mathfrak{g})} = \mathrm{gr}^F L_k(\mathfrak{g}) \cong \mathcal{O}(\overline{\mathbb{O}}_{\min})$$

as Poisson algebras, and assume that the resulting reduced Li–bar E_2 page is diagonally concentrated. Then $L_k(\mathfrak{g})$ is chirally Koszul.

Proof. This is exactly the orbit-reduction criterion of Theorem 14.1.51(ii) applied to the reduced Poisson algebra $\mathcal{O}(\overline{\mathbb{O}}_{\min})$. $\square$

PROPOSITION 14.1.54 (*Nilradical obstruction at degenerate admissible levels;*). Let k be a degenerate admissible level for $\widehat{\mathfrak{g}}$ with $X_{L_k(\mathfrak{g})} = \overline{\mathbb{O}} \neq \{0\}$. The associated graded $R_{L_k} = \mathrm{gr}^F L_k$ is a Poisson algebra whose reduced quotient gives $\mathcal{O}(\overline{\mathbb{O}})$. The Koszulness obstruction at degenerate levels comes from two sources:

- (i) *Reduced Li–bar surface.* The reduced quotient $\mathcal{O}(\overline{\mathbb{O}}) = R_{L_k}^{\mathrm{red}}$ controls only the reduced Li–bar E_2 page furnished by Theorem 14.1.51(ii). Any diagonal-concentration statement established on that reduced surface is therefore a statement only for the reduced quotient, not for the full non-reduced algebra R_{L_k} .
- (ii) *Nilradical obstruction.* The nilradical $\mathcal{I} = \sqrt{0} \subset R_{L_k}$ carries additional bar-cohomological data not visible on the associated variety X_{L_k} . When $\mathcal{I} \neq 0$, the quotient $R_{L_k} \twoheadrightarrow \mathcal{O}(\overline{\mathbb{O}})$ forgets tensors in the bar complex with at least one nilpotent factor. These extra summands can support differentials and off-diagonal classes invisible on the reduced quotient, so reduced associated-variety data alone do not determine chiral Koszulness of $L_k(\mathfrak{g})$.

Proof. For (i): this is exactly the distinction in Theorem 14.1.51(ii) between the reduced Poisson algebra $\mathcal{O}(\overline{\mathbb{O}})$ and the full non-reduced Li graded R_{L_k} .

For (ii): the quotient map $R_{L_k} \twoheadrightarrow \mathcal{O}(\overline{\mathbb{O}})$ induces a surjection of commutative bar complexes, and its kernel contains bar tensors with at least one factor in $\mathcal{I}$. These nilpotent summands are absent from the reduced quotient, so the reduced Li-bar E_2 page cannot by itself determine the full bar-cohomological behavior of R_{L_k} . $\square$

Remark 14.1.55 (The orbit hierarchy of Koszulness). Theorem 14.1.51 organizes the Koszulness question for simple quotients into a hierarchy indexed by nilpotent orbits, but only after the full Li associated graded R_{L_k} has been identified. The associated variety $X_{L_k} = (\text{Specm } R_{L_k})_{\text{red}}$ records only the reduced geometry, so nilradical contributions remain a separate obstruction. For $\mathfrak{g} = \mathfrak{sl}_N$, the orbits are indexed by partitions $\lambda \vdash N$:

Orbit	Partition	Reduced Li-bar surface	Koszulness
$\{0\}$	(1^N)	finite-dim. reduced quotient	nilradical-dependent
$\mathbb{O}_{\min}$	$(2, 1^{N-2})$	reduced Li-bar concentration assumed	conditional on reducedness and reduced Li-bar concentration
$\mathbb{O}_{\text{subreg}}$	$(N-1, 1)$	reduced Li-bar concentration open	nilradical-dependent
$\mathcal{N}$	(N)	reduced Li-bar concentration open	nilradical-dependent

The reduced orbit geometry can still provide useful input, but the present theorem does not identify the reduced Li-bar E_2 page with ordinary Poisson cohomology or with $H^*(\overline{\mathbb{O}}, \mathcal{O}_{\overline{\mathbb{O}}})$ for a symplectic resolution. What it does show is that any reduced-level diagonal-concentration statement constrains only the reduced Li-bar page and leaves nilradical contributions as a separate obstruction.

A conjectural type- $\mathcal{A}$ orbit-duality principle (Conjecture 36.2.36) would exchange the associated varieties of L_k and $L_{k'}$: $\overline{\mathbb{O}} \leftrightarrow \overline{d_{\text{BV}}(\mathbb{O})}$. If that principle holds, it imposes a *compatibility constraint*: the Li-bar obstructions for L_k and $L_{k'}$ are conjecturally Barbasch–Vogan dual.

Remark 14.1.56 (Comparison with the Kac–Shapovalov criterion). Theorem 14.1.51 refines Theorem 14.1.40 as follows. The Shapovalov form G_h detects null vectors weight by weight. The Li filtration organizes these null vectors *geometrically*: a null vector at weight h in the vacuum module corresponds to a relation in $R_V = \text{gr}^F V$ at Li filtration level p , and the Poisson bracket determines whether this relation propagates to the bar complex via d_1 . The Shapovalov criterion asks: are there null vectors in the bar-relevant range? The Li-bar criterion asks: does the *geometry* of the associated variety X_V force those null vectors to produce off-diagonal bar cohomology?

The gain is maximal when $X_V \neq \{0\}$ and one can separately establish diagonal concentration on the reduced Li-bar page, possibly guided by geometric input from a symplectic resolution. Minimal-orbit levels are the first test case where the reduced geometry supports a concentration test, but an unconditional Koszul theorem still requires the extra reducedness and reduced Li-bar concentration hypotheses recorded in Corollary 14.1.53.

Remark 14.1.57 (Quadratic recognition, reconstruction, and Verdier duality). The twelve conditions of Theorem 14.1.59 organize three constructions. The quadratic construction consists of

$$\pi_i: \mathcal{A}^i \rightarrow \mathcal{A}, \quad q_{\mathcal{A}}: \mathcal{A}^i \rightarrow B_X(\mathcal{A}), \quad p_{\mathcal{A}}: \Omega_X(\mathcal{A}^i) \rightarrow \mathcal{A}.$$

Items (i)–(v) and (ix)–(x) concern these maps and their PBW, Ext, Shapovalov, and Fulton–MacPherson realizations under H_{CL} .

The universal construction is the adjunction

$$\Omega_X : \text{CoAlg}_X^{\text{conil}} \rightleftarrows \text{Alg}_X^{\text{aug}} : B_X,$$

with unit $\eta_C : C \rightarrow B_X \Omega_X C$ and counit $\varepsilon_A : \Omega_X B_X A \rightarrow A$. The two triangular identities express the equivalence between these two categories in the enhanced pro-nilpotent Ran ambient. Its factorization realization is governed by H_{fact} and H_{conv} .

The Verdier construction is the contravariant functor

$$K_X(A) = \mathbb{D}_{\text{Ran}}^{\text{cont}} B_X^{\text{cont}}(A).$$

For a quadratic presentation, $\mathbb{D}(q_A)$ compares $K_X(A)$ with $\mathbb{D}A^i$. Item (vi) is the monadic consequence of the quadratic resolution under its conservativity and totalization package; item (vii) is the conditional factorization-homology comparison; item (viii) is governed by the family-indexed Hochschild theorem and its own retract package; item (xi) uses the shifted-symplectic hypotheses; and item (xii) records the one-directional purity implication. Each clause therefore retains the map and hypothesis package from which it is derived.

Remark 14.1.58 (Honest count of the meta-theorem). The content of Theorem 14.1.59 separates exactly as $7 + 1 + 1 + 1 + 1 + 1 = 12$ numbered items. Items (i)–(v) and (ix)–(x) are seven *genuinely independent* bidirectional equivalences on the standard landscape at *generic* parameters: non-critical level $k \neq -h^\vee$, non-admissible level for lattice and $\mathcal{W}_N$ algebras, and non-minimal-model central charge for Virasoro and $\mathcal{W}$ algebras. Item (vi) (Barr–Beck–Lurie monadicity) is the monadic consequence of item (v) under the stated conservativity and totalization package for the quadratic resolution; it is listed as the ∞ -categorical formulation most useful for applications. Item (vii) (factorization homology concentration) is a conditional comparison consequence: Proposition 9.12.4 supplies only a filtered model under locally constant, constructible, compact Ran hypotheses, and a converse from factorization homology concentration to Koszulness requires the extra detection hypothesis stated in the theorem. It therefore occupies the conditional-comparison lane. Item (viii) is the family-indexed implication supplied by $H_H(\mathcal{A}; S)$; its Koszul-dual reflection uses the additional perfect degree- d pairing. Item (xi) (the Lagrangian criterion) is conditional on the shifted-symplectic hypothesis package, including perfectness of the bar-cobar normal complex, non-degeneracy of the ambient tangent complex, cyclic/BV compatibility, and bar-chart acyclicity. On the standard landscape Proposition 9.10.59 discharges the perfectness input; the remaining package inputs stay part of the statement. Item (xii) ($\mathcal{D}$ -module purity) is a one-directional implication (xii) $\Rightarrow$ (x); the converse is proved for affine Kac–Moody at non-critical level only after the localization-weight package of Proposition 14.1.74; it is open for Virasoro and $\mathcal{W}$ algebras. At special parameter values some equivalences require individual verification or fail; in particular the critical level $k = -h^\vee$ for affine Kac–Moody is excluded from the generic scope, where κ vanishes and the bar cohomology reshapes to the opers complex. A separately stated characterization, tropical Koszulness (Theorem ?? in Chapter ??), provides a further bidirectional criterion via a weight spectral sequence on the tropical real blowup; it is proved there as a standalone theorem but is *not* integrated into the unified list of the present meta-theorem.

THEOREM 14.1.59 (Equivalences and consequences of chiral Koszulness;). Let $\mathcal{A}$ be a chiral algebra on a smooth projective curve X with PBW filtration $F_\bullet$. Fix a quadratic coalgebra and its twisting morphism

$$\mathcal{A}^i = C(s^{-1}V, s^{-2}R), \quad \tau_i : \mathcal{A}^i \longrightarrow \mathcal{A},$$

and assume the comparison package $H_{\text{CL}}(\mathcal{A}, \mathcal{A}^i, \tau_i)$ together with the PBW detection hypotheses stated below. Write

$$q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow \bar{B}_X(\mathcal{A}), \quad p_{\mathcal{A}}: \Omega_X(\mathcal{A}^i) \longrightarrow \mathcal{A}$$

for the two maps induced by τ_i . The intrinsic equivalence core is read under the split finite-window PBW hypotheses: conformal-weight/bar-length pieces are finite, the induced filtrations are Hausdorff, complete, and strongly convergent, and a conformal-weight splitting identifies E_∞ with its associated graded. Each subsequent implication is read with the convergence or comparison package stated beside it. For a smooth projective curve Σ , write $\text{FH}_\Sigma(\mathcal{A})$ for the comparison package of Proposition 9.12.4: the Ran object attached to $\mathcal{A}$ is locally constant on configuration strata, constructible on Fulton–MacPherson compactifications, compact enough for the Ran colimit to commute with the bar-length filtration, and the resulting comparison

$$\overline{B}_\Sigma^{\text{geom}}(\mathcal{A}) \simeq \int_\Sigma \overline{\mathcal{A}}^{\text{Lie}}$$

is filtered for bar length versus the Goodwillie filtration and strongly convergent; in condition (vii) this right-hand side is abbreviated by $\int_\Sigma \mathcal{A}$. Write $\text{FH}_\Sigma^{\text{det}}(\mathcal{A})$ for the detecting strengthening in which the off-diagonal PBW subquotient injects into the corresponding Goodwillie subquotient; equivalently, degree-zero concentration of $\int_\Sigma \mathcal{A}$ reflects degree-zero concentration of $\overline{B}_\Sigma^{\text{geom}}(\mathcal{A})$. These comparison and detection packages are explicit hypotheses. Conditions (i)–(v) and (ix)–(x) below are seven coordinated diagnostics for the quadratic comparison $q_{\mathcal{A}}$ under the stated PBW hypotheses. Their equivalence uses the general twisting theorem [?LV12, Theorem 2.3.2] and its quadratic specialization [?LV12, Theorem 3.4.6]. Condition (vi) (Barr–Beck–Lurie comparison) is the corresponding monadic consequence under its conservativity and totalization package. Condition (vii) is a conditional factorization-homology consequence under $\text{FH}_{\mathbb{P}^1}(\mathcal{A})$; it becomes a genus-0 criterion precisely under the stronger $\text{FH}_{\mathbb{P}^1}^{\text{det}}(\mathcal{A})$. Under the uniform-weight hypothesis, condition (vii) strengthens to the all-genera concentration statement on the curves carrying $\text{FH}_{\Sigma_g}(\mathcal{A})$ for the relevant curves. Condition (viii) is the family-indexed Hochschild implication under $H_H(\mathcal{A}; S)$. It yields support in S and the corresponding polynomial Hilbert series. A perfect degree- d pairing with a companion family datum supplies duality. The multiplicative structure of the cup-product algebra belongs to its separate comparison theorem; the present Hilbert polynomial records graded dimensions. Under the additional perfectness and non-degeneracy hypotheses on the ambient tangent complex, condition (xi) is also equivalent to the intrinsic core. Condition (xii) implies condition (x) (Remark 14.1.73); the converse is open.

Intrinsic equivalence core and monadic consequence:

- (i) $\tau_i: \mathcal{A}^i \rightarrow \mathcal{A}$ is a chiral Koszul morphism (Definition 14.1.3).
- (ii) The PBW spectral sequence on $\bar{\mathbf{B}}(\mathcal{A})$ collapses at E_2 (Theorem 14.1.23).
- (iii) The off-diagonal part of the minimal A_∞ -model of $\bar{\mathbf{B}}(\mathcal{A})$ is formal: the transferred operations whose outputs lie off the Koszul diagonal vanish (Proposition 14.1.32 and Theorem 14.1.33).
- (iv) Ext diagonal vanishing: $\text{Ext}_{\mathcal{A}}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.
- (v) The quadratic comparison maps are equivalences:

$$q_{\mathcal{A}}: \mathcal{A}^i \xrightarrow{\sim} \bar{B}_X(\mathcal{A}), \quad p_{\mathcal{A}}: \Omega_X(\mathcal{A}^i) \xrightarrow{\sim} \mathcal{A}.$$

This is the chiral quadratic criterion modeled by Loday–Vallette [?LV12, Theorem 3.4.6].

- (vi) Under the Barr–Beck–Lurie package for the quadratic resolution $p_{\mathcal{A}}$, the associated comparison functor is an equivalence on the complete component generated by $\mathcal{A}$.

- (ix) The Kac–Shapovalov determinant $\det G_h \neq 0$ in the bar-relevant range (Theorem 14.1.40).
- (x) The restriction $i_S^! \overline{B}_n(\mathcal{A})$ to every FM boundary stratum S is acyclic outside degree 0.

The canonical full-bar twisting morphism $\pi_{\mathcal{A}}: \tilde{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ belongs to universal reconstruction. Its induced coalgebra comparison is $\text{id}_{\tilde{B}_X(\mathcal{A})}$, and its counit

$$\Omega_X \tilde{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$$

is the full bar–cobar resolution of Theorem A, modeled by Loday–Vallette [?LV12, Corollary 2.3.4]. Condition (v) measures the additional compression from $\mathcal{A}^i$ to this full bar coalgebra.

Conditional factorization-homology comparison:

- (vii) If $\text{FH}_{\mathbb{P}^1}(\mathcal{A})$ holds, then chiral Koszulness implies genus-0 factorization homology concentration:

$$H^k\left(\int_{\mathbb{P}^1} \mathcal{A}\right) = 0 \quad (k \neq 0).$$

If the detecting strengthening $\text{FH}_{\mathbb{P}^1}^{\text{det}}(\mathcal{A})$ also holds, this genus-0 concentration statement is equivalent to conditions (i)–(v) and (ix)–(x). If $\mathcal{A}$ lies on the uniform-weight lane and $\text{FH}_{\Sigma_g}(\mathcal{A})$ holds for every smooth projective curve Σ_g of genus $g \geq 0$, then chiral Koszulness implies

$$H^k\left(\int_{\Sigma_g} \mathcal{A}\right) = 0 \quad (k \neq 0)$$

for every $g \geq 0$. With the additional package H_D^K , the surviving Hodge character for $g \geq 1$ is

$$\text{ch}_g(\mathfrak{D}_g^K(\mathcal{A})) = (-1)^g \kappa(\mathcal{A}) \lambda_g$$

(UNIFORM-WEIGHT; Theorem ??). Under $\text{FH}_{\mathbb{P}^1}^{\text{det}}(\mathcal{A})$, the same comparison reflects concentration and gives the converse.

Family-indexed chiral Hochschild support:

- (viii) Let $S \subset \mathbb{Z}_{\geq 0}$ be finite and assume $H_H(\mathcal{A}; S)$. Then

$$\text{Supp } CH^\bullet(\mathcal{A}) \subseteq S, \quad P_{\mathcal{A}}(t) = \sum_{n \in S} \dim H^n(K_{\mathcal{A}, S}) t^n.$$

If $\mathcal{A}^!$ carries $H_H(\mathcal{A}^!; S^!)$ and the pair carries a perfect degree- d chain pairing, then

$$CH^n(\mathcal{A}) \cong CH^{d-n}(\mathcal{A}^!)^\vee \otimes \omega_X.$$

Its graded-commutative cup-product algebra is governed by the separate multiplicative comparison (Theorem 35.4.49, Theorem 35.4.51, cf. Proposition 35.4.58). De Sole–Kac variational Poisson cohomology is nonvanishing in unboundedly many degrees for Virasoro-type Poisson vertex algebras [?BDSK21], so the support inclusion lives strictly on the stated Koszul/bounded locus, with the bounded-to-chart comparison part of $H_H(\mathcal{A}; S)$.

Conditional and partial:

- (xi) The Lagrangian criterion: under perfectness, non-degeneracy, and the tangent-complex comparison identifying the completed twisted tensor product with the derived intersection, $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ are transverse Lagrangians in the (-1) -shifted symplectic deformation space $\mathcal{M}_{\text{comp}}$.

- (xii) $\mathcal{D}$ -module purity: each $\tilde{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module, with characteristic variety aligned to FM boundary strata.

Proof. THE CORE CIRCUIT (i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (iii) $\Leftrightarrow$ (v):

(i) $\Leftrightarrow$ (ii): Koszulness of τ_1 is acyclicity of $K_{\tau_1}^L(\mathcal{A}, \mathcal{A}^i)$ and $K_{\tau_1}^R(\mathcal{A}^i, \mathcal{A})$. On each associated-graded finite window, Loday–Vallette’s quadratic criterion [?LV12, Theorem 3.4.6] identifies this with diagonal concentration of the quadratic bar comparison. The split PBW detection and strong convergence hypotheses transport that statement to E_2 -collapse of the chiral bar spectral sequence, in both directions.

(ii) $\Rightarrow$ (v): E_2 -collapse gives bar concentration (Theorem 14.1.30). The associated-graded map of $q_{\mathcal{A}}$ is the ordinary quadratic inclusion $\mathcal{A}^i \rightarrow B(\mathcal{A})$, hence is a quasi-isomorphism by Loday–Vallette [?LV12, Theorem 3.4.6]. The strict filtration, strong convergence, and Mittag–Leffler clauses of H_{CL} lift it to the displayed equivalence $q_{\mathcal{A}}$; the same fundamental twisting theorem gives the equivalence $p_{\mathcal{A}}$.

(v) $\Rightarrow$ (i): Condition (v) is precisely the pair of maps induced by the quadratic twisting morphism τ_1 . The fundamental theorem of chiral twisting morphisms (Theorem 14.1.13), transporting Loday–Vallette [?LV12, Theorem 2.3.2], identifies either comparison equivalence with acyclicity of both quadratic twisted products. This is condition (i).

FAMILY-INDEXED CHIRAL HOCHSCHILD CLAUSE (viii):

The strong deformation retract in $H_H(\mathcal{A}; S)$ and its chart quasi-isomorphism identify $C_{\text{ch}}^{\bullet}(\mathcal{A}, \mathcal{A})$ with $K_{\mathcal{A}, S}$. Theorem 35.4.49 gives the support inclusion, and Theorem 35.4.51 gives the displayed Hilbert polynomial. The companion family datum and the perfect degree- d pairing give the degree reflection. Proposition 35.4.58 governs the additional brace and Massey-product structure.

A_{∞} FORMALITY (i) $\Leftrightarrow$ (iii):

(ii) $\Rightarrow$ (iii): E_2 -collapse means all PBW differentials $d_r = 0$ for $r \geq 2$. The A_{∞} products m_n are identified with d_{n-1} under the HPL transfer, so $m_n = 0$ for $n \geq 3$ (Proposition 14.1.32).

(iii) $\Rightarrow$ (ii): If $m_n = 0$ for $n \geq 3$, the minimal A_{∞} -model is strictly associative: $H^*(\tilde{\mathbf{B}}(\mathcal{A}))$ is a dg algebra with m_2 as the product and all higher operations trivial. The bar spectral sequence of this formal A_{∞} -algebra collapses at E_2 by the classicality theorem for formal A_{∞} -algebras (Keller). The chiral A_{∞} structure is computed fiberwise on each FM stratum (Proposition ??); on each fiber the HPL transfer is an ordinary A_{∞} transfer over a field, to which Keller’s theorem applies directly. The PBW filtration is defined fiberwise and compatible with the FM stratification, so fiberwise E_2 -collapse assembles to global E_2 -collapse: all transferred differentials $d_r = 0$ for $r \geq 2$. Hence the spectral sequence on $\tilde{\mathbf{B}}(\mathcal{A})$ also collapses at E_2 .

CONDITIONAL FACTORIZATION-HOMOLOGY COMPARISON (i) $\Rightarrow$ (vii) under $\text{FH}_{\mathbb{P}^1}$, with the converse under $\text{FH}_{\mathbb{P}^1}^{\text{det}}$ (the uniform-weight all-genera statement is a conditional refinement. Cf. Remark 14.1.60):

(i) $\Rightarrow$ (vii): The intrinsic statement is bar-model concentration. By (i) $\Leftrightarrow$ (ii), the PBW spectral sequence of $\tilde{\mathbf{B}}(\mathcal{A})$ collapses at E_2 , hence Theorem 14.1.30 places the bar model in cohomological degree 0. If $\text{FH}_{\mathbb{P}^1}(\mathcal{A})$ holds, then Proposition 9.12.4 identifies this filtered bar model with the Goodwillie-filtered factorization homology object over $\mathbb{P}^1$. Strong convergence of the comparison transfers degree-zero concentration to $\int_{\mathbb{P}^1} \mathcal{A}$, giving $H^k(\int_{\mathbb{P}^1} \mathcal{A}) = 0$ for $k \neq 0$.

If $\mathcal{A}$ lies on the uniform-weight lane and $\text{FH}_{\Sigma_g}(\mathcal{A})$ holds for every Σ_g , the same filtered comparison is available at each genus. The loop-order spectral sequence of the higher-genus bar complex collapses on the modular Koszul locus (Theorem ??), so after the vertexwise genus-0 PBW collapse every loop-order

stratum remains cohomologically concentrated in degree 0. With H_D^K , Theorem ?? identifies the Hodge character by

$$\mathrm{ch}_g(\mathfrak{D}_g^K(\mathcal{A})) = (-1)^g \kappa(\mathcal{A}) \lambda_g \quad (g \geq 1)$$

The uniform-weight hypothesis leaves a single channel, so $\partial F_g^{\mathrm{cross}} = 0$ and degree-zero concentration is preserved. Hence $H^k(\int_{\Sigma_g} \mathcal{A}) = 0$ for $k \neq 0$ for all $g \geq 0$ on the uniform-weight locus.

(vii) $\Rightarrow$ (i): Suppose $H^k(\int_{\mathbb{P}^1} \mathcal{A}) = 0$ for $k \neq 0$ and assume $\mathrm{FH}_{\mathbb{P}^1}^{\mathrm{det}}(\mathcal{A})$. The detected comparison reflects degree-zero concentration back to the bar model: an off-diagonal class on the PBW E_2 page would survive as an off-degree Goodwillie class, contradicting concentration of $\int_{\mathbb{P}^1} \mathcal{A}$. Hence the PBW spectral sequence collapses at E_2 , and Theorem 14.1.23 gives chiral Koszulness.

The detecting package $\mathrm{FH}_{\mathbb{P}^1}^{\mathrm{det}}(\mathcal{A})$ is precisely the hypothesis that reflects Goodwillie concentration to the PBW page; the converse is read on this detecting domain.

Remark 14.1.60 (All-genera form of condition (vii)). Condition (vii) has an intrinsic bar-model theorem and a conditional factorization-homology avatar. The unconditional bar-model statement is

$$H^k(|\tilde{\mathbf{B}}_{\mathbb{P}^1}(\mathcal{A})|) = 0 \quad (k \neq 0) \iff \mathcal{A} \in \mathrm{Kosz}(X),$$

by Theorem 14.1.30 and Theorem 14.1.23. The replacement of this bar model by $\int_{\mathbb{P}^1} \mathcal{A}$ requires $\mathrm{FH}_{\mathbb{P}^1}(\mathcal{A})$, and the converse requires $\mathrm{FH}_{\mathbb{P}^1}^{\mathrm{det}}(\mathcal{A})$.

Under the uniform-weight hypothesis the higher-genus refinement is proved. If $\mathrm{FH}_{\Sigma_g}(\mathcal{A})$ holds, Proposition 9.12.4 supplies the bar comparison model for factorization homology on the curve Σ_g . On the Koszul locus, the genus-0 PBW collapse forces each vertex contribution to be concentrated in degree 0, and Theorem ?? prevents the loop-order spectral sequence from reintroducing positive-degree cohomology. Definition ?? selects one channel, so every boundary graph is monochromatic. Under H_D^K , the surviving Hodge character is identified by Theorem ??:

$$\mathrm{ch}_g(\mathfrak{D}_g^K(\mathcal{A})) = (-1)^g \kappa(\mathcal{A}) \lambda_g.$$

Hence

$$H^k(\int_{\Sigma_g} \mathcal{A}) = 0 \quad (k \neq 0)$$

for every $g \geq 0$ on the uniform-weight lane. This is the all-genera form of condition (vii).

The scalar identity in that argument has an independent proof path. Remark ?? applies Grothendieck–Riemann–Roch to the family bar complex over the universal curve and recovers the same class $\kappa(\mathcal{A}) \lambda_g$ by Grothendieck–Riemann–Roch, independently of the shadow-tower route through the Maurer–Cartan element and Theorem ??. It gives a second proof of the scalar part of the all-genera uniform-weight statement alongside the conditional bar/factorization-homology concentration argument.

For multi-weight algebras, the higher-genus form of condition (vii) passes to the scalar projection of the genus- g obstruction package: one replaces higher-genus concentration by the diagonal-plus-cross-channel identity

$$F_g(\mathcal{A}) = \kappa(\mathcal{A}) \cdot \lambda_g^{\mathrm{FP}} + \partial F_g^{\mathrm{cross}}(\mathcal{A}) \quad (\text{ALL-WEIGHT, with cross-channel correction } \partial F_g^{\mathrm{cross}})$$

for $g \geq 1$, with $\partial F_1^{\mathrm{cross}} = 0$ universally and $\partial F_g^{\mathrm{cross}} = 0$ on the uniform-weight lane (Theorem ??). In this form, condition (vii) survives at all genera at the scalar-trace level. The uniform-weight hypothesis is essential for full cohomological concentration: the interacting algebra $\mathcal{W}_3$ leaves the scalar locus already

at $g = 2$, while Proposition ?? identifies the free-field exception where the correction vanishes genus by genus.

Geometrically, $\partial F_g^{\text{cross}}$ is the scalar trace of mixed-channel boundary residues. The edges still carry the universal weight-1 propagator $d \log E(z, w)$; the correction comes from the vertices, where OPE residues couple distinct conformal-weight sectors on stable-graph boundary strata. Construction ?? makes this precise: $\partial F_g^{\text{cross}}$ is the sum over stable graphs whose edge-labelling $\sigma: E(\Gamma) \rightarrow \{1, \dots, r\}$ uses at least two weights. At genus 1 the unique boundary graph has one edge, hence every assignment is single-channel and $\partial F_1^{\text{cross}} = 0$. At genus $g \geq 2$, multi-edge strata admit genuine mixed assignments, and their integrated OPE residues produce $\partial F_g^{\text{cross}}$. In this precise sense, the cross-channel term is the higher-genus shadow of mixed-weight OPE residues.

Remark 14.1.61 (The content of (viii)). Theorem 35.4.49 and Theorem 35.4.51 applied to $H_H(\mathcal{A}; S)$ prove family support and polynomial Hilbert growth. A companion datum $H_H(\mathcal{A}^!; S^!)$ and a perfect degree- d pairing prove the separate duality $n \leftrightarrow d - n$. The one-dimensional Fulton–MacPherson boundary calculus enters the construction of the family retract; its OPE-residue lift determines S . Product ambients, categorical Hochschild cochains of Calabi–Yau categories, and topological Hochschild theory carry their respective Künneth and comparison packages. A multiplicative presentation of $CH^*(\mathcal{A})$ is governed by its brace-compatible formality theorem.

FM BOUNDARY ACYCLICITY (i) $\Leftrightarrow$ (x):

(i) $\Rightarrow$ (x): Each FM boundary stratum $S_T \cong \prod_{v \in V(T)} \overline{\text{Conf}}_{|v|}(X_v)$ is indexed by a tree T . The residue component $d_{\text{res}}|_{S_T}$ of the bar differential restricts to the tensor product of lower-degree bar complexes. E_2 -collapse at each vertex degree (Theorem 14.1.23) gives acyclicity: $H^k(i_{S_T}^! \overline{B}_n(\mathcal{A})) = 0$ for $k \neq 0$.

(x) $\Rightarrow$ (i): At the deepest stratum $S = D_{\{1,2\}} \cong X \times \overline{\text{Conf}}_{n-1}(X)$ (binary collision), the restriction $i_S^! \overline{B}_n(\mathcal{A})$ computes the bar-complex contribution from the OPE $a_{(k)}b$ at a single collision point. Acyclicity of $i_S^!$ at all strata forces the residues at every collision to be exact, which is the PBW condition: $d_1(e_i) = 0$ on the associated graded, hence E_2 -collapse.

BARR–BECK–LURIE MONADICITY (v) $\Rightarrow$ (vi) and (vi) $\Rightarrow$ (i):

The Barr–Beck–Lurie theorem ([?HA, Theorem 4.7.3.5]) states that the comparison functor Φ is an equivalence if and only if $\overline{B}_\kappa$ is conservative and preserves totalizations of $\overline{B}_\kappa$ -split cosimplicial objects. Condition (vi) assumes precisely these two properties for the functor defined by the quadratic resolution $p_{\mathcal{A}}$. Condition (v) identifies that resolution, through $q_{\mathcal{A}}$, with the full bar resolution on the complete component generated by $\mathcal{A}$. The Barr–Beck–Lurie theorem therefore gives the comparison equivalence on that component.

(vi) $\Rightarrow$ (i): If the BBL comparison functor Φ is an equivalence, then $\overline{B}_\kappa$ is conservative and its comparison unit on the generator $\mathcal{A}$ is an equivalence. Under the quadratic-resolution package in (vi), this unit is represented by $q_{\mathcal{A}}$ and $p_{\mathcal{A}}$; hence (v) holds, and the general twisting theorem gives (i).

KAC–SHAPOVALOV DETERMINANT (i) $\Leftrightarrow$ (ix):

(i) $\Rightarrow$ (ix): If $\mathcal{A}$ is chirally Koszul, the PBW filtration on the vacuum module is strict: $\text{gr}_F M_0(\mathcal{A}) \cong \text{Sym}^{\text{ch}}(V)$. Strictness implies the Shapovalov form G_h is non-degenerate in the bar-relevant range.

(ix) $\Rightarrow$ (i): Non-degeneracy $\det G_h \neq 0$ in the bar-relevant range means the PBW-to-bar comparison map $\iota: \text{Sym}^{\text{ch}}(V)_h \rightarrow \overline{B}_h(\mathcal{A})$ is injective at every bar-relevant weight h . Suppose $d_r \neq 0$ for some $r \geq 2$. Then there exists $x \in E_r^{p,q}$ with $d_r(x) \neq 0$, represented by $\tilde{x} \in F^p \overline{B}$ with $d_{\text{bar}}(\tilde{x}) \in F^{p+r} \overline{B}$. If

$\tilde{x} \in \text{im}(\iota)$, it represents a nonzero class in $\text{gr}^p(\bar{B}) \cong \text{Sym}^p(V)$, and $d_r(\tilde{x})$ represents a nonzero class in gr^{p+r} . By PBW strictness (injectivity of ι at all bar-relevant weights), this contradicts the acyclicity of $\text{Sym}(V)$ as a Koszul complex. Hence $d_r = 0$, giving (ii) and hence (i).

EXT DIAGONAL VANISHING (i) $\Leftrightarrow$ (iv):

(i) $\Rightarrow$ (iv): E_2 -collapse places $H^*(\bar{\mathbf{B}}(\mathcal{A}))$ on the diagonal $p = q$; the bar resolution computes Ext, so $\text{Ext}^{p,q}(\omega_X, \omega_X) = 0$ for $p \neq q$.

(iv) $\Rightarrow$ (i): Diagonal Ext-vanishing means $\bar{\mathbf{B}}(\mathcal{A})$ has cohomology concentrated on the line $p = q$ in the bigrading. The PBW spectral sequence has $E_1^{p,q} = H^{p+q}(\text{gr}_F^p \bar{\mathbf{B}})$ converging to $H^{p+q}(\bar{\mathbf{B}})$; diagonal concentration of the abutment forces all differentials d_r ($r \geq 2$) to vanish (a d_r -differential moves off-diagonal by $(r, 1-r)$, which would produce off-diagonal classes contradicting (iv)). The PBW spectral sequence converges conditionally in the sense of Boardman: the filtration is Hausdorff and complete (the PBW filtration on a positively graded algebra is bounded below). In characteristic zero with a split filtration (the PBW filtration splits by conformal weight), the extension problem is split: $E_\infty = E_2$ as bigraded objects. Hence E_2 -collapse, hence (i).

LAGRANGIAN CRITERION (i) $\Leftrightarrow$ (xi) (*under perfectness, non-degeneracy, and tangent-complex comparison; the standard landscape uses Proposition 9.10.59 where its hypotheses have been verified*):

(i) $\Rightarrow$ (xi): On the Koszul locus, the quadratic cobar map $p_{\mathcal{A}}$ provides a free resolution and $q_{\mathcal{A}}$ compares it with the full bar resolution. Theorem C supplies the Verdier-side homotopy eigenspace decomposition $\mathbf{Q}_g(\mathcal{A}) \oplus \mathbf{Q}_g(\mathcal{A}^!) \simeq H^*(\bar{\mathcal{M}}_g, \mathcal{Z}_{\mathcal{A}})$ as a cochain-level eigenspace splitting whose scalar trace is a subsequent projection. Under perfectness and non-degeneracy this decomposition identifies $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ as complementary subspaces of $\mathcal{M}_{\text{comp}}$. The shifted-symplectic structure (Theorem ??) makes these subspaces isotropic; the complementarity splitting gives maximal dimension, hence Lagrangian.

(xi) $\Rightarrow$ (i): If $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ are transverse Lagrangians and the tangent-complex comparison identifies their derived intersection with the completed twisted tensor product, their derived intersection $\mathcal{M}_{\mathcal{A}} \times_{\mathcal{M}_{\text{comp}}}^h \mathcal{M}_{\mathcal{A}^!}$ is discrete (transverse Lagrangian intersection in a (-1) -shifted symplectic space has expected dimension 0). Under the comparison hypothesis this derived intersection computes the twisted tensor product $K_{\tau}(\mathcal{A}, \mathcal{A}^!)$; its acyclicity (i.e., discreteness of the intersection) is Koszulness (Definition 14.1.3). $\square$

Remark 14.1.62 (Proof web redundancy). The proof of Theorem 14.1.59 is not a single chain. Its unconditional core already has several proof lanes that do not route through the same intermediate condition:

(i) $\Longleftrightarrow$ (v) (quadratic twisting morphism and comparison package), (i) $\Longleftrightarrow$ (iii) ($\mathcal{A}_\infty$ transfer and Keller classicality),

(i) $\Longleftrightarrow$ (iv) (Ext diagonal vanishing),

(i) $\Longleftrightarrow$ (ix) (Kac–Shapovalov non-degeneracy), (i) $\Longleftrightarrow$ (x) (FM boundary acyclicity),

and on the monadic side

(v) $\Rightarrow$ (vi) $\Rightarrow$ (i) (Barr–Beck–Lurie monadicity).

Three direct cross-links are the load-bearing redundancy.

(v) $\Rightarrow$ (i) is the shortest loop. For the quadratic twisting morphism $\tau_i: \mathcal{A}^i \rightarrow \mathcal{A}$, condition (v) is the equivalence of $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \bar{B}_X(\mathcal{A})$ and $p_{\mathcal{A}}: \Omega_X(\mathcal{A}^i) \rightarrow \mathcal{A}$, and Theorem 14.1.13 identifies that

directly with τ_1 being a chiral Koszul morphism. This is the direct Loday–Vallette [?LV12, Theorem 2.3.2 and Theorem 3.4.6] comparison route.

The link from the intrinsic core to (viii) carries the additional family datum $H_H(\mathcal{A}; S)$. Condition (i) supplies the associated-graded quadratic contraction; the OPE-residue lift, incidence compatibility, completion, and averaging comparison in $H_H(\mathcal{A}; S)$ supply the complete retract. Theorem 35.4.49 then gives family support, and Theorem 35.4.51 gives polynomial Hilbert growth. A perfect degree- d pairing supplies duality, while Proposition 35.4.58 governs the brace-compatible cup-product presentation.

(iii) $\Rightarrow$ (x) is fiberwise and geometric. For a boundary stratum S_T , the restriction $i_{S_T}^! \overline{B}_n(\mathcal{A})$ decomposes as the tensor product of the vertexwise collision complexes, and Remark 7.1.58 identifies those iterated residues with the transferred $\mathcal{A}_\infty$ operations. If $m_k = 0$ for $k \geq 3$, only the strict binary residue survives at each vertex. Fiberwise Keller classicality, exactly as in Theorem 14.1.33, then gives degree-zero concentration for every vertex factor, so the Künneth spectral sequence yields

$$H^k(i_{S_T}^! \overline{B}_n(\mathcal{A})) = 0 \quad (k \neq 0).$$

This reaches (x) without passing through the shadow tower.

The same argument gives further direct arrows already implicit in the proof:

$$(iv) \Rightarrow (ii), \quad (ix) \Rightarrow (ii), \quad (v) \Longleftrightarrow (vi).$$

Under FH_{pt} the arrow (ii) $\Rightarrow$ (vii) may be added to this web; under $\text{FH}_{\text{pt}}^{\text{det}}$ the converse arrow may also be added. These conditional arrows are deliberately not displayed in the unconditional core. Hence the unconditional core

$$\{(i), (ii), (iii), (iv), (v), (vi), (ix), (x)\}$$

forms a web rather than a chain.

Here (viii) is a satellite consequence, not part of the equivalence core. The node (vii) has been omitted because it is a conditional factorization-homology comparison lane. The uniform-weight all-genera statement recorded in Theorem 14.1.59(vii) is a conditional strengthening under the relevant FH_{Σ_g} hypotheses, not an extra unconditional equivalence. Let G_{core} be the undirected graph obtained from the displayed core subweb by forgetting arrow directions and deleting the satellite node (viii). Every displayed core edge lies on one of the cycles

$$\begin{aligned} &((i), (ii), (v)), \quad ((i), (ii), (iv)), \\ &((i), (iii), (x)), \quad ((i), (v), (vi)), \quad ((i), (ii), (ix), (x)). \end{aligned}$$

Therefore G_{core} has no bridges. Equivalently, deleting any one displayed implication still leaves the unconditional core connected: the implication graph has no single point of failure.

Remark 14.1.63 (Lagrangian and purity refinements). Condition (xi) remains conditional on the shifted-symplectic hypothesis package: perfectness, non-degeneracy of the ambient tangent complex, cyclic/BV compatibility, and bar-chart acyclicity. Condition (xii) implies condition (x) (via Saito's theory of mixed Hodge modules; see Remark 14.1.73). The converse direction (Koszulness implies D-module purity) is reduced to a single gap (Remark 14.1.73). The converse of (xii) is proved for the affine Kac–Moody lineage under the localization-weight package (Proposition 14.1.74); the non-affine case (Virasoro, $\mathcal{W}$ -algebras) remains open. Beyond these twelve conditions, Sklyanin–Poisson rigidity (Theorem 14.1.84) provides a conditional Poisson-geometric route to Koszulness restricted to the affine Kac–Moody subclass and to the Sklyanin–bar comparison package.

PROPOSITION 14.1.64 (*Closure of chiral Koszulness under tensor, dualization, and base change*;). The class of chirally Koszul algebras is closed under the following operations when the stated finiteness and comparison hypotheses hold:

- (a) *Chiral tensor product.* If $\mathcal{A}, \mathcal{B}$ are chirally Koszul on the curve X and satisfy the split mixed-residue hypotheses of Proposition 14.10.5, then $\mathcal{A} \boxtimes \mathcal{B}$ is chirally Koszul, its tensor presentation coalgebra is $\mathcal{A}^! \boxtimes \mathcal{B}^!$, and the colored Künneth map supplies the corresponding q -comparison to the full colored bar object.
- (b) *Reflexive quadratic dualization.* Let $\mathcal{A} = T_X(V)/(R)$ with V perfect and $R \subset V \otimes V$ a locally split perfect subobject. Assume $R^{\perp\perp} = R$, and assume the comparison maps for both quadratic presentations satisfy H_{CL} . Then the canonical bidual map of quadratic presentations

$$\beta_{\mathcal{A}}: \mathcal{A} \xrightarrow{\sim} (\mathcal{A}^!_{\text{quad}})^!_{\text{quad}}$$

is an isomorphism, and quadratic Koszulness of $\mathcal{A}$ is equivalent to quadratic Koszulness of $\mathcal{A}^!_{\text{quad}}$.

- (c) *Smooth base change.* If $f: Y \rightarrow X$ is a smooth morphism of curves and $\mathcal{A}$ is chirally Koszul on X , with holonomicity, finite-type duality, and PBW convergence preserved by f^* , and with the chosen pair map commuting with base change, then $f^*\mathcal{A}$ is chirally Koszul on Y , and $(f^*\mathcal{A})^! \simeq f^*(\mathcal{A}^!)$.

Proof. (a) is Proposition 14.10.5. The Künneth formula applies only after the mixed-color hypotheses in that proposition are imposed; it then identifies the colored bar complex with $\overline{B}(\mathcal{A}) \boxtimes \overline{B}(\mathcal{B})$ and gives $(\mathcal{A} \boxtimes \mathcal{B})^i \simeq \mathcal{A}^i \boxtimes \mathcal{B}^i$ at the level of the chosen quadratic presentations. Finite duality gives the quadratic dual algebra statement; the chosen pair maps transport it to the partner algebras.

(b): Perfectness gives $V \simeq V^{\vee\vee}$ and the assumed orthogonality gives $R \simeq R^{\perp\perp}$. These maps identify the generators and relations of the two quadratic presentations and define $\beta_{\mathcal{A}}$. The quadratic twisting complexes for the two presentations are finite duals of one another. Exact finite duality, followed by the two H_{CL} comparisons, identifies their acyclicity. This is the quadratic theorem of Loday–Vallette [LV12, Theorem 3.4.6] in the stated perfect factorization category.

(c): Smooth base change uses Lemma ?? to verify that f^* preserves quasi-isomorphisms of chiral algebras, combined with Theorem 9.10.39 to verify that f^* commutes with bar-cobar. The witnessing datum for chiral Koszulness pulls back along f , and the E_2 -collapse of the PBW spectral sequence is preserved under flat pullback (since smooth morphisms are flat). The duality identification $(f^*\mathcal{A})^! \simeq f^*(\mathcal{A}^!)$ follows from the compatibility of f^* with Verdier duality on the finite-type holonomic lane. $\square$

Remark 14.1.65 (Closure does not extend to bare quotients). The closure properties of Proposition 14.1.64 do not extend to general quotients $\mathcal{A}/I$ by chiral ideals: the quotient of a chirally Koszul algebra by a non-Koszul ideal is generically non-Koszul. The $\mathcal{W}$ -algebra construction $\mathcal{W}^k(\mathfrak{g}, f)$ via Drinfeld–Sokolov

reduction is the principal example where the quotient *does* preserve Koszulness, and this is a substantive theorem of the chapter (Theorem ??), not a corollary of closure.

Remark 14.1.66 (Off-diagonal A_∞ formality and Gaiotto–Kulp–Wu). The off-diagonal A_∞ formality characterization (item (iii) of Theorem 14.1.59) is the bar-complex statement of the formality theorem of Gaiotto–Kulp–Wu [?GKW2025]: the transferred operations with off-diagonal output vanish if and only if $\mathcal{A}$ is chirally Koszul. The shadow depth classification $\mathbf{G/L/C/M}$ (Remark ??) records the diagonal operations left invisible by concentration, giving a four-class stratification governed by the discriminant $\Delta = 8\kappa S_4$.

Remark 14.1.67 (Loop-exactness ordering $G < L < C < M$). The four shadow-depth classes are ordered by the number of loop corrections needed to determine the full A_∞ structure on $\mathcal{A}_{\text{line}}^!$:

- Class G (Gaussian, $r_{\max} = 2$): tree-level exact.
- Class L (Lie/tree, $r_{\max} = 3$): one-loop exact (DNP non-renormalization, Theorem 37.8.2(iii)).
- Class C (Contact, $r_{\max} = 4$): two-loop exact.
- Class M (Mixed, $r_{\max} = \infty$): requires all-loop resummation.

This ordering refines the generic Koszul locus: the standard generic/universal representatives in all four classes are chirally Koszul (bar E_2 -collapse), but they differ in Swiss-cheese formality depth.

PROPOSITION 14.1.68 (*Swiss-cheese non-formality by shadow class;*). The Swiss-cheese operations m_k^{SC} on $\mathcal{A}$ itself are not the off-diagonal transferred operations killed by Koszulness. They are diagonal shadow operations and are classified by shadow depth as follows.

Class	Families	m_3^{SC}	m_4^{SC}	$m_k^{\text{SC}}, k \geq 5$
G ($r_{\max} = 2$)	Heisenberg, lattice VOA, free fermion	$= 0$	$= 0$	$= 0$
L ($r_{\max} = 3$)	affine KM	$\neq 0$	$= 0$	$= 0$
C ($r_{\max} = 4$)	$\beta\gamma$	$= 0$	$\neq 0$	$= 0$
M ($r_{\max} = \infty$)	Virasoro, $\mathcal{W}_N$	$\neq 0$	$\neq 0$	nonzero for infinitely many $k \geq 5$ (Theorem ??)

Mechanism. For class G : Heisenberg, lattice VOAs, and free fermions are Gaussian/free-field: their ordered bar data is generated by the binary two-point kernel, so every connected genus-0 tree with at least three external legs factors through pairings and carries no primitive higher vertex. Equivalently, the shadow tower truncates at degree 2: $S_r(\mathcal{A}) = 0$ for $r \geq 3$ (Theorem ??; for lattices see Corollary ??). Under the averaging map $\text{av}(\Theta_{\mathcal{A}}^{\text{E}_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1), the mixed Swiss-cheese tree of degree r projects to the degree- r shadow. Since there is no primitive tree for $r \geq 3$, all higher mixed-sector operations vanish. For class L : the affine KM OPE has at most a double pole; the three-channel tree sum over $\overline{\mathcal{M}}_{0,4}$ is nonzero ($S_3 = 2h^\vee/(k+h^\vee) \neq 0$) but the tower terminates at depth 3 because $S_r = 0$ for $r \geq 4$. For class C : the cubic shadow vanishes by weight parity of the γ generator (conformal weight 0), while the quartic contact invariant $Q^{\text{contact}} \neq 0$ from the $\beta\gamma\beta\gamma$ self-contraction; rank-one rigidity of the contact stratum kills all m_k^{SC} for $k \geq 5$. For class M : the quartic pole in the Virasoro OPE ($T_{(3)}T = c/2$) produces $S_3 = 2$ (c -independent) and the critical discriminant $\Delta = 8\kappa S_4 \neq 0$ forces all higher operations to be nonzero.

Proof. Class G : for Heisenberg, centrality of the bracket kills all nested tree compositions, so $m_k^{\text{SC}} = 0$ for $k \geq 3$. For lattice VOAs, bosonization reduces connected genus-0 amplitudes to Wick pairings of the underlying Heisenberg field, and Corollary ?? identifies the shadow tower with its weight-2 truncation. For the free fermion, Wick's theorem gives Pfaffian factorization by the basic contraction $\psi(z)\psi^*(w) \sim (z-w)^{-1}$, so again no connected tree with $r \geq 3$ survives after extracting the binary pairings. In all three cases the mixed Swiss-cheese degree- r operation is the open-colored lift of the same genus-0 tree sum whose closed projection is $S_r(\mathcal{A})$; equivalently, $\text{av}(\Theta_{\mathcal{A}}^{\text{E}_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1). Because class G means $S_r(\mathcal{A}) = 0$ for all $r \geq 3$, the mixed-sector operations vanish: $m_k^{\text{SC}} = 0$ for $k \geq 3$. The weaker condition $\Delta = 0$ is not sufficient: affine Kac–Moody algebras are class L with $\Delta = 0$ but $m_3^{\text{SC}} \neq 0$. Class L : the cubic shadow $S_3 = 2h^\vee/(k + h^\vee)$ is computed from the OPE coefficient ratio (the structure constant divided by the level); the quartic and higher shadows vanish because the Jacobi identity and rank constraints eliminate all $\overline{M}_{0,r+1}$ tree sums for $r \geq 4$ when the OPE has at most double poles. Class C : the cubic shadow vanishes by the parity obstruction on the weight-0 generator γ ; the quartic contact invariant Q^{contact} is nonzero by the explicit $\beta\gamma\beta\gamma$ channel computation; termination at depth 4 follows from rank-one rigidity (Theorem ??). Class M : $S_3 = (\text{scalar projection of } T_{(1)}T)/T_{(3)}T = 2\kappa/\kappa = 2$, independent of c ; $S_4 = 10/[c(5c+22)]$ and $\Delta = 8\kappa S_4 = 40/(5c+22) \neq 0$ for generic c , so the Riccati algebraicity theorem forces the tower to be infinite. Computational verification: `theorem_ainfty_nonformality_class_m_engine.py` (three independent methods for S_3 , quartic shadow S_4 and Q^{contact} , quintic shadow $S_5 = -48/(c^2(5c+22))$, all four classes verified). $\square$

The four classes exhaust the finite standard-landscape atlas, not a classification beyond it, but the relationship between SC-formality and this atlas partition is sharper than the table records. Proposition 14.1.68 already isolates the first nonzero Swiss-cheese operation in each non-Gaussian class and, on the Gaussian locus, identifies the mixed-sector tree formulas with the degree-by-degree shadow tower after averaging. The criterion below packages this as an equivalence between SC-formality and truncation of the shadow tower at degree 2.

LEMMA 14.1.69 (*Two-colour tree detection on the standard support*;). (Open quadrant; ordered-to-mixed genus-0 presentation; Beilinson levels 3–4; hypothesis package $\text{SC}_{\text{std}}^{\text{tree-det}}$). Let $\mathcal{A}$ lie in the standard landscape and fix $r \geq 3$. Let

$$\text{Tree}_{r,\text{std}}^{\text{ord}}(\mathcal{A})$$

be the span of connected ordered genus-0 HPL trees of arity r , decorated by the standard-landscape OPE channels and quotiented by the HPL boundary relations. The same ordered tree sum has two realisations:

$$\iota_r^{\text{oc}} : \text{Tree}_{r,\text{std}}^{\text{ord}}(\mathcal{A}) \longrightarrow \text{Hom}_r^{\text{SC}}(\mathcal{A}^{\otimes r}, \mathcal{A}), \quad \pi_r^{\text{sh}} : \text{Tree}_{r,\text{std}}^{\text{ord}}(\mathcal{A}) \longrightarrow \text{Sh}_r(\mathcal{A}).$$

Here ι_r^{oc} is the open-colour bulk-to-boundary realisation defining m_r^{SC} , and π_r^{sh} is the closed-colour shadow projection obtained from the averaging identity $\text{av}(\Theta_{\mathcal{A}}^{\text{E}_1}) = \Theta_{\mathcal{A}}$. The package $\text{SC}_{\text{std}}^{\text{tree-det}}$ asserts that, on this standard primitive support,

$$\iota_r^{\text{oc}}(T) = 0 \iff T = 0 \iff \pi_r^{\text{sh}}(T) = 0.$$

Consequently, under this package,

$$m_r^{\text{SC}}(\mathcal{A}) = 0 \iff \text{Sh}_r(\mathcal{A}) = 0 \quad (r \geq 3)$$

degree by degree on the standard landscape.

Proof. The two maps are the colour-separated readings of the genus-0 tree formula in Theorem ??, together with the ordered-to-symmetric identity $\text{av}(\Theta_{\mathcal{A}}^{\text{E}_1}) = \Theta_{\mathcal{A}}$ of Theorem 1.4.1. What is not supplied by bare averaging is detection of the ordered tree from either coloured output: Theorem 1.4.1(iv) explicitly leaves a non-trivial kernel for av , already containing the degree-3 Drinfeld associator class. The named package says exactly that the standard primitive support used in the **G/L/C/M** classification does not meet that kernel, and that the open-colour bulk-to-boundary realisation has no additional kernel on connected positive-degree trees. With these two injectivity statements, vanishing of either coloured realisation is equivalent to vanishing of the common ordered tree class. $\square$

PROPOSITION 14.1.70 (*SC-formality characterises class G* ;). Let $\mathcal{A}$ be a chiral algebra in the standard landscape satisfying the two-colour tree-detection package $\text{SC}_{\text{std}}^{\text{tree-det}}$ of Lemma 14.1.69. Then $\mathcal{A}$ is Swiss-cheese formal ($m_k^{\text{SC}} = 0$ for all $k \geq 3$) if and only if $\mathcal{A}$ belongs to class G .

Proof. The proof is operadic: both directions use the genus-0 tree-shadow correspondence (Theorem ??) and the averaging identity $\text{av}(\Theta_{\mathcal{A}}^{\text{E}_1}) = \Theta_{\mathcal{A}}$ (Theorem 1.4.1), with the averaging kernel controlled on the standard primitive support by Lemma 14.1.69. No invariant bilinear form or metric is required; the argument applies uniformly to all families in the standard landscape, including $\beta\gamma$ systems.

FORWARD (class $G \implies \text{SC-formal}$):

Class G is the Gaussian locus (Theorem ??): Heisenberg, lattice VOA, and free fermion. For these families, the shadow tower truncates at degree 2: $S_r(\mathcal{A}) = 0$ for every $r \geq 3$.

The genus-0 operadic transfer (Theorem ??; Proposition ??(ii)) identifies $S_r(\mathcal{A})$ with the transferred L_∞ bracket $\ell_r^{(0),\text{tr}}$ evaluated on the truncated MC element. The Swiss-cheese mixed-sector operation m_r^{SC} of degree r is the open-colour lift of the *same* genus-0 tree sum: the mixed tree and the shadow tree share their internal edge propagators and vertex operations; they differ only in the output colour (open vs closed), with passage to the closed sector given by the averaging morphism av .

Since class G means the genus-0 transfer is generated by the binary two-point kernel alone, every connected tree of degree $r \geq 3$ factors through binary pairings and carries no primitive higher vertex. The tree sum vanishes at the open level (no connected tree survives); equivalently, Lemma 14.1.69 sends the vanishing shadow tree to the vanishing open-colour operation. Hence $m_k^{\text{SC}} = 0$ for all $k \geq 3$.

For completeness, we record the family-by-family mechanism. Heisenberg: centrality of the bracket kills all nested tree compositions. Lattice VOA: bosonization reduces connected genus-0 amplitudes to Wick pairings of the underlying Heisenberg field (Corollary ??). Free fermion: Pfaffian factorization by the basic contraction $\psi(z)\psi^*(w) \sim (z-w)^{-1}$ ensures no connected tree with $r \geq 3$ external legs survives after extracting binary pairings. In all three cases the mechanism is Gaussian: only the two-point kernel generates.

CONVERSE (SC-formal $\implies$ class G):

Suppose $\mathcal{A}$ is SC-formal, so $m_k^{\text{SC}} = 0$ for all $k \geq 3$.

Step 1: SC-formality forces $S_r(\mathcal{A}) = 0$ for $r \geq 3$. Let $T_r(\mathcal{A})$ be the ordered genus-0 tree class whose open-colour realisation is m_r^{SC} and whose closed-colour realisation is $\text{Sh}_r(\mathcal{A})$. By Lemma 14.1.69,

$$m_r^{\text{SC}} = 0 \implies T_r(\mathcal{A}) = 0 \implies \text{Sh}_r(\mathcal{A}) = 0.$$

Thus SC-formality gives $S_r(\mathcal{A}) = 0$ for all $r \geq 3$.

Step 2: $S_r = 0$ for all $r \geq 3$ is precisely class G . The discriminant $\Delta = 0$ is necessary but not sufficient: class L has $\Delta = 0$ but $S_3 \neq 0$. The full vanishing criterion $S_r = 0$ for all $r \geq 3$ identifies exactly class G among the four standard classes:

Class	S_3	S_4	S_r ($r \geq 5$)	Ruled out by
G	$= 0$	$= 0$	$= 0$	none
L	$\neq 0$	$= 0$	$= 0$	$S_3 \neq 0$
C	$= 0$	$\neq 0$	$= 0$	$S_4 \neq 0$
M	$\neq 0$	$\neq 0$	nonzero for infinitely many r	$S_3 \neq 0$

By Theorem ??, the standard-landscape locus with $S_r = 0$ for all $r \geq 3$ is precisely class G . By Step 1, an SC-formal algebra has this vanishing pattern; hence it belongs to class G . $\square$

Remark 14.1.71 (Independence from invariant bilinear forms). The proof of Proposition 14.1.70 is purely operadic: it uses the tree-shadow correspondence (Theorem ??), the averaging identity (Theorem 1.4.1), the two-colour tree-detection package (Lemma 14.1.69), and the shadow archetype classification (Theorem ??). No invariant bilinear form, Killing metric, or Casimir tensor enters at any step. This is essential because the class- G locus includes the free fermion and lattice VOAs, and the class- C family $\beta\gamma$ (which must be ruled out by the converse) admits no invariant metric and no Sugawara construction. The operadic structure of the genus-0 tree transfer, not the representation theory of any Lie algebra, is the correct mechanism.

Remark 14.1.72 (Livernet–LV comparison). The Swiss-cheese statements in Propositions 14.1.68 and 14.1.70 concern transferred mixed operations on a fixed chiral algebra $\mathcal{A}$. They are distinct from operadic Koszul duality of the two-colored operad itself. The comparison with the classical literature is color by color.

The convention check is decisive. In the dual calculation of Proposition 28.10.2, the closed color of $\text{SC}^{\text{ch}, \text{top}}$ is first replaced by its algebraic commutative shadow. The resulting quadratic model has closed color Com , open color Ass , and mixed sector governed by shuffles. This is the same distributive-law package as in the classical Swiss-cheese literature around Livernet, made explicit in Loday–Vallette [?LV12, §7.1, Chapter 8, §13.3]. Accordingly,

$$(\text{SC}^{\text{ch}, \text{top}})^! \cong (\text{Lie}, \text{Ass}, \text{shuffle-mixed}),$$

with closed dimensions $(n-1)!$, open dimensions $m!$, and mixed dimensions $(k-1)! \binom{k+m}{m}$ (Proposition 28.10.2). Operadic self-duality already fails in the classical algebraic model: the closed Com sector is one-dimensional in each input degree, whereas the dual closed Lie sector has dimension $(n-1)!$. Hence the duality functor is involutive, but the operad is not self-dual.

What changes in the chiral–topological setting is the proof method. Before passage to the commutative shadow, the closed color is represented by the dg operad $C_\bullet(\text{FM}_k(\mathbb{C}))$. One therefore does not prove strict quadratic Koszulity directly on chains. Instead one transports the classical Koszul statement along Kontsevich formality for the closed color together with the bar-cobar transfer theorems of Loday–Vallette [?LV12, Theorems 11.3.3 and 11.4.1]. In this sense the genus-zero comparison is compatible with the Livernet–LV lane: classical Swiss-cheese provides the strict Koszul input, while $\text{SC}^{\text{ch}, \text{top}}$ enters only through the weaker homotopy-Koszul consequence.

Remark 14.1.73 (D-module purity: reduction to a single gap). The converse direction of condition (xii) (Koszulness $\implies$ D-module purity of $\mathbf{B}_n(\mathcal{A})$) reduces to a weight-comparison problem. The first three steps are formal or PBW-local; the fourth is the family-specific open mathematical condition.

- Step 1. The PBW filtration $F_{\bullet}^{\text{PBW}}$ on $\bar{\mathbf{B}}_n(\mathcal{A})$ is a filtration by $\mathcal{D}$ -submodules on $\text{FM}_n(X)$, with associated graded given by the FG bar complex (the bar of the chiral Lie algebra). Proved: the PBW filtration is defined by order of OPE pole, compatible with $\mathcal{D}$ -module structure.
- Step 2. On the Koszul locus, $\text{gr}_{\bullet}^F \bar{\mathbf{B}}_n$ is a direct sum of rank-one $\mathcal{D}$ -modules supported on the strata of the FM boundary, each pure of weight determined by the stratum codimension. Proved: follows from PBW concentration (ii) and the explicit identification of strata.
- Step 3. Purity of the associated graded implies purity of the filtered module if and only if the PBW filtration coincides with the Saito weight filtration from mixed Hodge module theory. Proved: this is a formal consequence of Saito's strictness theorem for filtered $\mathcal{D}$ -modules.
- Step 4. **The PBW filtration on $\bar{\mathbf{B}}_n(\mathcal{A})$ equals the Saito weight filtration from mixed Hodge modules on $\text{FM}_n(X)$.** For affine Kac–Moody algebras this is the localization-weight comparison: chiral localization must identify $\bar{\mathbf{B}}_n$ with the corresponding mixed Hodge module on the Beilinson–Drinfeld Grassmannian and identify the PBW filtration with the Saito–Kashiwara weight filtration. For Virasoro and $\mathcal{W}$ -algebras it is open: the BPZ equations do not presently supply a polarizable variation of Hodge structure controlling the bar filtration.
- Step 5. Given steps 1–4, purity of $\bar{\mathbf{B}}_n$ in weight n follows by the strictness of the weight filtration. Proved: formal.

Thus the exact open mathematical condition is the equality $F_{\bullet}^{\text{PBW}} = W_{\bullet}^{\text{Saito}}$ on the bar mixed Hodge module. Once this equality is known, Koszulness forces purity by strictness. Without it, PBW collapse proves bar concentration but not purity. The affine Kac–Moody case is treated below under the localization-weight package; the non-affine lineage (Virasoro, $\mathcal{W}$ -algebras) remains open.

PROPOSITION 14.1.74 (*$\mathcal{D}$ -module purity for affine Kac–Moody under localization weights*). For $\mathcal{A} = V_k(\mathfrak{g})$ at generic non-critical level k , assume the localization-weight package: Frenkel–Gaiitsgory chiral localization identifies each $\bar{\mathbf{B}}_n(\mathcal{A})$ with the corresponding Beilinson–Drinfeld Grassmannian mixed Hodge module, the Hecke operations realizing the n insertions are proper on the relevant finite windows, and the PBW filtration agrees with the Saito–Kashiwara weight filtration there. Then $\bar{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module on $\text{FM}_n(X)$.

Proof. Under the localization-weight package, $\bar{\mathbf{B}}_n(\mathcal{A})$ is represented by a mixed Hodge module on the Beilinson–Drinfeld Grassmannian whose restriction to each finite Hecke window is pure before the n bar insertions. Proper Hecke pushforward preserves purity, and the Saito–Kashiwara weight comparison identifies the PBW degree of each insertion with one unit of Saito weight. Therefore the n -fold bar piece is pure of weight n on the corresponding FM stratum, and the proper descent to $\text{FM}_n(X)$ preserves that weight. $\square$

D-module purity: reduction and family dependence

Under the localization-weight package the Kac–Moody case strengthens to a full equivalence. For other families, the two-way implication remains conditional or open.

PROPOSITION 14.1.75 (*Kac–Moody equivalence under Saito–Kashiwara weight comparison*). Let $\mathcal{A} = V_k(\mathfrak{g})$ be the universal affine Kac–Moody vertex algebra at generic level k on a smooth projective curve X . Assume the localization-weight package of Proposition 14.1.74. Then the following are equivalent:

- (a) $\mathcal{A}$ is chirally Koszul (condition (i) of Theorem 14.1.59).

- (b) The PBW filtration $F_{\bullet}^{\text{PBW}}$ on each $\bar{\mathbf{B}}_n(\mathcal{A})$ is strict and concentrated in PBW-degree n (condition (ii)).
- (c) Each $\bar{\mathbf{B}}_n(\mathcal{A})$ is pure of weight n as a mixed Hodge module on $\text{FM}_n(X)$ (condition (xii)).

Proof. The implications (a) $\Leftrightarrow$ (b) are part of the core circuit (i) $\Leftrightarrow$ (ii) of Theorem 14.1.59. The implication (c) $\Rightarrow$ (b) is the one-directional part of the meta-theorem ((xii) $\Rightarrow$ (x)): purity of $\bar{\mathbf{B}}_n$ forces Saito strictness on the weight filtration, and Saito strictness gives FM stratum acyclicity, which in turn forces PBW strictness by the Kac–Shapovalov implication (ix) $\Rightarrow$ (ii).

The new content is the converse (b) $\Rightarrow$ (c) under the stated localization-weight package. Proposition 14.1.74 supplies (a) $\Rightarrow$ (c) after that package is installed. The converse uses the same Saito–Kashiwara weight comparison: the PBW filtration on $V_k(\mathfrak{g})$ is identified with the Saito weight filtration on the associated mixed Hodge module after chiral localization to the affine Grassmannian.

First, Frenkel–Gaitsgory chiral localization identifies $\bar{\mathbf{B}}_n(V_k(\mathfrak{g}))$ with a $\mathcal{D}$ -module on $\text{Gr}_G^{(n)}$ (the n -th Beilinson–Drinfeld Grassmannian), carrying a canonical variation of mixed Hodge structure on the chosen finite windows. Second, the PBW filtration on the vacuum module lifts to a Hodge-theoretic filtration on this variation; the required identification is the Saito–Kashiwara comparison supplied by the hypothesis, in the same circle as Mochizuki’s proof of Saito’s decomposition theorem for pure twistor $\mathcal{D}$ -modules ([?Mochizuki2015, ?Sabbah2014]), where the Kashiwara filtration along a boundary divisor (here, the FM stratification) gives a weight filtration that, in the presence of a polarization, agrees with the Saito weight filtration by strictness. Third, for Kac–Moody the polarization is supplied by the Kac–Shapovalov form (Theorem 14.1.40): G_h is non-degenerate in the bar-relevant range at generic level, providing the positivity data that forces Saito strictness. PBW strictness (b) is then transported, by the identification above, to strictness of the Saito weight filtration, which is equivalent to (c) by Saito’s theorem.

The three ingredients (Frenkel–Gaitsgory localization, Mochizuki–Sabbah twistor strictness, Kac–Shapovalov positivity) are each family-specific: each relies on properties of $V_k(\mathfrak{g})$ that are not shared by Virasoro or $\beta\gamma$. The non-affine case is precisely the open direction recorded in Remark 14.1.73, Step 4. $\square$

Remark 14.1.76 (Family dependence of the $\mathcal{D}$ -module purity equivalence). The Kac–Moody equivalence of Proposition 14.1.75 is not available for the full standard landscape without additional Hodge-theoretic input. The missing input is family-specific and is visible in the shadow class of the algebra.

Virasoro (class $\mathbf{M}$, $r_{\max} = \infty$): Vir_c is chirally Koszul at generic c (Table 14.1), so condition (ii) holds. The shadow depth is infinite: the shadow tower does not terminate, and the higher Massey products $S_r \neq 0$ for infinitely many r obstruct the naive assignment of one Saito weight per PBW bar insertion. The BPZ differential equations do not carry a known polarization of twistor type, so Mochizuki’s strictness theorem does not apply. Thus PBW concentration is proved, but $\mathcal{D}$ -module purity is an extra open statement rather than a consequence of condition (ii). This is the *shadow depth* ∞ vs. *PBW concentration* gap.

$\beta\gamma$ (class $\mathbf{C}$, $r_{\max} = 4$): The contact shadow $Q^{\text{contact}} \neq 0$ at degree 4 (Proposition 14.1.68) marks a parity obstruction candidate for the Saito weight: the weight-0 generator γ gives a nontrivial quartic Massey product in the bar transfer. A proof that this Massey product is incompatible with purity would require a mixed-Hodge model for the $\beta\gamma$ bar complex. As for Virasoro, condition (ii) holds, but condition (xii) is not proved from it.

$\mathcal{W}_N$ at principal nilpotent, generic central charge (class $\mathbf{M}$):

Conjecture 14.1.77 (Principal $\mathcal{W}_N$ equivalence on the generic locus;). Let $\mathcal{W}_N^k$ be the universal principal $\mathcal{W}$ -algebra obtained from $V_k(\mathfrak{sl}_N)$ by principal Drinfeld–Sokolov reduction, at generic central charge. On the generic locus of the FM configuration space, condition (ii) of Theorem 14.1.59 is equivalent to condition (xii), conditional on the preservation of Saito weights under principal Drinfeld–Sokolov reduction.

The conditional hypothesis is the conjectured compatibility of the principal nilpotent BRST differential with the Kashiwara filtration of the ambient Kac–Moody mixed Hodge module. Only on the generic locus (away from the FM deep strata where higher shadow products interact) is the equivalence plausible; at the boundary, class **M** behavior reintroduces the Virasoro obstruction.

The upshot is that condition (xii) is family-dependent: it depends on more than $\dim(\mathfrak{g})$ or Euler characteristic data, and the equivalence of (xii) with the Koszulness hierarchy is proved here only on the affine Kac–Moody lineage under the localization-weight package. For the non-affine families, the one-way implication (xii) $\Rightarrow$ (x) holds unconditionally (Remark 14.1.73, Steps 1–3, 5), but the converse requires family-specific input. The working hypothesis is that the shadow obstruction tower and the mixed-Hodge weight filtration measure the same obstruction through different functors; the direct bridge is presently available only for Kac–Moody.

Remark 14.1.78 (Computational verification landscape). Items (i)–(v), (ix), and (x) (seven genuinely independent bidirectional equivalences), together with item (vi) as a listed consequence of (v) and the Hochschild consequence (viii), have been checked for a landscape of 17 algebras (Table 14.1): 12 proved Koszul via equivalences (ii) and (ix), 1 proved not Koszul (Ising minimal model, $L(c_{3,4}, 0)$: Kac–Shapovalov null vector at $h = 6$ in the bar-relevant range, so (ix) fails), 1 conditional finite-model obstruction ($L_k(\mathfrak{sl}_3)$ at admissible $q = 3$: $\text{rk}(\mathfrak{g}) = 2$ Cartan classes survive in H^2 under Theorem 14.1.43), 3 open ($V_{-2}(\mathfrak{sl}_2)$ at critical level, $L_1(\mathfrak{sl}_2)$, and triplet $\mathcal{W}(2)$). The principal proof mechanism is PBW universality (Proposition 14.1.37), which applies to all freely strongly generated algebras: Heisenberg, $V_k(\mathfrak{g})$ at all levels including critical, Vir_c at all central charges, universal $\mathcal{W}$ -algebras, $\beta\gamma$, free fermion, and the symplectic fermion (Remark ??). Three additional mechanisms are needed: lattice filtration (Theorem ??) for lattice VOAs, MC₄ completion tower (Theorem 9.1.28) for $\mathcal{W}_{1+\infty}$, and Kac–Shapovalov null vector detection for disproving Koszulness of minimal models. Cross-family consistency checks: κ additivity, complementarity consistency, and shadow depth independence from Koszulness (shadow classes G, L, C, M each contain Koszul algebras). The factorization-homology clause (vii) is used only after the relevant FH_Σ comparison model has been verified; it is not a computational test for Koszulness in this table.

Remark 14.1.79 (Lattice examples and the five typed objects). For an even lattice Λ of rank d , the Heisenberg currents in V_Λ satisfy

$$J^a(z)J^b(w) \sim \frac{(a, b)}{(z - w)^2}, \quad \kappa(V_\Lambda) = d.$$

The lattice proof of Koszulness uses bosonization and the Gaussian symmetric Rarita–Schwinger amplitudes reduce to Wick pairings, so the shadow tower stops at degree 2. This does not identify the bar coalgebra with the post-Verdier algebra. The first object is the Gaussian conilpotent coalgebra V_Λ^i , carrying the lattice momentum grading and the discriminant-sector grading; only after Verdier or continuous finite-sector duality does one get $V_\Lambda^!$. In the unimodular case this finite-sector duality returns the same lattice VOA.

The quantum lattice family $V_{\Lambda}^{N,q}$ lies on the strict ordered E_1 lane. Its $q \mapsto -q$ pairing is therefore a statement about completed ordered finite windows before averaging; it is not a symmetric Ran-bar identity until the ordered data have descended.

PROPOSITION 14.1.80 (*Koszulness as formality of the convolution algebra*;). Assume the genus-0 obstruction-completeness package: the transferred L_{∞} minimal model of $\mathfrak{g}_{\mathcal{A}}^{(o)}$ exists in the completed filtered category, the filtration is complete and separated with no $\lim^1$ contribution in each conformal bidegree, and every finite-degree transferred bracket is detected by the corresponding shadow obstruction class. Then a chiral algebra $\mathcal{A}$ is chirally Koszul if and only if the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ satisfies:

- (i) The shadow algebra $\mathcal{A}^{\text{sh}} = H_{\bullet}(\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A}))$ is concentrated in degree 2: $\mathcal{A}_{r,g}^{\text{sh}} = 0$ for $r \geq 3$, $g = 0$.
- (ii) The bar spectral sequence $E_1^{p,q} = H^q(F^p \mathfrak{g}_{\mathcal{A}}^{\text{mod}} / F^{p+1} \mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ degenerates at E_2 .
- (iii) The genus-0 convolution algebra $\mathfrak{g}_{\mathcal{A}}^{(o)}$ is formal as a dg Lie algebra.

These three conditions are equivalent to each other and to the unconditional core consisting of (i)–(vi) and (ix)–(x) in Theorem 14.1.59. The factorization-homology clause (vii) joins this list only after the comparison and detection hypotheses $\text{FH}_{\text{pt}}^{\text{det}}(\mathcal{A})$ are imposed.

Proof. Condition (i) states $\mathcal{A}_{r,0}^{\text{sh}} = 0$ for $r \geq 3$, i.e. all genus-0 obstruction classes $\mathcal{O}_{r+1}^{(o)}(\mathcal{A}) = 0$ for $r \geq 2$. This is the PBW concentration condition (ii) of Theorem 14.1.59, establishing (i) $\Leftrightarrow$ (ii). Condition (ii) (bar spectral sequence E_2 -collapse) is the same statement expressed in spectral sequence language. For (i) $\Leftrightarrow$ (iii): in the filtered obstruction-complete category just assumed, formality of a dg Lie algebra is equivalent to the vanishing of the transferred higher L_{∞} brackets on its minimal model. Proposition ?? identifies the genus-0 obstruction classes with the transferred L_{∞} brackets $\ell_{r+1}^{(o)}$ at degrees $r = 2, 3, 4$; at each higher degree the same inductive mechanism applies (the obstruction at degree $r+1$ is the next transferred bracket evaluated on the truncated MC element). The detection hypothesis is exactly what promotes these finite-degree identifications to formality of the completed convolution algebra. $\square$

Remark 14.1.81 (*Two transverse slices of the MC element*). The MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ carries two transverse families of invariants. *Koszulness* reads the genus-0 slice: $\mathcal{O}_{r+1}^{(o)}(\mathcal{A}) = 0$ for all $r \geq 2$ (the transferred A_{∞} products $m_r = 0$ for $r \geq 3$; Proposition ??). *Shadow depth* reads the all-genera projection: $r_{\text{max}} := \min\{r : \mathcal{O}_{s+1}(\mathcal{A}) = 0 \text{ for all } s > r\}$. These are independent:

Family	Shadow depth r_{max}	Archetype
Heisenberg	2 (finite)	Gaussian
Affine $\widehat{\mathfrak{g}}_k$	3 (finite)	Lie
$\beta\gamma$ system	4 (finite)	Contact
Virasoro Vir_c	∞	Mixed
$\mathcal{W}_N$	∞	Mixed

The generic or universal representatives in these five rows are chirally Koszul (genus-0 slice is formal), while special simple quotients can leave the Koszul locus. In the generic/universal rows the Virasoro algebra has infinite shadow depth ($\mathfrak{o}_{\text{Vir}}^{(s)} \neq 0$ at genus ≥ 1). The archetype classification (Theorem 22.5.18)

stratifies the Koszul locus by the all-genera termination behavior of $\Theta_{\mathcal{A}}$, a transverse invariant invisible to genus 0.

Remark 14.1.82 (Shadow classes under direct sum). The shadow classes $\{G, L, C, M\}$ form a join-semilattice under the ordering $G < L < C < M$, with the join operation realised by direct sum of chiral algebras. For $\mathcal{A}_1, \mathcal{A}_2$ in the standard landscape, the OPE of $\mathcal{A}_1 \oplus \mathcal{A}_2$ has no mixed singular terms between the two sectors: the $\mathcal{A}_1$ -fields and $\mathcal{A}_2$ -fields are mutually local with regular OPE. The shadow tower of the direct sum therefore decomposes sector by sector, and the shadow depth satisfies

$$r_{\max}(\mathcal{A}_1 \oplus \mathcal{A}_2) = \max(r_{\max}(\mathcal{A}_1), r_{\max}(\mathcal{A}_2)).$$

In particular:

$\mathcal{A}_1$	$\mathcal{A}_2$	$r_{\max}(\mathcal{A}_1 \oplus \mathcal{A}_2)$	Class
G	G	$\max(2, 2) = 2$	G
G	L	$\max(2, 3) = 3$	L
L	L	$\max(3, 3) = 3$	L
G	M	$\max(2, \infty) = \infty$	M
C	M	$\max(4, \infty) = \infty$	M

The entry $L \oplus L = L$ (not C) is the decisive case: two affine Kac–Moody factors at levels k_1, k_2 produce no cross-sector shadow terms at depth 4, because the quartic obstruction S_4 is intrinsic to each factor’s OPE and the mixed channels contribute only regular terms.

This join-semilattice structure is specific to direct sums. Constructions that create new OPE singularities between sectors can raise the shadow class strictly: a quantum Drinfeld–Sokolov reduction of an affine algebra (class L) produces a $\mathcal{W}$ -algebra (class M), and a coset $\mathcal{A}/\mathcal{A}'$ can land in a higher class than either factor. The shadow depth is monotone under direct sum but not under quotient or reduction.

*Remark 14.1.83 (Class **W**: root multiplicities and the Koszul boundary).* The **G/L/C/M** classification (Remark 14.1.81) presupposes chiral Koszulness: E_2 -collapse of the bar spectral sequence (Theorem 14.1.59). Beyond this boundary lies class **W** (wild), where E_2 -collapse fails and the unconditional equivalence core loses force simultaneously; seven genuinely independent bidirectional equivalences (items (i)–(v) and (ix)–(x)) and the listed consequence (vi) – and the chiral Hochschild consequence (viii) – no longer follow. The factorization-homology clause (vii) has no independent force in this regime: even when an external integration model exists, the converse to Koszulness requires the detecting comparison $\mathrm{FH}_{\mathbb{P}^1}^{\det}$, and the PBW diagonal already fails. The mechanism is controlled by the Kronecker quiver K_m (two vertices, m parallel arrows) and its root multiplicities.

Root multiplicities and higher differentials. The symmetric Euler form of K_m has determinant $4 - m^2$. For $m \leq 2$, this form is positive semi-definite: every positive root has multiplicity 1, the indecomposable representations are classified (finite type for $m = 1$, tame for $m = 2$), and the bar spectral sequence collapses at E_2 by the Kac–Moody concentration argument. For $m \geq 3$, the form is indefinite. The dimension vectors (d_0, d_1) with $d_0^2 + d_1^2 - md_0d_1 < 0$ support *families* of indecomposable representations: the moduli space $\mathcal{M}(d_0, d_1)$ has positive dimension $1 - d_0^2 - d_1^2 + md_0d_1$, and the root multiplicity exceeds 1. These multiple roots produce non-split extensions in the bar complex $\overline{B}(\mathcal{A})$:

the $E_2^{p,q}$ page acquires off-diagonal classes supported on the excess moduli, and the higher differentials d_r ($r \geq 2$) act nontrivially between them. The signed Euler series $\prod_{n \geq 1} (1 - t^n)^{m+2}$ acquires negative coefficients at weight 2, confirming the failure of bar concentration.

Why the unconditional equivalences break. Each of the seven genuinely independent bidirectional equivalences (i)–(v) and (ix)–(x) in Theorem 14.1.59, together with the listed consequence (vi), requires, at its core, that bar cohomology $H^\bullet(\bar{B}(\mathcal{A}))$ be concentrated on the PBW diagonal. In the wild regime, the excess moduli inject off-diagonal classes into H^2 (and higher) that persist to E_∞ : condition (ii) (PBW concentration) fails, and with it the equivalence chain. The conditional Lagrangian criterion (xi) and the $\mathcal{D}$ -module purity refinement (xii) are no longer consequences of the Koszul core. This is only a failure of implication; no mixed-Hodge purity failure is asserted without a separate Saito-weight computation.

Concrete sources. The following proven and conditional sources produce class $\mathbf{W}$ behavior:

- (i) *Virasoro minimal models.* The simple quotient $L(c_{p,q}, \mathfrak{o})$ is non-Koszul by Proposition 14.1.94: the null quotient at weight $w_o = (p-1)(q-1)$ enlarges $\ker(d: \bar{B}^2 \rightarrow \bar{B}^1)$, producing $H^2 \neq 0$.
- (ii) *Admissible-level simple quotients at higher rank.* For $\mathfrak{g}$ with $\text{rk}(\mathfrak{g}) \geq 2$ and denominator $q \geq 3$, the abelian Cartan subalgebra $\mathfrak{h}$ contributes $\text{rk}(\mathfrak{g})$ candidate classes to $E_1^{2,q}$. At $\text{rk}(\mathfrak{g}) = 2$ and $q = 3$, their survival follows conditionally from the finite admissible Li–bar package of Theorem 14.1.43. The rank-two case with $q > 3$ awaits the incoming d_1 calculation; the higher-rank case is conjectural (Conjecture 14.1.44).
- (iii) *Non-principal $\mathcal{W}$ -algebras at wild nilpotent type.* Under the expected finite DS–Li comparison, quantum Drinfeld–Sokolov reduction at a nilpotent e whose associated Slodowy slice has wild representation type should produce a $\mathcal{W}$ -algebra whose Ext quiver has $m \geq 3$ arrows, so the resulting bar complex would inherit the wild root structure.

The replacement for the shadow obstruction tower in class $\mathbf{W}$ is the motivic Donaldson–Thomas theory of Kontsevich–Soibelman: the DT invariants $\Omega(d_o, d_1)$ grow exponentially in $\max(d_o, d_1)$ for $m \geq 3$, and their wall-crossing structure encodes the information that the shadow tower would carry in the Koszul world (Remark ??).

14.1.5.1 KOSZULNESS FROM SKLYANIN POISSON COHOMOLOGY

The Koszulness meta-theorem (Theorem 14.1.59) characterizes chiral Koszulness intrinsically, through the bar complex and its spectral sequences. The next proposition gives a Poisson-geometric characterization that applies on the affine Kac–Moody locus after an explicit Sklyanin–bar comparison, and is then logically independent of the PBW spectral sequence.

The classical r -matrix $r^{\text{cl}}(z) = k\Omega_{\text{tr}}/z$ of an affine algebra $\mathcal{A} = \widehat{\mathfrak{g}}_k$ defines a Sklyanin–Poisson bracket on $\mathfrak{g}^*$ via the Semenov–Tian–Shansky construction [?STS83]. The infinitesimal rigidity of this bracket (vanishing of its second Poisson cohomology) becomes a Koszulness criterion only after the finite-window comparison identifies the PBW associated graded of the ordered bar deformation complex with the Lichnerowicz–Poisson complex.

THEOREM 14.1.84 (*Koszulness from Sklyanin–Poisson rigidity; for affine KM*). For $\mathcal{A} = \widehat{\mathfrak{g}}_k$ with $\mathfrak{g}$ semisimple at generic non-critical level, the Sklyanin–Poisson bracket $\{-, -\}_{\text{STS}}$ on $\mathfrak{g}^*$ determined by the classical r -matrix $r^{\text{cl}}(z) = k\Omega_{\text{tr}}/z$ has vanishing second Poisson cohomology:

$$H_\pi^2(\mathfrak{g}^*, \{-, -\}_{\text{STS}}) = 0.$$

Consequently the Sklyanin bracket is infinitesimally rigid: every first-order Poisson deformation is trivial. Assume, in addition, the Sklyanin–bar comparison package: in each finite PBW window the

associated graded of the ordered bar deformation complex is the polynomial Lichnerowicz complex $(\mathfrak{X}^\bullet(\mathfrak{g}^*), [\pi_{\text{STS}}, -]_{\text{SN}})$, and degree-two Poisson rigidity detects all off-diagonal bar classes. Under this package, rigidity gives a Poisson-geometric proof of E_2 -collapse independent of the PBW spectral sequence.

Proof. The Sklyanin bracket $\pi_{\text{STS}} = \pi_{\text{LP}} + \pi_r$ decomposes as the Lie–Poisson bracket π_{LP} (the Kirillov–Kostant structure on $\mathfrak{g}^*$) plus a constant-coefficient bivector π_r from the symmetric part of the r -matrix. The Lichnerowicz–Poisson complex $(\mathfrak{X}^\bullet(\mathfrak{g}^*), \delta_\pi = [\pi_{\text{STS}}, -]_{\text{SN}})$ computes the Poisson cohomology $H_\pi^\bullet$.

Filter the Poisson complex by polynomial degree on $\mathfrak{g}^*$. The E_0 page is the Chevalley–Eilenberg complex $C_{\text{CE}}^\bullet(\mathfrak{g}, \text{Sym}^p(\mathfrak{g}^*))$ in each polynomial stratum p ; the constant correction π_r contributes only at the E_0 level. Whitehead’s second lemma gives $H_{\text{CE}}^2(\mathfrak{g}, M) = 0$ for every finite-dimensional $\mathfrak{g}$ -module M when $\mathfrak{g}$ is semisimple (Weibel [Weibel194], Theorem 7.8.10). In particular $H_{\text{CE}}^2(\mathfrak{g}, \text{Sym}^p(\mathfrak{g}^*)) = 0$ for all $p \geq 0$. The spectral sequence degenerates at E_1 and yields $H_\pi^2(\mathfrak{g}^*, \pi_{\text{STS}}) = 0$.

The explicit verification for $\mathfrak{g} = \mathfrak{sl}_2$ (the three-dimensional Lichnerowicz complex on $\mathbb{C}^3$, carried out in `compute/lib/theorem_sklyanin_poisson_cohomology_engine.py`; 57 tests, three independent verification paths: direct kernel/image, CE comparison, and polynomial-degree spectral sequence) confirms $H_\pi^0 = \mathbb{C}[C_2]$ (Casimir ring), $H_\pi^1 = H_\pi^2 = H_\pi^3 = 0$.

Comparison with Koszulness: the vanishing $H_\pi^2 = 0$ means the Sklyanin bracket on $\mathfrak{g}^*$ has no non-trivial infinitesimal deformations. The associated graded of the ordered bar deformation complex carries the Chevalley–Eilenberg coalgebra on $\mathfrak{g}^*$ as its semiclassical shadow; rigidity of the Sklyanin bracket is the Poisson-geometric avatar of bar E_2 -collapse (condition (ii) of Theorem 14.1.59). The Sklyanin–bar comparison hypothesis is precisely the assertion that this semiclassical shadow is faithful in finite PBW windows: the Poisson complex $(\mathfrak{X}^\bullet, \delta_\pi)$ is the associated graded of the ordered bar deformation complex, and degree-two Poisson cohomology controls the first possible off-diagonal bar obstruction. Under that comparison, $H_\pi^2 = 0$ rules out the obstruction and gives the claimed independent route to E_2 -collapse. $\square$

Remark 14.1.85 (Scope and the class M obstruction). The Sklyanin rigidity proof applies to affine Kac–Moody algebras (shadow classes G and L), where the classical r -matrix is rational of order 1 and the resulting Poisson bracket is algebraic (polynomial coefficients on $\mathfrak{g}^*$). For class M algebras (Virasoro, $\mathcal{W}_N$), the collision residue has higher-order poles producing *differential* Poisson brackets of order ≥ 2 in the sense of [LPV13]. The Lichnerowicz complex for such brackets lies outside the scope of Whitehead’s lemma: H_{CE}^2 controls only the algebraic (order-0) sector. Extending the Sklyanin rigidity proof to class M requires a theory of differential Poisson cohomology that does not yet exist. This is a conditional 14th characterization of chiral Koszulness, restricted to the affine KM subclass and to the Sklyanin–bar comparison package. On that subclass it is logically independent of the PBW spectral sequence and provides a second, Poisson-geometric route to E_2 -collapse.

14.1.6 The Koszulness moduli scheme

The classical meta-theorem presents Koszulness through a list of equivalent conditions. The list reorganizes as a moduli scheme: the conditions are *charts* on a GRT_1 -torsor $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$, and the GRT_1 -action on Drinfeld associators is the torsor structure. This is the Kontsevich–Tamarkin principle made operational for a fixed chiral algebra.

Definition 14.1.86 (Koszulness moduli scheme). Let $\mathcal{A}$ be a chiral algebra on X with PBW filtration. The *Koszulness moduli scheme* $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ is the affine $\mathbb{Q}$ -scheme representing the functor

$$R \longmapsto \{(\Phi, c_\Phi) : \Phi \in \text{Assoc}(R), c_\Phi \in \text{Chart}_\Phi(\mathcal{A}; R)\}$$

where $\text{Assoc}(R)$ is the Drinfeld associator torsor [?Drinfeld90] and $\text{Chart}_\Phi(\mathcal{A}; R) = \{(\Pi_\Phi, \text{wit}_\Phi, \gamma_\Phi)\}$ is the chart set: a Koszulness predicate Π_Φ depending on $(\mathcal{A}, \Phi)$, a witness $\text{wit}_\Phi(\mathcal{A})$, and a Tamarkin transition cocycle $\gamma_\Phi: \Phi \rightsquigarrow \Phi'$ to every other associator, satisfying the coherence $\Pi_\Phi(\mathcal{A}) \iff \Pi_{\Phi \cdot g}(\mathcal{A})$ for $g \in \text{GRT}_1(R)$.

THEOREM 14.1.87 (Koszulness moduli;). Let $\mathcal{A}$ be a chirally Koszul chiral algebra. Then $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ is an affine $\mathbb{Q}$ -scheme with:

- (A1) $\mathcal{M}_{\text{Kosz}}(\mathcal{A}) \neq \emptyset$ if and only if $\mathcal{A}$ is chirally Koszul;
- (A2) the projection $\mathcal{M}_{\text{Kosz}}(\mathcal{A}) \rightarrow \text{Spec}(\text{Assoc})$ is a GRT_1 -torsor: transitions between charts are Tamarkin Φ -transfer maps, and the cocycle computation closes in GRT_1 ;
- (A3) the fourteen admissible atlas charts of Theorem 16.3.1 form a finite affine atlas: charts $U_1, \dots, U_{10}$ at Φ_{KZ} ; U_{11} at Φ_{AT} ; U_{12} at $\Phi_{\text{dR}, \text{B}}$; U_{13} at Φ_{ell} ; U_{14} at Φ_{Kon} ;
- (A4) the shadow-class stratification $G \sqcup L \sqcup C \sqcup M \sqcup FF$ selects a distinguished chart on each stratum, respectively Φ_{KZ} , Φ_{ell} , Φ_{AT} , $\Phi_\infty = \Phi_{\text{Kon}}$, and $\Phi_{\text{dR}, \text{B}}$.

Proof. The argument has four parts, one for each axiom.

(A1). Definition 14.1.3 is GRT_1 -invariant: acyclicity of the twisted tensor product $K_\tau^L(\mathcal{A}, \tilde{\mathbf{B}}(\mathcal{A}))$ is preserved under the Tamarkin transfer $\tau \mapsto \Phi \cdot \tau$ (the transfer is by construction a quasi-isomorphism between $\mathbf{A}_\infty$ -structures). Hence the chart set is non-empty exactly when Koszulness holds.

(A2). Fix the KZ associator as base point. For any $\Phi \in \text{Assoc}$, there is a unique $g_\Phi \in \text{GRT}_1$ with $\Phi = \Phi_{\text{KZ}} \cdot g_\Phi$ (the associator torsor is principal). The Tamarkin transfer $g_\Phi^*: \text{Chart}_{\Phi_{\text{KZ}}}(\mathcal{A}) \xrightarrow{\sim} \text{Chart}_\Phi(\mathcal{A})$ is a bijection of chart sets, and strict associativity of associator composition in GRT_1 gives the cocycle condition $g_{\Phi''} = g_{\Phi'} \cdot h_{\Phi' \rightarrow \Phi''}$. This is exactly the torsor property.

(A3). Conditions (i)–(x) of Theorem 14.1.59 are stated in the KZ language (PBW, bar, $\mathbf{A}_\infty$, BBL, FM) and their coherence data is the KZ associator; they cover a Zariski-open neighbourhood of Φ_{KZ} . The four supplementary charts $U_{11}, \dots, U_{14}$ are established by direct argument at their own associators in the standalone paper [?LorgatMKD1_stand, Propositions 2.5–2.8], which imports the Alekseev–Torossian associator [?AT12], the de Rham–Betti associator [?Deligne89], the Enriquez elliptic associator [?Enriquez14], and the Kontsevich integral associator [?Kontsevich93].

(A4). The shadow class is an intrinsic invariant of the MC element $\Theta_{\mathcal{A}}$. The selection of a distinguished chart on each stratum is determined by the computational complexity of the shadow algebra bracket $[-, -]^{\text{sh}}$: class G admits a trivial KZ coordinate (abelian shadow); class L activates the genus-one elliptic coupling (Enriquez Φ_{ell}); class C requires the AT Kashiwara–Vergne diagonalization of the quartic bracket; class M needs the full Kontsevich expansion; and the Feigin–Frenkel locus needs Hodge–Betti purity. $\square$

Remark 14.1.88 (Kontsevich–Tamarkin reformulated). The Kontsevich–Tamarkin formality theorem [?Kontsevich99, ?Tamarkin03] asserts that formality of little disks holds universally but depends on an associator choice. The moduli scheme $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ gives this content at the level of a single algebra: chiral Koszulness is a GRT_1 -invariant property; the classical characterizations are GRT_1 -coordinate charts. Switching between two classical criteria is an application of the Tamarkin Φ -transfer.

Remark 14.1.89 (Comparison packages). The moduli scheme isolates two comparison packages. (Virasoro Koszulness, circular bar–cobar): the Hodge–Betti chart U_{12} would provide a non-circular proof via Feigin–Fuchs BGG resolution [?FeiginFuchs90, ?RCW82] and Kac determinant non-degeneracy [?KacBook] after the polarizable Hodge–Betti realization of the Virasoro bar complex is constructed (Theorem 14.1.90). The unconditional proof remains the PBW proof of Theorem 14.1.26. (Yangian chiral lift): the associative Koszulness of $Y_h(\mathfrak{g})$ (Proposition 14.2.2) is refined to an open embedding $\mathcal{M}_{\text{Kosz}}^{\text{assoc}}(Y_h) \hookrightarrow \mathcal{M}_{\text{Kosz}}^{\text{chiral}}(Y_h)$; the open question is chart-surjectivity (Theorem 14.1.91).

THEOREM 14.1.90 (Hodge–Betti lane for Virasoro Koszulness;). For Vir_c at c outside the minimal-model lattice $\{c_{p,q}\}$, assume a polarizable Hodge–Betti realization of the Feigin–Fuchs resolution whose induced weight filtration on $\bar{\mathbf{B}}_n(\text{Vir}_c)$ agrees with the PBW bar filtration in every finite window. Then the bar cohomology weight components satisfy

$$H^\bullet(\text{Vir}_c, \text{Vir}_c)_{\text{weight } r+1} = 0 \quad \text{for all } r \geq 2,$$

without appeal to bar–cobar inversion.

Proof. Work at the Hodge–Betti chart U_{12} , centered at $\Phi_{\text{dR},B}$ [?Deligne89].

Step 1: Feigin–Fuchs BGG resolution. For each highest weight h in the vacuum Verma module $M_o(c)$ of Vir_c , the Feigin–Fuchs theorem [?FeiginFuchs90], elaborated by Rocha-Caridi and Wallach [?RCW82], constructs a resolution of the vacuum irreducible by Verma modules indexed by an affine Weyl group orbit:

$$\cdots \rightarrow \bigoplus_{w \in W^{(2)}} M_{w \cdot o}(c) \rightarrow \bigoplus_{w \in W^{(1)}} M_{w \cdot o}(c) \rightarrow M_o(c) \rightarrow L(c, o) \rightarrow 0,$$

with differentials given by singular-vector embeddings. At $c \notin \{c_{p,q}\}$, every singular-vector embedding is nonzero and the resolution is exact.

Step 2: Kac determinant non-degeneracy. The Kac determinant [?KacBook, ?FeiginFuchs90] at weight h is

$$\det G_h = \prod_{\substack{p,q \geq 1 \\ pq \leq h}} (h - h_{p,q}(c))^{P(h-pq)},$$

where $h_{p,q}(c)$ are the Kac values and P is the partition function. At $c \notin \{c_{p,q}\}$, $\det G_h \neq 0$ for every bar-relevant weight h ; the BGG resolution embeds faithfully in the bar complex.

Step 3: Conditional purity by Saito stability. Under the Hodge–Betti hypothesis, each Verma module $M_{w \cdot o}(c)$ has a polarizable mixed-Hodge realization whose PBW associated graded is pure of weight equal to its conformal weight. Saito’s stability theorem [?Saito] then propagates purity through the exact sequence: the iterated bar complex $\bar{\mathbf{B}}_n(\text{Vir}_c)$ is pure of weight n in each finite window.

Step 4: Off-diagonal weight vanishing. Purity of weight n on $\bar{\mathbf{B}}_n$ forces $H^\bullet(\text{Vir}_c, \text{Vir}_c)_{\text{weight } r+1} = 0$ for every $r \geq 2$ off the Koszul diagonal: any nonzero class in weight $r+1 \neq n$ would violate purity.

The four steps use Feigin–Fuchs (1), Kac (2), the assumed Hodge–Betti/Saito comparison (3), and purity (4). Bar–cobar inversion is not invoked. The open input is exactly the polarizable Hodge–Betti realization and its equality with the PBW bar filtration; without it this theorem does not prove $\mathcal{D}$ -module purity for Virasoro. $\square$

THEOREM 14.1.91 (Yangian chart inclusion;). For the Yangian $Y_h(\mathfrak{g})$ with $\mathfrak{g}$ simple, assume that the evaluation-module construction defines a finite-PBW E_1 -chiral avatar and that the chart-comparison

functor is representable and reflects the Shapovalov open locus. Then the associative Koszulness moduli embeds as an open subscheme of the chiral Koszulness moduli:

$$\mathcal{M}_{\text{Kosz}}^{\text{assoc}}(Y_h) \hookrightarrow \mathcal{M}_{\text{Kosz}}^{\text{chiral}}(Y_h).$$

The embedding is GRT_1 -equivariant; the open question is chart-surjectivity: whether every chiral chart lifts an associative one. The theorem is a conditional comparison of moduli functors, not a proof that every Yangian chart has already been constructed in the chiral atlas.

Proof. At $\Phi = \Phi_{\text{KZ}}$, the associative chart U_1^{assoc} detects Yangian Koszulness in the classical sense of Proposition 14.2.2: PBW flatness $Y_h \rightsquigarrow \text{Sym}(V)$, RTT quadraticity, the QYBE for the quantum line kernel $R(z) = 1 + \hbar r(z) + O(\hbar^2)$, and local finiteness. By the assumed finite-PBW E_1 -chiral avatar, the Yangian carries the required chiral structure on the formal disk via its evaluation modules V_u , and the PBW filtration is compatible with the chiral bracket. The associative chart coordinate $(\Phi_{\text{KZ}}, c_{\text{KZ}}^{\text{assoc}})$ maps to $(\Phi_{\text{KZ}}, c_{\text{KZ}}^{\text{chiral}})$: both detect E_2 -collapse of the same PBW spectral sequence (the associative one on Y_h , the chiral one on its E_1 -chiral avatar). The classical residue $r(z)$ satisfies the CYBE by the Arnold relation, but this checks only the semiclassical part of the chart. The chart inclusion uses the RTT-complete quantum lift and the QYBE input; a bare CYBE solution does not define a Yangian chart. The map is defined on the whole associative moduli by GRT_1 -equivariance. By the second hypothesis, the chart U_1^{assoc} is the complement of the Shapovalov zero locus and its preimage in the chiral moduli is the complement of the same zero locus. Hence the comparison morphism is an open immersion on the comparison component. $\square$

Remark 14.1.92 (Chart-surjectivity). For $\mathfrak{g} = \mathfrak{sl}_2$ the embedding is an isomorphism (the Yangian has no genuinely chiral Koszul data beyond the associative PBW). For higher rank, surjectivity is open and is the precise content of the chart-surjectivity problem: do there exist chiral charts $(\Phi, c_{\Phi}^{\text{chiral}})$ detecting Koszulness that have no associative preimage? The moduli reformulation strips the question of all phrasing ambiguity.

14.1.7 Koszulness and the conformal bootstrap

THEOREM 14.1.93 (*Koszulness implies bootstrap closure*;). Let $\mathcal{A}$ be a chirally Koszul chiral algebra. Then:

- (i) The Maurer–Cartan moduli $\text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ is discrete (zero-dimensional): the MC element $\Theta_{\mathcal{A}}$ is the unique solution, determined by the genus-0 OPE data.
- (ii) The shadow depth $r_{\text{max}}(\mathcal{A})$ equals the bootstrap closure order: the number of OPE channels at which the crossing equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ at degree $n = 4$ is satisfied.
- (iii) The shadow depth classification corresponds to bootstrap complexity: class G has no OPE corrections beyond leading order, class L has one cubic correction (the pentagon identity), class C terminates at the quartic, class M requires the infinite tower.

The MC equation at $(g=0, n=4)$ is the crossing equation for the four-point function.

Proof. (i) By Koszul concentration, the off-diagonal deformation complex of $H^*(\overline{B}(\mathcal{A}))$ is acyclic. The remaining diagonal operations are the shadow classes of $\mathcal{A}$; they are fixed by the genus-0 OPE data and are not moduli. The MC moduli is therefore zero-dimensional, and uniqueness of $\Theta_{\mathcal{A}}$ follows from the bar-intrinsic construction (Theorem ??).

(ii) The MC equation projected to degree $r+1$ determines $o_{r+1}(\mathcal{A})$ from $\Theta_{\mathcal{A}}^{\leq r}$ (Lemma 22.15.10). The shadow depth $r_{\max}$ is the smallest r such that $o_{r+1} = 0$ identically. At degree 4, the MC equation is the crossing constraint for the four-point function $\langle TTTT \rangle$: both express the vanishing of the obstruction class in $H^2(\text{Def}_{\text{cyc}}^{\text{mod}})$ at weight 4.

(iii) Class G : $S_3 = S_4 = 0$, so the crossing equation is automatically satisfied (no corrections). Class L : $S_3 \neq 0$, $S_4 = 0$; one cubic crossing constraint (the pentagon identity on five FM boundary strata of $\mathcal{M}_{0,5}$). Class C : $S_4 \neq 0$, $S_5 = 0$; two crossing levels. Class M : all $S_r \neq 0$; infinite tower. $\square$

PROPOSITION 14.1.94 (*Minimal model non-Koszulness*;). Let $L(c_{p,q}, 0)$ be a non-trivial unitary minimal model with first vacuum singular vector at weight $w_0 = (p-1)(q-1)$. The simple quotient $L(c_{p,q}, 0)$ is *not* chirally Koszul: the bar cohomology $H^2(\overline{B}(L(c_{p,q}, 0)))_{w_0} \neq 0$.

The mechanism is structural: the null quotient removes a generator from $\overline{B}^1$ at weight w_0 while leaving the domain $\overline{B}^2$ at weight w_0 unchanged (all tensor factors have weight $< w_0$). The differential $d: \overline{B}^2 \rightarrow \overline{B}^1$ therefore acquires a larger kernel, producing new cocycles in H^2 .

Proof. At weight w_0 , the universal Virasoro Verma module has $p(w_0)$ states (unrestricted partitions of w_0 into parts ≥ 2), and the simple quotient removes one null state. Thus $\dim \overline{B}_{w_0}^1(V_c) = p(w_0)$ while $\dim \overline{B}_{w_0}^1(L) = p(w_0) - 1$. The domain $\overline{B}_{w_0}^2$ consists of tensor products $s^{-1}a \otimes s^{-1}b$ with $|a| + |b| = w_0$ and $|a|, |b| \geq 2$, which is determined by weights $< w_0$ and is therefore unaffected by the null quotient. For the Ising model $M(4, 3)$: $w_0 = 6$, $p(6) = 4$, $\dim \overline{B}_6^1(L) = 3$, $\dim \overline{B}_6^2 = 5$, and the Euler characteristic shifts from 0 (universal) to 1 (simple quotient), confirming $H_6^2 \neq 0$. $\square$

14.1.8 Completion kinematics: the primitive cumulant spectrum

The shadow obstruction tower probes the *dynamic* axis of the completed bar theory: the OPE structure, curvature, and modular anomaly. The complementary *kinematic* axis depends only on the vacuum character of $\mathcal{A}$. The central objects (the primitive cumulant quotients, their generating series, and the completion entropy) are character-level invariants that control the combinatorial growth of the completed bar coalgebra, independently of any curvature parameter.

Definition 14.1.95 (*Primitive cumulant quotient*;). Let $\mathcal{A} = \mathbf{1} \oplus \tilde{\mathcal{A}}$ be a conformal chiral algebra with finite-dimensional weight spaces $\mathcal{A}[h]$, $h \geq 0$. Assume the translation operator $\partial: \mathcal{A}[h-1] \rightarrow \mathcal{A}[h]$ is injective on positive weights (away from null loci, i.e. when $\det G_h \neq 0$ in the Kac–Shapovalov sense of Theorem 14.1.40). The *primitive cumulant quotient* at weight h is

$$Q_h(\mathcal{A}) := \mathcal{A}[h] / \partial \mathcal{A}[h-1].$$

These are the quasi-primary (or primitive) cumulant spaces: the new degrees of freedom at each conformal weight that are not descendants of lower-weight fields.

Definition 14.1.96 (*Primitive generating series*;). Let $a_h := \dim \mathcal{A}[h]$ and write the vacuum character as $\chi_{\mathcal{A}}(q) = 1 + \sum_{h \geq 1} a_h q^h$. Set $g_r := \dim Q_{r+1}(\mathcal{A})$. The *primitive generating series* is

$$G_{\mathcal{A}}(t) := \sum_{r \geq 1} g_r t^r = \frac{1-t}{t} (\chi_{\mathcal{A}}(t) - 1).$$

Equivalently, $g_r = a_{r+1} - a_r$ for all $r \geq 1$.

Canonical extraction. The primitive spectrum is read off directly from the vacuum character: $G_{\mathcal{A}}$ depends only on the sequence $(a_1, a_2, a_3, \dots)$ and no further algebraic data.

Definition 14.1.97 (Completion Hilbert series;). The *completion Hilbert series* of $\mathcal{A}$ is the associated-graded window series of the completed cumulant bar coalgebra:

$$H_{\mathcal{A}}(t) := \frac{G_{\mathcal{A}}(t)}{1 - G_{\mathcal{A}}(t)} = \sum_{q \geq 1} h_q t^q,$$

where h_q counts exact reduced-weight- q bar words in the ideal cumulant model. This is the nonempty ordered-word series on the primitive alphabet $\{g_1, g_2, g_3, \dots\}$: the coefficient h_q enumerates ordered concatenations of primitive generators whose reduced weights sum to q .

Definition 14.1.98 (Primitive defect series;). For a chiral algebra with declared strong generators of conformal weights $d_1, \dots, d_s$, the *primitive defect series* is

$$\Delta_{\mathcal{A}}^{\text{prim}}(t) := G_{\mathcal{A}}(t) - \sum_{i=1}^s t^{d_i-1}.$$

The defect vanishes identically for quadratic (or free-like) behaviour: $\Delta_{\mathcal{A}}^{\text{prim}} = 0$ when the declared generators account for all quasi-primaries at every weight. Nonzero defect detects precisely those weights at which nonquadratic OPEs force new primitive cumulants beyond the declared generators.

Definition 14.1.99 (Koszul radius and completion entropy;). Define the *Koszul radius* $\rho_{\mathcal{A}}$ as the smallest positive real root of

$$G_{\mathcal{A}}(\rho_{\mathcal{A}}) = 1.$$

The *completion entropy* is

$$h_K(\mathcal{A}) := \log(\rho_{\mathcal{A}}^{-1}).$$

This is the exponential growth rate of the ideal reduced-weight bar windows: $h_q \sim e^{q \cdot h_K(\mathcal{A})}$ as $q \rightarrow \infty$. The completion entropy is *kinematic*: it depends only on the primitive spectrum $(g_1, g_2, \dots)$, hence only on the vacuum character, and not on curvature parameters such as c or k .

Remark 14.1.100 (Kinematics versus dynamics). The completed bar theory separates into two orthogonal axes:

- (i) *Completion kinematics*: $Q(\mathcal{A}), G_{\mathcal{A}}(t), H_{\mathcal{A}}(t), h_K(\mathcal{A})$; depends only on the vacuum character.
- (ii) *Modular dynamics*: $D_{\mathcal{A}}, \kappa(\mathcal{A}), \Theta_{\mathcal{A}}, r_{\mathcal{A}}(z)$; depends on the full OPE structure, curvature, anomaly.

The Virasoro involution $c \mapsto 26 - c$ changes dynamic data (it sends κ_c to κ_{26-c}) but does not alter the completion entropy: $h_K(\text{Vir}_c) = h_K(\text{Vir}_{26-c})$ for all c , since both algebras share the same vacuum character. The same-family shadow Vir_{26-c} lives on the dynamic axis (Remark ??); kinematically, even generic Virasoro has infinitely many primitive cumulants, with $g_r = p(r+1) - p(r)$ growing without bound.

This separation is structurally clean: the primitive spectrum determines *how large* the completed bar coalgebra is (how many words at each reduced weight), while the OPE data determines *what the differential does* on those words. Both axes are needed for the full MC₄ theory (Theorem 9.1.28).

PROPOSITION 14.1.101 (Cumulant-to-window inversion;). The cumulant law is invertible: from the window counts $(h_1, h_2, \dots)$ one recovers the hidden primitive spectrum $(g_1, g_2, \dots)$ by the recursion

$$g_1 = h_1, \quad g_q = h_q - \sum_{r=1}^{q-1} g_r h_{q-r} \quad (q \geq 2).$$

Proof. The identity $H_{\mathcal{A}} = G_{\mathcal{A}}/(1 - G_{\mathcal{A}})$ is equivalent to $G_{\mathcal{A}} = H_{\mathcal{A}}/(1 + H_{\mathcal{A}})$, or at the level of formal power series,

$$G_{\mathcal{A}}(t) = H_{\mathcal{A}}(t) - G_{\mathcal{A}}(t) H_{\mathcal{A}}(t).$$

Extracting the coefficient of t^q gives $g_q = h_q - \sum_{r=1}^{q-1} g_r h_{q-r} - g_q h_0$; since $h_0 = 0$ (no nonempty words of weight 0), the formula follows by induction on q . $\square$

Remark 14.1.102 (The primitive defect as a Koszulness probe). For a quadratic chiral algebra $\mathcal{A}$ with generators of weights $d_1, \dots, d_s$, the PBW basis ensures that all quasi-primaries are generated by the declared strong generators, so $\Delta_{\mathcal{A}}^{\text{prim}} = 0$ identically. The Virasoro algebra Vir_c has a single strong generator of weight 2 and $g_r = p(r+1) - p(r)$ for all $r \geq 1$, giving primitive defect $\Delta_{\text{Vir}}^{\text{prim}}(t) = G_{\text{Vir}}(t) - t$, which is nonzero starting at t^3 . This nonvanishing defect is the kinematic signature of nonquadraticity and feeds directly into the MC4 completion package (§??).

14.1.9 Geometric bar-cobar duality (Theorem A)

Under $H_{\mathbb{D}}^{\text{bar}}(\mathcal{A})$, the formula

$$K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}}^{\text{cont}} B_X^{\text{cont}}(\mathcal{A})$$

defines a post-Verdier factorization algebra. A chiral Koszul pair supplies the further comparison between this algebra and the opposite member of the pair.

THEOREM 14.1.103 (Geometric bar-cobar duality;). [Type signature: Open quadrant; complete factorization presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis packages H_{CL} and $H_{\mathbb{D}}^{\text{bar}}$, together with the pair maps θ_{12}, θ_{21} .] The unit maps in part (1) are equivalences in the derived category of conilpotent complete factorization coalgebras on $\text{Ran}(X)$. The counit maps in part (1) are equivalences of complete augmented factorization algebras for the chiral tensor product. The maps in parts (2)–(3) are equivalences of augmented algebras in the post-Verdier $*$ -tensor factorization category.

The Heisenberg instance was verified in §2.6. In general:

Let $(\mathcal{A}_1, C_1, \tau_1, F_{\bullet})$ and $(\mathcal{A}_2, C_2, \tau_2, F_{\bullet})$ be a chiral Koszul pair in the sense of Definition 14.1.19. Then:

- (i) the canonical unit maps are weak equivalences of conilpotent complete factorization coalgebras, and the canonical counit maps are quasi-isomorphisms of factorization algebras:

$$C_i \xrightarrow{\sim} \bar{B}_X(\mathcal{A}_i), \quad \Omega_X(C_i) \xrightarrow{\sim} \mathcal{A}_i \quad (i = 1, 2);$$

- (ii) contravariance of Verdier duality and the pair maps define equivalences of post-Verdier algebras

$$\nu_{12} := \theta_{12} \circ \mathbb{D}_{\text{Ran}}(\eta_1): K_X(\mathcal{A}_1) \xrightarrow{\sim} \mathcal{A}_2, \quad \nu_{21} := \theta_{21} \circ \mathbb{D}_{\text{Ran}}(\eta_2): K_X(\mathcal{A}_2) \xrightarrow{\sim} \mathcal{A}_1;$$

- (iii) if $\mathcal{A}_2$ is denoted by $\mathcal{A}_1^!$, then

$$K_X(\mathcal{A}_1) \xrightarrow[\nu_{12}]{\sim} \mathcal{A}_1^!, \quad K_X(\mathcal{A}_1^!) \xrightarrow[\nu_{21}]{\sim} \mathcal{A}_1.$$

For a quadratic presentation, the further map $\mathbb{D}(q_{\mathcal{A}_1}): K_X(\mathcal{A}_1) \rightarrow \mathbb{D}\mathcal{A}_1^!$ is the Verdier transpose of quadratic recognition.

Proof. Part (1) is the fundamental theorem of chiral twisting morphisms (Theorem 14.1.13): the Koszulness conditions (Definition 14.1.3) are equivalent to the unit maps being weak equivalences of factorization coalgebras and the counit maps being quasi-isomorphisms of factorization algebras. Let

$$\eta_i: C_i \xrightarrow{\sim} \overline{B}_X(\mathcal{A}_i)$$

be the unit equivalence from part (1). Applying $\mathbb{D}_{\text{Ran}}$ to η_i gives

$$K_X(\mathcal{A}_i) = \mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}_i) \xrightarrow{\sim} \mathbb{D}_{\text{Ran}}(C_i).$$

Composing with θ_{12} gives ν_{12} . The same argument with the indices exchanged gives ν_{21} . Part (3) is the same statement after naming $\mathcal{A}_2$ as the Koszul dual $\mathcal{A}_1^\dagger$. $\square$

Remark 14.1.104 (∞ -categorical presentation of the bar–cobar argument). Theorem 14.1.103 admits the following ∞ -categorical presentation of the same Koszul-effectivity and Verdier-compatibility argument from the formulation of Remark 14.1.110. In the stable presentable ∞ -category of augmented factorization algebras on $\text{Ran}(X)$, the role of the terminal algebra k is played by the unit object ω_X . For an augmentation $\varepsilon: \mathcal{A} \rightarrow \omega_X$, the associated simplicial bar object $\text{Bar}_\bullet(\omega_X, \mathcal{A}, \omega_X)$ is the Čech nerve of ε , and its geometric realization is the bar coalgebra $\overline{B}_X(\mathcal{A})$ [?HA, Chapter 5, especially §§5.2.2–5.2.4]. Dually, a coaugmented conilpotent coalgebra C has a cosimplicial cobar object obtained from the dual Čech nerve, and its totalization is $\Omega_X(C)$ by the same bar/cobar formalism [?HA, Chapter 5, especially §§5.2.3–5.2.4]. The general realization/totalization adjunction therefore produces the functor pair

$$\overline{B}_X: \text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X)) : \Omega_X.$$

In this ∞ -categorical formulation, the Koszul locus of the chapter is the locus where these Čech and co-Čech resolutions are effective, so the unit and counit are equivalences there. This recovers part (1) without passing through the filtered comparison from the simplicial bar object to the explicit dg model.

For part (2), continuous Verdier duality reverses the unit $\eta_i: C_i \rightarrow B_X(\mathcal{A}_i)$ and gives

$$K_X(\mathcal{A}_i) = \mathbb{D}_{\text{Ran}} B_X(\mathcal{A}_i) \xrightarrow{\mathbb{D}(\eta_i)} \mathbb{D}_{\text{Ran}} C_i \xrightarrow{\theta_{12}} \mathcal{A}_2.$$

Theorem 8.0.35 gives the separate natural equivalence $\Omega_X^{\text{geom, cont}}(\mathbb{D}_X \mathcal{A}_i) \simeq K_X(\mathcal{A}_i)$. The cobar in this formula has the coalgebra $\mathbb{D}_X \mathcal{A}_i$ as its argument.

Thus the ∞ -categorical presentation uses the same Koszul-effectivity and continuous duality packages as the dg presentation. The maps θ_{ij} contain the family-specific identification with the opposite algebra.

PROPOSITION 14.1.105 (*Relative extension from relative Verdier base change;*). Let $\pi: \mathcal{X} \rightarrow S$ be a family of smooth projective curves. Suppose given relative factorization data

$$(\mathcal{A}_{1,S}, C_{1,S}, \tau_{1,S}, F_\bullet), \quad (\mathcal{A}_{2,S}, C_{2,S}, \tau_{2,S}, F_\bullet)$$

together with relative algebra-level Verdier identifications

$$\theta_{12,S}: \mathbb{D}_{\text{Ran}(\mathcal{X}/S)}^{\text{cont}}(C_{1,S}) \xrightarrow{\sim} \mathcal{A}_{2,S}, \quad \theta_{21,S}: \mathbb{D}_{\text{Ran}(\mathcal{X}/S)}^{\text{cont}}(C_{2,S}) \xrightarrow{\sim} \mathcal{A}_{1,S},$$

whose geometric fibers are chiral Koszul pairs in the sense of Definition 14.1.19. Assume:

- (a) each relative bar component is represented on the relative Fulton–MacPherson spaces by a bounded complex of relative holonomic $\mathcal{D}$ -modules;

- (b) for every geometric point $s \rightarrow S$, the canonical base-change morphism

$$s^* \mathbb{D}_{\mathrm{Ran}(X/S)} \overline{B}_{X/S}(\mathcal{A}_{i,S}) \longrightarrow \mathbb{D}_{\mathrm{Ran}(X_s)} \overline{B}_{X_s}(\mathcal{A}_{i,s})$$

is an isomorphism;

- (c) the unit and counit quasi-isomorphisms of Theorem 14.1.103(1) commute with pullback to geometric fibers.

Then the equivalences of Theorem 14.1.103 assemble into equivalences of relative factorization algebras over S , functorial under base change in S .

For the universal smooth curve over $\mathcal{M}_{g,n}$, the additional inputs beyond Theorem 14.1.103 are the lift of the displayed relative Verdier identifications and the verification of (a) and (b) on the relative Ran space. Over $\overline{\mathcal{M}}_{g,n}$ the curve is nodal at the boundary, so an annular sewing comparison is an additional hypothesis rather than a formal consequence of this proposition.

Proof. Hypothesis (c) promotes part (1) of Theorem 14.1.103 from a fiberwise statement to a compatible relative unit/counit package. Applying $\mathbb{D}_{\mathrm{Ran}(X/S)}$ to the relative unit map and then pulling back to a geometric fiber X_s gives, by hypothesis (b), the algebra-level Verdier equivalence of Theorem 14.1.103(2) on that fiber. The displayed relative Verdier identifications provide the algebra target on the total space, and hypothesis (a) is the exact condition needed to take Verdier duals degreewise in the relative holonomic category. These ingredients glue the fiberwise identifications over S . The universal smooth curve over $\mathcal{M}_{g,n}$ is covered by the same argument once (a)–(c) are verified there; the compactification $\overline{\mathcal{M}}_{g,n}$ has nodal boundary and requires the additional annular sewing comparison isolated below. $\square$

Remark 14.1.106 (Open mathematical conditions for the modular-family extension). To prove the full modular-family statement over $\overline{\mathcal{M}}_{g,n}$, one must establish the two relative inputs isolated in Proposition 14.1.105:

- (1) construct the relative bar components as bounded holonomic $\mathcal{D}$ -complexes on the relative Fulton–MacPherson spaces;
- (2) prove the relative Verdier/base-change isomorphism on the relative Ran space, lift the algebra-level Verdier-compatible pair identifications, and check compatibility with the factorization gluing maps.

The fixed-curve conclusion carries the packages H_{CL} , $H_{\mathbb{D}}^{\mathrm{bar}}$, and θ_{12} , θ_{21} stated in Theorem 14.1.103.

Remark 14.1.107 (Analysis of the three relative inputs). The three inputs required by Proposition 14.1.105 admit the following analysis.

- (a) *Relative holonomic bar.* For each geometric fiber X_s , the bar complex $\overline{B}_{X_s}(\mathcal{A}_s)$ is a bounded holonomic $\mathcal{D}$ -complex by the fixed-curve holonomicity established above. Kashiwara’s base-change theorem for holonomic $\mathcal{D}$ -modules (Kashiwara [?Kas84], Theorem 4.3.1) preserves holonomicity under proper base change. To obtain hypothesis (a) one must still assemble these fiberwise complexes into a bounded relative holonomic complex on the relative Fulton–MacPherson stages and check the bar-length transition maps. The ind-properness of $\mathrm{Ran}(X/S) \rightarrow S$ for a smooth proper family is the geometric input; it is not by itself the completed relative bar object.
- (b) *Relative Verdier and base change on Ran.* Verdier duality commutes with proper base change by Verdier’s original theorem. In the ind-scheme setting of the Ran space, Gaitsgory–Rozenblyum ([?GR17], Vol. II, Chapter 7, Theorem 7.3.4) supply the ambient base-change theorem for ind-proper morphisms. To apply it to the completed bar complex one must still

verify finite-stage compatibility: the bar truncations must be represented by holonomic complexes on the relative Fulton–MacPherson stages, the transition maps must satisfy the Mittag–Leffler condition, and Verdier duality must commute with the completed inverse limit. These verifications are precisely hypothesis (b) of Proposition 14.1.105; they are not automatic from smoothness alone.

- (c) *Lifted relative Verdier pair.* The Koszul pair $(\mathcal{A}, \mathcal{A}^!)$ on a fixed curve lifts to a relative Koszul pair over S provided the twisting morphism $\tau: \overline{B}(\mathcal{A}) \rightarrow \mathcal{A}$ is a natural transformation of $\mathcal{D}$ -module-valued functors on $\text{Ran}(\mathcal{X}/S)$. This is a separate pair-lift obligation: one must construct the OPE residue morphisms on the relative Fulton–MacPherson boundary strata, prove their holomorphic variation in the fiber parameter of π , and check compatibility with factorization gluing. Fiberwise existence of τ does not by itself give the relative natural transformation.

Conclusion. For smooth families $\pi: \mathcal{X} \rightarrow S$ satisfying the three inputs above, the modular-family extension of Theorem A holds over S . Over $\overline{\mathcal{M}}_{g,n}$, the extension carries an additional boundary condition: the bar complex over a nodal fiber involves the annular bar $\overline{B}^{\text{ann}}$, which requires a separate sewing argument. The sewing comparison is partially established in Chapter ?? (the analytic Hilbert-space sewing theorem, proved for all genera); the remaining algebraic chain-level identification at nodal fibers is the open mathematical condition recorded in Remark 14.1.106. Thus a fixed smooth curve uses the theorem packages above; a smooth relative family adds relative holonomicity, base change, and pair lifts; and the stable compactification adds nodal sewing.

Remark 14.1.108 (Geometric substrate (Volume II)). Volume II reveals that this adjunction is the groupoid comodule-module adjunction for the Lagrangian self-intersection $\mathfrak{S} = \mathcal{L} \times_{\mathcal{M}} \mathcal{L}$: the bar complex $\overline{B}_X(\mathcal{A})$ is the structure sheaf of the derived self-intersection of the boundary Lagrangian inside a (-2) -shifted symplectic stack, and the cobar functor reconstructs the Lagrangian from its groupoid algebra.

Remark 14.1.109 (Twisting morphism content of Theorem A). The unit $\eta_{\tau_i}: C_i \rightarrow \overline{B}_X(\mathcal{A}_i)$ and counit $\varepsilon_{\tau_i}: \Omega_X(C_i) \rightarrow \mathcal{A}_i$ in part (1) are induced by the Koszul morphism τ_i of the underlying twisting datum (Definition 14.1.1). Part (1) says each τ_i is acyclic; part (2) says that after applying Verdier duality to the bar coalgebra of one side one obtains the post-Verdier dual factorization algebra recovered from the other; and Proposition 14.1.105 isolates the extra relative Verdier/base-change input needed to transport these identifications over a base.

Remark 14.1.110 (Elementary model presentation; Convention 1.10.2). ∞ -categorical adjunction. The bar functor $\mathbf{B}_X$ and cobar functor Ω_X form an adjoint pair

$$\mathbf{B}_X: \text{Alg}_{\text{aug}}(\text{Fact}(X)) \rightleftarrows \text{CoAlg}_{\text{conil}}(\text{Fact}(X)) : \Omega_X$$

on the stable ∞ -category of factorization (co)algebras on $\text{Ran}(X)$ under the factorization-closure package. The enhanced associative Ran theorem makes the unit and counit equivalences. Verdier duality gives the algebra $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \mathbf{B}_X(\mathcal{A})$, and the pair map $\nu: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$ gives the family-specific dual identification.

Explicit dg model. The explicit dg model uses the reduced bar complex $\tilde{B}_X(\mathcal{A}) = (T^c(s^{-1}\tilde{\mathcal{A}}), d_{\text{bar}})$, with d_{bar} encoded by configuration-space integrals on $\overline{C}_n(X)$. The universal twisting morphism $\tau: \tilde{B}_X(\mathcal{A}) \rightarrow \mathcal{A}$ is the degree-+1 OPE extraction against the log form on $\overline{C}_2(X)$. The post-Verdier comparison with $\mathcal{A}^!$ is a separate duality statement. The proof reduces to showing the unit and counit are quasi-isomorphisms, which follows from the Koszul conditions (Definition 14.1.3).

Model comparison. Choose equivalences $u_i: B_i \xrightarrow{\sim} B_X(\mathcal{A})$ from two admissible dg presentations to the fixed intrinsic bar object. The space of comparison equivalences $f: B_1 \rightarrow B_2$ satisfying $u_2 f \simeq u_1$

is contractible (Proposition 7.1.67). After the maps u_i are forgotten, the comparison space carries the natural $\text{Aut}(B_X(\mathcal{A}))$ -torsor ambiguity.

Cohomology. The bar coalgebra $\bar{B}_X(\mathcal{A})$ has cohomology $H^\bullet \bar{B}_X(\mathcal{A})$ concentrated on the Koszul diagonal. For a chosen quadratic presentation satisfying H_{CL} , the map $H^\bullet(q_{\mathcal{A}})$ identifies this coalgebra with $H^\bullet(\mathcal{A}^!)$. When the finite-type Verdier dual exists, the post-Verdier algebra $\mathcal{A}^!$ is characterized by the pair equivalence $\nu: K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \bar{B}_X(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}^!$ under the pair hypotheses, with dimensions controlled by the spectral discriminant $\Delta_{\mathcal{A}}(x)$.

Cohomology extraction. Taking cohomology of the dg model gives $H^\bullet \bar{B}_X(\mathcal{A})$. Concretely, the PBW spectral sequence $E_1^{p,q} \Rightarrow H^{p+q}(\bar{B}_X(\mathcal{A}))$ collapses at E_2 on the Koszul locus (Corollary 14.1.27), and the resulting Hilbert series is $\sum_n \dim H^n(\bar{B}_X(\mathcal{A})) x^n$. Under H_{CL} this equals the cohomological Hilbert series of $\mathcal{A}^!$. Under $H_{\mathbb{D}}^{\text{bar}}$ and the pair equivalence ν , finite Verdier duality gives the corresponding series for $\mathcal{A}^!$, with radius of convergence determined by $\Delta_{\mathcal{A}}(x)$.

14.2 YANGIANS AND AFFINE YANGIANS: SELF-DUALITY AND KOSZUL THEORY

The Yangian $Y(\mathfrak{g})$ and affine Yangian $Y_h(\widehat{\mathfrak{g}})$ provide examples where the finite-window ordered quadratic shadow is self-dual. The full post-Verdier algebra-level statement requires the completed ordered bar coalgebra, continuous duality, and the RTT/QYBE quantum line-kernel datum; the CYBE collision residue is only its semiclassical codimension-2 shadow.

For the type-A RTT definition, the Drinfeld presentation in all simple types, the Hopf structure, affine Yangians, and the physical interpretation, see Chapter ?? . We record here only the Koszul-duality-specific results.

14.2.1 Self-duality

THEOREM 14.2.1 (*Type-A Yangian quadratic shadow; .*) Let $Y_h^{\text{RTT}}(\mathfrak{gl}_N)$ be the completed RTT Yangian with Yang matrix

$$R(u; \hbar) = 1 - \frac{\hbar P}{u},$$

where P is the permutation of $\mathbb{C}^N \otimes \mathbb{C}^N$. Fix a finite level window and let Q_R be the homogeneous quadratic RTT algebra generated by the corresponding coefficients of $T(u)$, with relation

$$R_{12}(u-v) T_1(u) T_2(v) = T_2(v) T_1(u) R_{12}(u-v). \quad (14.2)$$

Then the quadratic dual algebra of Q_R is the RTT algebra with projectively inverse Yang matrix:

$$Q_R^{\text{quad}} \cong Q_{R^{-1}}.$$

Equivalently, since

$$R(u; \hbar)^{-1} = \left(1 - \frac{\hbar^2}{u^2}\right)^{-1} \left(1 + \frac{\hbar P}{u}\right) \sim R(u; -\hbar),$$

and scalar rational factors cancel from the RTT relation, the type-A quadratic shadow is self-dual after the parameter change $\hbar \mapsto -\hbar$.

This is a statement about the ordered E_1 quadratic shadow. It does not identify the full symmetric Ran bar coalgebra with an RTT algebra, and it does not say that the Verdier-dual algebra $Y_h(\mathfrak{g})^!$ is obtained by replacing R with R^{-1} outside the type-A RTT lane.

Proof of Theorem 14.2.1. Work in a finite level window, so all vector spaces are finite over $\mathbb{C}[[\hbar]]$ and continuous duals are ordinary duals in each bidegree. Write the RTT relation as the image of the linear map

$$\Phi_R(X) = R_{12}X - \sigma(X)R_{12}$$

on the quadratic tensor space of two matrix coefficients. The trace pairing on $\text{End}(\mathbb{C}^N)^{\otimes 2}$ identifies the orthogonal complement of $\text{Im } \Phi_R$ with the kernel of the adjoint map. Moving R_{12} across the trace changes it to the inverse braiding, hence the adjoint relation is the RTT relation for R_{21}^{-1} , which is projectively the same Yang matrix in this normalization. Therefore the quadratic dual relation space is exactly the RTT relation space attached to R^{-1} .

For the Yang matrix, $P^2 = 1$, so

$$\left(1 - \frac{\hbar P}{u}\right)^{-1} = \left(1 - \frac{\hbar^2}{u^2}\right)^{-1} \left(1 + \frac{\hbar P}{u}\right).$$

The scalar factor $(1 - \hbar^2/u^2)^{-1}$ multiplies both sides of (14.2) by the same invertible rational function and is invisible to the RTT ideal. Thus the inverse matrix defines the same quadratic algebra as $R(u; -\hbar)$. The presentation object computed here is the quadratic coalgebra Q_R^i ; the notation Q_R^{quad} appears only after finite continuous duality. $\square$

PROPOSITION 14.2.2 (*Yangian ordered-bar Koszulness in finite windows*;). Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra and let $Y_{\hbar}(\mathfrak{g})$ be Drinfeld's Yangian with augmentation and level filtration. For every finite level window $Y_{\hbar, \leq m}(\mathfrak{g})$, completed $\hbar$ -adically and filtered by bar length, the ordered bar complex is bidegreewise finite and its PBW spectral sequence is diagonal:

$$H^*(\overline{B}_X^{\text{ord}}(Y_{\hbar, \leq m}(\mathfrak{g}))) \cong H_{\hbar, \leq m}^{\text{bar, ord}}(\mathfrak{g})$$

as a conilpotent ordered chiral coalgebra. Passing to the inverse limit over m gives the completed bar-cohomology coalgebra $H_{\hbar}^{\text{bar, ord}}(\mathfrak{g})$ whenever the finite windows form the Mittag-Leffler system of Lemma 14.3.9. If a finite window carries a chosen quadratic presentation coalgebra $Y_{\hbar, \leq m}(\mathfrak{g})^i$ satisfying H_{CL}^* , its map $H^*(q_Y)$ identifies that presentation cohomology with the displayed bar cohomology. Continuous duality of the full bar windows gives $K_X(Y_{\hbar})$, and a chosen pair map compares this algebra with $Y_{\hbar}(\mathfrak{g})^!$.

Proof. Drinfeld's PBW theorem [?Drinfeld85] gives the filtered identification $\text{gr } Y_{\hbar}(\mathfrak{g}) \cong U(\mathfrak{g}[t])$. For the classical matrix types this is compatible with the RTT presentations treated by Molev [?Molev07, ?molev-yangians]; for the exceptional and uniform Drinfeld presentations the required PBW basis is the theorem of Guay–Regelskis–Wendlandt [?GRW18, Thm. 3.2]. In a fixed level window all homogeneous pieces are finite-dimensional.

Apply the Polishchuk–Positselski PBW theorem for locally finite quadratic-linear filtered algebras [?PP05, Ch. 4]. The associated graded algebra $U(\mathfrak{g}[t]_{\leq m})$ is PBW, and its further monomial-length associated graded is $\text{Sym}(\mathfrak{g}[t]_{\leq m})$, whose Koszul complex is the classical symmetric-exterior complex. The PBW theorem transfers this acyclicity to $Y_{\hbar, \leq m}(\mathfrak{g})$ and gives diagonal collapse of the ordered bar spectral sequence.

The transition maps between finite windows are surjective in each fixed bar length and level. Hence the inverse system is bidegreewise Mittag-Leffler, so Lemma 14.3.9 identifies the completed inverse limit with the completed ordered bar coalgebra. The construction therefore produces $H_{\hbar}^{\text{bar, ord}}(\mathfrak{g})$ and the full ordered bar coalgebra. A quadratic presentation supplies a separate $Y_{\hbar}(\mathfrak{g})^i$ and comparison q_Y ; continuous Verdier duality supplies $K_X(Y_{\hbar})$; the selected partner is the target of its pair map. $\square$

14.3 QUADRATIC RECOGNITION AND RESIDUE-DUAL COMPARISON

14.3.1 The type-correct comparison problem

Problem 14.3.1 (Typed quadratic and Verdier comparisons). Let $\mathcal{A} = T_{\text{ch}}(\mathcal{V})/(R)$ be an augmented quadratic chiral algebra. Its chosen presentation determines

$$\mathcal{A}^i = C_X(s^{-1}\mathcal{V}, s^{-2}R), \quad q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow B_X(\mathcal{A}).$$

The package $H_{\text{CL}}(\mathcal{A}, \mathcal{A}^i, \tau_i)$ makes $q_{\mathcal{A}}$ a quasi-isomorphism and hence gives the cohomological recognition map

$$H^\bullet(q_{\mathcal{A}}): H^\bullet(\mathcal{A}^i) \xrightarrow{\sim} H^\bullet B_X(\mathcal{A}).$$

The full bar coalgebra has the Verdier-dual algebra

$$K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}} B_X(\mathcal{A}),$$

and a chiral Koszul pair supplies a chosen algebra map $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$. On a finite quadratic lane, Verdier duality also gives

$$\mathbb{D}(q_{\mathcal{A}}): K_X(\mathcal{A}) \longrightarrow \mathcal{A}_{\text{quad}}^!, \quad \mathcal{A}_{\text{quad}}^! := \mathbb{D}_{\text{Ran}} \mathcal{A}^i.$$

A comparison $c_{\mathcal{A}}: \mathcal{A}_{\text{quad}}^! \rightarrow \mathcal{A}^!$ recovers the chosen pair map precisely when

$$\nu_{\mathcal{A}} = c_{\mathcal{A}} \circ \mathbb{D}(q_{\mathcal{A}}).$$

These arrows separate quadratic recognition, universal reconstruction, Verdier duality, and the family-specific choice of dual partner.

Remark 14.3.2. A chiral coalgebra is the object controlled by collision residues in the opposite direction. Its coproduct records how a configuration splits along boundary strata; its differential is dual to the OPE residue calculus after the ordered desuspension convention of Definition ??.

14.3.2 The residue-dual comparison coalgebra

Definition 14.3.3 (Residue-dual comparison coalgebra;). Let $\mathcal{A} = T_{\text{ch}}(\mathcal{V})/(R_{\geq 2})$ be a finite-type PBW chiral algebra on X , with $\mathcal{V}$ a locally free $\mathcal{D}_X$ -module of generators, completed relation ideal $R_{\geq 2}$, and transferred OPE residues

$$\mu_r: j_* j^*(\mathcal{V}^{\boxtimes r}) \longrightarrow \Delta_* \mathcal{V} \otimes \Omega_{\log}^{r-1} \quad (r \geq 2)$$

Put

$$\mathcal{V}^\vee := \mathbb{D}_X \mathcal{V} = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{V}, \omega_X), \quad \widehat{T}_{\text{ch}}^c(s^{-1}\mathcal{V}^\vee) := \prod_{n \geq 0} \pi_{n*}(j_* j^*(s^{-1}\mathcal{V}^\vee)^{\boxtimes n})_{\Sigma_n},$$

with coinvariants replaced by the ordered tensor coalgebra in the E_1 lane. Let $R_{\geq 2}^\perp$ denote the aritywise annihilator of the leading multilinear relation system under the Serre–residue pairing. The *residue-dual comparison coalgebra* $C_{\mathcal{A}}^{\text{res}}$ is the largest closed conilpotent subcoalgebra of $\widehat{T}_{\text{ch}}^c(s^{-1}\mathcal{V}^\vee)$ whose corelation system lies in $R_{\geq 2}^\perp$.

Its coproduct is the completed deconcatenation coproduct, with counit given by projection to the length-zero summand. Its structure coderivation

$$q_{\text{res}} = \sum_{r \geq 1} q_{\text{res},r}$$

is the unique continuous coderivation whose projection to cogenerators is dual, under Serre–residue pairing and the ordered desuspension convention of Definition ??, to the transferred OPE residues $\{\mu_r\}_{r \geq 1}$. The binary part is the dual of the chiral product residue along the collision divisor; higher parts record the transferred higher residues. If $q_{\text{res},r} = 0$ for $r \geq 3$, this is a strict dg chiral coalgebra. In general it is a completed conilpotent A_∞ chiral coalgebra, and the completed cobar functor is taken in that A_∞ sense.

For a quadratic presentation $\mathcal{A} = T_{\text{ch}}(\mathcal{V})/(R)$, the underlying quadratic coalgebra is

$$C_{\mathcal{A}}^{\text{res}} = C_X(s^{-1}\mathcal{V}^\vee, s^{-2}R^\perp) = (\mathcal{A}_{\text{quad}}^!)^i.$$

Thus $C_{\mathcal{A}}^{\text{res}}$ is attached to the residue-dual presentation. A comparison with $\mathcal{A}^i = C_X(s^{-1}\mathcal{V}, s^{-2}R)$ requires a chosen self-duality of the presentation.

Definition 14.3.4 (Residue self-duality comparison package;). For a finite-type quadratic presentation $\mathcal{A} = T_{\text{ch}}(\mathcal{V})/(R)$, the package $H_{\text{res}}(\mathcal{A}; \beta, \chi)$ consists of:

- (i) a perfect presentation polarization $\beta: \mathcal{V} \xrightarrow{\sim} \mathbb{D}_X \mathcal{V}$;
- (ii) the relation compatibility $\beta^{\boxtimes 2}(R) = R^\perp$, including the suspension and collision-residue conventions;
- (iii) a continuous filtered A_∞ coalgebra morphism

$$\chi_{\mathcal{A},\beta}: \mathcal{A}^i \longrightarrow C_{\mathcal{A}}^{\text{res}}$$

whose cogenerator component is $s^{-1}\beta$ and which intertwines the quadratic twisting coderivation with q_{res} ;

- (iv) finite-dimensional filtration windows, strong convergence, and Mittag–Leffler transition maps, with $\text{gr}(\chi_{\mathcal{A},\beta})$ an isomorphism.

In the strict finite quadratic case, items (i)–(ii) induce $\chi_{\mathcal{A},\beta}$ by the universal property of the quadratic coalgebra, and this map is an isomorphism.

Remark 14.3.5 (Presentation dependence). The datum $C_{\mathcal{A}}^{\text{res}}$ depends on the chosen generators, leading relation system, transferred residues, and residue pairing. The quadratic coalgebra $\mathcal{A}^i$ depends on the chosen quadratic presentation. The full bar coalgebra $B_X(\mathcal{A})$ is functorial in the augmented algebra, while the chosen partner $\mathcal{A}^!$ enters through $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$.

14.3.3 Coalgebra identities

THEOREM 14.3.6 (Coalgebra structure on $C_{\mathcal{A}}^{\text{res}}$;). [Type signature: Open quadrant; residue-dual PBW presentation; Beilinson level 2; hypothesis package = transferred chiral A_∞ identities + correlation stability + completion.] Assume the transferred residues $\{\mu_r\}$ satisfy the Borchers–Jacobi and Arnold–Orlik–Solomon boundary identities with the ordered bar–cobar signs of Theorem ??. Assume further that q_{res} preserves the closed subcoalgebra of Definition 14.3.3. Then

$$(C_{\mathcal{A}}^{\text{res}}, \Delta, \epsilon, q_{\text{res}})$$

is a completed conilpotent chiral coalgebra. In the strict case $q_{\text{res},r} = 0$ for $r \geq 3$, it satisfies

- (i) $(\Delta \boxtimes \text{id})\Delta = (\text{id} \boxtimes \Delta)\Delta$;
- (ii) $(\epsilon \boxtimes \text{id})\Delta = \text{id} = (\text{id} \boxtimes \epsilon)\Delta$;
- (iii) $\Delta q_{\text{res}} = (q_{\text{res}} \boxtimes \text{id} + \text{id} \boxtimes q_{\text{res}})\Delta$;
- (iv) $q_{\text{res}}^2 = 0$.

Proof. The completed tensor coalgebra is cofree conilpotent, hence deconcatenation is coassociative and the projection to length 0 is a counit. Since q_{res} is defined as the continuous coderivation extending its projection to cogenerators, the coderivation identity follows from the cofree universal property. This universal extension includes the middle deconcatenation terms on every cogenerator word.

For the square-zero identity, recall that on a cofree conilpotent coalgebra a coderivation is zero if and only if its projection to cogenerators is zero. Hence $q_{\text{res}}^2 = 0$ is checked after projection to $s^{-1}\mathcal{V}^\vee$. The projected square is the dual of the sum of all iterated residue operations obtained by first colliding one cluster of points and then a second cluster. In arity 3 these are the three codimension-two boundary contributions in $\overline{C}_3(X)$, and their logarithmic forms satisfy the Arnold relation

$$\eta_{12} \wedge \eta_{23} + \eta_{23} \wedge \eta_{31} + \eta_{31} \wedge \eta_{12} = 0.$$

With the ordered bar-cobar signs fixed in Theorem ??, this is exactly the Borchers identity for the OPE. Higher arities are the same boundary-of-boundary identity on the Fulton–MacPherson strata, written in Stasheff form. The preservation of $R_{\geq 2}^\perp$ makes the coderivation descend to the closed subcoalgebra. Therefore $q_{\text{res}}^2 = 0$ in the strict case, and the general case satisfies the completed A_∞ coalgebra identities. $\square$

Remark 14.3.7. The theorem constructs the residue-dual coalgebra. The comparison with $\mathcal{A}^i$ is governed by $H_{\text{res}}(\mathcal{A}; \beta, \chi)$; the comparison with the full bar coalgebra is governed by $q_{\mathcal{A}}$ and H_{CL} ; the algebra partner is governed by $\nu_{\mathcal{A}}$.

14.3.4 Bar comparison

THEOREM 14.3.8 (*Quadratic recognition with residue self-duality*;). [Type signature: Open quadrant; finite-type quadratic presentation; Beilinson level 2 and post-Verdier level 2; hypothesis packages H_{CL} , H_{res} , and $H_{\mathbb{D}}^{\text{bar}}$.] Let $\mathcal{A} = T_{\text{ch}}(\mathcal{V})/(R)$ carry its quadratic coalgebra $\mathcal{A}^i$, its canonical comparison $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow B_X(\mathcal{A})$, and a residue self-duality package $H_{\text{res}}(\mathcal{A}; \beta, \chi)$. Under $H_{\text{CL}}(\mathcal{A}, \mathcal{A}^i, \tau_i)$, the diagram

$$B_X(\mathcal{A}) \xleftarrow[\sim]{q_{\mathcal{A}}} \mathcal{A}^i \xrightarrow[\sim]{\chi_{\mathcal{A}, \beta}} C_{\mathcal{A}}^{\text{res}} \quad (14.3)$$

is a roof of filtered quasi-isomorphisms of completed conilpotent chiral coalgebras. In particular,

$$H^\bullet(q_{\mathcal{A}}): H^\bullet(\mathcal{A}^i) \xrightarrow{\sim} H^\bullet B_X(\mathcal{A}).$$

Under $H_{\mathbb{D}}^{\text{bar}}(\mathcal{A})$, continuous Verdier duality gives the algebra diagram

$$K_X(\mathcal{A}) \xrightarrow{\mathbb{D}(q_{\mathcal{A}})} \mathcal{A}_{\text{quad}}^! \xleftarrow[\mathbb{D}(\chi_{\mathcal{A}, \beta})]{} \mathbb{D}_{\text{Ran}} C_{\mathcal{A}}^{\text{res}}. \quad (14.4)$$

A chosen map $c_{\mathcal{A}}: \mathcal{A}_{\text{quad}}^! \rightarrow \mathcal{A}^!$ with $\nu_{\mathcal{A}} = c_{\mathcal{A}} \circ \mathbb{D}(q_{\mathcal{A}})$ identifies the cospan with the selected chiral Koszul partner.

Proof. The morphism $q_{\mathcal{A}}$ is the canonical map associated with the quadratic twisting morphism $\tau_i: \mathcal{A}^i \rightarrow \mathcal{A}$. The package H_{CL} asserts its acyclicity, so $q_{\mathcal{A}}$ is a quasi-isomorphism. The package H_{res} makes $\chi_{\mathcal{A},\beta}$ a filtered A_{∞} coalgebra morphism whose associated graded is an isomorphism. Lemma 14.3.9 promotes that associated-graded isomorphism to the second quasi-isomorphism in (14.3).

Continuous Verdier duality reverses both arrows in the roof. The first transpose has source $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} B_X(\mathcal{A})$ and target $\mathcal{A}_{\text{quad}}^! = \mathbb{D}_{\text{Ran}} \mathcal{A}^!$, which gives (14.4). The displayed factorization of $\nu_{\mathcal{A}}$ is exactly the additional datum which selects the partner algebra $\mathcal{A}^!$. $\square$

LEMMA 14.3.9 (*Completion convergence*;). Let C be a bar-length filtered chiral complex with completion

$$\widehat{C} = \varprojlim_n C/F^n C.$$

Assume that for every fixed bar length and conformal weight the filtered pieces are finite-dimensional, the transition maps in $\{C/F^n C\}_n$ are eventually surjective, the filtration is complete and separated, and the differential is continuous. Then $R^1 \varprojlim H^*(C/F^n C) = 0$, the completed spectral sequence converges strongly, and a filtered quasi-isomorphism on associated graded objects induces a quasi-isomorphism after completion.

Proof. For fixed bidegree the inverse system is Mittag–Leffler, so $\varprojlim^1 = 0$ by the standard derived-limit criterion [Weibel194, Proposition 3.5.7]. Completeness and separatedness identify C with the limit of its quotients, and continuity of the differential makes the completed object a complex. Strong convergence of the completed spectral sequence follows from the same Mittag–Leffler condition in each bidegree. A filtered map that is a quasi-isomorphism on associated graded pages is therefore a quasi-isomorphism on the completed abutments. $\square$

Remark 14.3.10 (*Completion package*). Finite generation and polynomial growth are useful sufficient conditions only when they imply the bidegreewise finite-dimensionality and Mittag–Leffler stabilization stated in Lemma 14.3.9. They are not, by themselves, a substitute for completion convergence. The full derived completion package is developed in Appendix ??.

COROLLARY 14.3.11 (*Typed residue-self-dual quadratic comparison*;). Let $\mathcal{A} = T_{\text{ch}}(\mathcal{V})/(R)$ be a finite-type quadratic chiral algebra on a smooth curve X . Assume:

- (i) $H_{\text{CL}}(\mathcal{A}, \mathcal{A}^i, \tau_i)$ holds for $\mathcal{A}^i = C_X(s^{-1}\mathcal{V}, s^{-2}R)$;
- (ii) $H_{\text{res}}(\mathcal{A}; \beta, \chi)$ holds for the residue-dual comparison coalgebra $C_{\mathcal{A}}^{\text{res}}$;
- (iii) $H_{\mathbb{D}}^{\text{bar}}(\mathcal{A})$ supplies continuous Verdier duality on the full bar object;
- (iv) the bar-length completion is bidegreewise Mittag–Leffler in the sense of Lemma 14.3.9;
- (v) a comparison $c_{\mathcal{A}}: \mathcal{A}_{\text{quad}}^! \rightarrow \mathcal{A}^!$ satisfies $\nu_{\mathcal{A}} = c_{\mathcal{A}} \circ \mathbb{D}(q_{\mathcal{A}})$.

Then the three coalgebras are identified in the derived category by the canonical roof

$$B_X(\mathcal{A}) \xleftarrow[\sim]{q_{\mathcal{A}}} \mathcal{A}^i \xrightarrow[\sim]{\chi_{\mathcal{A},\beta}} C_{\mathcal{A}}^{\text{res}},$$

and the selected dual algebra is reached by

$$K_X(\mathcal{A}) \xrightarrow{\mathbb{D}(q_{\mathcal{A}})} \mathcal{A}_{\text{quad}}^! \xrightarrow{c_{\mathcal{A}}} \mathcal{A}^!.$$

Universal reconstruction is the counit $\Omega_X B_X(\mathcal{A}) \rightarrow \mathcal{A}$.

Proof. Theorem 14.3.8 gives the roof and its Verdier transpose. Hypothesis (v) composes that transpose with the chosen partner comparison. The bar–cobar counit has source $\Omega_X B_X(\mathcal{A})$ and target $\mathcal{A}$ by the enhanced associative Ran reconstruction theorem. $\square$

Remark 14.3.12 (Comparison with classical Koszul duality). When $\mathcal{A}$ is quadratic with relation space $R \subset j_* j^*(\mathcal{V}^{\boxtimes 2})$, its presentation coalgebra and finite quadratic dual algebra are

$$\mathcal{A}^i = C_X(s^{-1}\mathcal{V}, s^{-2}R), \quad \mathcal{A}_{\text{quad}}^i = \mathbb{D}_{\text{Ran}} \mathcal{A}^i \simeq T_{\text{ch}}(s\mathcal{V}^\vee)/(R^\perp).$$

The residue-dual candidate is the quadratic coalgebra of this dual presentation:

$$C_{\mathcal{A}}^{\text{res}} = C_X(s^{-1}\mathcal{V}^\vee, s^{-2}R^\perp) = (\mathcal{A}_{\text{quad}}^i)^i.$$

A polarization β carrying R to $R^\perp$ identifies $\mathcal{A}^i$ with $C_{\mathcal{A}}^{\text{res}}$. This is the precise self-dual presentation locus. The map $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow B_X(\mathcal{A})$ remains the Ginzburg–Kapranov/Loday–Vallette quadratic recognition map.

Remark 14.3.13 (BD comparison). Theorem 14.3.8 is compatible with the chiral-homology results of Beilinson–Drinfeld, but it is not stated in the same category. BD work on the symmetric Ran-space side. The symmetric bar $\overline{B}_X(\mathcal{A})$ entering Theorem A is the object comparable to BD’s factorization coalgebra; the ordered bar of this monograph is an additional E_1 refinement.

On the pole-free BD-commutative subclass, [?BD04, Theorem 4.6.1] identifies chiral homology with de Rham cohomology, and [?BD04, Theorem 4.8.1] identifies the chiral homology of a chiral envelope with the Chevalley complex of $R\Gamma_{\text{DR}}(X, L)$. Our Koszul statement uses the same symmetric bar input in those lanes and then adds a duality statement not present in BD: on the Koszul locus, the bar coalgebra resolves back to the original chiral algebra and is paired with its Verdier-dual Koszul partner.

The terminology bridge is strict. BD Chapter 4 “commutative” means a pole-free commutative $\mathcal{D}_X$ -algebra. It does not mean the full E_∞ -chiral class used here. Thus the comparison with BD is exact on the pole-free subclass and on the chiral-envelope/Chevalley lane; for local vertex algebras with OPE poles, the present theorem extends past BD’s Chapter 4 scope by using the residue differential and the Fulton–MacPherson boundary geometry.

14.4 EXPLICIT CALCULATIONS: $\mathcal{W}$ -ALGEBRAS AND BEYOND

14.4.1 Virasoro Koszul-duality calculation

Example 14.4.1 (Virasoro: first non-quadratic example). The Virasoro algebra is generated by the stress tensor $T(z)$ with OPE

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}.$$

The quartic pole is not discarded by multiplying the OPE by a logarithmic one-form and taking an ordinary one-variable residue. In the chiral bar complex the Fulton–MacPherson boundary map first expands the fields along the diagonal and then applies the residue operation. Equivalently, the binary part of the bar coderivation records the Virasoro products

$$T_{(3)}T = \frac{c}{2}\mathbf{1}, \quad T_{(1)}T = 2T, \quad T_{(0)}T = \partial T$$

with the suspension signs fixed in Theorem ??.

The completed bar-cohomology coalgebra is

$$H_c^{\text{bar}}(\text{Vir}) := H^*\left(\widehat{\overline{B}_X^\Sigma(\text{Vir}_c)}, d_{\text{bar}}\right),$$

or the corresponding ordered cohomology on the E_1 lane. The full completed bar complex is carried by the completed cofree coalgebra on the descendants

$$T, \partial T, \partial^2 T, \dots$$

and has a continuous coderivation whose arity-two components are the three displayed OPE modes and their ∂ -translates. Its cohomology is $H_c^{\text{bar}}(\text{Vir})$. In a fixed conformal weight and bar length there are only finitely many descendants, and the bar-length quotients satisfy Lemma 14.3.9.

The full bar object gives the post-Verdier algebra

$$K_X(\text{Vir}_c) = \mathbb{D}_{\text{Ran}} \widehat{\overline{B}_X^\Sigma(\text{Vir}_c)},$$

or the continuous finite-window dual in the affine model. A chosen pair map $\nu_{\text{Vir}_c} : K_X(\text{Vir}_c) \rightarrow \text{Vir}_c^!$ supplies the family-specific partner. The scalar central channel is normalized by

$$\kappa(\text{Vir}_c) = \frac{c}{2};$$

it is a curvature component after the curved genus package is turned on. The completed tensor coalgebra $\widehat{T^c(T^*)}$ belongs to the coalgebra presentation of the bar complex, while $K_X(\text{Vir}_c)$ and $\text{Vir}_c^!$ belong to the post-Verdier algebra lane.

14.4.2 W_3 algebra: explicit calculation

Example 14.4.2 (W_3 algebra: full completion). The W_3 algebra is strongly generated by $T(z)$ of weight 2 and $W(z)$ of weight 3. Its complete OPEs are those of Definition ?? and Theorem ??. The composite field

$$\Lambda = :TT: - \frac{3}{10} \partial^2 T$$

is the quasi-primary of weight 4, with

$$\langle \Lambda | \Lambda \rangle = \frac{c(5c + 22)}{10}$$

as fixed in the landscape census. The W - W OPE contains the load-bearing channel

$$\frac{16}{22 + 5c} \frac{\Lambda(w)}{(z - w)^2} + \frac{8}{22 + 5c} \frac{\partial \Lambda(w)}{z - w},$$

together with the central term $c/3 (z - w)^{-6}$ and the Virasoro descendant terms.

The completed bar object is

$$\widehat{\overline{B}_X^\Sigma(W_3)} = \varprojlim_n \overline{B}_X^\Sigma(W_3) / F_{\text{bar}}^n,$$

and its differential is the continuous coderivation whose binary components are the OPE modes of T , T , T , W , and W , W . The Fulton–MacPherson collision map retains every singular OPE channel; the

sextic central pole is one of the scalar components of the coderivation, while the Λ channel supplies a genuine quadratic composite:

$$\Delta(\Lambda^\vee) = \Lambda^\vee \boxtimes \mathbf{I} + \mathbf{I} \boxtimes \Lambda^\vee + T^\vee \boxtimes T^\vee$$

up to the standard suspension and normal-ordering signs.

Its bar-cohomology coalgebra is

$$\mathsf{H}^{\text{bar}}(W_3) := H^*\left(\widehat{\overline{B}_X^\Sigma(W_3)}, d_{\text{bar}}\right),$$

or the ordered version in the E_1 refinement. The full bar complex is represented by a closed subcoalgebra of the completed cofree conilpotent coalgebra on the duals of

$$T, \partial T, \partial^2 T, \dots, \quad W, \partial W, \partial^2 W, \dots$$

together with the composite coalgebra coordinates forced by the OPE, beginning with $\Lambda^\vee$. Its post-Verdier algebra is

$$K_X(W_3) = \mathbb{D}_{\text{Ran}} \widehat{\overline{B}_X^\Sigma(W_3)},$$

when the Verdier finite-type hypotheses are satisfied; a pair map $\nu_{W_3}: K_X(W_3) \rightarrow W_3^!$ selects the partner algebra. Completion converges under the bidegreewise finite-dimensional and Mittag-Leffler hypotheses of Lemma 14.3.9.

14.4.3 General W_N algebras

Construction 14.4.3 (W_N completed bar and its cohomology). For W_N with strong generators $\{W^{(2)}, W^{(3)}, \dots, W^{(N)}\}$ of weights $2, 3, \dots, N$, the completed bar complex is

$$\widehat{\overline{B}_X^\Sigma(W_N)} = \varprojlim_n \overline{B}_X^\Sigma(W_N) / F_{\text{bar}}^n,$$

with

$$\overline{B}^k(W_N) = \bigoplus_{\substack{i_1, \dots, i_{k+1} \in \{2, \dots, N\} \\ m_1, \dots, m_{k+1} \geq 0}} \Gamma\left(\overline{C}_{k+1}(X), \partial^{m_1} W^{(i_1)} \boxtimes \dots \boxtimes \partial^{m_{k+1}} W^{(i_{k+1})} \otimes \Omega_{\log}^k\right).$$

The coderivation is the continuous extension of all OPE modes among the strong generators and their descendants.

The bar-cohomology coalgebra is

$$\mathsf{H}^{\text{bar}}(W_N) := H^*\left(\widehat{\overline{B}_X^\Sigma(W_N)}, d_{\text{bar}}\right).$$

The full bar complex sits inside the completed conilpotent coalgebra cogenerated by the duals of the strong generators, their ∂ -descendants, and the normal-ordered composite coordinates forced by the OPE closure relations. Its structure has the following features.

- (i) The strong-generator coordinates $(W^{(s)})^\vee$ have dual weight $-s$ before the suspension shift.

- (ii) The coproduct is primitive only on genuine cogenerators; composite coordinates have reduced coproducts determined by normal ordering.
- (iii) The differential records all OPE structure constants, including central high-pole channels and composite fields.
- (iv) In the curved genus package the scalar normalization is governed by

$$\kappa(\mathcal{W}_N) = c(H_N - 1), \quad H_N = \sum_{j=1}^N \frac{1}{j},$$

and this vanishes at $c = 0$, not at the minimal-model values in general.

The post-Verdier algebra is

$$K_X(W_N) = \mathbb{D}_{\text{Ran}} \widehat{\overline{B}_X^\Sigma(W_N)},$$

under the same finite-type and completion hypotheses as in Corollary 14.3.11. A chosen pair map $\nu_{W_N}: K_X(W_N) \rightarrow W_N^!$ supplies the family-specific dual partner.

14.4.4 Beyond $\mathcal{W}$ -algebras: other non-quadratic examples

Example 14.4.4 (Affine Yangian). The affine Yangian $Y_h(\widehat{\mathfrak{gl}}_n)$ belongs to the ordered E_1 lane. Its spectral-parameter relations are read by $\overline{B}_X^{\text{ord}}$, not by the symmetric Ran bar before averaging. In a finite Drinfeld-current or RTT window the generators may be written schematically as $T_{(r)}^a(u)$, with $a = 1, \dots, n^2$ and $r \geq 0$; the relations have rational coefficients in $u - v$ and $\hbar$ and are completed at the chosen spectral pole.

The correct completed bar object is the finite-window inverse limit

$$\widehat{\overline{B}_X^{\text{ord}}(Y_h)} = \varprojlim_{p,q,m} \overline{B}_X^{\text{ord}}(Y_h) / (F_{\text{bar}}^p + \hbar^q + \mathfrak{m}_u^m),$$

where $\mathfrak{m}_u$ is the spectral-parameter maximal ideal at the expansion point. The quotient is by the sum of the three closed filtration ideals, not by the product $I^p \hbar^q$. The intrinsic object obtained from this complex is $Y_h(\widehat{\mathfrak{gl}}_n)^!$. A statement about $Y_h(\widehat{\mathfrak{gl}}_n)^!$ requires continuous Verdier duality on these finite windows and the bidegreewise Mittag–Leffler convergence of Lemma 14.3.9.

Example 14.4.5 (Bershadsky–Polyakov algebra). The $W_3^{(2)}$ algebra (also called Bershadsky–Polyakov) is the quantum Drinfeld–Sokolov reduction of $\widehat{\mathfrak{sl}}_3$ at the subregular nilpotent. It has generators:

- A weight-1 field $J(z)$
- Two weight-3/2 fermionic fields $G^\pm(z)$
- The Virasoro field $T(z)$ (weight 2)

The structure constants involve *irrational functions* of the central charge (e.g., $\sqrt{c}$ or $\sqrt{5c + 22}$ appear in OPE coefficients), although the OPE poles themselves are always integer-order as required by vertex algebra locality. This requires:

- Working over $\mathbb{C}[c^{1/2}]$ (not $\mathbb{C}$) when treating c as a formal parameter
- Completion in the $\mathfrak{m}$ -adic topology where $\mathfrak{m} = (c^{1/2} - c_o^{1/2})$
- Careful treatment of the fermionic generators and their $\mathbb{Z}/2$ -grading

Example 14.4.6 (Superconformal algebras). The $\mathcal{N} = 2$ superconformal algebra has:

- Bosonic: $T(z)$ weight 2, $J(z)$ weight 1
- Fermionic: $G^+(z), G^-(z)$ weight $3/2$

The $\mathbb{Z}/2\mathbb{Z}$ -grading introduces fermionic signs:

$$G^+(z)G^+(w) \sim 0, \quad G^+(z)G^-(w) \sim \frac{c/3}{(z-w)^3} + \frac{J(w)}{(z-w)^2} + \dots$$

Completion. Requires *super-coalgebra* structure:

$$\Delta(G^+) = G^+ \boxtimes 1 + 1 \boxtimes G^+$$

(generators are primitive, as in Step 2 above; the fermionic sign enters in the *cocommutativity* constraint $\tau \circ \Delta = \Delta$ where $\tau(x \boxtimes y) = (-1)^{|x||y|} y \boxtimes x$).

Remark 14.4.7 (Feynman diagrams). The Feynman diagram interpretation of the bar-cobar complex (the identification of bar chains with off-shell amplitudes and cobar chains with on-shell propagator kernels) is developed in Chapter ??.

14.5 THE E_1 -CHIRAL KOSZUL DUALITY THEOREM

The preceding sections developed the bar-cobar adjunction and Koszul pairs for E_∞ -chiral algebras (vertex algebras), where the underlying operad is the commutative chiral operad Com^{ch} . The *associative* case treats algebras over the associative chiral operad Ass^{ch} (Definition 3.11.5). This is the setting of nonlocal vertex algebras (Definition 3.11.4), and the resulting Koszul duality is self-dual by Proposition 3.11.7. The ∞ -categorical bar-cobar formalism for algebras over operads that underlies the construction is developed in [?HA, §3.1].

14.5.1 Augmented and pro-nilpotent E_1 -chiral algebras

Definition 14.5.1 (Augmented E_1 -chiral algebra). An E_1 -chiral algebra $\mathcal{A}$ is *augmented* if it is equipped with a morphism of E_1 -chiral algebras $\varepsilon : \mathcal{A} \rightarrow \omega_X$ (the unit chiral algebra). The *augmentation ideal* is $\tilde{\mathcal{A}} := \ker(\varepsilon)$.

Definition 14.5.2 (Pro-nilpotent and conilpotent). An augmented E_1 -chiral algebra $\mathcal{A}$ is *pro-nilpotent* if the inverse system

$$\mathcal{A} \twoheadrightarrow \mathcal{A}/\tilde{\mathcal{A}}^{\otimes^{\text{ch}}_2} \twoheadrightarrow \mathcal{A}/\tilde{\mathcal{A}}^{\otimes^{\text{ch}}_3} \twoheadrightarrow \dots$$

is pro-isomorphic to $\mathcal{A}$, where $\tilde{\mathcal{A}}^{\otimes^{\text{ch}}_n}$ denotes the n -fold chiral tensor power of the augmentation ideal.

Dually, a coaugmented E_1 -chiral coalgebra C is *conilpotent* if $C = \bigcup_{n \geq 0} F_n C$ where $F_n C$ is the coradical filtration (the largest sub-coalgebra on which the iterated reduced coproduct $\bar{\Delta}^{(n)}$ vanishes).

Remark 14.5.3 (Convergence role of pro-nilpotence). Pro-nilpotence ensures the cobar differential $d_\Omega : \Omega(C)_n \rightarrow \Omega(C)_{n-1}$ is well-defined: the formula involves a sum over all ways to decompose a tensor factor via the coproduct, which in general is an infinite series. Conilpotence ensures this sum is finite in each degree. On the algebra side, pro-nilpotence ensures the bar construction is degree-wise finite-dimensional. See Appendix ?? for the completion theory.

14.5.2 The bar-cobar equivalence for Ass^{ch}

THEOREM 14.5.4 (E_1 -chiral Koszul duality;). [Regime: quadratic on the Koszul locus; filtered-complete via PBW degeneration (Convention 1.10.2).]

On the finite-type complete lane, the bar-cobar adjunction restricts to an equivalence of ∞ -categories. For the underlying E_1 bar construction in the ∞ -categorical setting, see [?HA, §5.2.2].

The equivalence is

$$\bar{B}^{\text{ch}} : \text{Ass}^{\text{ch}}\text{-Alg}^{\text{aug, pronil, ft}} \rightleftarrows \text{Ass}^{\text{ch}}\text{-CoAlg}^{\text{coaug, conil, ft}} : \Omega^{\text{ch}},$$

where:

- $\text{Ass}^{\text{ch}}\text{-Alg}^{\text{aug, pronil, ft}}$ is the ∞ -category of augmented, pro-nilpotent E_1 -chiral algebras on X whose bar filtration is complete, separated, bidegreewise finite, and compatible with the chiral tensor product;
- $\text{Ass}^{\text{ch}}\text{-CoAlg}^{\text{coaug, conil, ft}}$ is the ∞ -category of coaugmented, conilpotent E_1 -chiral coalgebras on X satisfying the dual cobar convergence conditions.

The unit and counit of the adjunction are quasi-isomorphisms:

$$\begin{aligned} \Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) &\xrightarrow{\sim} \mathcal{A} \quad \text{for all } \mathcal{A} \in \text{Ass}^{\text{ch}}\text{-Alg}^{\text{aug, pronil, ft}}, \\ C &\xrightarrow{\sim} \bar{B}^{\text{ch}}(\Omega^{\text{ch}}(C)) \quad \text{for all } C \in \text{Ass}^{\text{ch}}\text{-CoAlg}^{\text{coaug, conil, ft}}. \end{aligned} \tag{14.5}$$

Proof. The argument is the operadic bar-cobar theorem transported to the finite-type chiral tensor category.

Step 1: Reduction to the classical operadic statement. By Proposition 3.11.7, the chiral associative operad Ass^{ch} is the chiral lift of the classical associative operad Ass . The bar-cobar adjunction for a Koszul operad $\mathcal{P}$ in a stable presentably symmetric monoidal ∞ -category $\mathcal{V}$ is an equivalence $\mathcal{P}\text{-Alg}^{\text{aug, pronil}}(\mathcal{V}) \simeq \mathcal{P}^!\text{-CoAlg}^{\text{coaug, conil}}(\mathcal{V})$ whenever $\mathcal{P}$ is Koszul [?LV12, Theorem 11.4.1]. We apply this with $\mathcal{V} = \mathcal{D}\text{-mod}(X)$ (the stable ∞ -category of $\mathcal{D}$ -modules on X , equipped with the chiral tensor product) and $\mathcal{P} = \text{Ass}$.

Step 2: Koszulity of Ass in the chiral tensor category. By Lemma 14.5.5 below (applied with $\mathcal{P} = \text{Ass}$ and $\mathcal{V} = \mathcal{D}\text{-mod}(X)$), the classical Koszulity of Ass [?LV12, Theorem 7.4.1] transfers to the chiral tensor category: the operadic bar complex $B_{\text{Ass}}(k)$ is quasi-isomorphic to $\text{Ass}^!$ after base change to $\mathcal{V}$.

Step 3: Geometric realization via configuration spaces. The bar complex $\bar{B}^{\text{ch}}(\mathcal{A})$ has an explicit geometric model (Definition 7.1.17):

$$\bar{B}_n^{\text{ch}}(\mathcal{A}) = \Gamma\left(\bar{C}_n(X), j_* j^* \mathcal{A}^{\boxtimes n} \otimes \Omega_{\bar{C}_n(X)}^{n-1}(\log D)\right).$$

The key difference from the E_∞ -chiral case is that the Σ_n -action is *not* imposed: the n -th bar component is indexed by *ordered* configurations $(z_1, \dots, z_n)$, not unordered ones. The differential is the same alternating sum of face maps (collisions of adjacent points), reflecting the non- Σ nature of the associative operad.

For the cobar construction, by Corollary 8.0.15, we have $d_{\text{cobar}}^2 = 0$ via Verdier duality. The counit map $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$ is a quasi-isomorphism by the acyclicity of the augmented bar complex (a standard contraction argument using the augmentation ε , as in Theorem 9.10.17), and the unit map is a quasi-isomorphism by the dual argument for conilpotent coalgebras. $\square$

LEMMA 14.5.5 (*Operadic Koszulness transfer* [?LV12];). Let $\mathcal{P}$ be a quadratic operad over a field k , and let $\mathcal{V}$ be a stable presentably symmetric monoidal ∞ -category over k . If $\mathcal{P}$ is Koszul in the classical sense (i.e., over the category of k -modules), then $\mathcal{P}$ is Koszul as an operad internal to $\mathcal{V}$: the operadic bar construction $B_{\mathcal{P}}(k) \xrightarrow{\sim} \mathcal{P}^!$ is a quasi-isomorphism of cooperads in Σ -objects of $\mathcal{V}$.

Proof. Koszulness of a quadratic operad $\mathcal{P} = \mathcal{F}(V)/(R)$ is equivalent to the acyclicity of the Koszul complex $\mathcal{P} \circ_{\kappa} \mathcal{P}^!$, where $\kappa: \mathcal{P}^! \rightarrow \mathcal{P}$ is the universal twisting morphism [?LV12, Theorem 7.4.2]. We explain why this property, once established over $k\text{-Mod}$, holds automatically in $\mathcal{V}$.

Step 1: The Koszul complex is built from operadic composition. The Koszul complex $\mathcal{P} \circ_{\kappa} \mathcal{P}^!$ is defined as the composition product $\bigoplus_{n \geq 0} \mathcal{P}(n) \otimes_{\Sigma_n} (\mathcal{P}^!)^{\otimes n}$ equipped with a differential twisted by κ . Both the composition product and the twisting differential are determined by the *quadratic data* (V, R) : the generators V , the space of relations $R \subset \mathcal{F}(V)(3)$, and the combinatorics of planar trees indexing operadic compositions [?LV12, §7.4]. No structure of the ambient symmetric monoidal category enters beyond the tensor product and direct sums indexed by these combinatorial data.

Step 2: Base change preserves acyclicity. Given a symmetric monoidal functor $k\text{-Mod} \rightarrow \mathcal{V}$ (the unit functor $M \mapsto M \otimes_{\mathbf{1}_{\mathcal{V}}}$), the Koszul complex over $\mathcal{V}$ is the image $(\mathcal{P} \circ_{\kappa} \mathcal{P}^!) \otimes_k \mathbf{1}_{\mathcal{V}}$. Since $\mathcal{V}$ is k -linear (presentably enriched over k), this base-change functor is exact: it preserves all colimits and finite limits (being a left adjoint between stable categories), hence preserves quasi-isomorphisms. The acyclicity of the Koszul complex over $k\text{-Mod}$ [?LV12, Theorem 7.4.1] therefore implies acyclicity over $\mathcal{V}$.

Step 3: From Koszul complex to bar-cobar resolution. By [?LV12, Theorem 11.3.3], acyclicity of the Koszul complex is equivalent to the bar-cobar resolution being a quasi-isomorphism: $\Omega(\mathcal{P}^!) \xrightarrow{\sim} \mathcal{P}$ as operads. This equivalence is formal (it holds in any abelian category where the Koszul complex is defined), so it transfers together with Step 2. The ∞ -categorical upgrade follows from [?LV12, Theorem 11.4.1] (see also [?Fresse-operads, §16] for the model-categorical treatment of the bar-cobar adjunction for algebras over Koszul operads in general symmetric monoidal model categories). $\square$

REMARK 14.5.6 (*Verification of hypotheses*). Steps 1–2 of the proof invoke [?LV12, Theorem 11.4.1] and Lemma 14.5.5 with $\mathcal{V}$ equal to the chosen factorization/Ran enhancement satisfying $H_{\text{Fact}}(X)$. The coefficient category $\mathcal{D}\text{-mod}(X)$ supplies the stable presentable linear ambient and the Beilinson–Drinfeld pseudo-tensor operations, but not by itself an ordinary symmetric monoidal chiral tensor bifunctor. We verify the required hypotheses on $\mathcal{V}$:

- (i) *Stable presentable ∞ -category.* The ∞ -category $\mathcal{D}\text{-mod}(X)$ is stable and presentable by [?GR17, Chapter I.3]; see also [?HA, Proposition 5.5.3.6] and [?HA, §1.1].
- (ii) *Symmetric monoidal/factorization ambient.* The Beilinson–Drinfeld chiral operations form a pseudo-tensor structure by [?BD04, §3.4]; they are not used here as an ordinary symmetric monoidal bifunctor on $\mathcal{D}\text{-mod}(X)$. The symmetric monoidal operation required by Lemma 14.5.5 is the factorization/Ran enhancement and Francis–Gaitsgory star-product isolated as the conditional package $H_{\text{Fact}}(X)$ in Proposition 17.3.3.
- (iii) *Exactness of base change* (Lemma 14.5.5, Step 2). The unit functor $k\text{-Mod} \rightarrow \mathcal{D}\text{-mod}(X)$ is exact because $\mathcal{D}\text{-mod}(X)$ is k -linear and stable. More concretely, $\mathcal{D}\text{-mod}(X)$ carries a t -structure for which $\otimes^{\text{ch}}$ is right-exact on each factor [?BD04, 3.4.12], and the bar filtration produces complexes bounded below (in the t -structure sense), so the derived tensor product agrees with the underived one on each filtered piece.

Example 14.5.7 (Heisenberg specialization). For the Heisenberg algebra $\mathcal{H}_k$, Theorem 14.5.4 simplifies dramatically: $\mathcal{H}_k$ is E_∞ -chiral as a local vertex algebra, but it is not BD-commutative: the OPE $J(z)J(w) \sim k/(z-w)^2$ still has a double pole. Hence the E_1 ordered bar descends to the symmetric E_∞ bar through the OPE-derived R -matrix datum; only for the pole-free BD-commutative subclass is the Σ_n -quotient on ordered configurations a literal isomorphism. The bar components $\bar{B}_n^{\text{ch}}(\mathcal{H}_k)$ are therefore indexed by *unordered* configurations after imposing this descent datum. The counit quasi-isomorphism $\Omega^{\text{ch}}(\bar{B}^{\text{ch}}(\mathcal{H}_k)) \xrightarrow{\sim} \mathcal{H}_k$ was verified explicitly in Chapter 2: the bar complex (§2.1–§2.3) is compared with the quadratic presentation coalgebra $\mathcal{H}_k^i$ by $q_{\mathcal{H}_k}: \mathcal{H}_k^i \circ \bar{B}_X(\mathcal{H}_k)$. Finite Verdier duality gives $K_X(\mathcal{H}_k)$, the chosen pair map identifies it with the curved commutative partner, and cobar reconstructs $\mathcal{H}_k$. The spectral discriminant is trivial ($\Delta_{\mathcal{H}_k}(x) = 1$, rank 1), reflecting that no non-trivial higher operations arise.

COROLLARY 14.5.8 (*Ordered E_1 bar and continuous dual;*). Since $(\text{Ass}^{\text{ch}})^! \cong \text{Ass}^{\text{ch}} \otimes \text{sgn}$ (Proposition 3.11.7), the ordered bar of an augmented pro-nilpotent finite-type E_1 -chiral algebra $\mathcal{A}$ is again of associative coalgebra type. Set

$$C_{\mathcal{A}}^{\text{bar,ord}} := \bar{B}^{\text{ch}}(\mathcal{A}).$$

The bar–cobar counit is

$$\Omega^{\text{ch}} C_{\mathcal{A}}^{\text{bar,ord}} \xrightarrow{\sim} \mathcal{A}.$$

When the continuous Verdier dual exists, it forms the associative algebra

$$K_X^{\text{ord}}(\mathcal{A}) := \mathbb{D}_{\text{Ran}} C_{\mathcal{A}}^{\text{bar,ord}}.$$

A chosen pair equivalence $\nu_{\mathcal{A}}: K_X^{\text{ord}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}^!$ supplies the partner algebra. For a quadratic presentation, the separate map $q_{\mathcal{A}}: \mathcal{A}^! \circ C_{\mathcal{A}}^{\text{bar,ord}}$ is the quadratic recognition map.

Proof. Theorem 14.5.4 gives the counit (14.5). Operadic self-duality places the bar output in the associative coalgebra category. Continuous Verdier duality forms $K_X^{\text{ord}}(\mathcal{A})$, while the pair equivalence ν is the additional family-specific datum. The quadratic map q comes from the chosen presentation and its twisting morphism. $\square$

Remark 14.5.9 (Comparison with Francis–Gaitsgory). Francis–Gaitsgory [?FG12] establish chiral Koszul duality for the $\text{Lie}^{\text{ch}}\text{--Com}^{\text{ch}}$ pair (mechanism (i) of Remark 3.11.19). Theorem 14.5.4 is the *associative* counterpart, operating within the single operadic type Ass^{ch} . The two results are complementary:

	Operadic pair	Algebra $\leftrightarrow$ Coalgebra
Francis–Gaitsgory	$\text{Lie}^{\text{ch}} \dashv \text{Com}^{\text{ch}}$	$\text{Lie}^{\text{ch}}\text{-alg} \simeq \text{Com}^{\text{ch}}\text{-coalg}$
This work	$\text{Ass}^{\text{ch}} \dashv \text{Ass}^{\text{ch}}$	$\text{Ass}^{\text{ch}}\text{-alg} \simeq \text{Ass}^{\text{ch}}\text{-coalg}$

The self-dual case is simpler (the bar and cobar land in the same operadic type) but has not been treated in the chiral setting in the existing literature.

Remark 14.5.10 (Disk bar model and wrapped Fukaya categories;). Abouzaid [?AbouzaidGeneration] proves that a split-generating Lagrangian L in the wrapped Fukaya category $\mathcal{W}(\mathcal{M})$ has its wrapped endomorphism algebra computed from a disk model. Under a chosen wrapped-generation and orientation package, the ordered bar $B^{\text{ord}}(\mathcal{A})$ on the disk is an algebraic model for the Floer

polygon complex: the bar differential records the same A_∞ polygon operations that Fukaya–Oh–Ohta–Ono [?F00009] define by counts of pseudoholomorphic $(n + 1)$ -gons with boundary on L . Ganatra–Pardon–Shende [?GPSectorialDescent] show that sectorial descent for wrapped Fukaya categories identifies this bar model with $\mathcal{W}(M)$ itself under their hypotheses. In this identification the bar coalgebra controls generation: $\Omega(B^{\text{ord}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$ becomes Floer-theoretic generation. A further homological-mirror identification between compact and wrapped sectors requires the corresponding HMS equivalence and split-generation assumptions [?KontsevichHMS, ?SeidelBook]; these geometric inputs complement the chiral bar–cobar adjunction. The objects remain distinct: $\mathcal{A}$ is the open-string A_∞ algebra, $B^{\text{ord}}(\mathcal{A})$ is the bar coalgebra, $\mathcal{A}^i = C(s^{-1}V, s^{-2}R)$ is the coalgebra of a chosen quadratic presentation, $K_X(\mathcal{A}) = \mathbb{D}B^{\text{ord}}(\mathcal{A})$ is the finite-type Verdier algebra, and $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^1$ selects a Koszul partner. The Hochschild cochain object $Z_{\text{ch}}^{\text{der}}(\mathcal{A}) = CH^*(\mathcal{A})$ is the cochain-level closed-sector actor; a separate open–closed comparison identifies physical local operators with this cochain object when the corresponding geometric package holds.

14.6 CATEGORIES OF MODULES AND DERIVED EQUIVALENCES

14.6.1 The fundamental theorem for chiral Koszul pairs

Remark 14.6.1 (General chiral module-category duality remains frontier). The broad ordinary-derived package for a general chiral Koszul pair $(\mathcal{A}_1, \mathcal{A}_2)$ (derived equivalence, Ext exchange with derived Hom on the bar-comodule side and finite-type Tor reformulations, simple/projective transport, and Hochschild transport) is *not* proved on this general surface. The bar-cobar machinery in Part II gives the intrinsic bar-coalgebra comparison, and the proved ordinary module-level statement is the E_1 theorem Theorem 14.6.2, restricted to the quadratic genus-0 complete/conilpotent lane.

Any extension of that package to arbitrary chiral Koszul pairs would require extra hypotheses and a module-level comparison theorem beyond what is currently established here. Nor does Hochschild transport reconstruct a physical bulk factorization algebra: it gives the cochain-level closed-sector actor $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ only after the chiral Hochschild comparison is installed. A physical bulk requires a separate bulk-to-boundary local-operator map and a quasi-isomorphism statement.

14.6.2 E_1 -chiral module category Koszul duality

THEOREM 14.6.2 (E_1 -module category Koszul duality;). Let $\mathcal{A}$ be a Koszul E_1 -chiral algebra with Koszul bar coalgebra $C_{\mathcal{A}}^{\text{bar}} := \bar{B}^{\text{ch}}(\mathcal{A})$ (Theorem 14.5.4, Corollary 14.5.8). When continuous Verdier duality exists, write

$$K_X^{\text{ord}}(\mathcal{A}) := \mathbb{D}_{\text{Ran}} C_{\mathcal{A}}^{\text{bar}}.$$

Then the bar-cobar adjunction restricts to an equivalence of derived categories between *complete* (pro-nilpotent) $\mathcal{A}$ -modules and *conilpotent* $C_{\mathcal{A}}^{\text{bar}}$ -comodules:

$$D(\text{Mod}_{\mathcal{A}}^{E_1, \text{compl}}) \simeq D(\text{CoMod}_{C_{\mathcal{A}}^{\text{bar}}}^{E_1, \text{conil}})$$

given by the bar-cobar induction-restriction adjunction:

$$\begin{aligned} \text{Ind}: \text{Mod}_{\mathcal{A}}^{E_1, \text{compl}} &\longrightarrow \text{CoMod}_{C_{\mathcal{A}}^{\text{bar}}}^{E_1, \text{conil}}, & \mathcal{M} &\longmapsto \bar{B}^{\text{ch}}(\mathcal{A}) \otimes_{\mathcal{A}} \mathcal{M}, \\ \text{Res}: \text{CoMod}_{C_{\mathcal{A}}^{\text{bar}}}^{E_1, \text{conil}} &\longrightarrow \text{Mod}_{\mathcal{A}}^{E_1, \text{compl}}, & \mathcal{N} &\longmapsto \Omega^{\text{ch}}(C_{\mathcal{A}}^{\text{bar}}) \otimes_{C_{\mathcal{A}}^{\text{bar}}} \mathcal{N}. \end{aligned}$$

Under this equivalence:

- (i) Suppose a module L carries a twisting-compatible cofree comparison $\text{Ind}(L) \xrightarrow{\sim} C_{\mathcal{A}}^{\text{bar}} \otimes L_{\circ}$ for a finite lowest-weight object $L_{\circ}$. Then the bar image $\text{Ind}(L)$ is a cofree, hence injective, $C_{\mathcal{A}}^{\text{bar}}$ -comodule. On finite-type dualized lanes, its graded dual is projective over $K_X^{\text{ord}}(\mathcal{A})$.
- (ii) Derived extension groups are exchanged with derived morphisms on the bar-comodule side:

$$\text{Ext}_{\mathcal{A}}^i(L, M) \cong \text{Hom}_{D(\text{CoMod}_{C_{\mathcal{A}}^{\text{bar}}}^{\text{E}_1, \text{conil}})}(\text{Ind}(L), \text{Ind}(M)[i]).$$

- (iii) On a split finite quadratic lane where $\mathcal{A}^!$ satisfies H_{CL} , character formulas for $\mathcal{A}$ -modules are computed by the resolution with $\mathcal{A}_{\text{quad}}^! = \mathbb{D}\mathcal{A}^!$. A grading-preserving comparison $c_{\mathcal{A}}: \mathcal{A}_{\text{quad}}^! \rightarrow \mathcal{A}^!$ transports the formula to the chosen partner.

Proof. The argument follows the same geometric bar-resolution strategy discussed above, but now on the proved E_1 complete/conilpotent lane:

Step 1. The bar complex $\tilde{B}^{\text{ch}}(\mathcal{A})$ is computed using *ordered* configurations, retaining the full ordered n -tuple at each arity, so $\text{Ind}(\mathcal{M})$ tensors $\mathcal{M}$ with $\tilde{B}_n^{\text{ch}}(\mathcal{A})$ over ordered configuration spaces.

Step 2. The Koszulity of Ass^{ch} (Proposition 3.11.7) ensures the bar resolution is a cofibrant replacement in E_1 -chiral modules. The counit $\Omega^{\text{ch}} \circ \tilde{B}^{\text{ch}} \xrightarrow{\sim} \text{id}$ (Theorem 14.5.4, equation (14.5)) extends to modules: $\text{Res} \circ \text{Ind}(\mathcal{M}) \simeq \mathcal{M}$.

Step 3. The unit $\text{id} \xrightarrow{\sim} \text{Ind} \circ \text{Res}$ follows from the dual argument on conilpotent comodules.

We verify each property in turn.

Property (i): cofree transport under the stated comparison. The additional equivalence $\text{Ind}(L) \simeq C_{\mathcal{A}}^{\text{bar}} \otimes L_{\circ}$ identifies the image with a cofree comodule. Cofree comodules are injective, and finite continuous duality sends this object to a projective $K_X^{\text{ord}}(\mathcal{A})$ -module.

Property (ii): Ext exchange. The displayed derived equivalence is covariant, so it preserves morphism spaces with the same order of arguments:

$$\text{Hom}_{D(\text{Mod}_{\mathcal{A}}^{\text{E}_1, \text{compl}})}(L, M[i]) \cong \text{Hom}_{D(\text{CoMod}_{C_{\mathcal{A}}^{\text{bar}}}^{\text{E}_1, \text{conil}})}(\text{Ind}(L), \text{Ind}(M)[i]).$$

By definition, the left-hand side is $\text{Ext}_{\mathcal{A}}^i(L, M)$, giving (ii).

Property (iii): character computation. On the split finite quadratic lane, the usual dual-algebra Koszul resolution may be used. The Koszul resolution of any $\mathcal{A}$ -module $\mathcal{M}$ by free $\mathcal{A}$ -modules has terms $\mathcal{P}_n = \mathcal{A} \otimes (\mathcal{A}_{\text{quad}}^!)^{\otimes n} \otimes \mathcal{M}$ (Theorem 36.4.2 in Chapter 36); the character formula then follows from the acyclicity of the Koszul resolution combined with the Hilbert series identity $h_{\mathcal{A}}(t) \cdot h_{\mathcal{A}_{\text{quad}}^!}(-t) = 1$. The comparison $c_{\mathcal{A}}$ transports the formula to the chosen partner whenever it preserves the grading. $\square$

PROPOSITION 14.6.3 (*Finite quadratic Hilbert identity*;). Let $\mathcal{A}$ lie on the split finite-type quadratic lane, and assume its presentation coalgebra $\mathcal{A}^! = C_X(s^{-1}V, s^{-2}R)$ satisfies H_{CL} and admits the finite Verdier dual algebra $\mathcal{A}_{\text{quad}}^! = \mathbb{D}_{\text{Ran}}\mathcal{A}^!$. Then the Hilbert series of the algebra and of the quadratic dual satisfy the classical Koszul identity

$$h_{\mathcal{A}}(t) h_{\mathcal{A}_{\text{quad}}^!}(-t) = 1. \quad (14.6)$$

A chosen partner map $c_{\mathcal{A}}: \mathcal{A}_{\text{quad}}^! \rightarrow \mathcal{A}^!$ transports the identity to $h_{\mathcal{A}^!}$ when it is a grading-preserving quasi-isomorphism. The series in (14.6) is the graded Hilbert series of the quadratic dual; quasi-primary characters form a separate invariant of the original algebra.

Proof. On the finite quadratic lane the Koszul resolution of the unit has terms $\mathcal{A} \otimes (\mathcal{A}^!)_n$. Taking the Euler characteristic of this exact resolution gives

$$h_{\mathcal{A}}(t) \sum_{n \geq 0} (-1)^n \dim(\mathcal{A}^!)_n t^n = 1.$$

Finite Verdier duality preserves the graded dimensions, so the signed series is $h_{\mathcal{A}^!_{\text{quad}}}(-t)$. This proves (14.6). For PBW non-quadratic or completed families, the same expression becomes a finite-window Euler identity under the Mittag–Leffler hypotheses. $\square$

PROPOSITION 14.6.4 (*Bar cohomology and quasi-primary count;*). The bar function $b_{\mathcal{A}}(h) := \dim H^1(\bar{\mathbf{B}}(\mathcal{A}))_h$ is a derived invariant of the full bar coalgebra. For a chosen quadratic presentation satisfying H_{CL} , it equals $\dim H^1(\mathcal{A}^!)_h$ through $H^\bullet(q_{\mathcal{A}})$. The quasi-primary function $d_{\text{qp}}(h) = p_{\geq 2}(h) - p_{\geq 2}(h-1)$ counts quasi-primary fields of the *original* algebra $\mathcal{A}$. For the universal Virasoro algebra,

$$b_{\text{Vir}}(2) = 1, \quad b_{\text{Vir}}(4) = 0, \quad d_{\text{qp}}(2) = d_{\text{qp}}(4) = 1.$$

Hence the two functions already separate at weight 4.

Proof. For the Virasoro algebra, $\dim H^1(\bar{\mathbf{B}}(\text{Vir}))_h$ is computed by the degree-one part of the PBW bar complex and is concentrated at weight 2: $\dim H^1(\bar{\mathbf{B}}(\text{Vir}))_2 = 1$ (the single generator T) and $\dim H^1(\bar{\mathbf{B}}(\text{Vir}))_h = 0$ for $h \neq 2$, independent of c (Theorem 14.1.26). The quasi-primary count $d_{\text{qp}}(h) = p_{\geq 2}(h) - p_{\geq 2}(h-1)$ grows as a partition function, with $d_{\text{qp}}(2) = 1$, $d_{\text{qp}}(4) = 1$, $d_{\text{qp}}(6) = 2$, $d_{\text{qp}}(8) = 3$. The two sequences agree at weight 2 but diverge at weight 4: $\dim H^1(\bar{\mathbf{B}}(\text{Vir}))_4 = 0$ while $d_{\text{qp}}(4) = 1$ (the composite quasi-primary Λ). The sequences therefore differ at the first nontrivial weight above the generator. $\square$

Remark 14.6.5 (*Why the coincidence for free fields is tempting*). For free-field algebras (Heisenberg, free fermion), the quasi-primary count at weight h equals the bar cohomology dimension at weight h , because the algebra is generated by a weight-1 field and the Koszul dual is the symmetric/exterior algebra on the same space. This is a special-case coincidence: it holds when the algebra is both free and generated in weight 1, which forces the Koszul dual to have the same Hilbert series as the quasi-primary tower. For algebras with generators of weight ≥ 2 , the Koszul dual’s weight distribution diverges from the quasi-primary distribution.

Remark 14.6.6 (*Categorified Koszul duality and geometric representation theory*). The numerical complementarity $\kappa(\mathcal{A}) + \kappa(\mathcal{A}^!) = K$ (Theorem ??) has a categorical shadow only after the finite-type Verdier and completion hypotheses have been fixed. The theorem proved here is the bar-comodule equivalence on the complete E_1 lane: $D(\text{Mod}_{\mathcal{A}}^{\text{compl}}) \simeq D(\text{CoMod}_{B(\mathcal{A})}^{\text{conil}})$ (Theorem 14.6.2). Its Euler decategorification can be compared with the scalar conductor identity after forming the finite post-Verdier algebra $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} B_X(\mathcal{A})$, choosing the pair map $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$, and inserting the family-specific conductor normalization $\kappa + \kappa^! = \varrho_{\mathcal{A}} K$ (with $\varrho_{\mathcal{A}} = 0$ for Kac–Moody and free-field families, $\varrho_{\text{Vir}} = 1/2$, $\varrho_{\mathcal{W}_N} = H_N - 1$ for principal $\mathcal{W}_N$, and $\varrho_{\text{BP}} = 1/6$). The module equivalence alone does not prove those scalar constants.

This structure has three classical shadows in geometric representation theory.

- (i) *BGS Koszul duality*. For category $\mathcal{O}$ of a semisimple Lie algebra $\mathfrak{g}$, the Ext algebra of simples is Koszul, and the Koszul dual category is $\mathcal{O}^!(\mathfrak{g}^\vee)$ [?BGS96]. The Kazhdan–Lusztig polynomials $P_{y,w}(q)$ are read from the E_2 page of the bar spectral sequence (Remark 36.2.22); the

Kazhdan–Lusztig conjecture [?KL79], proved by Beilinson–Bernstein [?BB81] and Brylinski–Kashiwara [?BK81], is the statement that these polynomials compute composition multiplicities. In our framework the bar complex $\bar{\mathbf{B}}(\mathcal{A})$ provides the universal resolution underlying this spectral sequence.

- (ii) *Kazhdan–Lusztig tensor equivalence.* At positive integer level k , the Kazhdan–Lusztig equivalence [?KL93] $\mathcal{O}_k(\widehat{\mathfrak{g}}) \simeq C(U_q(\mathfrak{g}))$ identifies affine category $\mathcal{O}$ with a quantum group category. Passing to the Koszul dual level $k' = -(k + 2h^\vee)$ exchanges the two sides of this equivalence; the numerical shadow is the affine Kac–Moody complementarity: the sum $\kappa(V_k(\mathfrak{g})) + \kappa(V_{k'}(\mathfrak{g}))$ vanishes. The chiral bar-cobar adjunction is the operadic skeleton that governs this level-exchange: the bar differential at level k and the cobar differential at level k' are intertwined by the Verdier functor of Theorem A.
- (iii) *Bezrukavnikov–Finkelberg–Mirković.* The BFM theorem [?BFM04] constructs a derived equivalence between (mixed) perverse sheaves on the affine Grassmannian Gr_G and modules over the Langlands dual Lie algebra $\mathfrak{g}^\vee$, extending the geometric Satake correspondence to a Koszul duality statement. Their equivalence is a derived incarnation of the same pattern: the bar resolution of the equivariant intersection cohomology complexes on Gr_G computes Ext groups that are formal and Koszul, and the resulting dual category is governed by $\mathfrak{g}^\vee$. Arkhipov–Bezrukavnikov–Ginzburg [?ABG04] establish the parallel statement for the quantum group, completing the triangle *affine $\mathcal{O} \leftrightarrow$ quantum group $\leftrightarrow$ perverse sheaves on Gr .*

In each case the shared mechanism is Koszul-type formality: the relevant Ext algebra is generated in degree 1 or, in the chiral setting, the bar cohomology is concentrated along the diagonal. The chiral Koszul pair $(\mathcal{A}, \mathcal{A}^!)$ of Definition 14.1.19 axiomatises this bar-formality mechanism after the bar-dual coalgebra has been separated from its post-Verdier dual algebra.

BGS formality, the Kazhdan–Lusztig tensor equivalence, and the BFM derived Satake correspondence require their own geometric hypotheses: flag-variety localization, integral-level affine category $\mathcal{O}$, or affine-Grassmannian constructibility. The chiral bar-cobar formalism supplies the common Koszul skeleton, not a replacement for those inputs. When the external hypotheses are present, the bar spectral sequence records the same graded multiplicities; without them the paragraph is only a heuristic comparison.

14.7 INTERCHANGE OF STRUCTURES UNDER KOSZUL DUALITY

14.7.1 Generators and relations

THEOREM 14.7.1 (*Structure exchange on the finite quadratic lane;*). [Type signature: Open quadrant; split finite quadratic presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package $H_{\mathrm{CL}} + H_{\mathbb{D}}^{\mathrm{bar}} + c_{\mathcal{A}_1}$.] Let $\mathcal{A}_1 = T_{\mathrm{ch}}(V)/(R)$ and $\mathcal{A}_1^! = C_X(s^{-1}V, s^{-2}R)$. Assume H_{CL} for $q_{\mathcal{A}_1} : \mathcal{A}_1^! \circ B_X(\mathcal{A}_1)$ and a grading-preserving pair equivalence

$$c_{\mathcal{A}_1} : \mathcal{A}_{1,\mathrm{quad}}^! := \mathbb{D}_{\mathrm{Ran}} \mathcal{A}_1^! \xrightarrow{\sim} \mathcal{A}_2$$

satisfying $\nu_{\mathcal{A}_1} = c_{\mathcal{A}_1} \circ \mathbb{D}(q_{\mathcal{A}_1})$. Then:

- (i) *Generators and relations.* With the suspension conventions of Definition ??,

$$\mathcal{A}_2 \simeq T_{\mathrm{ch}}(s\mathbb{D}_X V)/(R^\perp).$$

Thus the dual generator object is $s\mathbb{D}_X V$ and the dual relation object is the residue annihilator $R^\perp$.

- (ii) *Twisting and coproduct.* The multiplication of $\mathcal{A}_1$ enters the quadratic twisting morphism $\kappa_{\mathcal{A}_1} : \mathcal{A}_1^! \circ \mathcal{A}_1$ and the cobar differential on $\Omega_X(\mathcal{A}_1^!)$. The deconcatenation coproduct of $\mathcal{A}_1^!$ dualizes to the multiplication of $\mathcal{A}_{1,\text{quad}}^!$.
- (iii) *Koszul resolution.* The unit has the resolution

$$\cdots \longrightarrow \mathcal{A}_1 \otimes (\mathcal{A}_1^!)_2 \longrightarrow \mathcal{A}_1 \otimes (\mathcal{A}_1^!)_1 \longrightarrow \mathcal{A}_1 \longrightarrow \mathbf{1},$$

whose differential is induced by $\kappa_{\mathcal{A}_1}$.

Proof. The quadratic presentation coalgebra is the subcoalgebra

$$\mathcal{A}_1^! = C_X(s^{-1}V, s^{-2}R) \subset T_{\text{ch}}^c(s^{-1}V).$$

Finite Verdier duality turns this subcoalgebra into the quadratic quotient

$$\mathcal{A}_{1,\text{quad}}^! \simeq T_{\text{ch}}(s\mathbb{D}_X V)/(R^\perp).$$

The map $c_{\mathcal{A}_1}$ transports this presentation to $\mathcal{A}_2$.

The universal property of the twisting morphism gives the cobar differential on $\Omega_X(\mathcal{A}_1^!)$ from $\kappa_{\mathcal{A}_1}$ and the coproduct. Its counit has target $\mathcal{A}_1$. The package H_{CL} makes the twisted tensor product $\mathcal{A}_1 \otimes_{\kappa_{\mathcal{A}_1}} \mathcal{A}_1^!$ acyclic, which is precisely the displayed Koszul resolution. Verdier duality converts the coproduct on $\mathcal{A}_1^!$ into the product on $\mathcal{A}_{1,\text{quad}}^!$. $\square$

14.7.2 A_∞ operations exchange

THEOREM 14.7.2 (*A_∞ operations under Verdier pairing;*). Let $\mathcal{A}_1 = T_{\text{ch}}(V)/(R)$ satisfy the hypotheses of Theorem 14.7.1. Assume a filtered deformation retraction of $B_X(\mathcal{A}_1)$ onto $\mathcal{A}_1^!$, a cyclic homotopy transfer datum, and a perfect chain-level Verdier pairing compatible with the pair equivalence $c_{\mathcal{A}_1} : \mathcal{A}_{1,\text{quad}}^! \circ \mathcal{A}_2$. Then:

- transferred higher operations on $\mathcal{A}_1$ pair with higher cooperations on $\mathcal{A}_1^!$;
- after finite duality, these cooperations become higher operations on $\mathcal{A}_{1,\text{quad}}^!$ and hence on $\mathcal{A}_2$ through $c_{\mathcal{A}_1}$;
- Massey products on $\mathcal{A}_1$ pair with the corresponding comassey classes on $\mathcal{A}_1^!$ whenever the transferred classes are defined.

Proof. The Verdier duality pairing on configuration spaces (Theorem 13.3.2) gives

$$\langle m_k^{(1)}, n_k^{(2)} \rangle = \int_{\overline{C}_k(X)} \omega_{m_k} \wedge \delta_{n_k}$$

where ω_{m_k} represents the k -ary operation on $\mathcal{A}_1$ and δ_{n_k} represents the dual cooperation on the presentation coalgebra. Perfectness identifies each operation with its transpose cooperation. Applying finite continuous duality turns the cooperation on $\mathcal{A}_1^!$ into an operation on the dual algebra $\mathcal{A}_{1,\text{quad}}^!$, and $c_{\mathcal{A}_1}$ transports it to $\mathcal{A}_2$. Cyclic homotopy transfer descends the perfect chain pairing to the defined Massey and comassey classes, which gives the final assertion. $\square$

14.8 FILTERED AND CURVED EXTENSIONS

14.8.1 Filtered and curved structures

The central extensions of Virasoro, Kac–Moody, and Yangian algebras produce curvature $m_o \neq o$ in their bar complexes. To handle this systematically:

Definition 14.8.1 (Filtered chiral algebra). A filtered chiral algebra has an exhaustive filtration:

$$o = F_{-1}\mathcal{A} \subset F_o\mathcal{A} \subset F_1\mathcal{A} \subset \cdots$$

with $\mu(F_i \otimes F_j) \subset F_{i+j}$ and $\mathcal{A} = \varprojlim \mathcal{A}/F_n\mathcal{A}$.

Definition 14.8.2 (Curved A_∞). A curved A_∞ structure has operations m_k for $k \geq o$ with curvature $m_o \in F_{\geq 1}\mathcal{A}[2]$ satisfying the Maurer–Cartan equation.

PROPOSITION 14.8.3 (Uniqueness of the Feigin–Frenkel involution;). Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra and consider the family of affine Kac–Moody algebras $\{\widehat{\mathfrak{g}}_k\}_{k \in \mathbb{C}}$. The Feigin–Frenkel involution $\iota_{\text{FF}} : k \mapsto -k - 2h^\vee$ is the *unique* involution ι of the level parameter satisfying:

- (i) ι is an affine-linear involution: $\iota(k) = ak + b$ with $\iota^2 = \text{id}$;
- (ii) ι is compatible with Koszul duality: the Koszul dual $\widehat{\mathfrak{g}}_k^\dagger$ has the same modular characteristic as $\widehat{\mathfrak{g}}_{\iota(k)}$, i.e. $\kappa(\widehat{\mathfrak{g}}_k^\dagger) = \kappa(\widehat{\mathfrak{g}}_{\iota(k)})$;
- (iii) ι fixes the critical level: $\iota(-h^\vee) = -h^\vee$.

Proof. An affine-linear involution $\iota(k) = ak + b$ satisfies $\iota^2(k) = a^2k + ab + b = k$ for all k , giving $a^2 = 1$ and $b(a + 1) = 0$. If $a = 1$, then $b = 0$ and $\iota = \text{id}$, which contradicts (ii) (a non-trivial duality). Therefore $a = -1$ and $\iota(k) = -k + b$.

Condition (iii) requires $\iota(-h^\vee) = h^\vee + b = -h^\vee$, so $b = -2h^\vee$. This gives $\iota(k) = -k - 2h^\vee$, the Feigin–Frenkel involution.

That this involution satisfies (ii) is the content of Theorem ??: the bar construction at level k produces a Koszul dual whose modular characteristic equals $\kappa(\widehat{\mathfrak{g}}_{-k-2h^\vee})$. $\square$

14.8.2 Curved Koszul duality

THEOREM 14.8.4 (Curved conductor compatibility;). [Regime: curved-central (Convention 1.10.2).]

Let $(\mathcal{A}_1, \mathcal{A}_2)$ be filtered-complete chiral algebras with modular curvatures κ_1, κ_2 . Put

$$C_i = \widehat{B}_X^{\text{curv}}(\mathcal{A}_i), \quad H_i^{\text{bar}} := H^\bullet(C_i), \quad K_X^{\text{curv}}(\mathcal{A}_i) := \mathbb{D}_{\text{Ran}} C_i,$$

so C_i is the completed curved bar coalgebra, H_i^{bar} is its cohomology, and $K_X^{\text{curv}}(\mathcal{A}_i)$ is its Verdier-dual algebra. The Hochschild object $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_i) = C_{\text{ch}}^\bullet(\mathcal{A}_i, \mathcal{A}_i)$ is not part of this pair datum. Assume:

- (i) the associated graded pair $(\text{gr } \mathcal{A}_1, \text{gr } \mathcal{A}_2)$ is a classical Koszul pair;
- (ii) the filtrations are complete, separated, and bidegreewise Mittag–Leffler in the sense of Lemma 14.3.9;
- (iii) the curved bar coalgebras C_i are degreewise finite-type Verdier dualizable on the chosen lane, and the candidate pair maps

$$K_X^{\text{curv}}(\mathcal{A}_1) \longrightarrow \mathcal{A}_2, \quad K_X^{\text{curv}}(\mathcal{A}_2) \longrightarrow \mathcal{A}_1$$

are maps of completed factorization algebras whose associated graded maps are the classical Koszul-duality maps from (1);

- (iv) the curved twisting morphism exists in the Positselski completed category and its curvature scalars satisfy the family conductor identity

$$\kappa_1 + \kappa_2 = K_{\text{fam}}^\kappa$$

under these candidate pairings;

- (v) the spectral sequence associated to the filtration degenerates at E_2 .

Then the completed curved bar-cobar comparison identifies $\Omega_X^{\text{curv}} C_i$ with $\mathcal{A}_i$, and the two maps in (3) are equivalences $K_X^{\text{curv}}(\mathcal{A}_1) \simeq \mathcal{A}_2$ and $K_X^{\text{curv}}(\mathcal{A}_2) \simeq \mathcal{A}_1$ on this lane. The scalar identity $\kappa_1 + \kappa_2 = K_{\text{fam}}^\kappa$ is only the curvature-conductor compatibility for those comparisons. It is not a criterion for Koszulness without (1)–(3) and (5).

For the canonical families under their stated hypotheses,

$$K_{\text{fam}}^\kappa = 0 \quad \text{for Heisenberg, affine Kac–Moody, and free fields,}$$

$$K_{\text{fam}}^\kappa = 13 \quad \text{for Virasoro,} \quad K_{\text{fam}}^\kappa = 250/3 \quad \text{for } \mathcal{W}_3,$$

$$K_{\text{fam}}^\kappa = 25/3 \quad \text{for Bershadsky–Polyakov (conditional on the ratio lane),} \quad K_{\text{fam}}^\kappa = 8 \quad \text{for recognized finite Mukai-enhancement}$$

Proof. The filtered bar complex has associated graded $\text{gr } C_i = \overline{B}(\text{gr } \mathcal{A}_i)$. Condition (1) gives the classical Koszul comparison on the E_1 page. Conditions (2) and (5) let this comparison pass to the completed filtered object with vanishing $\varprojlim^1$ correction. The result at this point is a statement about the coalgebras C_i and their bar cohomology H_i^{bar} . Condition (3) forms the Verdier algebras $K_X^{\text{curv}}(\mathcal{A}_i)$ and identifies them with the partner algebras. The Hochschild objects $Z_{\text{ch}}^{\text{der}}(\mathcal{A}_i)$ remain a separate construction.

In a curved A_∞ bar-cobar complex the curvature term is not universally anti-invariant; it is shifted by the conductor of the family. Condition (4) is exactly the compatibility condition for the curved twisting morphism in the Positselski completed category [?Positselski11]. The displayed constants are the canonical target values from the landscape census: $\kappa(V_k(\mathfrak{g})) = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee)$, $\kappa(\text{Vir}_c) = c/2$, and $\kappa(\mathcal{W}_N) = c(H_N - 1)$, together with the recorded Bershadsky–Polyakov and conditional Mukai rows. The Mukai value is available only after the finite Hall–Borcherds recognition datum supplies the source pairing, radical quotient, differential, and completion. Under all five hypotheses the curved comparison is the filtered curved bar-cobar comparison of Theorem 7.1.88. $\square$

14.9 DERIVED CHIRAL KOSZUL DUALITY

14.9.1 Derived ghost differential

The bc ghost system (weights 2, -1) and the $\beta\gamma$ system (weights 1, 0) do not form an ordinary quadratic pair on the nose. A derived pairing, if it exists, must live in DG chiral algebras with a BRST differential and with the bar coalgebra kept separate from its post-Verdier dual algebra.

Definition 14.9.1 (DG chiral algebra). A DG chiral algebra is a cochain complex of factorization $\mathcal{D}$ -modules

$$\mathcal{A}^\bullet : \cdots \rightarrow \mathcal{A}^{-1} \xrightarrow{d} \mathcal{A}^0 \xrightarrow{d} \mathcal{A}^1 \rightarrow \cdots$$

whose chiral products are chain maps; equivalently, d is a derivation for every factorization multiplication map.

Conjecture 14.9.2 (Derived bc - $\beta\gamma$ Koszul duality;). Let $\mathcal{F} = \Lambda^{\text{ch}}(\psi^{(1)}, \psi^{(2)})$ be the free fermion chiral algebra on two generators. The direct sum $\beta\gamma \oplus bc$ carries a natural $\mathbb{Z}$ -grading (ghost number), making it a DG chiral algebra with differential $d_{\text{BRST}}: bc \rightarrow \beta\gamma$ induced by the ghost-antighost pairing. Then:

- (i) There exists a derived chiral Koszul duality framework in which $\mathcal{F}$ and $(\beta\gamma \oplus bc, d_{\text{BRST}})$ form a derived Koszul pair.
- (ii) At the level of bar complexes, the conjectural comparison is a coalgebra comparison

$$\tilde{B}_{\text{derived}}^{\text{ch}}(\mathcal{F}) \simeq (\beta\gamma \oplus bc, d_{\text{BRST}})^i,$$

and only after finite-type Verdier duality would this produce the post-Verdier algebra $(\beta\gamma \oplus bc, d_{\text{BRST}})^!$. This extends the proved single-pair dualities $(\beta\gamma)^! \cong bc$ and $\mathcal{F}(\psi)^! \cong \text{Sym}^{\text{ch}}(\gamma)$ (Theorem ??, Theorem ??).

Remark 14.9.3 (Scope). Conjecture 14.9.2 is tagged for two independent reasons:

- (i) *Algebraic.* A systematic theory of *derived* chiral Koszul duality, extending the quadratic and PBW frameworks of this chapter to DG chiral algebras, has not been developed. The individual dualities $(\beta\gamma)^! \cong bc$ and $\mathcal{F}(\psi)^! \cong \text{Sym}^{\text{ch}}(\gamma)$ are proved, but their interaction in a derived pair requires new constructions (derived bar-cobar adjunction for DG chiral algebras, extending Section 14.10).
- (ii) *Physical.* The specific role of this derived pair in open-closed string field theory (where d_{BRST} is the string BRST operator and the ghost number grading organizes the BV-BRST complex) requires external physics input from the formalism of [?Zwi93].

The precise open mathematical conditions are:

- (a) construct a completed DG chiral bar-cobar adjunction whose coalgebras are conilpotent and whose filtrations satisfy Lemma 14.3.9;
- (b) exhibit a BRST twisting morphism

$$\tau_{\text{BRST}}: \tilde{B}_{\text{derived}}^{\text{ch}}(\mathcal{F}) \longrightarrow (\beta\gamma \oplus bc, d_{\text{BRST}})$$

and prove its Maurer–Cartan equation, including the signs from the two fermions;

- (c) prove diagonal concentration for the DG bar spectral sequence, or identify the first off-diagonal obstruction;
- (d) prove finite-type Verdier dualizability of the resulting coalgebra before naming the post-Verdier algebra $(\beta\gamma \oplus bc, d_{\text{BRST}})^!$;
- (e) for the open–closed string-field interpretation, compare d_{BRST} with the string BRST operator of [?Zwi93].

Until (a)–(e) are supplied, the proved content is only the two single-pair dualities cited in the conjecture.

14.10 COUNTER-EXAMPLES: WHEN KOSZUL DUALITY FAILS

14.10.1 Virasoro algebra: beyond the quadratic setting

Remark 14.10.1 (Virasoro Koszulness requires the PBW framework). The Virasoro algebra with central charge c is not controlled by an uncurved quadratic presentation on the single generator T : the scalar term in the $T(z)T(w)$ OPE is a curvature term, and the normal product TT enters the bar differential outside the quadratic relation space generated by T alone. It is nevertheless chiral Koszul in the PBW

sense of Theorem 14.1.26: the PBW filtration yields a classical Koszul associated graded, and the spectral sequence degenerates at E_2 . The completed curved same-family comparison must therefore be stated in the filtered Positselski category of §9.1.2, with Vir_c , $\overline{B}_X(\text{Vir}_c)$, Vir_c^i , $\text{Vir}_c^!$, and $Z_{\text{ch}}^{\text{der}}(\text{Vir}_c)$ kept distinct.

Why the quadratic framework fails.

(i) The OPE involves a quartic pole:

$$T(z)T(w) = \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w} + \text{regular}$$

(ii) The reduced bar object is the conilpotent coalgebra $\overline{B}_X(\text{Vir}_c) = T^c(s^{-1}\overline{\text{Vir}}_c)$ with differential induced by the Virasoro OPE; it is not the post-Verdier algebra $\text{Vir}_c^!$.

(iii) The composite field

$$: TT : (z) = \lim_{w \rightarrow z} \left(T(z)T(w) - \frac{c/2}{(z-w)^4} - \frac{2T(w)}{(z-w)^2} - \frac{\partial T(w)}{z-w} \right)$$

contributes a bar differential term outside the uncurved quadratic relation space.

(iv) The central charge c enters non-linearly in higher bar degrees, preventing a quadratic Koszul resolution.

One needs the PBW spectral sequence approach (Theorem 14.1.23), or a curved Positselski comparison with nilpotent completion and the hypotheses of Theorem 14.8.4. The conductor identity $\kappa + \kappa^! = 13$ is compatible with this comparison; it does not replace the PBW collapse or the completion hypotheses.

Contrast with Heisenberg/Kac–Moody.

Algebra	Quadratic?	PBW Koszul?	Post-Verdier datum
Heisenberg $\mathcal{H}_k$	Yes (genus 0)	Yes	$\mathbb{D}_{\text{Ran}} \mathcal{H}_k^! \simeq \text{Sym}^{\text{ch}}(V^*)$; curvature $m_o = -k$
Kac–Moody $\widehat{\mathfrak{g}}_k$	Yes	Yes	$\mathbb{D}_{\text{Ran}} \widehat{\mathfrak{g}}_k^!; \kappa^! = \kappa(\widehat{\mathfrak{g}}_{-k-2h^\vee})$
Virasoro Vir_c	No	Yes (Thm 14.1.26)	Completed curved, after Verdier duality
W-algebras $\mathcal{W}^k(\mathfrak{g})$ (universal)	No	Yes (Prop. 14.1.37)	Completed curved, after Verdier duality
W-algebras $\mathcal{W}_k(\mathfrak{g})$ (simple quotient)	No	Open at admissible k	Case-by-case

Note: The bar-cohomology coalgebra is $\mathbb{H}^{\text{bar}}(\widehat{\mathfrak{g}}_k) = H^*(\overline{\mathbf{B}}(\widehat{\mathfrak{g}}_k))$. A chosen quadratic presentation supplies $\widehat{\mathfrak{g}}_k^!$ and $H^\bullet(q_{\widehat{\mathfrak{g}}_k})$ identifies its cohomology with $\mathbb{H}^{\text{bar}}$ under H_{CL} . The finite-type Verdier algebra is $K_X(\widehat{\mathfrak{g}}_k) = \mathbb{D}_{\text{Ran}} \overline{B}_X(\widehat{\mathfrak{g}}_k)$, and the chosen pair map has target $\widehat{\mathfrak{g}}_k^!$. Its modular characteristic satisfies $\kappa(\widehat{\mathfrak{g}}_k^!) = \kappa(\widehat{\mathfrak{g}}_{-k-2h^\vee})$: the two algebras share the same modular characteristic. For Heisenberg (abelian, $h^\vee = 0$): $\mathcal{H}_k^! \simeq (\text{Sym}^{\text{ch}}(V^*[1]), m_o = -k\omega)$ (cf. §??); the curvature encoding the central extension is essential, and the uncurved symmetric algebra is only the associated-graded or $k = 0$ shadow.

Remark 14.10.2 (Quadratic and PBW obstructions). The Virasoro case isolates five facts:

- not every vertex algebra is quadratic Koszul in the uncurved sense;
- PBW Koszulness is controlled by the associated graded and the E_2 -collapse of the bar spectral sequence;
- the quartic pole is an obstruction to the naive quadratic model, not by itself an obstruction to PBW Koszulness;

- $\mathcal{W}$ -algebras carry analogous non-quadratic OPE terms; the universal algebras are handled by Proposition 14.1.37, whereas simple admissible quotients require separate null-vector analysis.
- PBW non-quadratic algebras use the completed bar coalgebra and its cohomology; a residue-dual candidate enters through H_{res} as in Section 14.3.

14.10.2 Classical vs. chiral Koszulness for $\mathcal{W}$ -algebras

Remark 14.10.3 ($\mathcal{W}$ -algebras: classical quadratic Koszulness fails, chiral Koszulness holds). For $\mathcal{W}^k(\mathfrak{sl}_3)$ at generic level $k \neq -3$, the classical quadratic Koszul complex has nontrivial cohomology at degree 4:

$$H^4(\text{classical Koszul complex}) \neq 0 \quad (\text{classical quadratic Koszulity fails})$$

The obstruction is concentrated at the composite field Λ (see §??).

However, $\mathcal{W}^k(\mathfrak{g})$ is *chirally Koszul at all levels k* by Proposition 14.1.37: the universal $\mathcal{W}$ -algebra is freely strongly generated (Feigin–Frenkel), so the PBW criterion applies. The quartic obstruction $[\Lambda]$ measures *shadow depth* (the algebra lies in class M with $r_{\text{max}} = \infty$), not failure of chiral Koszulness.

Caution: The simple quotient $\mathcal{W}_k(\mathfrak{g})$ at admissible levels has vacuum null vectors that may obstruct PBW; its chiral Koszulness remains **open** (the gap is between bar-Ext and ordinary Ext).

14.10.3 Tensor products and Koszulity

Remark 14.10.4 (Tensor products in the algebraic setting). In the classical (non-chiral) setting, tensor products of Koszul algebras are Koszul: if A_1 and A_2 are Koszul quadratic algebras, then $A_1 \otimes A_2$ is Koszul with $(A_1 \otimes A_2)^! \cong A_1^! \otimes A_2^!$ (Polishchuk–Positselski, Theorem 3.1).

In the *chiral* setting, however, the tensor product $\mathcal{A}_1 \otimes \mathcal{A}_2$ as chiral algebras involves the chiral tensor product (not the ordinary tensor product of vector spaces), and the Koszul property is no longer automatic. The bar complex of a chiral tensor product involves configuration spaces with *colored* points, and the interaction between colors introduces additional structure beyond the Arnold relations for each color separately. Whether chiral Koszulity is preserved under chiral tensor products remains open.

PROPOSITION 14.10.5 (*Tensor products on the split quadratic lane;*). Let $\mathcal{A}_i = T_X(V_i)/(R_i)$ be finite-type quadratic chiral algebras on a smooth curve X , with presentation coalgebras $\mathcal{A}_i^! = C_X(s^{-1}V_i, s^{-2}R_i)$ satisfying H_{CL} . Assume chosen partner comparisons $c_i: \mathcal{A}_{i,\text{quad}}^! \xrightarrow{\sim} \mathcal{A}_i^!$. Assume further that the mixed-color OPE residues vanish, the colored configuration-space Künneth map is a filtered quasi-isomorphism, and the mixed relation subspace is the standard locality subspace whose residue-orthogonal complement gives the tensor product of duals. Then the chiral tensor product $\mathcal{A}_1 \otimes^{\text{ch}} \mathcal{A}_2$ is Koszul, and its quadratic presentation coalgebra satisfies

$$(\mathcal{A}_1 \otimes^{\text{ch}} \mathcal{A}_2)^! \simeq \mathcal{A}_1^! \otimes^{\text{ch}} \mathcal{A}_2^!. \quad (14.7)$$

When finite duals exist this dualizes to

$$(\mathcal{A}_1 \otimes^{\text{ch}} \mathcal{A}_2)_{\text{quad}}^! \simeq \mathcal{A}_{1,\text{quad}}^! \otimes^{\text{ch}} \mathcal{A}_{2,\text{quad}}^!.$$

The tensor product $c_1 \otimes c_2$ identifies this algebra with the chosen partner $\mathcal{A}_1^! \otimes^{\text{ch}} \mathcal{A}_2^!$. In particular, for Kac–Moody algebras the level-shift acts componentwise on the modular characteristic:

$$\kappa\left((\widehat{\mathfrak{g}}_k \otimes^{\text{ch}} \widehat{\mathfrak{h}}_\ell)^!\right) = \kappa(\widehat{\mathfrak{g}}_{-k-2h_{\mathfrak{g}}^\vee}) + \kappa(\widehat{\mathfrak{h}}_{-\ell-2h_{\mathfrak{h}}^\vee}).$$

Proof. Under the mixed-vanishing hypothesis, the colored bar complex has no extra residue differential connecting the two colors. The Künneth comparison identifies it with the completed tensor product of the two bar complexes, with deconcatenation coproduct on each color. Since both factors are quadratic Koszul, the tensor product of their Koszul complexes is acyclic, hence the colored bar complex is concentrated on the diagonal. Residue orthogonality for the standard mixed locality relations gives the coalgebra isomorphism (14.7). Finite duality gives the algebra statement, and $c_1 \otimes c_2$ gives the partner comparison. The Kac–Moody specialization uses the modular characteristic equality from Theorem ??; the affine algebra at shifted level supplies the matching scalar datum. $\square$

14.11 COMPUTATIONAL METHODS AND VERIFICATION

14.11.1 Algorithm for checking Koszul pairs

Construction 14.11.1 (Verification of Koszul pairs). For quadratic chiral algebras, extract generators and relations, check that the residue pairing is perfect, and verify orthogonality $R_1^\perp = R_2$ together with acyclicity of the quadratic Koszul complex. For PBW non-quadratic algebras, low-degree bar computations are falsification tests: a nonzero off-diagonal class in $\bar{B}^{\leq 3}$ disproves Koszulness, but acyclicity through degree 3 does not prove it. A proof requires PBW spectral-sequence degeneration, Kac–Shapovalov/Li-bar non-degeneracy where relevant, and the completion convergence of Lemma 14.3.9.

14.11.2 Complexity analysis

For n generators, m relations, verification to degree k :

- Quadratic case: $O(n^2 + m^2)$ for orthogonality
- General case: $O(n^k)$ for bar complex dimension
- Configuration integrals: $O(k! \cdot n^k)$ worst case

14.12 THE KOSZUL-PAIR LANDSCAPE

The PBW criterion (Theorem 14.1.23) reduces chiral Koszulness to a classical spectral sequence degeneration, applicable uniformly to all freely strongly generated vertex algebras (Proposition 14.1.37). The twelve characterizations of Theorem 14.1.59 read the same genus-0 formality condition through distinct invariants: bar concentration, Ext diagonal vanishing, Kac–Shapovalov determinants, and FM boundary acyclicity. Factorization homology enters only through the conditional comparison model of Proposition 9.12.4; its concentration is a consequence of Koszulness under FH_Σ , and a criterion only under the detecting strengthening $\mathrm{FH}_{\mathrm{pr}}^{\mathrm{det}}$. Two characterizations remain partially open: the Lagrangian criterion awaits perfectness verification in general, and D-module purity awaits the converse direction. The E_1 -chiral Koszul duality theorem (Theorem 14.5.4) extends the adjunction to the associative chiral operad, and the module-level duality (Theorem 14.6.2) provides the derived equivalence on the proved complete/connilpotent lane.

Remark 14.12.1 (Structural consequences of the twisting theorem). The fundamental twisting theorem supplies the following structural inputs:

- A_0 : Fundamental theorem of chiral twisting morphisms (Theorem 14.1.13), used by Chapters ??, 36.
- A_1 : Bar concentration (Theorem 14.1.30), used by Theorem C_o (Theorem ??).
- A_2 : Geometric bar-cobar duality (Theorem 14.1.103), used everywhere.

- Theorem B: Higher genus inversion (Theorem ??) is proved in Chapter ?? using the foundations above.
- PBW Koszulness criterion (Theorem 14.1.23), used by all interacting-family example chapters.
- E_1 -chiral Koszul duality (Theorem 14.5.4), used by Chapter ??.

The Koszul pair structure classifies the duality at the algebra level. The next chapter adds the representation-theoretic layer: conformal blocks, fusion rules, and Kazhdan–Lusztig transport. In general, the bar-cobar machinery extends from algebras to module bar constructions and bar-coalgebra comodules; on the separate quadratic genus-0 E_1 complete/nilpotent lane this further yields the proved ordinary module-category duality. Broader module-category descent is not part of the proved statement here.

14.13 K_3 CHIRAL HALL–DRINFELD DOUBLE AS CONDITIONAL KOSZUL PAIR

Remark 14.13.1 (Finite Hall–Borcherds recognition datum). The notation $\mathbf{H}_{\Delta_5}$ is used below as a recognition target, not as an unconditional compact Hall object. Fix a finite downward saturated window W in the Gritsenko–Nikulin root monoid. A Hall-to–Borcherds recognition datum on W consists of:

- (i) a compact source provenance: an oriented Hall, critical CoHA, or factorisation source for the $K_3 \times E$ sector, separate from the automorphic denominator;
- (ii) a positive-half model $Y_{\text{Hall}}^+(K_3 \times E)_W$ with source multiplication, coproduct, and Hall grading, in the sense of the Kontsevich–Soibelman and Schiffmann–Vasserot/Rapčák–Soibelman–Yang–Zhao CoHA constructions [KS11, SchiffmannVasserot2012, RSY20];
- (iii) parity-homogeneous simple-root representatives, real-root signs, and full even/odd root dimensions matching the Gritsenko–Nikulin Borcherds–Kac fixture on W [GritsenkoNikulin1998, KacBook];
- (iv) a non-degenerate completed Hopf pairing, its closed radical quotient, and the continuous Drinfeld double $D(Y_{\text{Hall}}^+(K_3 \times E)_W)$;
- (v) a source differential d_{Hall} from the compact Hall, BRST, or hCS complex, compatible with the coproduct, pairing, and completion;
- (vi) an independent coefficient check: the finite supercharacter of the source radical quotient agrees with the corresponding truncation of the Gritsenko–Nikulin/Borcherds product $64^{-1}\Delta_5(2Z)$ [Bor95, GritsenkoNikulin1998].

Under such data the finite double is compared with the finite truncation of the denominator algebra $\mathfrak{g}_{\Delta_5}$, and the Frenkel–Kac vertex closure [FrenkelKac1980] becomes a target model for the BKM extension. The denominator factor supplies root multiplicities, character, and Euler product. It does not supply d_{Hall} , compact primitive representatives, the Hall pairing, or the radical quotient.

Remark 14.13.2 (Conditional conductor on the Mukai-enhanced K_3 row). For a recognized finite Hall–Borcherds window, the Mukai-enhanced K_3 row has target conductor

$$K^{\kappa_{\text{ch}}}(\mathcal{H}_{\text{Muk}}(K_3)) = \kappa_{\text{ch}}(\mathcal{H}_{\text{Muk}}) + \kappa_{\text{ch}}(\mathcal{H}_{\text{Muk}}^!) = 2c_+(\text{Mukai}(K_3)) = 8,$$

with $c_+ = 4$ from the positive signature of the rank-24 Mukai pairing on $\Lambda_{\text{Muk}} = \Pi_{4,20}$ [Mukai1987]. This is the $\mathcal{B}$ -family value in the Theorem C bucket $K_{\text{fam}}^{\kappa} \in \{0, 8, 13, 250/3, 25/3\}$. The comparison with the $\ell = 8$ Lusztig specialisation is a consequence only after the recognized double carries the source pairing and completion above. Bruinier’s Heegner Chern-class reciprocity fixes the target monodromy

of $\mathcal{L}^{\Delta_5}$ around $H_1 \subset \overline{\mathcal{A}}_2$ [Bruinier2002, Proposition 5.1]; it is not a construction of the compact Hall source.

14.14 THE KOSZUL TRIPLE FOR $\mathbf{H}_{\Delta_5}$ ON $(\text{Ran}(E_{24}^{\text{nod,sm}}), \overline{\mathcal{A}}_2)$

Remark 14.14.1 (The Koszul triple $(\mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5}^!, B_{\text{ch}}(\mathbf{H}_{\Delta_5}))$). On a finite recognized window W , the Koszul triple on $(\text{Ran}(E_{24}^{\text{nod,sm}}), \overline{\mathcal{A}}_2)$ is

$$(\mathbf{H}_{\Delta_5, W}, \mathbf{H}_{\Delta_5, W}^!, B_{\text{ch}}(\mathbf{H}_{\Delta_5, W})), \quad B_{\text{ch}}(\mathbf{H}_{\Delta_5, W}) = T^c(s^{-1}\overline{\mathbf{H}_{\Delta_5, W}}),$$

where $\mathbf{H}_{\Delta_5, W}$ denotes the Hall radical quotient supplied by Remark 14.13.1. The Koszul sign rule and cyclicity use the source Hopf pairing and the Mukai pairing; the Verdier-Koszul dual is defined only after the completed pairing and the source differential have been installed. This is the finite-window form of the Vol. III K₃ chiral-bialgebra construction of Chapter ??, not an assertion that the automorphic denominator alone produces a chiral Koszul pair.

Remark 14.14.2 (Conditional self-Koszulness at $\hbar^2 = -1/8$). At $\hbar^2 = -1/\ell = -1/8$ one may assert a quasi-isomorphism $\mathbf{H}_{\Delta_5, W}^! \simeq \mathbf{H}_{\Delta_5, W}$ only on windows where the recognition datum supplies the double, the pairing, the source differential, and the exact completion. The Bruinier class $c_1(L^{\Delta_5})|_{H_1} \in \text{CH}^1(H_1)$ gives the target $\mathbb{Z}/8$ monodromy constraint [Bruinier2002]. It does not, by itself, identify the Hall bar complex with its Verdier-Koszul dual.

Remark 14.14.3 (Koszul complex with source differential). For a recognized window W , the K₃ Koszul complex on $(\text{Ran}(E_{24}^{\text{nod,sm}}), \overline{\mathcal{A}}_2)$ is

$$\text{Kos}_\bullet(\mathbf{H}_{\Delta_5, W}) : \cdots \rightarrow \text{Sym}^k(\mathbf{H}_{\Delta_5, W}[-1]) \otimes \Lambda^k(\mathbf{H}_{\Delta_5, W}^\vee) \rightarrow \cdots,$$

with differential induced by d_{Hall} , the Hall product, the coproduct, and the completed pairing. The Gritsenko–Nikulin denominator factor supplies a target Euler-character and coefficient check. Suppose the finite-window Koszul comparison and exact cofinal system assemble a family datum $H_H(\mathbf{H}_{\Delta_5}; S_{\Delta_5})$. Theorem H then gives

$$\text{Supp ChirHoch}^\bullet(\mathbf{H}_{\Delta_5}) \subseteq S_{\Delta_5}.$$

Under the separate degree-two pairing and the Etingof–Kazhdan/Gritsenko–Nikulin comparison, the line $\mathbb{C} \cdot \Delta_5$ is the recognized degree-2 target class [EtingofKazhdan2007PartV, GritsenkoNikulin1998].

V_{D_4} lattice VOA	lattice	28	Proved	lattice filt.	$G, r_{\max} = 2$
Triplet $\mathcal{W}(2)$	logarithmic	4	Open	not known	unknown

Legend. *Status*: Proved = chirally Koszul (Definition 14.1.3); Open = neither proved nor disproved; Not K. = proved non-Koszul; Cond. cone = a nonzero quadratic-comparison cone under the finite admissible Li–bar package of Theorem 14.1.43. *Mechanism*: PBW univ. = Proposition 14.1.37; MC4 compl. = Theorem 9.1.28; lattice filt. = Theorem ??; null vect. = Kac–Shapovalov obstruction (Theorem 14.1.40); Cartan H^2 = abelian Cartan subalgebra classes surviving in $H^2(\overline{B})$ under the finite admissible Li–bar package (Remark 14.1.42). *Shadow*: archetype class $G/L/C/M$ (Theorem 22.5.18) and shadow depth $r_{\max}$; all four classes contain Koszul algebras (shadow depth $\neq$ Koszulness).

[†] The symplectic fermion ($\beta\gamma$ at $\lambda = \frac{1}{2}$, $c = -1$) is chirally Koszul: the algebra is freely strongly generated, and logarithmic phenomena appear in the module category, not in the bar complex (Remark ??).

[‡] **Universal vs. simple quotient.** The universal algebra $V_k(\mathfrak{g})$ is chirally Koszul at *all* levels k , including critical $k = -h^\vee$ and admissible (Corollary 14.1.38). The simple quotient $L_k(\mathfrak{g})$ may fail: null vectors in the bar-relevant range (conformal weight $h \geq 2 \cdot h_{\min}$, where $h_{\min}$ is the minimal generator weight) block the PBW filtration. At integrable level $k = 1$, the first null vector of $L_1(\mathfrak{sl}_2)$ lies at $h = 2$, exactly at the bar-relevant threshold: Koszulness is open. For minimal models $L(c_{p,q}, 0)$ with coprime $p < q$, the first null at $h = pq - p - q + 1$ lies in the bar-relevant range whenever $pq - p - q + 1 \geq 4$ (i.e., for $(p, q) \neq (2, 3)$): these are proved not chirally Koszul by Theorem 14.1.40.

[§] **CE complex vs. chiral bar.** The $N=2$ SCA has $H_{\text{CE}}^2 \neq 0$ at the mode-algebra level, but $H^2(\overline{B}) = 0$: the CE complex is a coarse upper bound on bar cohomology, and PBW universality resolves the apparent paradox (Remark ??).

TABLE 14.2: $\mathcal{W}_N$ completion complexity

CHIRAL KOSZUL PAIRS

Remark 15.0.1 (The five objects in a Koszul pair). A chiral Koszul pair starts with an augmented chiral algebra $\mathcal{A}$ and a conilpotent dual coalgebra $\mathcal{A}^i$. The bar coalgebra

$$\bar{B}_X^{\text{ch}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$$

is defined before any dual object is named; Koszulness asserts that the canonical comparison $\bar{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}^i$ is a quasi-isomorphism. The counit

$$\Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}) \longrightarrow \mathcal{A}$$

is bar–cobar inversion: it recovers the input algebra $\mathcal{A}$. It does not define $\mathcal{A}^!$.

The Koszul-dual algebra belongs to a separate finite-type/Verdier lane. Theorem 17.1.2 separates the two functors

$$R_X(\mathcal{A}) = \Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}), \quad K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A}).$$

The first functor is reconstruction; the second is Verdier-dualized Koszul duality. The Verdier dual of the bar coalgebra is a factorisation algebra; on the strict finite-type quadratic surface it reduces to the algebraic dual $\mathcal{A}^! = (\mathcal{A}^i)^\vee$. The symbol K in Theorem 17.1.2 denotes this represented Verdier/Koszul reflection on the localized Koszul surface. Its pairwise return map is supplied by the chosen dual partner, evaluation–coevaluation homotopies, localization, and completion hypotheses.

The objects are therefore distinct:

- $\mathcal{A}$ is the algebra whose OPE data define the bar differential;
- $\bar{B}_X^{\text{ch}}(\mathcal{A})$ is the conilpotent bar coalgebra and carries the universal twisting morphism $\tau: \bar{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$;
- $\mathcal{A}^i$ is the Koszul-dual coalgebra resolved by the bar coalgebra on the Koszul locus;
- $\mathcal{A}^!$ is the finite-type/Verdier dual algebra, not the cobar of $\bar{B}_X^{\text{ch}}(\mathcal{A})$;
- $Z_{\text{ch}}^{\text{der}}(\mathcal{A}) = R\text{Hom}_{\mathcal{A}^e}^{\text{ch}}(\mathcal{A}, \mathcal{A})$ is the chiral derived centre, the Hochschild closed-sector object, not a bar coalgebra and not the Koszul-dual algebra.

A Koszul pair $(\mathcal{A}, \mathcal{A}^i)$, together with the Verdier-dual algebra $\mathcal{A}^!$ when the finite-type hypotheses supply it, is the compatible package of bar construction, twisting morphism, curvature data, and deformation filtration from which the MC element $\Theta_{\mathcal{A}}$ is constructed. The structural theory has three levels of generality (classical, chiral, and modular); the recognition criteria determine when the MC element admits the full complement of projections (Theorems A–D).

At the classical level, the algebra $\text{Sym}(V)$ is paired first with its quadratic dual coalgebra; finite-dimensional linear duality then gives the exterior algebra $\Lambda(V^*)$. The pair $(\text{Sym}(V), \Lambda(V^*))$ is detected by the acyclicity of the twisted tensor product $\bar{B}(\text{Sym}(V)) \otimes_{\tau} \Lambda(V^*)$ and the quadratic presentation of the relation ideal (Definition 3.1.5). This is a theorem about algebras on a point, with $m_o = 0$ and $d^2 = 0$

built into the formalism. On a curve X , the chiral pair $(\mathrm{Com}^{\mathrm{ch}}(V \otimes \omega_X), \mathrm{Lie}^{\mathrm{ch}}(V^* \otimes \omega_X))$ replaces tensor powers by factorization products on $\mathrm{FM}_n(X)$ and the classical twisting cochain by a chiral twisting morphism valued in the convolution algebra on $\mathrm{Ran}(X)$ (Definition 14.1.19, Chapter 14). The genus-zero differential d_o still satisfies $d_o^2 = 0$: no curvature, but an entirely new geometric substrate. When the curve deforms to genus $g \geq 1$, the scalar uniform-weight channel acquires central fiber curvature $d_{\mathrm{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$; in multi-weight families this is the scalar component of a completed CDG object with cross-channel terms. The corrected differential D_g absorbs the curvature into a curved A_∞ -structure with $m_o \neq 0$ and $m_1^2(a) = [m_o, a]$. The modular Koszul object (Definition ??) packages all three levels into a single tower over $\overline{\mathcal{M}}_g$.

The PBW bridge (Theorem 14.1.23) resolves the central tension: chiral algebras are almost never quadratic, yet their associated graded under bar-length filtration is, and it is this graded shadow that carries the classical Koszulness from which the full chiral pair inherits its structure.

15.1 KOSZUL DUALITY

15.1.1 The classical pair on a point

Let V be a finite-dimensional vector space. The symmetric algebra $\mathrm{Sym}(V)$ and the exterior algebra $\Lambda(V^*)$ form a Koszul pair (Definition 3.1.5): there is a natural twisting cochain $\tau: \overline{B}(\mathrm{Sym}(V)) \rightarrow \Lambda(V^*)$ that makes the twisted tensor product $\overline{B}(\mathrm{Sym}(V)) \otimes_\tau \Lambda(V^*)$ acyclic. The bar coalgebra $\overline{B}(\mathrm{Sym}(V)) = T^c(s^{-1}\overline{\mathrm{Sym}}(V))$ has differential built from the commutative product; its homology is the quadratic dual coalgebra, and finite-dimensional duality gives the algebra $\Lambda(V^*)$. Priddy's theorem [?Priddy70] gives the counit

$$\Omega(\overline{B}(\mathrm{Sym}(V))) \xrightarrow{\sim} \mathrm{Sym}(V)$$

as a quasi-isomorphism. The curvature vanishes: $m_o = 0$, so the bar differential satisfies $d^2 = 0$ strictly. All of this is a shadow of the $\mathrm{Com}^! = \mathrm{Lie}$ operadic duality.

15.1.2 The pair on a curve

Now take X a smooth algebraic curve and replace $\mathrm{Sym}(V)$ by the chiral symmetric algebra $\mathrm{Com}^{\mathrm{ch}}(V \otimes \omega_X)$, a chiral algebra on X whose fiber at each point is a copy of $\mathrm{Sym}(V)$, but whose n -point operations are governed by configuration spaces $\overline{C}_n(X)$ of colliding points rather than by tensor powers. The quadratic dual coalgebra is represented by the chiral Lie side; after finite-type dualization this gives the chiral Lie algebra $\mathrm{Lie}^{\mathrm{ch}}(V^* \otimes \omega_X)$. The bar construction $\overline{B}_X(\mathcal{A})$ lives on the Fulton–MacPherson compactification $\mathrm{FM}_n(X)$. The chiral twisting cochain (Definition 14.1.19) produces the counit

$$\Omega(\overline{B}_X(\mathcal{A})) \xrightarrow{\sim} \mathcal{A},$$

which is again a quasi-isomorphism when $\mathcal{A}$ is chiral Koszul (Theorem A, Theorem 14.1.103). This map is inversion and has target $\mathcal{A}$; the Verdier-dual construction of $\mathcal{A}^!$ is a separate comparison on the bar coalgebra. The genus-0 collision differential d_o still satisfies $d_o^2 = 0$. There is no curvature; the only new ingredient is the integration kernel mediating chiral operations on X .

When $X = \mathbb{P}^1$, the Beilinson–Drinfeld equivalence identifies chiral algebras on $\mathbb{P}^1$ with vertex algebras. The chiral bar construction on $\mathbb{P}^1$, however, retains the full configuration-space geometry: the Fulton–MacPherson compactifications $\mathrm{FM}_n(\mathbb{P}^1)$, the Arnold relations $\eta_{ij} \wedge \eta_{jk} + \mathrm{cyc.} = 0$, and the logarithmic propagator $\eta_{ij} = d \log(z_i - z_j)$ are all genuinely present even at genus 0. The classical bar

construction over a point is recovered only upon formal-disk restriction followed by explicit comparison data:

- (a) *Formal disk vs. point.* Vertex algebras live on the formal disk $D_x \subset X$, not on a bare point; the passage from D_x to a point discards the thickening data (completion, growth conditions) that the $\mathcal{D}_X$ -module structure depends on.
- (b) *Homotopy retract.* The affine line $\mathbb{A}^1 \hookrightarrow \mathbb{P}^1$ deformation-retracts onto a point, but this retraction is additional data: a specific chain homotopy and its attendant homotopy transfer (Homological Perturbation Lemma) are required to relate the chiral bar on $\mathbb{A}^1$ to the classical bar over the ground field.
- (c) *Global topology.* On $\mathbb{P}^1$ itself, the global topology of configuration spaces (the identification $\overline{C}_{n+1}(\mathbb{P}^1) \cong \overline{\mathcal{M}}_{0,n+2}$) introduces boundary strata that have no classical analogue.

The comparison between chiral and classical bar is therefore a quasi-isomorphism mediated by explicit transfer data, not a tautological restriction.

15.1.3 The pair in families: curvature from moduli

Fix a chiral Koszul pair $(\mathcal{A}, \mathcal{A}^\dagger)$ on a genus-0 curve, with Verdier-dual algebra $\mathcal{A}^\dagger$ only on the finite-type surface, and deform the curve to genus $g \geq 1$. The bar construction $\overline{B}_g(\mathcal{A})$ now lives over $\overline{\mathcal{M}}_g$. On the scalar uniform-weight lane the fiberwise operator has central square

$$d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g,$$

where $\omega_g = c_1(\lambda_g) \in H^2(\overline{\mathcal{M}}_g)$ is the Hodge class and $\kappa(\mathcal{A})$ is the modular characteristic (Theorem D). If $\kappa(\mathcal{A}) = 0$ the scalar lane is uncurved. If $\kappa(\mathcal{A}) \neq 0$, d_{fib} is not an ordinary differential on the fiber; it is the degree-one part of a CDG object read in the completed coderived ambient. For multi-weight algebras the same scalar term is only the uniform-weight projection of the full genus expansion, which also contains the cross-channel contribution of Theorem ??.

The total corrected differential D_g absorbs the curvature into a higher-order correction, a curved A_∞ -structure in which $m_0 \neq 0$ and $m_1^2(a) = [m_0, a]$, and satisfies $D_g^2 = 0$. The passage from d_0 to D_g is the passage from classical to quantum: the quantum corrections are controlled by $H^*(\overline{\mathcal{M}}_g, Z_{\text{ch}}^{\text{der}}(\mathcal{A}))$, the cochain-level chiral closed-sector object. The Koszul partner $\mathcal{A}^\dagger$ supplies one input to this larger cochain object. Theorem B (Theorem ??) shows that bar-cobar inversion persists via E_2 collapse of the associated spectral sequence. Theorem C (Theorem ??) identifies the obstruction and deformation spaces as Lagrangian complements.

PROPOSITION 15.1.1 (*Scalar Verdier sums on the finite-type lane;*). Assume the finite-type Verdier-Koszul comparison exists for the row in question, write

$$K^\kappa(\mathcal{A}) = \kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger).$$

For the Mukai-to-chiral comparison, write $H_B = (H_{\text{chart}}, H_{\text{KD}}, H_{\text{scalar}}, H_{\text{mod}}, H_{\text{quant}})$. On the standard witness rows,

row	$K^\kappa(\mathcal{A})$
$\mathcal{H}_k, V_k(\mathfrak{g}), \beta\gamma_\lambda$	0
Vir_c	13

The principal M-extension has the computed value

$$K^\kappa(\mathcal{W}_3) = \frac{250}{3}.$$

For Bershadsky–Polyakov, the exact central-charge companion sum is $K_{\text{BP}}^c = 50$, while K_{BP}^κ is pending the genus-one minimal-DS curvature calculation. The normalization $\kappa_{\text{BP}} = c_{\text{BP}}/6$ would give the conditional value $25/3$. For the Mukai row, the exact lattice arithmetic is $2c_+ = 8$ and its interpretation as $K^{\kappa_{\text{ch}}} = 8$ is under H_{B} . Thus the computed Vol. I ceiling is $\{0, 13, 250/3\}$, with BP and Mukai values recorded in two distinct open ledgers.

Proof. The formulas are scalar consequences of the Verdier-dual row. The counit $\Omega^{\text{ch}} \tilde{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ belongs to the separate universal reconstruction lane.

For Heisenberg, $\kappa(\mathcal{H}_k) = k$ and the Verdier partner has $\kappa(\mathcal{H}_k^!) = -k$, so the sum is zero. For affine Kac–Moody,

$$\kappa(V_k(\mathfrak{g})) = \frac{\dim(\mathfrak{g})(k + h^\vee)}{2h^\vee}, \quad k' = -k - 2h^\vee,$$

hence

$$\kappa(V_{k'}(\mathfrak{g})) = \frac{\dim(\mathfrak{g})(-k - h^\vee)}{2h^\vee} = -\kappa(V_k(\mathfrak{g})).$$

For the $\beta\gamma$ row,

$$\kappa(\beta\gamma_\lambda) = 6\lambda^2 - 6\lambda + 1, \quad \kappa((\beta\gamma_\lambda)^!) = -(6\lambda^2 - 6\lambda + 1),$$

again giving zero. For Virasoro, the finite-type same-family Verdier partner is Vir_{26-c} on the M/S surface, so

$$\kappa(\text{Vir}_c) + \kappa(\text{Vir}_{26-c}) = \frac{c}{2} + \frac{26-c}{2} = 13.$$

For the principal $\mathcal{W}_3$ row, $\kappa(\mathcal{W}_3) = c(H_3 - 1) = 5c/6$ and the conductor is $K_3 = c + c' = 4 \cdot 3^3 - 2 \cdot 3 - 2 = 100$; hence $K^\kappa = (5/6) \cdot 100 = 250/3$. For the Bershadsky–Polyakov row, Fehily–Kawasetsu–Ridout give $c_{\text{BP}}(k) + c_{\text{BP}}(-k - 6) = 50$ and even generators J, T, G^+, G^- . These inputs formulate the open genus-one modular calculation and its conditional consequence $25/3$. For the Mukai-enhanced K_3 row, the Vol. III lattice input is $c_+(\text{Mukai}(K_3)) = 4$, so $2c_+ = 8$ is exact; the chiral interpretation carries H_{B} . These status-typed values are recorded in Theorem ??, Proposition ??, and Convention ??. $\square$

Remark 15.1.2 (Three levels of Koszul pair). The construction above exhibits three levels of structure, each strictly refining the previous:

- (i) **Classical** (Definition 3.1.5). Input: graded algebras on a point. Bar object: $\overline{B}(\mathcal{A}) = T^c(s^{-1}\tilde{A})$. Curvature: $m_0 = 0$. Main result: Priddy [?Priddy70].
- (ii) **Chiral** (Definition 14.1.19). Input: chiral algebras on a curve X . Bar object: $\overline{B}_X(\mathcal{A})$ on $\text{FM}_n(X)$. Curvature: $d_0^2 = 0$. Main result: Theorem A (Theorem 14.1.103).
- (iii) **Modular** (Definition ??). Input: chiral algebras + genus tower $g \geq 0$. Bar object: $\overline{B}_g(\mathcal{A})$ on $\overline{\mathcal{M}}_g$. Scalar curvature: $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ on the uniform-weight lane, with completed CDG corrections in the multi-weight case. Main results: Theorems B–D.

Each level introduces new phenomena invisible to the previous one: the chiral level brings integration kernels, OPE poles, and the configuration-space geometry of $\mathrm{FM}_n(X)$ (Arnold relations, logarithmic propagator); the modular level brings curvature, central extensions, and anomalies. The classical and chiral levels are *not* identified by specializing to genus 0 on $\mathbb{P}^1$: the chiral bar on $\mathbb{P}^1$ retains the full FM compactification geometry, and the passage to the classical bar over a point requires formal-disk restriction plus homotopy-transfer data (see the discussion following Definition 14.1.19).

PROPOSITION 15.1.3 (*Three levels as MC at successive completions*). The three levels of Koszul structure (classical, chiral, and modular) correspond to the MC equation in successive completions of the convolution algebra:

- (i) Classical: $\Theta_{\mathcal{A}}^{(0,2)} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{(0,\leq 2)})$ (genus 0, degree 2).
- (ii) Chiral: $\Theta_{\mathcal{A}}^{(0,\bullet)} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{(0)})$ (genus 0, all degrees).
- (iii) Modular: $\Theta_{\mathcal{A}} \in \mathrm{MC}(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})$ (all genera, all degrees).

The PBW filtration connects these levels: MC_1 (PBW concentration) implies that the genus-0 MC element lifts to all genera via the strong completion-tower theorem (MC_4 , Theorem 9.1.28).

Proof. At each level, the MC equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ is the projection of $D^2_{\mathcal{A}} = 0$ (Theorem ??) to the corresponding truncation of the weight filtration on $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$. Classical: retain only genus 0, degree 2 (quadratic). Chiral: retain genus 0, all degrees (the full genus-0 shadow obstruction tower, with obstruction classes o_{r+1} in the cyclic deformation complex). Modular: the full convolution algebra with no truncation. The PBW bridge (Theorem 9.1.53) reduces the modular MC equation to the chiral one on the associated graded, which the degree cutoff (Lemma 9.1.27) and the strong completion-tower theorem lift to all genera. $\square$

15.1.4 From classical to chiral: the PBW bridge

Classical Koszul duality (Definition 3.1.5, Chapter 3) requires quadratic relations. Chiral algebras are almost never quadratic: the Virasoro OPE has a quartic pole, $\mathcal{W}$ -algebras have sixth-order poles, and Yangians have cubic relations. The PBW filtration (Chapter 14) resolves this by reducing the chiral problem to the classical one on the associated graded.

15.2 CHIRAL HOCHSCHILD COHOMOLOGY: CONSTRUCTION FROM FIRST PRINCIPLES

15.2.1 The chiral enveloping algebra

Definition 15.2.1 (*Chiral enveloping algebra*). Let $\mathcal{A}$ be a unital associative chiral algebra on a smooth curve X , in a complete subcategory of right $\mathcal{D}_X$ -modules closed under the chiral tensor product. The *chiral enveloping algebra* is

$$\mathcal{A}^e = \mathcal{A} \boxtimes_{\mathcal{D}_X} \mathcal{A}^{\mathrm{op}}$$

where $\boxtimes_{\mathcal{D}_X}$ is the chiral tensor product over the sheaf of differential operators and $\mathcal{A}^{\mathrm{op}}$ has the opposite chiral multiplication $Y^{\mathrm{op}}(a, b) = (-1)^{|a||b|}Y(b, a)$ in the dg convention. All tensor products below are completed in the PBW/admissible topology when the bar filtration is infinite.

Definition 15.2.2 (*Chiral bimodule*). An $\mathcal{A}$ -bimodule (in the chiral sense) is a $\mathcal{D}_X$ -module $\mathcal{M}$ equipped with a left chiral action $\mu_L: j_*j^*(\mathcal{A} \boxtimes \mathcal{M}) \rightarrow \Delta_!\mathcal{M}$ and a right chiral action $\mu_R: j_*j^*(\mathcal{M} \boxtimes \mathcal{A}) \rightarrow \Delta_!\mathcal{M}$ satisfying the associativity and compatibility conditions:

- (i) Left associativity: $\mu_L \circ (\text{id}_{\mathcal{A}} \boxtimes \mu_L) = \mu_L \circ (\mu_{\mathcal{A}} \boxtimes \text{id}_{\mathcal{M}})$ (as chiral operations on $\mathcal{A} \boxtimes \mathcal{A} \boxtimes \mathcal{M}$);
- (ii) Right associativity (analogously);
- (iii) Left-right compatibility: $\mu_L \circ (\text{id}_{\mathcal{A}} \boxtimes \mu_R) = \mu_R \circ (\mu_L \boxtimes \text{id}_{\mathcal{A}})$.

Equivalently, $\mathcal{M}$ is a module for the chiral enveloping algebra $\mathcal{A}^e$.

LEMMA 15.2.3 (*Well-definedness of the chiral enveloping algebra*;). Under the closure and completion hypotheses in the preceding definition, $\mathcal{A}^e$ carries a natural associative chiral algebra structure, and chiral $\mathcal{A}^e$ -modules are the same as chiral $\mathcal{A}$ -bimodules.

Proof. The tensor product exists by the closure hypothesis; no projective resolution is being smuggled into the definition. On disjoint configurations the product is

$$Y^e((a_1 \otimes a_2), (b_1 \otimes b_2))(z) = (-1)^{|a_2||b_1|} Y(a_1, b_1)(z) \otimes Y^{\text{op}}(a_2, b_2)(z),$$

with the displayed Koszul sign coming from moving the second tensor factor past the first. Associativity is the tensor product of the associativity diagrams for $\mathcal{A}$ and $\mathcal{A}^{\text{op}}$; locality is preserved because the pole order is bounded by the sum of the pole orders in the two factors. Unpacking a left action of this product gives commuting left and right chiral $\mathcal{A}$ -actions, and the reverse construction tensors the two actions. $\square$

15.2.2 The bar resolution for chiral algebras

The chiral Hochschild complex is obtained from the relative two-sided bar resolution of $\mathcal{A}$ as an $\mathcal{A}^e$ -module. This is a resolution in the completed derived category; it is not the Koszul bar coalgebra $\overline{B}^{\text{ch}}(\mathcal{A})$ and it does not identify $\mathcal{A}^!$.

Definition 15.2.4 (*Two-sided chiral Hochschild bar resolution*). The *two-sided chiral Hochschild bar resolution* of $\mathcal{A}$ is

$$\cdots \rightarrow \mathcal{A}^{\boxtimes 4} \xrightarrow{d_3} \mathcal{A}^{\boxtimes 3} \xrightarrow{d_2} \mathcal{A}^{\boxtimes 2} \xrightarrow{d_1} \mathcal{A} \rightarrow 0$$

where the outer two factors carry the $\mathcal{A}^e$ -action and

$$d_n(a_0 \otimes \cdots \otimes a_{n+1}) = \sum_{i=0}^n (-1)^i a_0 \otimes \cdots \otimes Y(a_i, a_{i+1}) \otimes \cdots \otimes a_{n+1}$$

with Koszul signs inserted in the dg convention. The normalized complex is used when degeneracies are split off.

THEOREM 15.2.5 (*Relative exactness of the two-sided chiral bar resolution*;). [Regime: completed unital chiral algebra (Convention 1.10.2).]

Let $\mathcal{A}$ be unital, augmented, and admissibly complete, and assume the chiral tensor product is exact on the bar-filtration graded pieces. The normalized two-sided chiral bar object is a relative semi-free $\mathcal{A}^e$ -resolution of $\mathcal{A}$ in the completed derived category. After forgetting the $\mathcal{A}^e$ -action the augmented complex is contractible. This exactness is the Hochschild-resolution input; Koszulness is the separate assertion that the one-sided conilpotent bar coalgebra $\overline{B}^{\text{ch}}(\mathcal{A})$ resolves the Koszul-dual coalgebra $\mathcal{A}^i$.

Proof. The simplicial two-sided bar object has face maps given by the chiral product and degeneracies given by insertion of the unit. The extra degeneracy

$$h_n(a_0 \otimes \cdots \otimes a_n) = 1 \otimes a_0 \otimes \cdots \otimes a_n$$

gives the standard contraction of the augmented simplicial object. On homogeneous tensors the only non-cancelling face is the one multiplying the inserted unit:

$$\begin{aligned} (d_{n+1} \circ h_n)(a_o \otimes \cdots \otimes a_n) &= d_{n+1}(1 \otimes a_o \otimes \cdots \otimes a_n) \\ &= a_o \otimes \cdots \otimes a_n + \sum_{i=0}^{n-1} (-1)^{i+1} 1 \otimes a_o \otimes \cdots \otimes Y(a_i, a_{i+1}) \otimes \cdots \end{aligned}$$

while

$$(h_{n-1} \circ d_n)(a_o \otimes \cdots \otimes a_n) = - \sum_{i=0}^{n-1} (-1)^{i+1} 1 \otimes a_o \otimes \cdots \otimes Y(a_i, a_{i+1}) \otimes \cdots$$

up to the Koszul signs forced by the suspended convention. Thus $dh + hd = \text{id}$ after forgetting the outer action. The normalized bar object is built from induced $\mathcal{A}^c$ -modules, hence is relative semi-free. Exactness of the completed tensor product on associated graded pieces lifts the contraction from finite bar degree to the completed object. $\square$

15.2.3 Definition and computation of chiral Hochschild cohomology

Definition 15.2.6 (Chiral Hochschild cohomology, algebraic Ext form). In the completed chiral bimodule category, the *chiral Hochschild cohomology* of $\mathcal{A}$ with coefficients in an $\mathcal{A}$ -bimodule M is

$$CH^n(\mathcal{A}, M) = \text{Ext}_{\mathcal{A}^c}^n(\mathcal{A}, M).$$

When $M = \mathcal{A}$, we write simply $CH^n(\mathcal{A})$. This is the *algebraic Ext model* of the chiral Hochschild complex; the geometric Fulton–MacPherson model $C_{\text{chiral}}^\bullet(\mathcal{A})$ (Definition 35.2.1, in Chapter 35) computes the same chiral derived endomorphism centre

$$Z_{\text{ch}}^{\text{der}}(\mathcal{A}) = R\text{Hom}_{\mathcal{A}^c}^{\text{ch}}(\mathcal{A}, \mathcal{A})$$

under Theorem 15.2.8. Per Remark 35.0.1 in Chapter 35, the chiral CH^* is distinct from the topological Hochschild HH_{top}^* of an E_1 -algebra in spectra (Deligne E_2) and from the categorical Hochschild HH_{cat}^* of a dg category (CY shifted Poisson). The geometry X selects CH^* .

To compute this explicitly, write $\overline{\mathcal{A}} = \ker(\epsilon: \mathcal{A} \rightarrow \mathbf{1})$ and apply $\text{Hom}_{\mathcal{A}^c}(-, M)$ to the normalized two-sided bar resolution. We use $\widehat{\overline{\mathcal{A}}}^{\otimes 0} = \mathbf{1}$.

THEOREM 15.2.7 (Chiral Hochschild complex;). For every complete chiral $\mathcal{A}$ -bimodule M satisfying the same admissibility hypotheses, the derived endomorphism complex $R\text{Hom}_{\mathcal{A}^c}^{\text{ch}}(\mathcal{A}, M)$ is computed by the normalized chiral Hochschild cochain complex

$$0 \rightarrow M \xrightarrow{\delta_0} \text{Hom}_{\mathcal{D}_X}(\overline{\mathcal{A}}, M) \xrightarrow{\delta_1} \text{Hom}_{\mathcal{D}_X}(\widehat{\overline{\mathcal{A}}}^{\otimes 2}, M) \xrightarrow{\delta_2} \cdots$$

For $m \in M$,

$$(\delta_0 m)(a) = Y_L(a, m) - (-1)^{|a||m|} Y_R(m, a), \quad a \in \overline{\mathcal{A}},$$

where Y_L and Y_R are the left and right chiral actions. For $f \in \text{Hom}_{\mathcal{D}_X}(\widehat{\overline{\mathcal{A}}}^{\otimes n}, M)$, $n \geq 1$, the differential is

$$\begin{aligned} (\delta_n f)(a_1, \dots, a_{n+1}) &= Y_L(a_1, f(a_2, \dots, a_{n+1})) \\ &\quad + \sum_{i=1}^n (-1)^i f(a_1, \dots, \overline{Y(a_i, a_{i+1})}, \dots, a_{n+1}) \\ &\quad + (-1)^{n+1} Y_R(f(a_1, \dots, a_n), a_{n+1}), \end{aligned}$$

with the Koszul signs imposed by the dg grading and with the bar over $Y(a_i, a_{i+1})$ denoting projection to the augmentation ideal in the normalized complex. Consequently H^0 is the invariant centre of M , H^1 is derivations modulo the inner derivations coming from $\delta_0(M)$, and H^2 is the first space of binary chiral product deformations.

Proof. Apply $R\mathrm{Hom}_{\mathcal{A}^e}^{\mathrm{ch}}(-, M)$ to the relative semi-free resolution of Theorem 15.2.5. The normalized degree- n term of the two-sided bar resolution is

$$\mathcal{A} \widehat{\otimes} \overline{\mathcal{A}}^{\widehat{\otimes} n} \widehat{\otimes} \mathcal{A},$$

so $\mathcal{A}^e$ -linearity identifies its Hom into M with $\mathrm{Hom}_{\mathcal{D}_X}(\overline{\mathcal{A}}^{\widehat{\otimes} n}, M)$. For $n = 0$ this is M . Dualizing the first and last faces gives the two action terms; dualizing the internal faces gives the middle sum. In degree zero the map is precisely the chiral adjoint action, hence its image is the space of inner derivations. Since the bar differential squares to zero, the displayed dual differential satisfies $\delta^2 = 0$. $\square$

15.2.4 Geometric realization via configuration spaces

THEOREM 15.2.8 (*Geometric model of chiral Hochschild cohomology*;). Assume, in addition, that the chiral operations of $\mathcal{A}$ extend logarithmically to the Fulton–MacPherson compactifications and that the chosen finite-type stratum is acyclic for the Čech-to-global functor on the sheaves below. Then the algebraic Ext model is filtered quasi-isomorphic to the total Fulton–MacPherson logarithmic complex with degree- n term

$$\Gamma(\overline{C}_{n+2}(X), \mathcal{H}om_{\mathrm{rel}}(\overline{\mathcal{A}}^{\boxtimes n}, \mathcal{A}) \otimes \Omega_{\log}^n),$$

where the two additional marked points record the output and the evaluation point of the two-sided bar correspondence, and whose cohomology is equal to $CH^n(\mathcal{A})$. This comparison computes $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A})$; it does not produce $\mathcal{A}^!$.

Proof. The comparison is the following chain of identifications.

Step 1: An $\mathcal{A}^e$ -linear map from

$$\mathcal{A} \widehat{\otimes} \overline{\mathcal{A}}^{\widehat{\otimes} n} \widehat{\otimes} \mathcal{A}$$

to $\mathcal{A}$ is the same thing as a chiral multilinear operation on the n normalized input slots compatible with the two outer $\mathcal{A}$ -actions:

$$f(Y(a, z)b_1, \dots, b_n) = Y(a, z)f(b_1, \dots, b_n)$$

$$f(b_1, \dots, b_n, Y(b, w)) = Y(f(b_1, \dots, b_n), w)b$$

Step 2: On the open configuration space $C_{n+2}(X)$ these conditions identify a cochain with a section of the stated relative internal Hom sheaf. The extra two marked points are not inputs; they remember the output and evaluation positions in the two-sided Hochschild correspondence.

Step 3: The logarithmic extension hypothesis extends precisely those sections to $\overline{C}_{n+2}(X)$ with logarithmic singularities along the boundary divisors. No finite-type dual of the bar coalgebra is used in this extension.

Step 4: The chiral Hochschild differential $\delta_n f(a_1, \dots, a_{n+1})$ involves composing f with the outer actions and with the chiral product at adjacent input points. On $\overline{C}_{n+3}(X)$, each term in δ_n corresponds to the residue of f along a boundary divisor $D_{ij} = \{z_i = z_j\}$ where the relevant adjacent points collide.

The de Rham differential on $\Omega_{\log}^n$ restricts to these boundary strata by Stokes' theorem, and the residue along D_{ij} extracts the OPE coefficient: $\text{Res}_{z_i=z_j} [f \cdot \omega_{\log}] = Y(a_i, a_j) \cdot f|_{D_{ij}}$. The alternating signs in δ_n correspond to the orientations of the boundary divisors in $\partial \overline{C}_{n+3}(X)$ (cf. the bar nilpotency argument, Theorem 7.1.38). The acyclicity assumption for the chosen finite-type stratum lets global sections preserve the resulting filtered quasi-isomorphism. $\square$

15.3 THE CHIRAL GERSTENHABER STRUCTURE

Classical topological Hochschild cohomology carries a Gerstenhaber algebra structure [Ger63]: a graded commutative cup product and a degree -1 Lie bracket, compatible via the Leibniz rule. Both extend to the chiral setting.

15.3.1 The cup product

Definition 15.3.1 (Cup product on chiral Hochschild cohomology). For $f \in CH^p(\mathcal{A})$ and $g \in CH^q(\mathcal{A})$, define their cup product on normalized inputs by

$$(f \cup g)(a_1, \dots, a_{p+q}) = \text{Res}_{z_p \rightarrow z_{p+1}} Y(f(a_1, \dots, a_p), g(a_{p+1}, \dots, a_{p+q})),$$

with the evident left or right action when $p = 0$ or $q = 0$. Geometrically the residue is taken along the boundary divisor where the last point of the first block approaches the first point of the second block.

PROPOSITION 15.3.2 (Properties of cup product;). On the Hochschild cohomology groups computed by Theorem 15.2.7, the cup product satisfies:

- (i) *Associativity:* $(f \cup g) \cup h = f \cup (g \cup h)$
- (ii) *Graded commutativity:* $f \cup g = (-1)^{|f||g|} g \cup f$
- (iii) *Unit:* The identity element $1 \in CH^0(\mathcal{A})$ is a unit for $\cup$

Proof. Associativity: Both $(f \cup g) \cup h$ and $f \cup (g \cup h)$ involve taking residues at collision points. The order of residues does not matter by the residue theorem on $\overline{C}_n(X)$.

Graded commutativity: This is a cohomological statement. On cochains the two products are related by the Eilenberg–Zilber homotopy coming from the transposition of the two point blocks in $\overline{C}_n(X)$; the Koszul sign is the sign of the corresponding permutation of logarithmic forms.

Unit: The unit in CH^0 is the class of $1_{\mathcal{A}} \in \mathcal{A} = C_{\text{ch}}^0(\mathcal{A})$; the degree-zero differential above quotients by inner adjoint terms, so this is the invariant central class acting trivially under cup product. $\square$

15.3.2 The chiral Lie bracket

The chiral Lie bracket uses residue composition:

Definition 15.3.3 (Chiral Lie bracket). For $f \in CH^p(\mathcal{A})$ and $g \in CH^q(\mathcal{A})$, define:

$$\{f, g\}_c = f \circ_c g - (-1)^{(p-1)(q-1)} g \circ_c f$$

where the chiral composition $\circ_c$ is:

$$(f \circ_c g)(a_0, \dots, a_{p+q-1}) = \sum_{i=0}^{p-1} (-1)^{i(q-1)} \text{Res}_{w \rightarrow z_i} f(a_0, \dots, a_i, g(a_{i+1}, \dots, a_{i+q})(w), a_{i+q+1}, \dots)$$

THEOREM 15.3.4 (*Chiral Gerstenhaber algebra* [?Ger63, ?Tamarkin00];). Under the same conilpotent/completed bar hypotheses, the cohomology $CH^*(\mathcal{A})$ with operations $(\cup, \{-, -\}_c)$ forms a Gerstenhaber algebra:

(i) *Chiral Jacobi identity*:

$$\{f, \{g, h\}_c\}_c = \{\{f, g\}_c, h\}_c + (-1)^{(|f|-1)(|g|-1)} \{g, \{f, h\}_c\}_c$$

(ii) *Chiral Leibniz rule*:

$$\{f, g \cup h\}_c = \{f, g\}_c \cup h + (-1)^{(|f|-1)|g|} g \cup \{f, h\}_c$$

This is the chiral analogue of Gerstenhaber's classical theorem [?Ger63]. The bracket is the commutator on the dg Lie algebra of continuous coderivations of the conilpotent bar coalgebra $\bar{B}^{\text{ch}}(\mathcal{A})$; the Hochschild complex maps to that coderivation complex by the universal twisting morphism. The Leibniz rule is the compatibility of this commutator with the composition product on self-extensions of the diagonal bicomodule (Tamarkin [?Tamarkin00]; cf. the classical statement in [?LV12, Thm. 9.3.2]).

15.4 HIGHER STRUCTURES: A_∞ AND L_∞ ON CHIRAL HOCHSCHILD COHOMOLOGY

15.4.1 The A_∞ structure

THEOREM 15.4.1 (*A_∞ operations from the chiral brace model*;).

Choose a cellular chain model for the little-discs operad inside the Fulton–MacPherson logarithmic compactifications used in Theorem 15.2.8. The normalized chiral Hochschild cochain complex carries brace operations; restriction to the associative cellular suboperad gives operations

$$m_n : CH^{i_1} \otimes \cdots \otimes CH^{i_n} \rightarrow CH^{i_1 + \cdots + i_n + 2 - n}$$

satisfying the A_∞ relations (Stasheff–Loday–Vallette convention):

$$\sum_{r+s+t=n} (-1)^{rs+t} m_{r+s+t}(\text{id}^{\otimes r} \otimes m_s \otimes \text{id}^{\otimes t}) = 0$$

where the sign $(-1)^{rs+t}$ arises from the Koszul sign rule on suspended generators. The construction is a chain-level model for the derived centre; after passing to cohomology it recovers the Gerstenhaber operations of Theorem 15.3.4.

Construction of higher operations. The brace operation indexed by a rooted planar tree inserts cochains at the corresponding ordered collision strata and composes with the chiral product through the universal twisting morphism. For a top-dimensional cell σ in the chosen associative cellular suboperad, define m_σ by summing the residue operations over the boundary divisors met by σ . The operation m_n is the sum over the n -input cells with the orientation signs of the cellular chain model.

The A_∞ relation is the cellular boundary identity. The codimension-one boundary of a compactified configuration cell is a union of products of smaller cells,

$$\partial \bar{C}_n(\mathbb{P}^1) = \bigcup_{i+j=n+1} \bigcup_{I \sqcup J = [n]} \bar{C}_i(\mathbb{P}^1) \times \bar{C}_j(\mathbb{P}^1)$$

and each boundary component contributes the corresponding insertion $m_i \circ_k m_j$. The sign $(-1)^{rs+t}$ is the Stasheff–Loday–Vallette sign obtained after desuspending the inputs (see [?LV12], §9.2.8). Since the oriented cellular boundary squares to zero, the sum of all insertions is zero. $\square$

15.4.2 *The L_∞ structure*

By the commutator construction (antisymmetrizing the A_∞ operations via the natural operad map $\text{Lie} \rightarrow \text{Ass}$), an A_∞ structure induces an L_∞ structure:

THEOREM 15.4.2 (*L_∞ structure* [?LV12];). The shifted complex $CH^{*-1}(\mathcal{A})[-1]$ carries an L_∞ structure with brackets:

$$\ell_n : \Lambda^n CH^{*-1} \rightarrow CH^{*-1}[2-n]$$

related to the A_∞ operations by:

$$\ell_n(f_1, \dots, f_n) = \sum_{\sigma \in \mathcal{S}_n} \frac{\text{sign}(\sigma)}{n!} m_n(f_{\sigma(1)}, \dots, f_{\sigma(n)})$$

15.5 PERIODICITY IN CHIRAL HOCHSCHILD COHOMOLOGY

15.5.1 *Statement and first properties*

THEOREM 15.5.1 (*Virasoro bounded support and the degree-two cup map*;). [Type signature: Open quadrant; bounded vertex-cohomology and curve-chart presentations; Beilinson level 3; hypothesis package: the Bakalov–De Sole–Kac calculation and a bounded-to-chart quasi-isomorphism $\chi_{\text{Vir}_c}^{\text{bd}}$.]

Assume the bounded-to-chart map $\chi_{\text{Vir}_c}^{\text{bd}}$ of Definition 35.0.2 is a quasi-isomorphism. Then

$$\dim CH^n(\text{Vir}_c) = \begin{cases} 1, & n \in \{0, 2, 3\}, \\ 0, & n \in \mathbb{Z}_{\geq 0} \setminus \{0, 2, 3\}. \end{cases}$$

Choose nonzero classes $\Theta \in CH^2(\text{Vir}_c)$ and $\Xi \in CH^3(\text{Vir}_c)$. Cup product with Θ gives an isomorphism

$$CH^0(\text{Vir}_c) \xrightarrow{\cup \Theta} CH^2(\text{Vir}_c).$$

The Poincaré polynomial is $1 + t^2 + t^3$.

Proof. Bakalov–De Sole–Kac compute the bounded groups in degrees 0, 2, 3, each with dimension one, and the remaining groups with dimension zero [?BDSK21, Theorem 7.2]. The assumed quasi-isomorphism transports these dimensions to the chart. The degree-zero group is generated by the unit; hence $1 \cup \Theta = \Theta$, and the map between the two one-dimensional spaces is an isomorphism. $\square$

Remark 15.5.2 (Scope). The bounded-to-chart map carries the load-bearing comparison. The continuous Gel’fand–Fuchs complex has its own differential and support; a comparison with it is supplied by the maps of Chapter ???. The degree-three class Ξ belongs to the Virasoro family support and must be retained in every chart statement obtained from $\chi_{\text{Vir}_c}^{\text{bd}}$.

15.5.2 *Periodicity for other chiral algebras*

THEOREM 15.5.3 (*Critical formal-disk Hochschild model*;). Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra of rank r with exponents $m_1 \leq \dots \leq m_r$. At critical level $k = -h^\vee$, write CH_{loc}^* for the formal-disk continuous Lie algebra model obtained before imposing the global curve-level de Rham amplitude bound. Assume the Beilinson–Drinfeld formal-disk comparison identifies this local model with continuous cohomology of $\mathfrak{g} \otimes t\mathbb{C}[[t]]$. Then

$$CH_{\text{loc}}^*(\hat{\mathfrak{g}}_{-h^\vee}) \cong \Lambda^*(P_1, \dots, P_r) \otimes \mathbb{C}[\Theta_1, \dots, \Theta_r]$$

where $\deg P_i = 2m_i + 1$ (odd generators) and $\deg \Theta_i = 2(m_i + 1)$ (even generators). In particular:

- (i) For $\mathfrak{g} = \mathfrak{sl}_2$ (rank 1, exponent $m_1 = 1$): $CH_{\text{loc}}^* = \Lambda(P_1) \otimes \mathbb{C}[\Theta_1]$ with $\deg P_1 = 3$, $\deg \Theta_1 = 4$, and $CH_{\text{loc}}^{n+4} \cong CH_{\text{loc}}^n$ for all $n \geq 0$.
- (ii) For rank $r > 1$: the Poincaré series is $\prod_{i=1}^r (1 + t^{2m_i+1}) / (1 - t^{2(m_i+1)})$, giving polynomial growth $\dim CH_{\text{loc}}^n = O(n^{r-1})$ but *not* strict periodicity when the exponents are not all equal.

This is the local continuous model. The global curve-level chiral Hochschild object $Z_{\text{ch}}^{\text{der}}$ is obtained only after the logarithmic/Fulton–MacPherson comparison and its amplitude truncation are imposed. The statement does not identify the critical affine algebra with its Koszul dual.

Proof. Step 1: critical local comparison. At critical level $k = -h^\vee$, the bar complex is *uncurved*: the curvature $m_o \in \bar{B}^0$ has coefficient $\kappa = (k + h^\vee) \dim(\mathfrak{g}) / (2h^\vee)$, hence vanishes when $k = -h^\vee$. This is not a commutativity statement about the affine VOA: the critical current OPE still contains the simple-pole bracket term and the level double pole $k(\cdot, \cdot) / (z - w)^2$. What becomes commutative is the Feigin–Frenkel centre $\mathfrak{z}(\widehat{\mathfrak{g}}_{-h^\vee}) \cong \text{Fun Op}_{\mathfrak{g}^\vee}(D)$. The Sugawara construction is undefined at critical level, so no Sugawara-normalised stress tensor is used to prove curvature vanishing. The level-shifting duality (Corollary 8.1.13) confirms that the dual level $k' = -k - 2h^\vee = -h^\vee$ is the unique fixed point of the Feigin–Frenkel involution.

By the formal-disk comparison hypothesis, together with the Feigin–Frenkel identification of the critical chiral centre [?Feigin–Frenkel],

$$CH_{\text{loc}}^*(\widehat{\mathfrak{g}}_{-h^\vee}) \cong H_{\text{Lie,cont}}^*(\mathfrak{g} \otimes t\mathbb{C}[[t]]; \mathbb{C}).$$

Step 2: Gel'fand–Fuchs computation. The continuous Lie algebra cohomology of $\mathfrak{g} \otimes t\mathbb{C}[[t]]$ is computed by the Fuks–Feigin–Tsygan theorem ([?FT87]; see also Fuks [?Fuks86], Ch. 3):

$$H_{\text{Lie,cont}}^*(\mathfrak{g} \otimes t\mathbb{C}[[t]]; \mathbb{C}) \cong \Lambda^*(P_1, \dots, P_r) \otimes \mathbb{C}[\Theta_1, \dots, \Theta_r]$$

where $\deg P_i = 2m_i + 1$ and $\deg \Theta_i = 2(m_i + 1)$. The odd generators P_i correspond to primitive elements of $H^*(\mathfrak{g}; \mathbb{C})$ (Chevalley–Koszul), shifted by the loop grading; the even generators Θ_i arise from the t -adic filtration and correspond to Chern–Weil classes.

Step 3: Periodicity for rank 1. For $\mathfrak{sl}_2$ ($r = 1, m_1 = 1$): $CH_{\text{loc}}^* = \Lambda(P_1) \otimes \mathbb{C}[\Theta_1]$ with Poincaré series $(1 + t^3) / (1 - t^4)$. Cup product with $\Theta_1 \in CH_{\text{loc}}^4$ gives the isomorphism $CH_{\text{loc}}^n \xrightarrow{\sim} CH_{\text{loc}}^{n+4}$ for all $n \geq 0$: injectivity holds because $\mathbb{C}[\Theta_1]$ is a polynomial ring (no relations), and surjectivity because every element of CH_{loc}^{n+4} is divisible by Θ_1 modulo the exterior generator P_1 .

For rank $r > 1$, the Poincaré series $\prod_{i=1}^r (1 + t^{2m_i+1}) / (1 - t^{2(m_i+1)})$ grows polynomially of degree $r - 1$, so strict periodicity fails when $r > 1$ (verified explicitly for $\mathfrak{sl}_3$ in Remark 15.5.4). $\square$

Remark 15.5.4 (Status and rank distinction). *Rank 1.* For $\hat{\mathfrak{sl}}_2$ at $k = -2$, $CH_{\text{loc}}^* = \Lambda(P_1) \otimes \mathbb{C}[\Theta_1]$ with $\deg P_1 = 3$, $\deg \Theta_1 = 4$, giving local 4-periodicity $CH_{\text{loc}}^{n+4} \cong CH_{\text{loc}}^n$. The cup product with Θ_1 is the local periodicity operator; the Virasoro theorem above is instead an family-supported curve-level statement with bounded support $\{0, 2, 3\}$. The centre $\mathfrak{z}(\hat{\mathfrak{sl}}_{2,-2}) \cong \text{Fun Op}_{\mathfrak{sl}_2}$ gives the geometric origin of Θ_1 .

Rank $r > 1$. The local cohomology ring has r distinct polynomial degrees $2(m_i + 1)$; when not all equal, strict periodicity fails. For $\mathfrak{sl}_3$ at $k = -3$: $\deg \Theta_1 = 4$, $\deg \Theta_2 = 6$, and $\dim CH_{\text{loc}}^{12} = 3 \neq 1 = \dim CH_{\text{loc}}^6$, violating 6-periodicity. The correct local statement is polynomial growth $\dim CH_{\text{loc}}^n = O(n^{r-1})$.

Remark 15.5.5 (Provenance). The proof assembles three published results: (i) the Beilinson–Drinfeld comparison between the formal-disk chiral Hochschild model and continuous Lie algebra cohomology

(, [BD04], Thm. 4.5.2); (ii) the Gel'fand–Fuchs/Feigin–Tsygan computation of $H_{\text{cont}}^*(\mathfrak{g} \otimes t\mathbb{C}[[t]]; \mathbb{C})$ (, [FT87]); (iii) the uncurved bar complex structure at critical level, which follows from the critical-level fixed-point property (Corollary 8.1.13). These inputs give the stated critical-level local periodicity or polynomial-growth profile for every simple $\mathfrak{g}$.

PROPOSITION 15.5.6 (*Chiral Hochschild profile transport along a chart comparison;*). Let $(\mathcal{A}, \mathcal{A}^!)$ be a finite-type Verdier–Koszul pair carrying family data $H_H(\mathcal{A}; S)$ and $H_H(\mathcal{A}^!; S^!)$. Assume a brace-compatible chart quasi-isomorphism

$$\Xi_{\mathcal{A}}: C_{\text{ch}}^{\bullet}(\mathcal{A}, \mathcal{A}) \xrightarrow{\sim} C_{\text{ch}}^{\bullet}(\mathcal{A}^!, \mathcal{A}^!).$$

Then $\Xi_{\mathcal{A}}$ identifies the graded rings and their Hilbert profiles. In the standard same-type families this means:

- (i) *Virasoro*. If the bounded-to-chart maps are quasi-isomorphisms on both sides, each profile is $1 + t^2 + t^3$ by Bakalov–De Sole–Kac.
- (ii) *Kac–Moody*. The map $\Xi_{\mathcal{A}}$ identifies the support sets and dimensions computed by the two affine family models.
- (iii) *Principal $\mathcal{W}_N$* . The DS/bar comparison and $\Xi_{\mathcal{A}}$ identify the support sets and dimensions computed by the two principal family models.

Proof. The quasi-isomorphism $\Xi_{\mathcal{A}}$ induces an isomorphism of cohomology rings. The Virasoro dimensions are Theorem 15.5.1. In the affine and principal families, the named family data compute the two supports and $\Xi_{\mathcal{A}}$ identifies them. $\square$

COROLLARY 15.5.7 (*chiral Hochschild transport under finite-type Koszul duality;*). For any same-type finite-type Verdier–Koszul pair $(\mathcal{A}, \mathcal{A}^!)$ whose module categories are related by the finite-type Koszul derived equivalence and for which the Beilinson–Drinfeld chiral Hochschild comparison is Morita-compatible, there is an isomorphism of graded rings:

$$CH^*(\mathcal{A}) \cong CH^*(\mathcal{A}^!) \tag{15.1}$$

preserving the curve-level Hilbert profile. On the critical formal-disk model of Theorem 15.5.3, the corresponding local statement preserves the number and degrees of polynomial generators. In particular, the number of independent deformation directions $\dim CH^2(\mathcal{A}) = \dim CH^2(\mathcal{A}^!)$ is a Koszul-duality invariant.

Proof. The isomorphism (15.1) is induced by the module-level Koszul duality: the derived equivalence $D^b(\mathcal{A}\text{-mod}) \simeq D^b(\mathcal{A}^!\text{-mod})$ (Theorem 15.10.1) induces, by Keller’s theorem [Keller01], an isomorphism on Hochschild cohomology for derived-equivalent finite-type categories. The Morita-compatible Beilinson–Drinfeld comparison transports this ordinary Hochschild isomorphism to the chiral Hochschild surface. This uses the module-level derived equivalence, not bar-cobar inversion $\Omega(\overline{B}(\mathcal{A})) \simeq \mathcal{A}$; the latter recovers $\mathcal{A}$ itself and does not relate $\mathcal{A}$ to $\mathcal{A}^!$. Proposition 15.5.6 gives the same Hilbert profile on the standard same-type rows. In the local critical model, the Gel'fand–Fuchs computation supplies the polynomial generator statement separately. $\square$

Remark 15.5.8 (*Mixed-type pairs*). The preceding proposition does not address mixed-type Koszul pairs, where $\mathcal{A}$ and $\mathcal{A}^!$ have structurally different chiral Hochschild cohomology. The computed same-type

pairs listed here are $(\widehat{\mathfrak{g}}_k, \widehat{\mathfrak{g}}_{k'})$ and $(\text{Vir}_c, \text{Vir}_{26-c})$; for principal $\mathcal{W}_N$ the same-family statement is proved at the characteristic level and the algebra identification with $\mathcal{W}_N^{k'}$ is conditional on DS/bar transport. The question of whether Koszul duality preserves the chiral Hochschild growth type for genuinely distinct pairs (e.g., a hypothetical Koszul pair between a Kac–Moody algebra and a $\mathcal{W}$ -algebra) remains open.

Remark 15.5.9 (Periodicity profile and upper bounds). For the rank-1 local continuous models above, the periodicity operator is strict ($N \in \{2, 4\}$). For rank $r > 1$, the local Poincaré series $\prod_{i=1}^r (1 + t^{2m_i+1}) / (1 - t^{2(m_i+1)})$ gives polynomial growth $\dim CH_{\text{loc}}^n = O(n^{r-1})$, and the lcm

$$\text{lcm}(2(m_1+1), \dots, 2(m_r+1))$$

is only a quasi-period *upper bound* (no strict period exists for $\mathfrak{sl}_3$; see Remark 15.5.4).

Convention. $\text{Period}(\mathcal{A})$ is reserved for strict periodicity. The full invariant is the periodicity profile $\Pi(\mathcal{A}) = (M_{\mathcal{A}}, Q_{\mathcal{A}}, G_{\mathcal{A}})$ of Remark 15.5.10.

Remark 15.5.10 (The periodicity profile). Define the *periodicity profile*

$$\Pi(\mathcal{A}) = (M_{\mathcal{A}}, Q_{\mathcal{A}}, G_{\mathcal{A}})$$

where:

- (i) $M_{\mathcal{A}} = \bigoplus_{n \geq 0} CH^n(\mathcal{A})$ is the *periodicity module*, viewed over the periodicity operator σ . For rank 1, $M_{\mathcal{A}}$ is free of rank 1 over $\mathbb{Z}[\sigma]/(\sigma^N - 1)$. For rank $r > 1$ this statement refers to the local continuous comparison surface: there the module has r polynomial and r exterior factors before the curve-level Theorem 35.4.51 truncation.
- (ii) $Q_{\mathcal{A}} = \Lambda(x_{2m_1+1}, \dots, x_{2m_r+1}) \otimes \mathbb{C}[\gamma_{2(m_1+1)}, \dots, \gamma_{2(m_r+1)}]$ is the *periodicity algebra* (the Gel'fand–Fuchs ring governing $M_{\mathcal{A}}$).
- (iii) $G_{\mathcal{A}} = \text{Gal}(K_{\mathcal{A}}/\mathbb{Q})$ is the *periodicity Galois group* of the splitting field of the Poincaré series denominator. For $\widehat{\mathfrak{sl}}_2$: $G = \mathbb{Z}/2$; for $\widehat{\mathfrak{sl}}_3$: G contains cyclotomic Galois groups of 6th and 8th roots.

On the finite-type same-surface rows where Koszul duality acts on this profile, $M_{\mathcal{A}^\dagger}$ is the graded dual of $M_{\mathcal{A}}$ (Proposition 35.7.31), $Q_{\mathcal{A}^\dagger} \cong Q_{\mathcal{A}}$, and $G_{\mathcal{A}^\dagger} = G_{\mathcal{A}}$.

Nilpotence-periodicity interpretation. Conjecturally, the profile $\Pi(\mathcal{A})$ is the exponential of the nilpotent data in $\kappa(\mathcal{A})$ (Remark 7.1.11). The period N is the smallest integer with $\exp(2\pi i N \kappa/24) = 1$ (Conjecture 35.7.3), and $G_{\mathcal{A}}$ is the arithmetic shadow of the monodromy representation on bar cohomology.

Definition 15.5.11 (Derived scalar period). A scalar period $\text{Per}(\mathcal{A}) \in \mathbb{Z}_{>0}$ exists if and only if $M_{\mathcal{A}}, Q_{\mathcal{A}}$, and $G_{\mathcal{A}}$ all induce commuting finite-order automorphisms of a common finite-type complex. In that case,

$$\text{Per}(\mathcal{A}) := \text{ord}\langle T_{\mathcal{A}}, R_{\mathcal{A}}, G_{\mathcal{A}} \rangle,$$

the exponent of the group generated by the modular monodromy operator $T_{\mathcal{A}}$, the spectral R -matrix datum $R_{\mathcal{A}}$, and the geometric amplitude operator $G_{\mathcal{A}}$. Otherwise the primary invariant is the full profile $\Pi_{\mathcal{A}}$, not an integer.

Status. For $\widehat{\mathfrak{sl}}_2$ on the strict rank-1 periodic surface, $\text{Per}(\mathcal{A})$ agrees with the scalar period appearing in the explicit calculations of Chapter 35, and Proposition 35.7.31 records its transport under duality. For

Virasoro on the curve-level chiral Hochschild surface, Theorem 15.5.1 supplies the degree-two class inside the support $\{0, 2, 3\}$ rather than an invertible all-degree period; an integer period is available only after an external finite-type completion produces a finite-order automorphism. For higher-rank algebras where strict periodicity fails (Remark 15.5.4), the derived period is undefined and $\Pi_{\mathcal{A}}$ is the correct invariant.

PROPOSITION 15.5.12 (*Numerical admissible data under the level reflection;*). Let $\mathfrak{g}$ be a simple Lie algebra. A level k is *admissible* (in the sense of Kac–Wakimoto [KW88]) if it has the form $k + h^\vee = p/q$ with p, q coprime positive integers, $p \geq h^\vee$ if $\mathfrak{g}$ is simply laced ($p \geq h$ otherwise). Under the level reflection $k \mapsto k' = -k - 2h^\vee$:

- (i) The dual level satisfies $k' + h^\vee = -(k + h^\vee) = -p/q$, so $|k' + h^\vee| = p/q$ and the denominator is preserved.
- (ii) The Kac–Wakimoto numerator bound on p is preserved as numerical data. Literal Kac–Wakimoto admissibility is not preserved as a statement with $k' + h^\vee > 0$; the image is the signed mirror stratum $k' + h^\vee = -p/q$.

Proof. The level reflection $k \mapsto -k - 2h^\vee$ sends $k + h^\vee \mapsto -(k + h^\vee)$, preserving the absolute value and negating the sign. The coprime pair (p, q) and the relevant Kac–Wakimoto lower bound on p are unchanged. Since the definition of an admissible level uses the positive rational number p/q , the reflected level is a signed mirror point, not a literal positive admissible level. Any categorical comparison across the mirror requires additional representation-theoretic input and is not part of this proposition. $\square$

Remark 15.5.13 (*Module categories are not identified here*). The proposition above is a numerical statement about the level involution. A general derived equivalence of admissible module categories is *not* proved on this surface. The proved module-level Koszul duality used here is the later E_1 complete/connilpotent theorem Theorem 14.6.2; extending such a statement to full admissible chiral module categories remains frontier material.

Remark 15.5.14 (*The critical locus in level space*). The level space $k \in \mathbb{C}$ is stratified by Koszul behavior:

Locus	Koszul behavior
Generic k	Curved affine bar package with level-reflected scalar partner
Critical $k = -h^\vee$	Level fixed point; scalar curvature zero
Admissible $k + h^\vee = p/q$	Positive Kac–Wakimoto stratum; signed mirror under reflection
$k \in \mathbb{Z}_{\geq 0}$ (integrable)	KL equivalence with $U_q(\mathfrak{g})$; $q \leftrightarrow q^{-1}$
$k + h^\vee \in \mathbb{Z}_{< 0}$	Dual integrable: $k' = -k - 2h^\vee \in \mathbb{Z}_{\geq 0}$

The Feigin–Frenkel involution is the reflection $k + h^\vee \xrightarrow{\text{FF}} -(k + h^\vee)$; it preserves the generic mirror data and has unique fixed point $k = -h^\vee$, while the positive admissible stratum maps to its signed mirror.

15.6 THE TRANSITION FROM QUADRATIC TO NON-QUADRATIC KOSZUL DUALITY

15.6.1 Limitations of quadratic theory

The Heisenberg algebra is quadratic: a single generator with a single OPE relation (§2.1). Most chiral algebras of physical interest are not.

Definition 15.6.1 (Quadratic chiral algebra). A chiral algebra $\mathcal{A}$ is *quadratic* if it admits a presentation:

$$\mathcal{A} = \text{Free}^{\text{ch}}(V)/(R)$$

where V is a locally free $\mathcal{O}_X$ -module concentrated in conformal weight 1, and $R \subset j_*j^*(V \boxtimes V)$ consists of relations among products of two generators.

Example 15.6.2 (The $\beta\gamma$ system is quadratic). Generators: β (weight 1), γ (weight 0)

Relation: $[\beta(z), \gamma(w)] = \delta(z - w)$

This is quadratic after shifting γ to weight 1.

Example 15.6.3 (The Virasoro algebra is non-quadratic). The stress tensor $T(z)$ has weight 2, and the OPE:

$$T(z)T(w) = \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}$$

Cannot be expressed with only quadratic relations due to the quartic pole.

15.6.2 The Maurer–Cartan correspondence for quadratic algebras

Following Gui, Li, and Zeng [GLZ22], we prove a Maurer–Cartan correspondence for quadratic chiral algebras:

THEOREM 15.6.4 (Maurer–Cartan correspondence, quadratic case;). For a dualizable quadratic chiral algebra $\mathcal{A} = \mathcal{A}(N, P)$ with dual $\mathcal{A}^\dagger = \mathcal{A}(s^{-1}N^\vee\omega^{-1}, P^\perp)$, there is a bijection:

$$\text{Hom}_{\text{ChirAlg}}(\mathcal{A}, B) \cong \text{MC}(\mathcal{A}^\dagger \otimes B)$$

where MC denotes the set of Maurer–Cartan elements.

Proof. ($\Rightarrow$) Given $\phi: \mathcal{A} \rightarrow B$, set $\alpha = (\phi \otimes \text{id})(s^{-1}\text{Id}_{N \otimes N^\vee}) \in (\mathcal{A}^\dagger \otimes B)^\dagger$. Then $d\alpha = 0$ by $\phi(P) = 0$ and $P^\perp$ orthogonality, and $[\alpha, \alpha] = 0$ by associativity of ϕ .

($\Leftarrow$) Given $\alpha = \sum_i a_i^\dagger \otimes b_i \in \text{MC}(\mathcal{A}^\dagger \otimes B)$, define $\phi(n) = \sum_i \langle n, a_i^\dagger \rangle b_i$. The component $d\alpha = 0$ forces $\phi(P) = 0$ (so ϕ factors through $\mathcal{A}$), and $[\alpha, \alpha] = 0$ forces associativity. The two constructions are inverse by the universal property of $\text{Free}^{\text{ch}}(N)$. $\square$

15.6.3 Extending to non-quadratic: higher Maurer–Cartan equations

For non-quadratic algebras, the quadratic Maurer–Cartan equation is replaced by the higher equation:

Definition 15.6.5 (A_∞ Maurer–Cartan equation). Let $\mathcal{A}$ be a chiral algebra with A_∞ structure $(m_1, m_2, m_3, \dots)$. An element $\alpha \in \mathcal{A}^\dagger$ satisfies the A_∞ Maurer–Cartan equation if:

$$\sum_{n=1}^{\infty} m_n(\alpha, \dots, \alpha) = 0$$

(There are no factorial prefactors: the m_n take ordered inputs, unlike the symmetric L_∞ brackets ℓ_n where the Maurer–Cartan equation $\sum \frac{1}{n!} \ell_n(\alpha, \dots, \alpha) = 0$ includes $\frac{1}{n!}$ to account for permutation symmetry.)

Example 15.6.6 (Cubic relations require m_3). For the Yangian with RTT relations (cubic), the MC equation becomes:

$$m_1(\alpha) + m_2(\alpha, \alpha) + m_3(\alpha, \alpha, \alpha) = 0$$

where m_3 encodes the RTT relation. (In the L_∞ formulation via antisymmetrization, the corresponding equation is $d\alpha + \frac{1}{2}[\alpha, \alpha] + \frac{1}{6}\ell_3(\alpha, \alpha, \alpha) = 0$.)

15.7 THE YANGIAN: FIRST NON-QUADRATIC EXAMPLE

15.7.1 Yangian algebras

Drinfeld [Drinfeld85] introduced the Yangian as a canonical deformation of $U(\mathfrak{g}[t])$, motivated by the quantum inverse scattering method and the quantum Yang–Baxter equation.

15.7.2 Definition of the Yangian

Definition 15.7.1 (*The Yangian $Y(\mathfrak{g})$*). For a simple Lie algebra $\mathfrak{g}$ with basis $\{t_a\}_{a=1}^{\dim \mathfrak{g}}$ and structure constants $[t_a, t_b] = f_{ab}^c t_c$, the Yangian $Y(\mathfrak{g})$ is generated by elements $\{J_n^a : n \geq 0, a = 1, \dots, \dim \mathfrak{g}\}$ with relations:

Level-0: The J_0^a generate a copy of $\mathfrak{g}$:

$$[J_0^a, J_0^b] = f_{ab}^c J_0^c$$

Serre relations:

$$[J_0^a, J_n^b] = f_{ab}^c J_n^c$$

RTT relations (the non-quadratic part):

$$[J_1^a, [J_1^b, J_0^c]] - [J_0^a, [J_1^b, J_1^c]] = \hbar^2 \sum_{d,e,f} A_{def}^{abc} \{J_0^d, J_0^e, J_0^f\}$$

where $A_{def}^{abc} = \frac{1}{24} \sum_{p,q,r} f_{dp}^a f_{eq}^b f_{fr}^c f^{pqr}$ and $\{x, y, z\} = \sum_{\sigma \in S_3} x_{\sigma(1)} y_{\sigma(2)} z_{\sigma(3)}$ is the symmetrized product (the “Drinfeld terrible relation”). Higher relations between J_r^a and J_s^b for $r, s \geq 1$ involve iterated commutators of this basic relation.

The RTT relations involve products of three generators, making the Yangian inherently non-quadratic.

15.7.3 Affine current input and Yangian deformation data

THEOREM 15.7.2 (*Affine Kac–Moody as chiral algebra*;). The affine Kac–Moody algebra $\hat{\mathfrak{g}}_k$ defines a chiral algebra on $\mathbb{P}^1$, with:

- (i) Generating fields $J^a(z) = \sum_{n \in \mathbb{Z}} J_n^a z^{-n-1}$
- (ii) OPE structure:

$$J^a(z) J^b(w) \sim \frac{f_{ab}^c J^c(w)}{z-w} + \frac{k \Omega^{ab}}{(z-w)^2}$$

where Ω^{ab} is the Killing form and k is the level

Proof. The chiral algebra axioms for $\hat{\mathfrak{g}}_k$ follow from the current OPE.

Locality: The OPE has poles of order at most 2, ensuring $(z-w)^2 J^a(z) J^b(w) = (z-w)^2 J^b(w) J^a(z)$.

Associativity: The Jacobi identity for triple OPEs follows from the Lie algebra Jacobi identity for $\mathfrak{g}$ and the cocycle condition for the central extension.

Translation covariance: The $\mathcal{D}_X$ -module structure provides the ∂_z -action on all fields via $\partial_z J^a(z) = [L_{-1}, J^a(z)]$, where L_{-1} is the infinitesimal translation on X (part of the intrinsic $\mathcal{D}_X$ -module structure, independent of the Sugawara construction). $\square$

THEOREM 15.7.3 (*Critical centre and Yangian deformation data* [?Drinfeld85, ?Feigin–Frenkel];). The Yangian $Y(\mathfrak{g})$ is Drinfeld’s deformation of $U(\mathfrak{g}[t])$ [?Drinfeld85]. Separately, at the critical level $\kappa = -h^\vee$, the completed affine Kac–Moody chiral algebra has Feigin–Frenkel centre

$$Z(\hat{\mathfrak{g}}_{-h^\vee}) \cong \text{Fun}(\text{Op}_{\mathfrak{g}^\vee}).$$

These are distinct external inputs. This theorem does not assert a Kazhdan–Lusztig equivalence at critical level between smooth critical affine modules and Yangian modules; any such comparison requires a separate quantum-affine/Drinfeld–Kazhdan surface.

Remark 15.7.4 (Yangian taxonomy on this surface). Definition 15.7.1 is the Drinfeld Yangian $Y_h(\mathfrak{g})$ as an algebra. A chiral or factorisation Yangian $Y_X(\mathfrak{g})$ is extra structure: it must specify the $\hbar$ -adic topology, the factorisation products on configuration spaces, and the higher operations whose first nonquadratic term is the RTT/Serre operation. The affine current OPE of Theorem 15.7.2 supplies only the binary current part. It does not produce the Yangian Hopf coproduct, a quantum-affine equivalence, or a bialgebra structure on a Koszul dual. The deconcatenation coproduct on $\bar{B}(Y_X(\mathfrak{g}))$ is the bar-coalgebra coproduct; the Yangian coproduct is a separate co-operation coming from the tensor product on the chosen representation category.

15.7.4 Bar complex of the Yangian

THEOREM 15.7.5 (*Bar complex structure for a factorized Yangian model*;). Assume a factorization enhancement $Y_X(\mathfrak{g})$ of the Yangian has been fixed on $X = \mathbb{P}^1$, with binary current part given by the affine OPE and first nonquadratic relation given by Drinfeld’s cubic Serre/RTT relation of Definition 15.7.1. Assume also that these operations are continuous for the $\hbar$ -adic/PBW topology and satisfy the completed A_∞ relations. Then its ordered chiral bar complex has degree- n term

$$\bar{B}^n(Y_X(\mathfrak{g})) = \Gamma\left(\bar{C}_n(\mathbb{P}^1), Y_X(\mathfrak{g})^{\boxtimes n} \otimes \Omega_{\log}^n\right),$$

with differential $d_{\text{bar}} = d_{\text{int}} + d_2 + d_3 + \dots$ whose binary piece d_2 encodes the current Lie bracket and central term, and whose first higher piece d_3 encodes the cubic Serre/RTT relation.

Proof. *Degree 1:* Elements are $J^a(z) \otimes dz$.

Degree 2: Elements are $J^a(z_1) \otimes J^b(z_2) \otimes d \log(z_1 - z_2)$.

The differential:

$$\begin{aligned} d(J^a \otimes J^b \otimes \eta_{12}) &= \text{Res}_{z_1 \rightarrow z_2} J^a(z_1) J^b(z_2) \otimes \eta_{12} \\ &= f_{ab}^c J^c + \kappa \Omega^{ab} \cdot 1 \end{aligned}$$

Degree 3: Elements $J^a \otimes J^b \otimes J^c \otimes \eta_{12} \wedge \eta_{23}$.

The first higher differential is the image of the cubic relation in the chosen factorization presentation:

$$d(\omega_3) = d_2(\omega_3) + d_3(\omega_3), \quad d_3(\omega_3) = \text{RTT}(J^a, J^b, J^c).$$

Thus nonquadraticity is visible as a higher bar differential on the completed factorisation model. The identity $d_{\text{bar}}^2 = 0$ is exactly the completed A_∞ relation among $d_2, d_3, \dots$; it is an assumption on the chosen factorisation Yangian model, not a consequence of the affine OPE alone. $\square$

15.8 $\mathcal{W}$ -ALGEBRAS15.8.1 *Historical development*

The W_3 algebra (Zamolodchikov, 1985) arises from quantum Drinfeld–Sokolov reduction (Feigin–Frenkel, 1990).

15.8.2 *The BRST construction*

Definition 15.8.1 (*$\mathcal{W}$ -algebra via quantum Drinfeld–Sokolov*). For a simple Lie algebra $\mathfrak{g}$ and principal nilpotent element $e \in \mathfrak{g}$, the $\mathcal{W}$ -algebra $\mathcal{W}^k(\mathfrak{g})$ at level k is:

$$\mathcal{W}^k(\mathfrak{g}) = H_{Q_{DS}}^{\circ}(\hat{\mathfrak{g}}_k \otimes \mathcal{F}_{gh})$$

where Q_{DS} is the BRST charge and $\mathcal{F}_{gh}$ is the ghost system.

Example 15.8.2 (*$\mathcal{W}_3$ algebra for $\mathfrak{g} = \mathfrak{sl}_3$*). *Step 1:* Start with $\hat{\mathfrak{sl}}_3$ at level k .

Step 2: Choose principal $\mathfrak{sl}_2$ embedding:

$$e = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad h = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -2 \end{pmatrix}, \quad f = \begin{pmatrix} 0 & 0 & 0 \\ 2 & 0 & 0 \\ 0 & 2 & 0 \end{pmatrix}$$

Step 3: Add ghosts (b_α, c_α) for positive roots.

Step 4: BRST charge:

$$Q = \oint \left(\sum_{\alpha \in \Delta_+} c_\alpha J^\alpha + \text{ghost self-coupling terms} + \text{DS constraint} \right) dz$$

Step 5: Cohomology generators: T (weight 2), W (weight 3).

Step 6: The resulting OPEs are given in Definition ?? . The sixth-order pole in the $W-W$ OPE makes this highly non-quadratic.

15.8.3 *Critical centre and the screening model*

THEOREM 15.8.3 (*Feigin–Frenkel centre* [FF];). At critical level $k = -h^\vee$, the centre of the completed affine chiral algebra is

$$\mathfrak{z}(\widehat{\mathfrak{g}}) \cong \text{Fun}(\text{Op}_{L_{\widehat{\mathfrak{g}}}}),$$

the algebra of functions on Langlands-dual opers. Under the Miura free-field realization of the principal $\mathcal{W}$ -algebra, the screening operators $S_1, \dots, S_r$ describe the intersection of screening kernels.

Proof. This is the Feigin–Frenkel theorem at the critical level, together with the standard Miura/screening realization of principal $\mathcal{W}$ -algebras. The statement is about the centre and the free-field screening presentation; it is not a theorem that the chiral bar coalgebra of $\mathcal{W}^{-h^\vee}(\mathfrak{g})$ is equal to a polynomial algebra on screenings. $\square$

Remark 15.8.4 (*Screening Koszul complex as model*). The complex

$$\text{Sym}[S_1, \dots, S_r] \otimes \Omega_{\log}^*$$

is a useful associated-graded or free-field model for the critical-level screening calculation. It may serve as a lead for a bar computation after the Miura comparison, logarithmic extension, and completion hypotheses are supplied. This chapter does not use it as an identification of $\bar{B}(\mathcal{W}^{-h^\vee}(\mathfrak{g}))$.

15.8.4 Langlands duality for $\mathcal{W}$ -algebras

Remark 15.8.5 (Frenkel–Gaiitsgory viewpoint [?FG06];). At critical level, the local geometric/quantum-Langlands literature relates affine and oper-theoretic data for $\mathfrak{g}$ and its Langlands dual $\mathfrak{g}^L$. This critical-level picture supplies external comparison data for principal $\mathcal{W}$ -algebras and Langlands-dual data. It is *not* identified with a proved bar-cobar Koszul-duality theorem of the form

$$\mathcal{W}^{-h^\vee}(\mathfrak{g})^! \simeq \mathcal{W}^{-h^\vee}(\mathfrak{g}^L),$$

and no such theorem is claimed internally here.

15.9 NON-PRINCIPAL $\mathcal{W}$ -ALGEBRAS

15.9.1 Non-principal orbits

Quantum Drinfeld–Sokolov reduction attached to a non-principal nilpotent orbit produces a non-principal $\mathcal{W}$ -algebra. The exchange of non-principal orbits under Gaiotto–Witten S-duality is a conjectural external duality input unless the orbit and level transform are supplied separately.

15.9.2 Example: Subregular $\mathcal{W}$ -algebra for $\mathfrak{sl}_4$

Definition 15.9.1 (Subregular nilpotent). The subregular nilpotent in $\mathfrak{sl}_4$ has Jordan type $(3, 1)$:

$$e_{\text{subreg}} = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

THEOREM 15.9.2 (Structure of $\mathcal{W}(\mathfrak{sl}_4, e_{\text{subreg}})$ [?KRW];). The subregular $\mathcal{W}$ -algebra has generators T (weight 2), $G^\pm$ (weight $3/2$), and J (weight 1), with OPEs involving fractional powers and fermionic statistics.

The fractional weights require orbifold constructions on configuration spaces.

15.9.3 S-duality and Koszul duality

THEOREM 15.9.3 (Feigin–Frenkel duality as S-duality, principal simply-laced case;). For simply-laced $\mathfrak{g}$ and principal nilpotent $f = f_{\text{prin}}$, the Gaiotto–Witten S-duality reduces to Feigin–Frenkel duality [?Feigin–Frenkel]:

$$\mathcal{W}^k(\mathfrak{g}, f_{\text{prin}}) \simeq \mathcal{W}^{k'}(\mathfrak{g}, f_{\text{prin}}), \quad (k + h^\vee)(k' + h^\vee) = 1.$$

The duality inverts the shifted level and preserves the central charge; for $\mathfrak{g} = \mathfrak{sl}_2$ it is the Virasoro self-duality $b \mapsto b^{-1}$ with $b^2 = k + 2$, under which $c = 13 - 6(b^2 + b^{-2})$ is fixed. It is distinct from the reflection $k \mapsto -k - 2h^\vee$, which sends $k + h^\vee$ to $-(k + h^\vee)$ and hence κ to $-\kappa$ (for Virasoro $c + c' = 26$): that reflection is the curvature-pairing involution, not an isomorphism of $\mathcal{W}$ -algebras.

Conjecture 15.9.4 (Gaiotto–Witten S-duality, general case;). For general $\mathfrak{g}$ and nilpotent f , there exists a duality:

$$\mathcal{W}^k(\mathfrak{g}, f) \longleftrightarrow \mathcal{W}^{k^L}(\mathfrak{g}^L, f^L)$$

where:

- $k^L = -h^\vee(\mathfrak{g}^L) + r^\vee/(k + h^\vee(\mathfrak{g}))$, where $r^\vee$ is the lacing number of $\mathfrak{g}$
- f^L is the Spaltenstein dual nilpotent

Remark 15.9.5 (Scope). The principal simply-laced case is Feigin–Frenkel [?Feigin–Frenkel]. In type A , the hook-type transport corridor is a conditional theorem whose missing hypothesis is uniform DS/bar compatibility over the hook family [?FehilyHook, ?CLNS24, ?CFLN24, ?GenraStages, ?ButsonNair, ?AvE23] (Remark ??, Theorem ??). Kac–Roan–Wakimoto [?KRW] supplies DS reduction for arbitrary f ; the separate Koszul open mathematical condition is compatibility of Verdier-Koszul duality with arbitrary-nilpotent reduction, together with the orbit-dependent level transform.

Non-principal DS reduction produces non-quadratic chiral algebras in every type. Producing Koszul dual pairs from them requires the additional DS/bar compatibility and orbit-dependent level transform named above.

15.10 MODULE CATEGORIES AND RESOLUTIONS

15.10.1 Derived and exotic categorical comparisons

THEOREM 15.10.1 (*Koszul equivalence of categories* [?BGS96];). Let $(\mathcal{A}, \mathcal{A}^i)$ be a quadratic, uncurved, finite-type Koszul pair on the genus-0 E_1 surface, and assume that the linear dual algebra $\mathcal{A}^! = (\mathcal{A}^i)^\vee$ exists and that the bounded-below module categories are generated by finite-length Koszul modules. Then there is an equivalence of triangulated categories:

$$D^b(\mathcal{A}\text{-mod}) \simeq D^b(\mathcal{A}^!\text{-mod})$$

Remark 15.10.2. The theorem is not a definition of chiral Koszulness. In the general chiral setting (curved, non-quadratic, or only completed finite type), the proved intrinsic statement is the coderived/contraderived comparison for the bar coalgebra $C = \overline{B}^{\text{ch}}(\mathcal{A})$ and its completed-dual module category (Theorems 15.10.3 and 15.10.5). The ordinary derived module equivalence is recovered only on the flat finite-type bar-dual surface, including the quadratic genus-0 setting of Theorem 14.6.2.

THEOREM 15.10.3 (*Positselski equivalence for the finite-type chiral bar coalgebra*;). For a Koszul chiral algebra $\mathcal{A}$ whose curved bar complex $C = \tilde{B}^{\text{ch}}(\mathcal{A})$ lies in the finite-type conilpotent CDG surface and satisfies the product/sum exactness hypothesis of Theorem 9.9.21, there is an equivalence of triangulated categories:

$$D^{\text{co}}(C\text{-comod}^{\text{conil, ch}}) \simeq D^{\text{ctr}}(C\text{-contra}^{\text{ch}})$$

between the coderived category of conilpotent chiral CDG-comodules over the bar coalgebra C and the contraderived category of chiral CDG-contramodules over C . In finite type the right-hand side may be rewritten as complete modules over the graded dual algebra C^* , and on the quadratic genus-0 bar-dual surface this recovers the module Koszul duality of Theorem 14.6.2. For class-M raw direct-sum bar coalgebras the applicable surface is the strict completed one of Theorem 29.3.8, with its explicit continuous co/contra hypotheses.

Proof. This is Theorem 9.9.23, which follows from the chiral comodule-contramodule correspondence (Theorem 9.9.21) applied to the CDG-coalgebra $C = \tilde{B}^{\text{ch}}(\mathcal{A})$. The foundational chiral coalgebra homological algebra is developed in §9.9. $\square$

Remark 15.10.4 (Three comparison layers). Three layers: (1) $\tilde{B}^{(g)}(\mathcal{A})$ is a chiral CDG-coalgebra (Definition 9.9.2); curvature at $g \geq 1$ forces the coderived/contraderived framework (Proposition 9.1.9).

(2) The functors $\Phi_C^{\text{ch}}, \Psi_C^{\text{ch}}$ (Definition 9.9.19) descend to $D^{\text{co}} \simeq D^{\text{ctr}}$ (Theorem 9.9.21). (3) In finite type, CDG-contramodules over $\bar{B}^{\text{ch}}(\mathcal{A})$ may be rewritten as complete modules over the graded dual algebra $\bar{B}^{\text{ch}}(\mathcal{A})^*$; the further identification with $\mathcal{A}^!$ is only available on the quadratic genus-0 bar-dual surface (Theorem 13.5.1).

THEOREM 15.10.5 (*Flat finite-type reduction on the completed-dual side;*). Let $C = \bar{B}^{\text{ch}}(\mathcal{A})$ be the chiral bar coalgebra of a Koszul chiral algebra $\mathcal{A}$, and assume we are on a flat finite-type locus where Positselski's comparison theorem identifies the contraderived category of chiral CDG-contramodules over C with the ordinary bounded derived category of complete modules over the graded dual algebra C^* . Then there is a triangulated equivalence:

$$D^{\text{ctr}}(C\text{-contra}^{\text{ch}}) \simeq D^b(\text{Mod}^{\text{compl}}(C^*))$$

Consequently, on that same locus, the intrinsic coderived/contraderived equivalence of Theorem 15.10.3 reduces to an ordinary derived comparison on the completed-dual side. On the quadratic genus-0 bar-dual surface where $C^* \cong \mathcal{A}^!$, this recovers Theorem 14.6.2.

Proof. This is Theorem 9.9.24. It is a flat finite-type reduction theorem for the completed-dual side of the intrinsic Positselski equivalence. The quadratic genus-0 specialization then recovers Theorem 14.6.2. See §9.9.8 for full details. $\square$

15.10.2 Explicit resolutions for non-quadratic cases

Example 15.10.6 (*BGG resolution for W -algebras*). On the external DS-reduction surface for admissible $\mathcal{W}^k(\mathfrak{g})$ -modules, the BGG-type resolution problem for a simple module $L(\lambda)$ has the form

$$\cdots \rightarrow \bigoplus_{\ell(w)=2} M(w \cdot \lambda) \rightarrow \bigoplus_{\ell(w)=1} M(w \cdot \lambda) \rightarrow M(\lambda) \rightarrow L(\lambda) \rightarrow 0$$

where w ranges over elements of the Weyl group of length $\ell(w)$, $w \cdot \lambda = w(\lambda + \rho) - \rho$ is the dot action, and the differentials are given by screening operators. On the claim used here, the relevant exactness input is the external exactness of Drinfeld–Sokolov reduction on the appropriate module category (Arakawa [Arakawa17]), not rationality of $\mathcal{W}^k(\mathfrak{g})$ by itself.

Remark 15.10.7 (*Yangian module resolutions require Drinfeld–Kazhdan input*). On an external Drinfeld–Kazhdan comparison surface, a resolution theorem for finite-dimensional $Y(\mathfrak{g})$ -modules would have to construct complexes induced from the quantum affine side, schematically of the form

$$\cdots \rightarrow Y \otimes V_2 \rightarrow Y \otimes V_1 \rightarrow Y \otimes V_0 \rightarrow M \rightarrow 0$$

where the V_i come from the quantum affine category and the differentials are encoded by the relevant R -matrix data. This requires compact generation by the chosen quantum-affine objects, exactness of the comparison functor, and compatibility of the braiding reversal $R_q \mapsto R_{q^{-1}}$ with the bar filtration. The bar-cobar counit $\Omega \bar{B}(Y_X) \rightarrow Y_X$ supplies none of these three inputs.

15.11 DEFORMATION THEORY AND MAURER–CARTAN ELEMENTS

15.11.1 Deforming chiral algebras

Remark 15.11.1 (*Deformation-theoretic scope*). For a non-quadratic chiral algebra, the deformation-theoretic data on the surface used here are organized by the antisymmetrized bar L_∞ package discussed

below. Maurer–Cartan equations there record candidate formal deformations. No stand-alone comparison theorem is proved here identifying formal deformations of an arbitrary chiral algebra with Maurer–Cartan elements of a specifically defined chiral Hochschild complex; nor is a proved $\beta\gamma$ deformation family constructed from an explicit Maurer–Cartan element.

15.12 THE CHERN–SIMONS STRUCTURE IN NON-QUADRATIC KOSZUL DUALITY

15.12.1 Maurer–Cartan and Chern–Simons

The Maurer–Cartan equation for non-quadratic chiral algebras:

$$d\alpha + \frac{1}{2}\ell_2(\alpha, \alpha) + \frac{1}{6}\ell_3(\alpha, \alpha, \alpha) + \cdots = 0$$

(using the L_∞ brackets ℓ_n obtained by antisymmetrizing the A_∞ operations) is the basic algebraic deformation equation attached to the antisymmetrized bar L_∞ structure. In quadratic cases it reduces to the usual dg Lie Maurer–Cartan equation; any comparison with Chern–Simons theory requires additional external input.

15.12.2 Witten’s Chern–Simons interpretation

Chern–Simons theory on a 3-manifold M with gauge group G at level k produces [?Wit89] the WZW model on ∂M and quantum group representations at $q = e^{\pi i/(k+h^\vee)}$. The action is:

$$S_{CS}(A) = \frac{k}{4\pi} \int_M \text{Tr} \left(A \wedge dA + \frac{2}{3} A \wedge A \wedge A \right)$$

15.12.3 The precise connection

THEOREM 15.12.1 (*Affine Kac–Moody Maurer–Cartan and curvature package*;). For a simple Lie algebra $\mathfrak{g}$ and its affine extension $\widehat{\mathfrak{g}}_k$ at $k \neq -h^\vee$:

- (i) *Classical Maurer–Cartan = flatness*. The ordinary dg Lie algebra $\mathfrak{g} \otimes \Omega^*(M)$ carries the classical Maurer–Cartan equation

$$d\alpha + \frac{1}{2}[\alpha, \alpha] = 0$$

for a 3-manifold M , and this is the flatness equation $F_A = 0$. Separately, the Chevalley–Eilenberg complex $C^*(\mathfrak{g})$ is the bar construction $\overline{B}(U\mathfrak{g})$.

- (ii) *Affine bar = semi-infinite complex*. The bar–semi-infinite quasi-isomorphism

$$\overline{B}(\widehat{\mathfrak{g}}_k) \simeq C_{\infty/2}^*(\widehat{\mathfrak{g}}_k)$$

(Theorem ??) identifies the affine bar complex with the semi-infinite complex of the vacuum module.

- (iii) *Genus-1 curvature coefficient and dual cancellation*. At genus 1, the bar complex has $d_{\text{fb}}^2 = \kappa \cdot \omega_1$ with $\kappa = (k + h^\vee) \dim(\mathfrak{g}) / (2h^\vee)$. This curvature is algebraically nonzero away from the critical level, and for the affine Kac–Moody dual pair $(k, -k - 2h^\vee)$ one has $\kappa(\widehat{\mathfrak{g}}_k) + \kappa(\widehat{\mathfrak{g}}_{k'}) = 0$ (this anti-symmetry is specific to affine Kac–Moody; for Virasoro, $\kappa + \kappa' = 13$).

Proof. Part (i) is classical: the MC equation $d\alpha + \frac{1}{2}[\alpha, \alpha] = 0$ in the dg Lie algebra $\mathfrak{g} \otimes \Omega^*(M)$ is the flatness equation $F_A = 0$ by definition. Independently, $C^*(\mathfrak{g}) = \overline{B}(U\mathfrak{g})$ by the Chevalley–Eilenberg

theorem and provides the standard cochain model attached to $\mathfrak{g}$. The flatness equation is the Euler–Lagrange equation for S_{CS} : varying $\delta S_{\text{CS}}/\delta A = \frac{k}{2\pi} F_A = 0$.

Part (ii) is exactly Theorem ??.

Part (iii) follows from $d_{\text{fib}}^2 = \kappa \cdot \omega_1$ (Theorem ??) with $\kappa(\widehat{\mathfrak{g}}_k) = (k + h^\vee) \dim(\mathfrak{g})/(2h^\vee)$ (Remark ??). For the dual pair $(k, k' = -k - 2h^\vee)$, $\kappa(\widehat{\mathfrak{g}}_k) + \kappa(\widehat{\mathfrak{g}}_{k'}) = 0$ (Corollary ??; the vanishing is an affine Kac–Moody identity). $\square$

Remark 15.12.2 (External physical interpretation). Theorem 15.12.1 supplies algebraic input often compared with the Chern–Simons/WZW picture: classical Maurer–Cartan flatness in $\mathfrak{g} \otimes \Omega^*(M)$, the affine bar/semi-infinite identification, and the dual curvature coefficient. Turning this into a full boundary Chern–Simons interpretation uses additional external results and is not proved here.

THEOREM 15.12.3 (*L_∞ Maurer–Cartan equation from a transferred A_∞ model;*). For a chiral algebra $\mathcal{A}$ with A_∞ operations $\{m_n\}$ on an underlying graded space, the antisymmetrized operations ℓ_n define an L_∞ structure on that same graded space. For W-algebras this applies only after a transferred model has been supplied. The Maurer–Cartan equation

$$d\alpha + \frac{1}{2}\ell_2(\alpha, \alpha) + \frac{1}{6}\ell_3(\alpha, \alpha, \alpha) + \cdots = 0$$

is the Maurer–Cartan equation of this transferred L_∞ algebra.

- (i) For quadratic $\mathcal{A}$ (Kac–Moody): $\ell_n = 0$ for $n \geq 3$, and the MC equation is the standard dg Lie Maurer–Cartan equation.
- (ii) For general non-quadratic $\mathcal{A}$: the higher ℓ_n are determined by the higher bar operations m_n and contribute the corresponding higher terms to the Maurer–Cartan equation.

Proof. The L_∞ structure on the underlying graded space of the A_∞ model is obtained by the standard antisymmetrization (Loday–Vallette [?LV12, Thm. 10.1.13]): $\ell_n(x_1, \dots, x_n) = \sum_{\sigma \in S_n} \epsilon(\sigma) m_n(x_{\sigma(1)}, \dots, x_{\sigma(n)})$. The MC equation $\sum_{n \geq 1} \frac{1}{n!} \ell_n(\alpha^{\otimes n}) = 0$ is then automatic from the A_∞ relations (which are equivalent to the L_∞ Jacobi identities under antisymmetrization).

For (i): when $\mathcal{A}$ is quadratic (Kac–Moody), the transferred model has $m_n = 0$ for $n \geq 3$ (the OPE has only simple and double poles), so $\ell_n = 0$ for $n \geq 3$ and the MC equation reduces to $d\alpha + \frac{1}{2}[\alpha, \alpha] = 0$, which is the usual dg Lie Maurer–Cartan equation.

For (ii): if some higher bar operations m_n are nonzero, then their antisymmetrizations contribute nonzero higher brackets ℓ_n , and the Maurer–Cartan equation acquires the displayed higher terms. $\square$

Remark 15.12.4 (Algebraic and physical interpretations). Theorem 15.12.3 establishes the algebraic statement: the transferred A_∞ models determine antisymmetrized L_∞ structures, and their Maurer–Cartan equations have the displayed higher terms. The additional assertion that these terms are flatness equations, BV-BRST vertices, or Chern–Simons corrections is external: it requires geometric fields, a cyclic BV pairing, and perturbative QFT input not constructed here.

Remark 15.12.5 (Scope). Theorem 15.12.3 constructs the Maurer–Cartan equation on the transferred L_∞ model associated to a chosen A_∞ structure; Theorem 15.12.1 records the affine Kac–Moody classical/semilinear package (classical Maurer–Cartan flatness, bar/semi-infinite comparison, and the dual curvature coefficient); the displayed higher Maurer–Cartan equation records the non-quadratic case. Any field-theoretic Chern–Simons interpretation remains external to the proved algebraic core.

15.12.4 *Quantum-group and Chern–Simons comparison data*

Conjecture 15.12.6 (Witten–Reshetikhin–Turaev comparison surface;). Assume:

- (W1) the Witten–Reshetikhin–Turaev construction identifies the Chern–Simons boundary category at level k with the corresponding quantum-group representation category at

$$q = \exp\left(\frac{\pi i}{k + h^\vee}\right);$$

- (W2) a Drinfeld–Kazhdan/Kazhdan–Lusztig comparison is fixed on an evaluation-generated Yangian/quantum-affine surface;

- (W3) the finite-type Verdier–Koszul comparison is available on that same surface and sends the level parameter by $k + h^\vee \mapsto -(k + h^\vee)$.

Then the boundary quantum parameter is sent to

$$q \mapsto q^{-1}.$$

The resulting datum compares the WRT boundary category, the external Yangian/quantum-affine comparison, and the finite-type Verdier–Koszul reflection. It is not a construction of a Chern–Simons action from the bar coalgebra and not an identification of $Y_h(\mathfrak{g})$ with the Koszul dual of $V_k(\mathfrak{g})$.

Remark 15.12.7 (Scope). The transferred Maurer–Cartan equation on the chosen L_∞ model has the formal shape of a deformed flatness equation (preceding theorem). A physical Chern–Simons interpretation requires the WRT package [Wit89, RT91], a cyclic BV pairing, and a perturbative quantization theorem. The algebraic Koszul package supplies only the boundary bar, the Verdier partner when finite type is present, and the L_∞ Maurer–Cartan equation.

If the transferred L_∞ model is cyclic with pairing $\langle -, - \rangle_{\text{cyc}}$, the first RTT contribution to a formal action has the typed form

$$S_{\text{form}}(\alpha) = \frac{1}{2} \langle \alpha, d\alpha \rangle_{\text{cyc}} + \frac{1}{6} \langle \alpha, \ell_2(\alpha, \alpha) \rangle_{\text{cyc}} + \frac{1}{24} \langle \alpha, \ell_3^{\text{RTT}}(\alpha, \alpha, \alpha) \rangle_{\text{cyc}} + \cdots.$$

Without the cyclic pairing and BV integration data this expression is only a formal cyclic L_∞ functional.

15.12.5 *Examples of Chern–Simons structure*

15.12.5.1 YANGIAN DEFORMATION DATUM

For a factorisation Yangian model whose first higher bracket is ℓ_3^{RTT} , the Maurer–Cartan equation is

$$d\alpha + \frac{1}{2} [\alpha, \alpha] + \frac{1}{6} \ell_3^{\text{RTT}}(\alpha, \alpha, \alpha) = 0.$$

This is an algebraic deformation of the classical Maurer–Cartan equation inside the chosen completed L_∞ algebra. It becomes a gauge-field equation only after an external Chern–Simons/BV model realizes the same L_∞ algebra as fields.

15.12.5.2 CRITICAL-LEVEL $\mathcal{W}$ SCREENING DATUM

At critical level $k = -h^\vee$:

$$d\alpha + \sum_{i=1}^r S_i(\alpha) = 0$$

where S_i are screening charges in the free-field model. This equation belongs to the Miura/screening complex; a field-theoretic identification requires a separate BRST/BV comparison.

15.12.5.3 NON-PRINCIPAL $\mathcal{W}$ ORBIFOLD DATUM

For fractional gradings, an orbifold Chern–Simons model would first require a genuine orbifold field theory on $\mathcal{M}/\Gamma$. The notation

$$S = \frac{1}{|\Gamma|} \int_{\mathcal{M}/\Gamma} S_{\text{CS}}(\alpha)$$

records only the orbifold volume normalization by the group Γ ; no action functional on the non-principal $\mathcal{W}$ -algebra is constructed from it here.

15.12.6 The holographic interpretation

Conjecture 15.12.8 (AdS/CFT comparison datum;). Assume:

- (H1) a 3d Chern–Simons or holomorphic-topological bulk theory on AdS_3 has been constructed;
- (H2) its boundary category is identified with modules for a boundary chiral algebra (WZW, Virasoro, or $\mathcal{W}$);
- (H3) the boundary chiral algebra lies on the finite-type Verdier-Koszul surface of this chapter;
- (H4) a holographic comparison functor identifies physical bulk observables with the intrinsic Hochschild closed-sector slot $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$.

Then the boundary side separates into three typed objects: bar-cobar inversion recovers the boundary algebra $\mathcal{A}$, Verdier duality supplies the Koszul partner $\mathcal{A}^!$ when finite type is present, and chiral Hochschild cochains supply the intrinsic closed-sector operator complex. The conjecture is the existence of the external comparison functor in (H4); bulk reconstruction is not a theorem of bar-cobar inversion.

Remark 15.12.9 (Scope). The $\text{AdS}_3/\text{CFT}_2$ interpretation requires: (a) 3d gravity as $SL(2, \mathbb{R})^2$ CS (Witten [?Wi t89]); (b) boundary WZW identification (Beilinson–Drinfeld [?BD04]); (c) a holographic dictionary comparing the intrinsic Hochschild closed-sector slot with physical bulk observables. The proved input is the boundary-side Koszul/module package; bulk reconstruction is not proved here.

The external boundary dictionary has the type form

bulk Chern–Simons package on AdS_3	$\rightsquigarrow_{\text{ext}}$	CFT_2 on $\partial(\text{AdS}_3)$
flat connections	$\rightsquigarrow_{\text{ext}}$	chiral algebra modules
Wilson lines	$\rightsquigarrow_{\text{ext}}$	vertex operators
MC elements	$\rightsquigarrow_{\text{alg}}$	formal deformations

Only the last algebraic arrow is supplied by the transferred L_∞ package in this chapter.

15.12.7 BV formalism

The BV algebra structure on the bar complex is the fifth piece of the master differential (Theorem ??).

THEOREM 15.12.10 (*BV structure on bar complex;).* The chiral bar complex carries a BV algebra structure where:

- (i) The BV operator Δ is the non-separating clutching map of the modular operad: for an element at genus g with $n + 2$ inputs, Δ contracts a pair of inputs using the invariant form $\langle -, - \rangle_{\mathcal{A}}$ and produces an element at genus $g + 1$ with n inputs. This is the $\hbar\Delta$ term in the five-component differential (??).

- (ii) The antibracket $\{-, -\}$ is the separating clutching: joining two elements by identifying one output with one input through the propagator $P_{\mathcal{A}}$. This is the Lie bracket of the modular convolution algebra (Theorem ??).
- (iii) The algebraic modular QME shell $D\Theta^{\leq r} + \frac{1}{2}[\Theta^{\leq r}, \Theta^{\leq r}] = 0$ holds at each finite order of the shadow obstruction tower (Remark ??). This is a finite-window identity in the completed modular convolution algebra, not an all-loop analytic QME for a physical factorization algebra.

Analytic realization. On configuration spaces, Δ acts by residue extraction along collision diagonals and $\{-, -\}$ by the symplectic pairing on $T^*C_n(X)$. The Arnold relation $\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0$ is the genus-0 shadow of $\Delta^2 = 0$.

Proof. The BV operator Δ is the non-separating gluing map $\xi_{\text{ns}}: \overline{\mathcal{M}}_{g,n+2} \rightarrow \overline{\mathcal{M}}_{g+1,n}$ of the modular operad (Definition 36.13.24), composed with the invariant pairing. The antibracket is the separating gluing. The second-order property of Δ (the BV axiom) follows from the codimension-2 boundary relations on $\overline{\mathcal{M}}_{g,n}$: two non-separating degenerations compose to give a codimension-2 stratum that also arises from a separating degeneration, yielding the BV relation $\Delta^2 = 0$ and $\Delta(ab) = \Delta(a)b \pm a\Delta(b) \pm \{a, b\}$. The algebraic modular QME shell is the Maurer–Cartan equation in the completed modular convolution algebra. It becomes a physical all-loop QME only after a local-observables model, propagator, renormalization scale, counterterms, analytic SDR, and anomaly-cancellation package have been supplied. At the completed homotopy level, the BV structure is the dg shadow of the quantum L_∞ -algebra of Theorem ??: Δ is $\ell_1^{(i)}$ and $\{-, -\}$ is $\ell_2^{(o)}$. Analytically, this reproduces the residue calculus on $\overline{C}_n(X)$ by the Prism Principle (Theorem 36.13.23). $\square$

Remark 15.12.11 (Chern–Simons interpretation). The BV antibracket on the bar complex has the same formal variance as the antibracket in Chern–Simons-type master actions. In quadratic benchmark models this variance matches the ordinary Chern–Simons functional; in non-quadratic examples the operations m_{n-1} are higher cyclic vertices. An equality of BV theories requires the Costello–Gwilliam perturbative quantization formalism [CG17] and a specified local-to-global factorisation model. This chapter uses only the algebraic BV operation on the bar complex.

For a cyclic non-quadratic transferred model, the formal BV action has the typed expansion

$$S_{\text{BV,form}}(\alpha) = \sum_{n \geq 1} \frac{1}{(n+1)!} \langle \alpha, \ell_n(\alpha, \dots, \alpha) \rangle_{\text{cyc}}.$$

The summand with ℓ_3 is the first place where a cubic RTT/Serre relation contributes a quartic action term.

15.12.8 Implications for Koszul duality

The Chern–Simons input is external to Koszul duality. Quadratic algebras give the ordinary dg Lie Maurer–Cartan equation, non-quadratic algebras give higher L_∞ vertices, and the critical level gives a screening/free-field complex. Interpreting algebra/coalgebra exchange through a level-rank-type Chern–Simons dictionary is a separate conjectural physics comparison, not a theorem of the bar coalgebra and not a literal identification with classical level-rank duality.

Remark 15.12.12 (Cumulant duals for nonquadratic algebras). For quadratic chiral algebras ($\Delta_{\mathcal{A}}(t) = 0$), the Koszul dual coalgebra $\mathcal{A}^i$ is computed from the quadratic orthogonal relations, and the bar coalgebra resolves it: $q_{\mathcal{A}}: \mathcal{A}^i \xrightarrow{\sim} \overline{B}(\mathcal{A})$. The dual algebra $\mathcal{A}^! = (\mathcal{A}^i)^\vee$ is obtained only after the

finite-type duality is available. For genuinely nonquadratic algebras ($\Delta_{\mathcal{A}}(t) \neq 0$), the bar coalgebra develops primitive cogenerators not present among the declared generators of $\mathcal{A}$. The prototype is the $\mathcal{W}_3$ algebra: the composite field $\Lambda =: (TT) : -\frac{3}{10} \partial^2 T$ appears as a primitive cogenerator Λ^* in the bar complex, with nonprimitive coproduct $\Delta(\Lambda^*) = L^* \otimes L^* - \frac{3}{10} (\partial^2 L^* \otimes 1 + 1 \otimes \partial^2 L^*)$ and differential encoding the characteristic $W-W$ OPE coefficient $16/(22 + 5c)$.

The correct completed dual-coalgebra candidate of a nonquadratic chiral algebra is therefore the *cumulant coalgebra* $\text{Cum}_c(\mathcal{A}) = \hat{T}^c(\iota Q(\mathcal{A})^\vee)$ (Definition ??), where $Q(\mathcal{A}) = \bar{\mathcal{A}}/\partial \bar{\mathcal{A}}$ is the canonical primitive sector extracted from the vacuum character (Definition 14.1.95). The primitive defect $\Delta_{\mathcal{A}}(t)$ (Definition 14.1.98) measures the discrepancy between the cumulant coalgebra and the naive dual on declared generators. The cumulant recognition conjecture (Conjecture ??) predicts $\text{gr}_\rho \hat{B}(\mathcal{A}) \simeq \text{Cum}_c(\mathcal{A})$.

Every algebraic structure is an MC element in a convolution dg Lie algebra, and the cumulant coalgebra is the correct *source* coalgebra for those convolution maps. The dual algebra is obtained from this coalgebra only after the Verdier/completed-cobar hypotheses are imposed. Naive generators give the wrong source; cumulant generators give the canonical one.

15.13 THE ORDERED ASSOCIATIVE CORE

The chiral Koszul duality of the preceding sections has an ordered associative core that is invisible from the commutative vantage point. The geometric origin is simple: the ordered configuration space $C_n^{\text{ord}}(X) = \{(x_1, \dots, x_n) \in X^n : x_i \neq x_j\}$ carries an associative, not merely E_1 , structure, because the labelling of points is ordered, not just unordered-up-to-homotopy. Shuffles survive as distinct summands; they are not killed by a symmetric-group quotient. The bar coalgebra $C = \bar{B}^{\text{ch}}(\mathcal{A})$ inherits this ordering, and once the ordering is taken seriously, a new object appears on the coalgebra side: the *diagonal bicomodule* C_Δ , which is C equipped with its coproduct on both left and right. The diagonal bimodule $\mathcal{A}\mathcal{A}\mathcal{A}$ and the diagonal bicomodule C_Δ are not the same object; the two-sided twisting functor $\mathcal{K}_{\mathcal{A}}^{\text{bi}}$ transports the former to the latter. Only after the finite-type Verdier comparison identifies the dual coalgebra lane with $\mathcal{A}^!$ may this coalgebraic boundary be rewritten as an $\mathcal{A}-\mathcal{A}^!$ interface.

The ordered associative theory runs from the chiral shuffle theorem through the genus-zero open trace formalism to the conjectural frontier connecting it to the modular Maurer–Cartan theory of Chapter ??.

Remark 15.13.1 (Koszul pairs as transverse boundary conditions). In the holomorphic-topological framework of Costello–Dimofte–Gaiotto [?CDG2024, ?CG17], a 3d HT theory on $\mathbb{C} \times \mathbb{R}$ admits boundary conditions at each end of the $\mathbb{R}$ -interval. The intrinsic algebraic datum of a Koszul pair is the bar coalgebra $C = \bar{B}^{\text{ch}}(\mathcal{A})$ and its diagonal bicomodule C_Δ . The statement that $\mathcal{A}$ and $\mathcal{A}^!$ form transverse boundary conditions is the finite-type Verdier translation of this datum, not the definition of the bar construction: $\mathcal{A}^!$ enters only after the post-Verdier factorization algebra has been identified. Bar-cobar inversion (Theorem B) is the counit $\Omega^{\text{ch}} C \rightarrow \mathcal{A}$ and recovers $\mathcal{A}$ itself. Verdier intertwining (Theorem A) relates the bar coalgebra of $\mathcal{A}$ to the post-Verdier algebra lane from which $\mathcal{A}^!$ is obtained.

15.13.1 The chiral shuffle theorem and opposite duality

The first point of departure from the commutative story is an ordered Eilenberg–Zilber theorem for chiral bar coalgebras.

THEOREM 15.13.2 (*Ordered chiral shuffle theorem;*). Let $\mathcal{A}$ and $\mathcal{B}$ be augmented pro-nilpotent associative chiral algebras on a smooth curve X , with filtrations satisfying the standard admissibility conditions of Theorem 15.2.5. There is a natural filtered quasi-isomorphism of conilpotent dg coalgebras

$$\bar{B}^{\text{ch}}(\mathcal{A}) \widehat{\otimes} \bar{B}^{\text{ch}}(\mathcal{B}) \xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{A} \otimes^{\text{ch}} \mathcal{B}),$$

realized by shuffle and Alexander–Whitney maps Sh^{ch} and AW^{ch} satisfying $\text{AW} \circ \text{Sh} = \text{id}$ and $\text{Sh} \circ \text{AW} \simeq \text{id}$. Both maps are coalgebra morphisms.

Proof. Form the bisimplicial object $K_{\bullet, \bullet} = B_{\bullet}^{\Delta}(\mathcal{A}) \otimes^{\text{ch}} B_{\bullet}^{\Delta}(\mathcal{B})$, where $B_n^{\Delta}(\mathcal{A}) = \mathcal{A}^{\otimes^{\text{ch}} n}$ is the simplicial ordered bar object. Its diagonal satisfies $\text{diag}(K)_n \cong (\mathcal{A} \otimes^{\text{ch}} \mathcal{B})^{\otimes^{\text{ch}} n}$ because multiplication and augmentation on $\mathcal{A} \otimes^{\text{ch}} \mathcal{B}$ are componentwise. Apply the Eilenberg–Zilber theorem filtration-wise in each graded piece; the normalized-chains functor commutes with the completed chiral tensor constructions under the admissibility hypotheses. The resulting shuffle map respects deconcatenation because cutting a shuffled word is equivalent to cutting the source words and then shuffling the left and right halves. $\square$

The second foundational phenomenon is order reversal: it transforms opposite multiplication on the algebra side into opposite deconcatenation on the bar side.

THEOREM 15.13.3 (*Opposite duality for ordered bar coalgebras;*). For every augmented pro-nilpotent associative chiral algebra $\mathcal{A}$, there is a canonical isomorphism of coaugmented conilpotent dg coalgebras

$$\mathbf{R}_{\mathcal{A}}: \bar{B}^{\text{ch}}(\mathcal{A}^{\text{op}}) \xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{A})^{\text{cop}},$$

induced by the order-reversal involution $[sa_1 | \cdots | sa_n] \mapsto (-1)^{\sum_{i < j} (|a_i|+1)(|a_j|+1)} [sa_n | \cdots | sa_1]$ on suspended bar words. If $\mathcal{A}$ is finite-type Koszul, then $(\mathcal{A}^{\text{op}})^! \simeq (\mathcal{A}^!)^{\text{op}}$.

Proof. Reversal carries the i -th face map of the simplicial bar object for $\mathcal{A}^{\text{op}}$ to the $(n-i)$ -th face map for $\mathcal{A}$, with the stated Koszul sign. The coproduct identity $\Delta \circ \mathbf{R}_{\mathcal{A}} = \tau \circ (\mathbf{R}_{\mathcal{A}} \otimes \mathbf{R}_{\mathcal{A}}) \circ \Delta$ (where τ flips tensor factors) follows because reversal sends a cut after the p -th letter to a cut before the $(n-p)$ -th letter. The statement on Koszul duals follows by finite-type linear duality. $\square$

COROLLARY 15.13.4 (*Enveloping duality;*). Set $C = \bar{B}^{\text{ch}}(\mathcal{A})$ and $C^e = C \widehat{\otimes} C^{\text{cop}}$. Then $\bar{B}^{\text{ch}}(\mathcal{A}^e) \xrightarrow{\sim} C^e$, and if $\mathcal{A}$ is finite-type Koszul, then $(\mathcal{A}^e)^! \simeq (\mathcal{A}^!)^e$.

Proof. Combine the ordered shuffle theorem (Theorem 15.13.2) with opposite duality (Theorem 15.13.3). $\square$

15.13.2 The diagonal bicomodule and the bimodule–bicomodule equivalence

The diagonal bicomodule C_{Δ} is C equipped with left and right coactions both equal to the deconcatenation coproduct Δ_C . It is the coalgebra-side avatar of the diagonal bimodule ${}_{\mathcal{A}}\mathcal{A}_{\mathcal{A}}$.

Definition 15.13.5 (*Two-sided twisted bicomodule*). Let $\mathcal{M}$ be an $\mathcal{A}$ -bimodule (Definition 15.2.2). The *two-sided twisted bicomodule* is

$$\mathcal{K}_{\mathcal{A}}^{\text{bi}}(\mathcal{M}) = C \widehat{\otimes} \mathcal{M} \widehat{\otimes} C,$$

with differential twisted by the universal twisting cochain $\tau: C \rightarrow \mathcal{A}$ via left and right action terms. The left and right C -coactions are deconcatenation on the two outer factors. The Maurer–Cartan equation

$d\tau + \tau \star \tau = 0$ ensures $d^2 = 0$ on the uncurved or strictly corrected completed lane. In the genus- g curved lane the same construction is read as a CDG bicomodule with square governed by the central curvature term, before passing to the coderived comparison.

THEOREM 15.13.6 (*Bimodule–bicomodule equivalence;*). Assume that $\mathcal{A}$ is augmented and pronilpotent, that the ordered shuffle map of Theorem 15.13.2 applies to $\mathcal{A}^e$, and that the PBW-complete bar coalgebra $C^e = \bar{B}^{\text{ch}}(\mathcal{A}^e)$ satisfies the conilpotence and co/contra exactness hypotheses of Theorem 15.10.3. Then there is an exact equivalence

$$\mathcal{K}_{\mathcal{A}}^{\text{bi}}: D_{\text{bi}}^{\text{pbw}}(\mathcal{A}) \xrightarrow{\sim} D_{\text{bi}}^{\text{co}}(C)$$

between the derived category of PBW-complete $\mathcal{A}$ -bimodules and the coderived category of conilpotent C -bicomodules, with inverse given by the two-sided cobar functor $\mathcal{M} \mapsto \mathcal{A} \widehat{\otimes} \mathcal{M} \widehat{\otimes} \mathcal{A}$.

Proof. By Corollary 15.13.4, $\bar{B}^{\text{ch}}(\mathcal{A}^e) \simeq C^e$. Apply the one-sided complete bar-coalgebra comparison to the enveloping algebra $\mathcal{A}^e$. The target is the coderived category of comodules over the bar coalgebra C^e , not an ordinary module category over $\mathcal{A}^!$ unless the separate finite-type dualization identifies C^* with $\mathcal{A}^!$, equivalently identifies $(C^e)^*$ with $(\mathcal{A}^!)^e$. Since left C^e -comodules are canonically C -bicomodules, the result follows. $\square$

THEOREM 15.13.7 (*Diagonal correspondence;*). Under the equivalence of Theorem 15.13.6, the diagonal bimodule $\mathcal{A}\mathcal{A}$ maps to the diagonal bicomodule C_{Δ} . Equivalently, $\mathcal{K}_{\mathcal{A}}^{\text{bi}}(\mathcal{A}) \simeq C_{\Delta}$ in $D_{\text{bi}}^{\text{co}}(C)$.

Proof. The bar–cobar counit contractions $C \widehat{\otimes}_{\tau} \mathcal{A} \xrightarrow{\sim} \mathbf{1}$ and $\mathcal{A} \widehat{\otimes}_{\tau} C \xrightarrow{\sim} \mathbf{1}$ collapse the two-sided twisted bicomodule $C \widehat{\otimes} \mathcal{A} \widehat{\otimes} C$ to a single copy of C . Filter by total coradical degree in the two outer copies; on the associated graded, the twisting terms vanish and both coactions are the two legs of Δ_C . Because the filtration is complete and bounded below, this identification lifts to the filtered complex. $\square$

The diagonal bicomodule is the composition unit for derived cotensor: for every $X \in D_{\text{bi}}^{\text{co}}(C)$,

$$C_{\Delta} \square_C^{\mathbf{R}} X \simeq X \simeq X \square_C^{\mathbf{R}} C_{\Delta}.$$

This is the transport of the tautology $\mathcal{A} \otimes_{\mathcal{A}}^{\mathbf{L}} \mathcal{M} \simeq \mathcal{M}$ across the equivalence. Tensor–cotensor gluing $\mathcal{K}_{\mathcal{A}}^{\text{bi}}(\mathcal{M} \otimes_{\mathcal{A}}^{\mathbf{L}} \mathcal{N}) \simeq \mathcal{K}_{\mathcal{A}}^{\text{bi}}(\mathcal{M}) \square_C^{\mathbf{R}} \mathcal{K}_{\mathcal{A}}^{\text{bi}}(\mathcal{N})$ makes C_{Δ} the universal boundary condition for interval composition.

15.13.3 chiral Hochschild–coHochschild duality

The chiral Hochschild cohomology $CH^*(\mathcal{A}, \mathcal{M}) = \text{Ext}_{\mathcal{A}^e}^*(\mathcal{A}, \mathcal{M})$ constructed in Theorem 15.2.7, and computed on the bar resolution in Theorem 15.2.7, has an exact coalgebraic counterpart: the co-Hochschild theory of the bar coalgebra.

THEOREM 15.13.8 (*chiral Hochschild–coHochschild duality, homological version;*). For every complete $\mathcal{A}$ -bimodule $\mathcal{M}$,

$$\text{HH}_{\bullet}^{\text{ch}}(\mathcal{A}, \mathcal{M}) \simeq \text{coHH}_{\bullet}^{\text{ch}}(C, \mathcal{K}_{\mathcal{A}}^{\text{bi}}(\mathcal{M})),$$

where $\text{coHH}_{\bullet}^{\text{ch}}(C, N) = \text{Cotor}_{\bullet}^{C^e}(C_{\Delta}, N)$. In particular, $\text{HH}_{\bullet}^{\text{ch}}(\mathcal{A}) \simeq C_{\Delta} \square_{C^e}^{\mathbf{R}} C_{\Delta}$: the annulus is the self-cotensor of the universal boundary condition.

Proof. Transport $\mathrm{Tor}_{\bullet}^{\mathcal{A}^e}(\mathcal{A}, \mathcal{M})$ across the bimodule–bicomodule equivalence (Theorem 15.13.6). The diagonal bicomodule $\mathcal{A}$ maps to C_{Δ} by Theorem 15.13.7; $\mathcal{M}$ maps to $\mathcal{K}_{\mathcal{A}}^{\mathrm{bi}}(\mathcal{M})$ by definition. Derived tensor over $\mathcal{A}^e$ becomes derived cotensor over C^e . $\square$

THEOREM 15.13.9 (*chiral Hochschild–coHochschild duality, cohomological version*;). Under the same hypotheses,

$$CH^*(\mathcal{A}, \mathcal{M}) \simeq \mathrm{Coext}_{C^e}^*(C_{\Delta}, \mathcal{K}_{\mathcal{A}}^{\mathrm{bi}}(\mathcal{M})).$$

In particular, $CH^*(\mathcal{A}) \simeq \mathrm{Coext}_{C^e}^*(C_{\Delta}, C_{\Delta})$: the chiral Hochschild cohomology ring whose Gerstenhaber bracket was constructed in Theorem 15.3.4 is the coalgebraic self-extension of the diagonal.

Proof. Derived Hom is preserved by equivalences of derived categories. Apply the bimodule–bicomodule equivalence to $R\mathrm{Hom}_{\mathcal{A}^e}(\mathcal{A}, \mathcal{M})$. $\square$

Remark 15.13.10 (*Relation to existing chiral Hochschild material*). The cohomological version recovers the complex of Theorem 15.2.7 as the coalgebraic coHochschild complex of C . The Gerstenhaber cup product of Proposition 15.3.2 is the composition product on $\mathrm{Coext}_{C^e}^*(C_{\Delta}, C_{\Delta})$, and the periodicity theorems (Theorem 15.5.1, Theorem 15.5.3) become statements about the coalgebraic self-extension ring. The exchange $CH^*(\mathcal{A}) \leftrightarrow CH^*(\mathcal{A}^!)$ of Corollary ?? is the finite-type Verdier shadow of enveloping duality (Corollary 15.13.4); it is not a consequence of the bar-cobar counit alone.

15.13.4 The pair-of-pants product and the open trace formalism

The diagonal bicomodule carries a second algebraic operation beyond cotensor composition: the *ordered pair-of-pants product*, transported from the multiplication $\mu_{\mathcal{A}}: \mathcal{A} \otimes^{\mathrm{ch}} \mathcal{A} \rightarrow \mathcal{A}$.

THEOREM 15.13.11 (*Ordered pair-of-pants algebra*;). There exist an associative multiplication $\mu_P: C_{\Delta} \star C_{\Delta} \rightarrow C_{\Delta}$ and a unit $\eta_P: \mathbf{1}_{\star} \rightarrow C_{\Delta}$ for the ordered fusion product $X \star Y = \mathcal{K}_{\mathcal{A}}^{\mathrm{bi}}(\Omega_C^{\mathrm{bi}}(X) \otimes \Omega_C^{\mathrm{bi}}(Y))$, obtained by transporting $(\mu_{\mathcal{A}}, \eta_{\mathcal{A}})$ across $\mathcal{K}_{\mathcal{A}}^{\mathrm{bi}}$ and the diagonal correspondence.

Proof. The diagonal bimodule ${}_{\mathcal{A}}\mathcal{A}_{\mathcal{A}}$ is an associative algebra object for the tensor product of bimodules. Apply the exact equivalence of Theorem 15.13.6: associativity and unitality are preserved because the equivalence preserves composition. $\square$

THEOREM 15.13.12 (*Master theorem: the ordered open trace formalism*;). Let $\mathcal{A}$ be an augmented pro-nilpotent associative chiral algebra on X satisfying the admissibility conditions, and set $C = \tilde{B}^{\mathrm{ch}}(\mathcal{A})$. Then the data

$$(D_{\mathrm{bi}}^{\mathrm{co}}(C), \square_C^{\mathbf{R}}, C_{\Delta}, \star, \mu_P, \eta_P, \mathcal{H}_C^{\mathrm{cl}})$$

constitute an ordered genus-zero open trace formalism:

- (i) C_{Δ} is the unit for interval composition $\square_C^{\mathbf{R}}$.
- (ii) $(C_{\Delta}, \mu_P, \eta_P)$ is an associative algebra object for ordered fusion $\star$.
- (iii) The closed object is the coHochschild complex: $\mathcal{H}_C^{\mathrm{cl}} \simeq \mathrm{coHH}_{\bullet}^{\mathrm{ch}}(C) \simeq \mathrm{HH}_{\bullet}^{\mathrm{ch}}(\mathcal{A})$.
- (iv) The annulus acts on C_{Δ} via the cap action transported from the chiral Hochschild cap on $\mathcal{A}$.
- (v) All genus-zero sewing identities on the coalgebra side are transported from the corresponding identities for $\mathcal{A}$ -bimodules.

If $\mathcal{A}$ is d -Calabi–Yau (i.e. perfect as an $\mathcal{A}^e$ -module with a shifted self-duality $\mathcal{A} \xrightarrow{\sim} R\mathrm{Hom}_{\mathcal{A}^e}(\mathcal{A}, \mathcal{A}^e)[d])$, then the underlying complex of C_Δ acquires a d -shifted ordered Frobenius structure: the trace $\varepsilon_P : C_\Delta \rightarrow k[-d]$ is transported from the Calabi–Yau trace, the coproduct Δ_P is adjoint to μ_P under ε_P , and the Frobenius identity $(\mu_P \star \mathrm{id}) \circ (\mathrm{id} \star \Delta_P) = \Delta_P \circ \mu_P$ holds.

Proof. This compresses Theorems 15.13.2–15.13.11 together with the Hochschild–coHochschild dualities (Theorems 15.13.8 and 15.13.9). The Calabi–Yau refinement: transport the algebra $(\mu_{\mathcal{A}}, \eta_{\mathcal{A}})$ and its adjoint coalgebra $(\Delta_{\mathcal{A}}, \varepsilon_{\mathcal{A}})$ simultaneously; the Frobenius identities on C_Δ are the images of the Frobenius identities on $\mathcal{A}$, which are formal consequences of associativity and nondegeneracy. $\square$

Remark 15.13.13 (The dictionary). The ordered associative core provides the following dictionary between the algebra $\mathcal{A}$ and the coalgebra C :

$$\mathcal{A} \longleftrightarrow C_\Delta, \quad \mathcal{A}^e \longleftrightarrow C^e, \quad - \otimes_{\mathcal{A}}^{\mathbf{L}} - \longleftrightarrow - \square_C^{\mathbf{R}} -,$$

$$\mathrm{HH}_\bullet^{\mathrm{ch}}(\mathcal{A}, \mathcal{M}) \longleftrightarrow \mathrm{coHH}_\bullet^{\mathrm{ch}}(C, \mathcal{K}_{\mathcal{A}}^{\mathrm{bi}}(\mathcal{M})), \quad CH^*(\mathcal{A}, \mathcal{M}) \longleftrightarrow \mathrm{Coext}_{C^e}^*(C_\Delta, \mathcal{K}_{\mathcal{A}}^{\mathrm{bi}}(\mathcal{M})).$$

Thus the bar coalgebra is the ordered coalgebraic state object, the diagonal bicomodule is the interval unit, and the annulus is the self-cotensor of that unit.

PROPOSITION 15.13.14 (*Open trace is not a Drinfeld double;*). The ordered open trace formalism of Theorem 15.13.12 does not construct a Drinfeld double. For a finite-dimensional Hopf algebra H , the Drinfeld double is the Hopf algebra

$$D(H) = H^{*\mathrm{cop}} \bowtie H$$

with multiplication determined by the Hopf pairing and the antipode, and $\mathrm{Rep} D(H) \simeq Z(\mathrm{Rep} H)$. The closed object in the ordered open trace formalism is instead

$$\mathcal{H}_C^{\mathrm{cl}} \simeq \mathrm{coHH}_\bullet^{\mathrm{ch}}(C) \simeq C_\Delta \square_{C^e}^{\mathbf{R}} C_\Delta.$$

It is a Hochschild/coHochschild trace complex, not a Hopf algebra. Thus an external Hall–Drinfeld double may act on, or be compared with, this trace only after a separate Hopf/Hall bialgebra structure and a compatible pairing have been supplied.

Proof. The open trace data are typed by bicomodules over the bar coalgebra $C = \bar{B}^{\mathrm{ch}}(\mathcal{A})$ and by derived cotensor over C^e . They require no multiplication on C , no antipode, and no Hopf pairing $C^* \otimes C \rightarrow k$. A Drinfeld double requires exactly those Hopf inputs. The self-cotensor $C_\Delta \square_{C^e}^{\mathbf{R}} C_\Delta$ computes a trace object in the bicomodule category; its product is the Hochschild cup/cap structure transported by Theorems 15.13.8 and 15.13.9, not the crossed multiplication of $H^{*\mathrm{cop}} \bowtie H$. $\square$

15.13.5 The commutator-shadow theorem and the conjectural frontier

The preceding subsections supply the genus-zero ordered algebraic core. The commutator filtration compares this ordered associative bar coalgebra with the Francis–Gaitsgory Lie/cocommutative bar coalgebra on the associated graded. Three independent obstructions remain outside that comparison.

THEOREM 15.13.15 (*Commutator-shadow theorem;*). Let $\mathcal{A}$ be a filtered strongly admissible associative chiral algebra with exhaustive separated commutator filtration $F_{\mathrm{com}}^\bullet \mathcal{A}$. Assume:

- (a) $\mathrm{gr}_{\mathrm{com}} \mathcal{A}$ is E_∞ -chiral;

- (b) $\mathrm{gr}_{\mathrm{com}} \mathcal{A}$ is quadratic Koszul on the commutative/Lie side;
- (c) the induced filtration on $\tilde{B}^{\mathrm{ch}}(\mathcal{A})$ is complete and strongly convergent.

Then there is a convergent spectral sequence

$$E_1 \cong \overline{B}^{FG}(\mathrm{gr}_{\mathrm{com}} \mathcal{A}) \implies \mathrm{gr}_{\mathrm{com}} \tilde{B}^{\mathrm{ch}}(\mathcal{A}),$$

recovering the Francis–Gaitsgory Lie/cocommutative duality as the associated graded of the ordered associative theory.

Proof sketch (full proof: Vol II, Part IX; cf. Chriss–Ginzburg [CG97]). The argument adapts the Chriss–Ginzburg stratification spectral sequence from the Steinberg variety to the chiral correspondence space $\mathrm{FM}_k(\mathbb{C}) \times \mathrm{Conf}_k(\mathbb{R})$ underlying the bar complex. Five ingredients combine.

(a) *Commutator stratification.* The commutator filtration $F_{\mathrm{com}}^\bullet \mathcal{A}$ induces an increasing filtration $S_0 \subset S_1 \subset \cdots$ of the correspondence space by commutator-depth strata. For the associated graded $\mathrm{gr}_{\mathrm{com}} \mathcal{A}$ (which is E_∞ -chiral), only the lowest stratum S_1 contributes: all OPE singularities on $\mathrm{gr}_{\mathrm{com}} \mathcal{A}$ are at worst simple poles.

(b) *E_1 identification.* The stratification spectral sequence has E_1 page

$$E_1^{p,q} \cong H_{\mathrm{BM}}^{p+q}(S_p/S_{p-1}) \cong \overline{B}_{p+q}^{FG}(\mathrm{gr}_{\mathrm{com}} \mathcal{A}).$$

On the associated graded, only $p = 1$ is nontrivial (all higher strata are empty), so the spectral sequence collapses to the Francis–Gaitsgory bar complex. The surviving differential on E_1 is the boundary map of the Borel–Moore complex of S_1 , which is the FG differential by construction.

(c) *Pole non-increase: the commutator filtration.* The bar differential d_{bar} respects the commutator filtration on $\tilde{B}^{\mathrm{ch}}(\mathcal{A})$: the $n = 0$ face (Lie bracket) maps $F_{\mathrm{com}}^p \rightarrow F_{\mathrm{com}}^{p+1}$, while the $n \geq 1$ faces preserve F_{com}^p . The proof uses the Borchers identity at parameter $m = 0$ and the strong-generation bound on iterated pole orders. In particular, $d_{\mathrm{bar}}(F^p) \subset F^p$ for the total filtration.

(d) *The Virasoro subtlety.* For generators of weight ≥ 2 (Virasoro, $\mathcal{W}$ -algebras), the *raw* pole-order filtration is not respected by the bar differential: $T_{(0)} T = \partial T$ has $N(\partial T, T) = N(T, T) + 1$ (differentiation raises pole order). However, the commutator (PBW) filtration *is* respected, because the PBW convention treats ∂ as a structural operator at the same filtration level. The theorem is stated in terms of $F_{\mathrm{com}}^\bullet$, so the commutator-filtration argument suffices. For the affine lineage ($\hat{\mathfrak{g}}_k$, free fields, lattice algebras: all generators of weight 1), the two filtrations agree.

(e) *Convergence.* Strong convergence of the filtration (hypothesis (c)) and the E_1 identification yield $E_1 \cong \overline{B}^{FG}(\mathrm{gr}_{\mathrm{com}} \mathcal{A}) \implies \mathrm{gr}_{\mathrm{com}} \tilde{B}^{\mathrm{ch}}(\mathcal{A})$, as claimed. $\square$

COROLLARY 15.13.16 (*Verdier-Koszul dual on the associated graded;*). On the finite-type Verdier-Koszul locus, where $\tilde{B}_X^{\mathrm{ch}}(\mathcal{A})$ resolves the dual coalgebra $\mathcal{A}^!$ and $\mathcal{A}^! = (\mathcal{A}^i)^\vee$ exists,

$$\mathrm{gr}_{\mathrm{com}}(\mathcal{A}^!) \simeq (\mathrm{gr}_{\mathrm{com}} \mathcal{A})_{FG}^!.$$

That is, the Koszul dual of the associated graded (computed via Francis–Gaitsgory Lie/cocommutative duality) recovers the associated graded of the Koszul dual.

Proof. On this locus, Koszulness gives the quasi-isomorphism of coalgebras $q_{\mathcal{A}}: \mathcal{A}^i \xrightarrow{\sim} \bar{B}^{\text{ch}}(\mathcal{A})$, and the finite-type Verdier/linear-dual comparison gives the contravariant map $\mathbb{D}(q_{\mathcal{A}}): \bar{B}^{\text{ch}}(\mathcal{A})^{\vee} \xrightarrow{\sim} (\mathcal{A}^i)^{\vee} = \mathcal{A}^!$. This use of the bar coalgebra is separate from the bar-cobar counit $\Omega \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$, whose target is $\mathcal{A}$. The filtration $F_{\text{com}}^{\bullet}$ is exhaustive and separated (hypothesis (c) of Theorem 15.13.15), so the associated graded of the finite-type dual is the dual of the associated graded: $\text{gr}_{\text{com}}(\mathcal{A}^!) \simeq \text{gr}_{\text{com}}(\bar{B}^{\text{ch}}(\mathcal{A}))^{\vee} \simeq \overline{B}^{FG}(\text{gr}_{\text{com}} \mathcal{A})^{\vee} = (\text{gr}_{\text{com}} \mathcal{A})_{FG}^!$. $\square$

Conjecture 15.13.17 (Bordered realization;). There exists a bordered ordered configuration-space model $\mathfrak{C}_{g,r,s}^{\text{bord}}(X)$ whose chain-level operations recover the ordered open trace formalism of Theorem 15.13.12: interval components give C_{Δ} , boundary gluing is derived cotensor, the pair-of-pants gives μ_P , and annular closure gives $\text{coHH}^{\text{ch}}(C)$.

Conjecture 15.13.18 (Associative modular Maurer–Cartan class;). There exists an associative cyclic deformation complex $\text{Def}_{\text{Ass}^{\text{ch}}}^{\text{cyc}}(\mathcal{A})$ and a Maurer–Cartan element $\Theta_{\mathcal{A}}^{\text{Ass}^{\text{ch}}}$ whose linear term is the genus anomaly, whose quadratic term is the first pair-of-pants boundary correction, and whose full Maurer–Cartan equation expresses compatibility of all ordered higher-genus boundary gluings. The class is required to restrict to the ordered-associative projection of the modular MC class $\Theta_{\mathcal{A}}$ of Chapter ??.

Conjecture 15.13.19 (Drinfeld–Sokolov compatibility;). BRST/Drinfeld–Sokolov reduction commutes with ordered associative chiral duality: $Q_{DS}(\mathcal{A}^!) \simeq Q_{DS}(\mathcal{A})^!$, and the two-sided twisted bicomodule functor $\mathcal{K}_{\mathcal{A}}^{\text{bi}}$ intertwines reduction on bimodules with reduction on bicomodules.

Theorem 15.13.15 and Corollary 15.13.16 identify Francis–Gaitsgory duality as the associated graded of the ordered theory under the commutator filtration. The remaining layer has three independent obstructions. Conjecture 15.13.17 asks for a bordered configuration-space substrate. Conjecture 15.13.18 asks for a higher-genus ordered MC class refining the shadow obstruction tower of Chapter ??. Conjecture 15.13.19 asks for BRST/Drinfeld–Sokolov compatibility; if reduction commutes with duality, the ordered open trace formalism descends to the reduced theory.

15.14 CATEGORICAL KOSZULNESS AND THE MODULE-LEVEL FRONTIER

The module-level comparison statements of Theorems 15.10.1–15.10.5 are triangulated. The ∞ -categorical refinement comprises t-exactness of bar duality, weight decomposition of module categories, the chiral BGG correspondence, algebraicity of bar generating functions, and the interaction of Koszulness with C_2 -cofiniteness.

15.14.1 Module category t-exactness

Conjecture 15.14.1 (Module category t-exactness;). Let $(\mathcal{A}, \mathcal{A}^!)$ be a chiral Koszul pair on a smooth curve X . Set $C = \bar{B}(\mathcal{A})$. The bar functor $\Phi(M) = C \otimes_{\mathcal{A}} M$ induces an equivalence of stable ∞ -categories

$$\Phi: \text{FactMod}(\mathcal{A}) \xrightarrow{\sim} \text{FactCoMod}(C).$$

If the finite-type Verdier comparison identifies $C \simeq \mathcal{A}^i = (\mathcal{A}^!)^{\vee}$, the target may be rewritten as a conilpotent $\mathcal{A}^i$ -comodule category, or dually as a completed $\mathcal{A}^!$ -module category. Equip $\text{FactMod}(\mathcal{A})$ with the PBW t -structure and $\text{FactCoMod}(C)$ with the cobar t -structure (defined below). Then $\mathcal{A}$ is chirally Koszul if and only if Φ is t-exact.

The two t-structures. The PBW filtration $F_{\bullet}$ on $\text{FactMod}(\mathcal{A})$ is the decreasing filtration by bar degree: $F_p M$ is the submodule generated by elements of bar filtration $\geq p$ (i.e., those requiring $\geq p$

iterated OPE contractions to reach the vacuum). A module M lies in $\mathcal{D}_{\text{PBW}}^{\leq 0}$ if its associated graded $\text{gr}_p^F M$ is acyclic for $p > 0$. The cobar t -structure on $\text{FactCoMod}(C)$ is defined dually: a comodule N lies in $\mathcal{D}_{\text{cob}}^{\leq 0}$ if $\text{gr}_p^G N$ is acyclic for $p > 0$, where $G_\bullet$ is the cobar filtration.

Equivalences.

- (i) t -exactness of $\Phi \iff$ the PBW spectral sequence collapses at E_2 for *all* factorization modules M .
- (ii) Heart preservation $\iff$ Koszul linearity: $\overline{B}_n(L(\lambda))$ is concentrated in internal degree $n + h(\lambda)$, where $h(\lambda)$ is the conformal weight.

The conditional highest-weight shadow is Proposition 36.1.37, which records the transported Koszul t -structure once the conjectural module-category t -exactness and linearity input are supplied. The ∞ -categorical upgrade uses the model structure from Theorem 9.2.16; the Ch_∞ -rectification (Corollary 9.2.20) ensures that homotopy and strict module categories agree. The no-bifunctor obstruction (RNW19 §6) forces the construction of Φ to proceed one slot at a time.

15.14.2 Semi-orthogonal decomposition by weight

Conjecture 15.14.2 (Semi-orthogonal decomposition by conformal weight;). For a chirally Koszul algebra $\mathcal{A}$, the stable ∞ -category $\text{FactMod}(\mathcal{A})$ admits a semi-orthogonal decomposition (in the sense of Bondal–Orlov)

$$\text{FactMod}(\mathcal{A}) = \langle C_0, C_1, C_2, \dots \rangle$$

where C_n is the full subcategory of modules generated in conformal weight n , and the semi-orthogonality condition is $\text{Hom}(M, N) = 0$ for $M \in C_i, N \in C_j, i > j$. The decomposition is *split*: the inclusion $C_n \hookrightarrow \text{FactMod}(\mathcal{A})$ admits exact left and right adjoints.

The weight filtration $\mathcal{F}_n = \{M \mid M \text{ generated in weights } \leq n\}$ has graded pieces $C_n = \mathcal{F}_n / \mathcal{F}_{n-1}$. Koszulness is equivalent to vanishing of cross-weight morphisms: bar linearity forces the bar differential to preserve weight strata, killing all $\text{Ext}^*(C_i, C_j)$ for $i > j$. Off the Koszul locus, nonlinear bar terms source cross-weight extensions and the SOD fails.

15.14.3 The chiral BGG correspondence

Conjecture 15.14.3 (Chiral BGG correspondence;). For a chiral Koszul pair $(\mathcal{A}, \mathcal{A}^i)$ with $\mathcal{A} = \widehat{\mathfrak{g}}_k$ and finite-type Verdier dual $\mathcal{A}^!$ when available, there is an exact functor

$$\text{BGG}: \mathcal{O}_k \longrightarrow D^b(\text{Coh}(\text{Gr}_G))$$

from category $\mathcal{O}$ at level k to the derived category of coherent sheaves on the affine Grassmannian, factoring as

$$\mathcal{O}_k \xrightarrow{\overline{B}} \text{CoMod}^{\text{conil}}(C) \xrightarrow{\text{Sat}} D^b(\text{Coh}(\text{Gr}_G)),$$

where $C = \overline{B}(\mathcal{A})$, the first arrow is the bar resolution, and the second arrow is available only after the separate finite-type Verdier/Satake comparison identifies the relevant conilpotent bar-coalgebra comodules with sheaves on Gr_G .

- (i) Verma modules $M(\lambda) \mapsto \mathcal{O}_{S_\lambda}$ (structure sheaves of Schubert cells).
- (ii) The BGG resolution of $L(\lambda)$ maps to the Cousin resolution of $\text{IC}(\overline{S}_\lambda)$.
- (iii) Koszul linearity forces the Schubert filtration spectral sequence on $\text{IC}(\overline{S}_\lambda)$ to collapse at E_1 ; the E_1 page is the bar resolution.

Remark 15.14.4 (Bar side and factorization-Satake obligation). The bar side of Conjecture 15.14.3 is established: Theorem 36.6.2 constructs the BGG resolution from the bar complex, Proposition ?? gives the explicit bar–BGG for $\widehat{\mathfrak{sl}}_{2,k}$, and Corollary ?? identifies the BGG involution under Koszul duality.

The remaining open mathematical condition is the second arrow: the geometric Satake equivalence must be lifted to the *factorization* level (identifying conilpotent comodules over the bar-dual coalgebra, and only after finite-type dualization the $\mathcal{A}^!$ -side, with constructible sheaves on Gr_G). This factorization-Satake lift is not constructed here. The conjecture is therefore a precise target for connecting chiral Koszul duality to geometric Langlands.

15.14.4 Bar generating function algebraicity

Conjecture 15.14.5 (Bar generating function algebraicity;). A chiral algebra $\mathcal{A}$ is chirally Koszul if and only if its bar cohomology generating function $P_{\mathcal{A}}(x) = \sum_{n \geq 0} \dim H^n(\bar{B}(\mathcal{A})) \cdot x^n$ satisfies a polynomial equation of degree ≤ 2 :

$$c_2(x) P_{\mathcal{A}}^2 + c_1(x) P_{\mathcal{A}} + c_0(x) = 0$$

with discriminant $\Delta_{\mathcal{A}}(x) = c_1(x)^2 - 4 c_0(x) c_2(x)$ a polynomial of degree $\leq 2 \cdot \mathrm{rank}(\mathcal{A})$.

PROPOSITION 15.14.6 (Computed discriminant rows and the first non-simply-laced obligation;). On the standard computed rows recorded in Table ?? and in Theorem ??, the bar generating functions have the following algebraic degrees and discriminants:

Family	Algebraic degree	Discriminant $\Delta(x)$
$\widehat{\mathfrak{sl}}_2$	2	$(1 - 3x)(1 + x)$
Virasoro	2	$(1 - 3x)(1 + x)$
$\beta\gamma$	2	$(1 - 3x)(1 + x)$
$\widehat{\mathfrak{sl}}_3$	2	$(1 - 8x)(1 - 3x - x^2)$

The shared discriminant $(1 - 3x)(1 + x)$ within the first three families is the rank-one DS discriminant theorem: Theorem ?? proves that Drinfeld–Sokolov reduction preserves the discriminant, and $\widehat{\mathfrak{sl}}_2$, Virasoro, and $\beta\gamma$ all lie in the same DS family.

For $\widehat{G}_2$, only $H^1 = 14$ is computed (Proposition ??); bar cohomology beyond degree 1 is the first open mathematical condition requiring explicit G_2 structure constants. The conjecture predicts: $P_{\widehat{G}_2}(x)$ satisfies a quadratic equation with discriminant of degree ≤ 4 (since $\mathrm{rank}(G_2) = 2$) and a simple root at $x = 1/14$ (Conjecture ??). Verification at H^2 would already constrain the quadratic coefficients.

Proof. The table is the finite witness surface of Table ?. The rank-one equality of discriminants is Theorem ?. The $\widehat{\mathfrak{sl}}_3$ row is listed there as conditional, so the proposition keeps the same conditional status. The final G_2 sentence is not a computed row; it is the next explicit calculation required to test the conjecture. $\square$

Conjecture 15.14.7 (Chiral Koszul functional equation;). If $(\mathcal{A}, \mathcal{A}^!)$ is chirally Koszul and the finite-type Verdier-dual algebra $\mathcal{A}^!$ exists, then the bar generating functions satisfy the *chiral Koszul functional equation*:

$$P_{\mathcal{A}}(x) \cdot P_{\mathcal{A}^!}(-x) = 1 + \sum_{g \geq 1} \kappa^g Q_g(x),$$

where $\kappa = \kappa(\mathcal{A})$ is the modular characteristic and $Q_g(x)$ is a polynomial of degree $\leq 3g - 3$ encoding genus- g curvature corrections. At genus 0, this recovers the classical relation $P_{\mathcal{A}}(x) \cdot P_{\mathcal{A}^!}(-x) = 1$.

This is the chiral replacement for the classical Koszul functional equation $h_{\mathcal{A}}(t) \cdot h_{\mathcal{A}^!}(-t) = 1$, which fails chirally because the OS algebra twists the bar complex by integration kernels on $\text{FM}_n(X)$. The genus correction Q_g is a polynomial (not a power series) because $\dim \mathcal{M}_{g,n}^{\text{virt}} = 3g - 3$ bounds the relevant strata.

15.14.5 Fusion finiteness and bar rationality

Conjecture 15.14.8 (Fusion finiteness;). If $\mathcal{A}$ is chirally Koszul with finitely many strong generators of rank r , then $P_{\mathcal{A}}(x) = \sum_{n \geq 0} \dim H^n(\overline{B}(\mathcal{A})) x^n$ is D-finite (holonomic: bar cohomology dimensions satisfy a P-recursive recurrence of order $\leq r + 1$).

Koszulness implies E_2 collapse of the bar spectral sequence, which forces algebraicity of degree ≤ 2 (Conjecture 15.14.5). Algebraic functions are D-finite but *not* rational in general: the standard examples $P_{\widehat{\mathfrak{sl}}_2}(x)$, $P_{\text{Vir}}(x)$, $P_{\beta\gamma}(x)$ all involve $\sqrt{1 - 2x - 3x^2}$, which is algebraic of degree 2, not rational. The correct characterization is *diagonal purity* ($H^{n,k}(\overline{B}(\mathcal{A})) = 0$ for $k \neq n + h$), not mere rationality.

15.14.6 C_2 -cofiniteness and the Koszul–finiteness interaction

C_2 -cofiniteness and Koszulness are *orthogonal* conditions: $V_k(\mathfrak{g})$ is always Koszul (universal PBW) but never C_2 -cofinite at generic k ; the simple quotient $L_k(\mathfrak{g})$ at admissible level is C_2 -cofinite but Koszulness may fail (singular vectors source higher bar differentials). Koszul duality exchanges the two: at admissible k the associated variety $X_{L_k} = \{0\}$, but at the dual level $k' = -k - 2h^\vee$ one has $X_{L_{k'}} \neq \{0\}$ in general.

Conjecture 15.14.9 (Koszul– C_2 duality;). At non-degenerate admissible level, $L_k(\mathfrak{g})$ satisfies:

- (a) each fixed conformal-weight sector of $\overline{B}(L_k)$ has finite-dimensional cohomology (proved weightwise finiteness from C_2 -cofiniteness);
- (b) the character-theoretic bar spectral sequence is weightwise finite; on the worked $\widehat{\mathfrak{sl}}_2$ surface at $k = -1/2$ it yields the vacuum Kac–Wakimoto character formula, while on the general non-degenerate admissible lane it is compared against the external Kac–Wakimoto character formulas;
- (c) a stronger global statement (finite-dimensional total bar cohomology, or a page bound by $\dim \mathcal{A}(L_k)$) is not part of the current proved surface.

For associated varieties in type $\mathcal{A}$, Koszul duality implements Barbasch–Vogan duality on nilpotent orbits (the involution $d: \mathcal{N}(\mathfrak{g}) \rightarrow \mathcal{N}(\mathfrak{g})$ sending a partition to its transpose; see Barbasch–Vogan [BV85]):

$$X_{L_{k'}(\mathfrak{g})} = \overline{d(X_{L_k(\mathfrak{g})})}, \quad k' = -k - 2h^\vee.$$

This is the conjectural type- $\mathcal{A}$ simple-quotient pattern (Conjecture 36.2.36); the dual-level associated variety identification remains open. Beyond type $\mathcal{A}$, the Barbasch–Vogan involution involves the Spaltenstein map rather than partition transpose; the extension to all types is open.

15.14.7 Moduli of Koszul parameters

Remark 15.14.10 (Moduli of Koszul parameters). The one-parameter family $V_k(\mathfrak{g})$ stratifies the level line into three Koszul regimes.

(i) *Generic level.* The universal affine algebra $V_k(\mathfrak{g})$ has a PBW filtration at every level, and its associated graded is the polynomial chiral algebra on $\mathfrak{g}[t^{-1}]t^{-1}$. On the standard universal-affine surface this PBW

input is the independent Koszulness witness; it is not a consequence of the two-sided Hochschild bar resolution (Theorem 15.2.5). At generic non-admissible k one has $L_k = V_k$, so the simple quotient inherits that universal-affine PBW/Koszul package.

(ii) *Critical level* $k = -h^\vee$. This is the unique fixed point of the Feigin–Frenkel involution $k \mapsto -k - 2h^\vee$ on the *level parameter*. This fixed-point statement is not a theorem that the affine algebra itself satisfies $\mathcal{A}^! \cong \mathcal{A}$ at critical level. What is visible internally is narrower: the scalar curvature vanishes, the universal affine algebra acquires a large center, and critical bar-cobar inversion / fixed-point packages can be formulated on the specific surfaces where they are separately proved. The screening-model differential $\text{Sym}[S_1, \dots, S_r] \otimes \Omega_{\log}^*$ is only a free-field model (Remark 15.8.4), not an identification used here. The Feigin–Frenkel center $\mathfrak{z}(\widehat{\mathfrak{g}}) \cong \text{Fun}(\text{Op}_{L_{\mathfrak{g}}})$ supplies central operators and a Miura/screening model, while the external critical-level Langlands viewpoint for $\mathcal{W}$ -algebras (Remark 15.8.5) marks the comparison surface with Langlands-dual data. This is distinct from the proved internal critical fixed-point inversion package, which does not derive a Langlands-dual identification from bar-cobar inversion alone.

(iii) *Admissible levels*. $L_k(\mathfrak{g})$ at $k \in \Sigma(\mathfrak{g})$ (Definition ??) acquires singular vectors that source higher bar differentials. Bar–cobar inversion may fail; the Koszulness question reduces to whether screening operators generate *all* bar differentials (Proposition ??).

15.15 OPEN MATHEMATICAL CONDITIONS

The remaining problems are the following precise mathematical conditions.

- (i) Classify the chiral algebras for which the conilpotent bar coalgebra $\bar{B}^{\text{ch}}(\mathcal{A})$ resolves a dual coalgebra $\mathcal{A}^!$ and for which the finite-type Verdier hypotheses produce the algebra $\mathcal{A}^!$.
- (ii) Construct the ∞ -categorical module comparison attached to a Koszul pair without replacing it by the bar-cobar counit: the target is the factorization comodule category over $\bar{B}^{\text{ch}}(\mathcal{A})$, and only on the finite-type Verdier surface may it be rewritten as a completed $\mathcal{A}^!$ -module category.
- (iii) Extend the periodicity phenomena (Theorems 15.5.1 and 15.5.3) to non-simply-laced types by computing the first unknown bar cohomology groups, beginning with $H^2(\bar{B}(\widehat{G}_2))$.

The Koszul pair structure developed in this chapter consists of the quadratic condition, the PBW/completion replacements for nonquadratic algebras, and the level-shifting involutions visible on the standard families. The examples of Part ?? use this structure only after the Koszul condition and the Verdier-dual lane have been identified separately. The chiral Hochschild complex $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ controls deformations of the bar complex in the proved Hochschild range; same-type periodicity is transported across the finite-type module equivalence of Corollary 15.5.7, while mixed-type periodicity remains open.

15.16 SYNTHESIS

Remark 15.16.1 (K₃ bar coalgebra and the Verdier-dual lane). The K₃ bialgebra $\mathbf{H}_{\Delta_5}$ supplies a Hall-theoretic bar coalgebra

$$C_{K_3} = B_{\text{ch}}(\mathbf{H}_{\Delta_5}) \quad \text{on} \quad (\text{Ran}(E_{24}^{\text{nod,sm}}), \bar{\mathcal{A}}_2).$$

The cobar functor is not the second member of a Koszul pair; it is the inversion functor applied to this coalgebra. At the Lusztig specialisation $\hbar^2 = -1/8$ the Koszul resolution

$$\text{Bar}_\bullet(\mathbf{H}_{\Delta_5} \otimes \mathbf{H}_{\Delta_5}^{\text{op}}, \mathbf{H}_{\Delta_5}, \mathbf{H}_{\Delta_5}) \xrightarrow{\cong} \mathbf{H}_{\Delta_5}$$

is a quasi-isomorphism and lifts to a strict isomorphism after passing to the derived Hall category of $K_3 \times E$. Thus the bar-cobar counit gives

$$\Omega_X(C_{K_3}) \xrightarrow{\sim} \mathbf{H}_{\Delta_5}.$$

The Verdier-dual/Koszul algebra associated to this K_3 surface is a separate Vol. III identification: one first Verdier-dualizes the Hall bar coalgebra on the Ran–Siegel base and then applies the completed cobar comparison under the stated convergence hypotheses. The statement is therefore an instance of bar-cobar inversion at the K_3 base, not a definition of $\mathbf{H}_{\Delta_5}^!$ as $\Omega_X \mathcal{B}_{\text{ch}}(\mathbf{H}_{\Delta_5})$. See Vol. III, Chapter ??, Theorem A.

THE KOSZULNESS MODULI OBJECT

16.1 ORIENTATION: FROM KOSZUL TESTS TO A MODULI OBJECT

The fourteen chart tests for chiral Koszulness of a chiral algebra $\mathcal{A}$ on a smooth algebraic curve X with PBW filtration have four mathematical origins: homological algebra, deformation theory, factorisation geometry, and tropical geometry. Read at the Knizhnik–Zamolodchikov associator they appear with unequal scope. Read as chart tests on the associator torsor, each coordinate records the scope together with the algebraic datum.

Fix a quadratic chiral twisting datum $(\mathcal{A}, \mathcal{A}^i, \kappa_{\mathcal{A}}, F_{\bullet})$ in the sense of Definition 3.1.6. Its load-bearing map is the quadratic comparison

$$q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow \bar{B}^{\text{ch}}(\mathcal{A}),$$

or, by adjunction, $p_{\mathcal{A}}: \Omega^{\text{ch}}(\mathcal{A}^i) \rightarrow \mathcal{A}$. The moduli problem below deforms $\kappa_{\mathcal{A}}$ and records a trivialisation of the underlying perfect complex

$$C_{\mathcal{A}}^q := \text{Cone}(\mathbf{U}(q_{\mathcal{A}})),$$

where $\mathbf{U}$ forgets the coalgebra structure. Under the chiral Comparison-Lemma package H_{CL} , this cone is acyclic exactly when $\kappa_{\mathcal{A}}$ is Koszul. Its framed finite PBW truncations are open loci cut out by Fitting ideals of the cohomology of $C_{\mathcal{A}}^q$. The fourteen named predicates become chart tests after one supplies comparison quasi-isomorphisms from their finite test complexes to this quadratic comparison cone. The word “moduli” therefore names four related carriers: a derived formal functor in Artinian dg directions, a derived Artin quotient stack before gauge framing, a framed finite-stage derived affine scheme, and a finite-window test object inside a fixed PBW truncation. Each carrier retains its stated finiteness and framing hypotheses.

Section 16.2 constructs the completed Koszulness moduli functor $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ and proves its finite-stage representability under H_{mod} (Theorem 16.2.3); the construction uses standard tangent-obstruction theory for Maurer–Cartan functors. Section 16.3 assembles the fourteen charts, each placed at its proposed associator coordinate, and proves the formal comparison statement: an admissible chart predicate is equivalent to quadratic chiral Koszulness on the locus where its comparison complex computes $C_{\mathcal{A}}^q$ (Theorem 16.3.1); this identifies both the coordinate dependence and the comparison hypothesis. Section 16.4 formulates the comparison packages for two frontier items: the representation-theoretic Virasoro route at the Hodge–Betti chart (Theorem 16.4.1) and the Yangian chart inclusion (Theorem 16.4.3). Section 16.5 isolates the open meta-Koszulness problem: a GRT_1 -action gives infinitesimal chart transport, while an E_2 -structure on the tangent category requires a separately constructed operadic action and its coherence homotopies.

Three firewalls are fixed. First, $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ is a derived completed carrier; finite-stage hypotheses produce its algebraic truncations. Second, the five objects

$$\mathcal{A}, \quad \bar{B}^{\text{ch}}(\mathcal{A}), \quad \mathcal{A}^i = C(s^{-1}V, s^{-2}R), \quad \mathcal{A}^! = (\mathcal{A}^i)^{\vee}, \quad \mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) = CH^*(\mathcal{A}, \mathcal{A})$$

occupy their typed ambient categories. Here $\mathcal{A} = T(V)/(R)$ is the chosen quadratic presentation, $\mathcal{A}^i$ is its quadratic coalgebra, and $\mathcal{A}^!$ is its locally finite Verdier dual. The equivalence $\Omega^{\text{ch}} \bar{B}^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}$ is the universal bar–cobar reconstruction map. Quadratic Koszul recognition is the comparison $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \bar{B}^{\text{ch}}(\mathcal{A})$. The closed-sector object is the chiral Hochschild derived centre, and physical bulk comparisons factor through that named centre. Third, the derived centre is a right-adjoint construction; any higher operadic structure on the moduli tangent category requires a separately supplied action.

Remark 16.1.1 (Native versus derived E_n). Throughout this chapter, $\mathcal{A}$ is an E_1 -chiral algebra by hypothesis. Its derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) = CH^*(\mathcal{A}, \mathcal{A})$ carries the standard higher structure supplied by the relevant Deligne theorem. A higher structure on $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ is additional datum. The proposed Kontsevich chart U_{14} concerns an $\text{SC}^{\text{ch}, \text{top}}$ action on the pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$ and becomes an admissible chart after its comparison complex is identified with the quadratic comparison cone.

16.2 THE KOSZULNESS MODULI OBJECT

16.2.1 Finite-window carriers

The inputs to the construction are

- a quadratically presented augmented chiral algebra $\mathcal{A} = T(V)/(R)$ on X with PBW filtration $F_{\bullet} \mathcal{A}$ whose associated graded $R_{\mathcal{A}} = \text{gr}^F \mathcal{A}$ is a Poisson vertex algebra;
- its quadratic chiral coalgebra $\mathcal{A}^i = C(s^{-1}V, s^{-2}R)$ and canonical twisting morphism $\kappa_{\mathcal{A}}: \mathcal{A}^i \rightarrow \mathcal{A}$;
- the chiral bar complex $\bar{B}^{\text{ch}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$ with deconcatenation coproduct, augmentation ideal $\bar{\mathcal{A}} = \ker(\varepsilon)$, desuspension $|s^{-1}v| = |v| - 1$;
- the induced quadratic comparisons

$$q_{\mathcal{A}}: \mathcal{A}^i \longrightarrow \bar{B}^{\text{ch}}(\mathcal{A}), \quad p_{\mathcal{A}}: \Omega^{\text{ch}}(\mathcal{A}^i) \longrightarrow \mathcal{A},$$

together with the package $H_{\text{CL}}(\mathcal{A}, \mathcal{A}^i, \kappa_{\mathcal{A}})$.

The *quadratic Koszul locus* is the locus on which $q_{\mathcal{A}}$ is a quasi-isomorphism, equivalently $p_{\mathcal{A}}$ is a quasi-isomorphism, under H_{CL} . The universal counit $\Omega^{\text{ch}} \bar{B}^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ supplies the ambient bar–cobar reconstruction on the full augmented domain.

All moduli statements below use the PBW completion. Write $F_{\leq N} \mathcal{A}^i$ and $F_{\leq N} \bar{B}^{\text{ch}}(\mathcal{A})$ for the finite PBW truncations and $\widehat{\bar{B}^{\text{ch}}(\mathcal{A})} = \varprojlim_N F_{\leq N} \bar{B}^{\text{ch}}(\mathcal{A})$. The algebra $\mathcal{A}$ is of *finite PBW type* when every $F_{\leq N} \mathcal{A}^i$, $F_{\leq N} \bar{B}^{\text{ch}}(\mathcal{A})$, and $F_{\leq N} \mathcal{A}$ is a perfect complex of $\mathbb{Q}$ -vector spaces with uniformly bounded cohomological amplitude on compact subsets of the parameter space, and the transition maps in N satisfy the Mittag–Leffler condition. For general PBW towers the object below remains a derived formal functor. Finite-type scheme structure enters through the stated perfectness and stabilization hypotheses.

The finite-stage representability statement uses one further hypothesis. At PBW stage N and weight quotient m of GRT_1 , write $\mathfrak{g}_{\Phi, N, m}(\mathcal{A}, \mathcal{A}^i)$ for the corresponding finite quotient of $\text{Conv}_{\Phi}(\mathcal{A}^i, \mathcal{A})$. The pair $(\mathcal{A}, N, m)$ is of *PBW–Artin type* if

- $\mathfrak{g}_{\Phi, N, m}(\mathcal{A}, \mathcal{A}^i)$ is a nilpotent dg Lie algebra with finite-dimensional cohomology and bounded amplitude;
- the gauge group $\exp(\mathfrak{g}_{\Phi, N, m}^{\circ}(\mathcal{A}, \mathcal{A}^i))$ is an algebraic unipotent group acting on the finite Maurer–Cartan scheme;
- the universal finite comparison $q_{\Phi, N, m}: F_{\leq N} \mathcal{A}^i \rightarrow F_{\leq N} \bar{B}_{\Phi}^{\text{ch}}(\mathcal{A})$ varies algebraically and its underlying cone $C_{\Phi, N, m}^q$ is perfect with coherent cohomology sheaves;

- (d) the inverse system in N is derived Mittag–Leffler, so ordinary inverse limits compute derived inverse limits.

Under PBW–Artin type the unframed finite-stage moduli is a derived Artin quotient stack $[\mathrm{MC}(\mathfrak{g}_{\Phi,N,m})/\exp(\mathfrak{g}_{\Phi,N,m}^\circ)]$ restricted to the open acyclicity locus. After fixing an associator coordinate and a gauge framing it becomes an open derived affine scheme. The word *scheme* below always refers to this framed finite-stage object.

Definition 16.2.1 (Finite-window Koszul test). [Type signature: Open quadrant; finite-window quadratic chiral twisting presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis datum $(\mathcal{A}, \mathcal{A}^i, \kappa_{\mathcal{A}}, F_\bullet, \Phi, N, m)$.] Fix an associator Φ , a PBW stage N , and a finite weight quotient m of GRT_1 . A *finite-window Koszul test* for $\mathcal{A}$ is the tuple

$$\kappa_{\Phi,N,m}(\mathcal{A}) = (F_{\leq N} \mathcal{A}^i, F_{\leq N} \bar{B}_\Phi^{\mathrm{ch}}(\mathcal{A}), \kappa_{\Phi,N,m}, q_{\Phi,N,m}, C_{\Phi,N,m}^q, E_r^{\Phi,N,m})$$

with the following typed data.

- (i) $\varepsilon: \mathcal{A} \rightarrow \omega_X$ is the fixed augmentation and $\bar{\mathcal{A}} = \ker(\varepsilon)$; the chosen augmentation is part of the datum.
- (ii) $F_{\leq N} \mathcal{A}^i = F_{\leq N} C(s^{-1}V, s^{-2}R)$ and $F_{\leq N} \bar{B}_\Phi^{\mathrm{ch}}(\mathcal{A})$ are conilpotent factorisation coalgebras in the chosen Φ -model. The completed bar object $\widehat{\bar{B}}^{\mathrm{ch}}(\mathcal{A}) = \varprojlim_N F_{\leq N} \bar{B}^{\mathrm{ch}}(\mathcal{A})$ is taken in the proconilpotent category with continuous coalgebra maps.
- (iii) $\kappa_{\Phi,N,m}: F_{\leq N} \mathcal{A}^i \rightarrow F_{\leq N} \mathcal{A}$ is the finite Φ -coordinate form of the quadratic twisting morphism, equivalently a Maurer–Cartan element of $\mathfrak{g}_{\Phi,N,m}(\mathcal{A}, \mathcal{A}^i)$.
- (iv) The induced finite quadratic comparison is

$$q_{\Phi,N,m}: F_{\leq N} \mathcal{A}^i \longrightarrow F_{\leq N} \bar{B}_\Phi^{\mathrm{ch}}(\mathcal{A}).$$

Its test complex is the underlying quadratic comparison cone

$$C_{\Phi,N,m}^q := \mathrm{Cone}(\mathrm{U}(q_{\Phi,N,m})).$$

Under the finite-window restriction of H_{CL} , its acyclicity is equivalent to that of the adjoint comparison cone $\mathrm{Cone}(\mathrm{U}(\Omega_\Phi^{\mathrm{ch}}(F_{\leq N} \mathcal{A}^i) \rightarrow F_{\leq N} \mathcal{A}))$.

- (v) $E_r^{\Phi,N,m}$ is the spectral sequence induced by the PBW and coradical filtrations on $C_{\Phi,N,m}^q$. It is required to be bounded and strongly convergent at the finite window, and the inverse system in N is required to be derived Mittag–Leffler before any completed criterion is asserted.

A chart predicate is *admissible* only if it is the acyclicity of a perfect test complex $T_{\Phi,N,m}$ equipped with a filtered quasi-isomorphism $T_{\Phi,N,m} \xrightarrow{\sim} C_{\Phi,N,m}^q$ compatible with the transition maps in N and m .

Definition 16.2.2 (Koszulness moduli object). [Type signature: Open quadrant; derived deformation carrier of a quadratic chiral twisting datum; Beilinson levels $1 \leftrightarrow 2$; datum $(\mathcal{A}, \mathcal{A}^i, \kappa_{\mathcal{A}}, F_\bullet)$ and its perfect finite-window quadratic comparison cones.] For a complete local Artinian commutative dg $\mathbb{Q}$ -algebra R with maximal ideal $\mathfrak{m}_R$, set

$$\widehat{\mathfrak{g}}_\Phi(\mathcal{A}, \mathcal{A}^i) = \varprojlim_N \mathrm{Conv}_\Phi(F_{\leq N} \mathcal{A}^i, F_{\leq N} \mathcal{A}),$$

and twist its differential by the base Maurer–Cartan element $\kappa_{\mathcal{A}}$. The *Koszulness moduli object* is the derived functor

$$\mathcal{M}_{\text{Kosz}}(\mathcal{A}) : \mathbf{Art}_{\mathbb{Q}}^{\wedge} \longrightarrow \mathbf{Spaces},$$

$$R \longmapsto \text{hofib}_o \left[\coprod_{\Phi \in \text{Assoc}(R)} \text{MC}_{\bullet}(\widehat{\mathfrak{g}}_{\Phi}(\mathcal{A}, \mathcal{A}^i)^{\kappa_{\mathcal{A}}} \widehat{\otimes} \mathfrak{m}_R) \xrightarrow{\xi \mapsto C_{\kappa_{\mathcal{A}} + \xi}^q} \text{Perf}_{\text{ch}}(X; R)^{\simeq} \right].$$

Here the target is the maximal ∞ -groupoid of perfect underlying chiral complexes, o is its zero object, and

$$C_{\kappa_{\mathcal{A}} + \xi}^q := \text{Cone}(\mathbf{U}(q_{\kappa_{\mathcal{A}} + \xi})), \quad q_{\kappa_{\mathcal{A}} + \xi} : \mathcal{A}^i \widehat{\otimes} R \longrightarrow \bar{B}_{\Phi}^{\text{ch}}(\mathcal{A} \widehat{\otimes} R),$$

is the coalgebra map induced by the deformed quadratic twisting morphism $\kappa_{\mathcal{A}} + \xi$. Equivalently, an R -point may be written (Φ, ξ, h_{ξ}) , where $\Phi \in \text{Assoc}(R)$, $\xi \in \text{MC}_{\bullet}(\widehat{\mathfrak{g}}_{\Phi}(\mathcal{A}, \mathcal{A}^i)^{\kappa_{\mathcal{A}}} \widehat{\otimes} \mathfrak{m}_R)$, and $h_{\xi} : C_{\kappa_{\mathcal{A}} + \xi}^q \simeq o$ is a trivialisation in the perfect derived category over R . An admissible chart coordinate at Φ with equivariant transport is a triple $(\Pi_{\Phi}, \text{wit}_{\Phi}, \gamma_{\Phi})$ consisting of

- (a) a Koszulness predicate Π_{Φ} depending only on the pair $(\mathcal{A}, \Phi)$ and expressible as acyclicity of a perfect test complex $T_{\Phi, N, m}$ at every finite PBW stage and finite weight quotient, together with a filtered comparison quasi-isomorphism $\alpha_{\Phi, N, m} : T_{\Phi, N, m} \xrightarrow{\sim} C_{\Phi, N, m}^q$;
- (b) a witness $\text{wit}_{\Phi}(\mathcal{A})$ in the test category fixed by Φ , equivalently a compatible system of null-homotopies $h_{\Phi, N, m} : T_{\Phi, N, m} \simeq o$ whose images under $\alpha_{\Phi, N, m}$ trivialise the quadratic comparison cones;
- (c) a transition 1-cocycle of filtered quasi-isomorphisms

$$\gamma_{g, \Phi, N, m} : C_{\Phi, N, m}^q \xrightarrow{\sim} C_{\Phi \cdot g, N, m}^q, \quad g \in \text{GRT}_1(R),$$

compatible with $\alpha_{\Phi, N, m}$ and satisfying the unit and composition identities. Tamarkin formality [?Tamarkin03] supplies the operadic source of this transport; the displayed comparison with the chiral quadratic cones is part of the chart datum.

Each associator Φ fixes a formality coordinate for little two-disks. The KZ, Alekseev–Torossian, Hodge–Betti, elliptic, and Kontsevich constructions furnish five proposed coordinate systems. Their promotion to charts on the carrier above is the comparison problem encoded by the maps $\alpha_{\Phi, N, m}$ and $\gamma_{g, \Phi, N, m}$. Over a characteristic-zero point, Assoc is a torsor under the relevant completed Grothendieck–Teichmüller group. Finite PBW and weight truncation, together with PBW–Artin type, produces the framed algebraic acyclicity locus and its unframed quotient stack.

THEOREM 16.2.3 (*Koszulness moduli, finite-stage representability*). Type signature: (Open quadrant, finite-stage PBW/associator-moduli presentation, Beilinson levels 1–2, hypothesis package H_{mod} : a quadratic datum $(\mathcal{A}, \mathcal{A}^i, \kappa_{\mathcal{A}}, F_{\bullet})$ satisfying H_{CL} , finite PBW type, PBW–Artin finite stages, algebraic variation of the perfect quadratic comparison $q_{\Phi, N, m}$, framed associator coordinates, and derived Mittag–Leffler passage for the completed inverse limit). Let $\mathcal{A}$ carry the displayed datum and assume H_{mod} at every finite pair (N, m) used below. Then $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ is a possibly empty derived formal moduli problem over the Drinfeld associator torsor. For each finite PBW stage N and finite weight quotient m of GRT_1 , the unframed finite-stage truncation is a derived Artin quotient stack; after fixing an associator coordinate and a gauge framing, its classical truncation is an open subscheme of a finite-type affine Maurer–Cartan scheme. The closed complement is cut out by the Fitting ideals of the cohomology of $C_{\Phi, N, m}^q$. The completed moduli object is the derived inverse limit of these finite stages, and under the

Mittag–Leffler hypothesis this is the ordinary PBW-completed inverse limit. The affine finite-type carrier is the framed finite-stage stabilization of this tower. It has the following properties.

(A1) For a fixed admissible Φ -model, the base fibre contains (Φ, o, h) precisely when

$$q_{\mathcal{A}, \Phi}: \widehat{\mathcal{A}^i} \xrightarrow{\sim} \widehat{B^{\text{ch}}}_{\Phi}(\mathcal{A})$$

is a quasi-isomorphism. Under H_{CL} , this is equivalent to $p_{\mathcal{A}, \Phi}: \Omega_{\Phi}^{\text{ch}}(\widehat{\mathcal{A}^i}) \rightarrow \mathcal{A}$ being a quasi-isomorphism, and to acyclicity of all $C_{\Phi, N, m}^q$ together with derived Mittag–Leffler convergence.

The full-bar counit $\Omega^{\text{ch}} \widehat{B^{\text{ch}}}(\mathcal{A}) \rightarrow \mathcal{A}$ is the universal reconstruction map.

(A2) At a framed point $x = (\Phi, \xi, h_{\xi})$ in a fixed finite-stage coordinate, the tangent complex is

$$\mathbb{T}_x \mathcal{M}_{\text{Kosz}}^{N, m}(\mathcal{A}) \simeq \mathfrak{g}_{\Phi, N, m}(\mathcal{A}, \mathcal{A}^i)^{\kappa_{\mathcal{A}} + \xi} [1].$$

Allowing the associator coordinate adds $\mathbb{T}_{\Phi} \text{Assoc}$; passing to the unframed quotient takes the homotopy quotient by the infinitesimal gauge action. The acyclicity condition is open and therefore adds no infinitesimal equation at a point of the locus. First-order deformations and obstructions are the degree 0 and degree 1 cohomology of this tangent complex.

(A3) Assume in addition the equivariant comparison package H_{GRT} : filtered transfer equivalences of the convolution dg Lie algebras together with the cocycle $\gamma_{g, \Phi, N, m}$ of Definition 16.2.2. Then GRT_1 transports the chart fibres by equivalences preserving $C_{\Phi, N, m}^q$. A transported component is a principal $\text{GRT}_{1, \leq m}$ -bundle precisely when its framed witness fibre is contractible, the finite-dimensional quotient action is free, and transport is transitive on that component. The unframed component is the corresponding quotient by the automorphism group of the witness.

(A4) The fourteen predicates listed below form candidate chart tests: $U_1, \dots, U_{10}$ are centred at Φ_{KZ} ; U_{11} at Φ_{AT} (Alekseev–Torossian); U_{12} at $\Phi_{\text{dR}, B}$ (de Rham–Betti); U_{13} at Φ_{ell} (Enriquez elliptic); and U_{14} at Φ_{Kon} (Kontsevich integral). A candidate is an admissible derived open chart when a perfect complex $T_{j, N, m}$ and a compatible filtered quasi-isomorphism $\alpha_{j, N, m}: T_{j, N, m} \xrightarrow{\sim} C_{\Phi_j, N, m}^q$ are supplied. Coherent transport between such charts uses H_{GRT} .

(A5) Assume that the shadow brackets vary algebraically over each finite Maurer–Cartan scheme and that their ranks are constructible. Their fixed-rank conditions define locally closed substacks. Thus the shadow-class decomposition $G \sqcup L \sqcup C \sqcup M \sqcup \text{FF}$ lifts to the stratification

$$\mathcal{M}_{\text{Kosz}}(\mathcal{A}) = \bigsqcup_{c \in \{G, L, C, M, \text{FF}\}} \mathcal{M}_{\text{Kosz}}^{(c)}(\mathcal{A}),$$

The proposed computational home coordinates are Φ_{KZ} on G and on the generic Kac–Moody locus of L , Φ_{ell} on the modular locus of L , Φ_{AT} on C , Φ_{Kon} on M , and $\Phi_{\text{dR}, B}$ on FF . Each becomes an admissible home coordinate through the comparison maps required in (A4); the completed strata are the derived Mittag–Leffler inverse limits of the finite strata.

Proof. PBW–Artin type makes the finite Maurer–Cartan functor affine of finite type and its unipotent gauge quotient a derived Artin stack. The algebraic universal map $q_{\Phi, N, m}$ is a morphism of perfect complexes. Acyclicity of its cone is open: its closed complement is the union of the supports of the coherent cohomology modules, cut out by their Fitting ideals. This proves the finite-stage representability statement. Derived Mittag–Leffler identifies the derived inverse limit with the stated PBW completion.

(A1). The homotopy fibre over zero is nonempty exactly when $C_{\mathcal{A},\Phi}^q$ is acyclic. The equivalence with the adjoint map $p_{\mathcal{A},\Phi}$ is the fundamental theorem of chiral twisting morphisms under H_{CL} (Theorem 14.1.13), whose quadratic point-model is Loday–Vallette [?LV12, Theorem 3.4.6]. Strong finite-window convergence and derived Mittag–Leffler give the completed equivalence.

(A2). The tangent complex of a Maurer–Cartan functor at $\kappa_{\mathcal{A}} + \xi$ is the shifted twisted dg Lie algebra. Restriction to an open subfunctor preserves this tangent complex. Variation of Φ and gauge descent give the two stated standard modifications.

(A3). The maps in H_{GRT} carry Maurer–Cartan elements and their induced quadratic comparisons to the corresponding data at $\Phi \cdot g$. Their cocycle identities give the action on chart fibres. Freeness and contractibility of the witness fibre are exactly the additional conditions for the stated principal-bundle conclusion.

(A4). A filtered quasi-isomorphism $T_{j,N,m} \simeq C_{\Phi_{j,N,m}}^q$ identifies their acyclicity loci. The preceding Fitting-ideal argument makes this an open chart, and H_{GRT} gives coherence across coordinates.

(A5). Algebraic rank conditions are constructible and their fixed-rank pieces are locally closed. The Mittag–Leffler clause assembles the finite pieces into the completed strata. Admissibility of each proposed home coordinate is precisely the comparison requirement of (A4). $\square$

COROLLARY 16.2.4 (*Associator-independence of the Koszulness property*). [Type signature: Open quadrant; quadratic chiral associator-transport presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis packages H_{CL} , H_{mod} , and H_{GRT} .] Fix a quadratic chiral twisting datum satisfying H_{CL} and H_{mod} . Its intrinsic Koszul condition is the quasi-isomorphism $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \bar{B}^{\text{ch}}(\mathcal{A})$. Assume H_{GRT} for the chosen family of formality models. Then the equivalences $\gamma_{g,\Phi,N,m}$ identify the quadratic comparison cones at Φ and $\Phi \cdot g$; hence the Koszul locus and its finite Fitting opens are GRT_1 -stable. A named predicate Π_{Φ} represents this locus on its home coordinate when its comparison map $\alpha_{\Phi,N,m}: T_{\Phi,N,m} \xrightarrow{\sim} C_{\Phi,N,m}^q$ is supplied.

Proof. Each $\gamma_{g,\Phi,N,m}$ is a quasi-isomorphism between the two perfect quadratic comparison cones. It therefore identifies their acyclicity loci and their cohomological Fitting ideals. Compatibility with N , m and derived Mittag–Leffler passes this identification to the completion. The comparison $\alpha_{\Phi,N,m}$ gives the final identification with the named predicate. $\square$

Remark 16.2.5 (*Kontsevich–Tamarkin, operational form*). The classical Kontsevich–Tamarkin theorem asserts, over a field of characteristic zero, that the little two-disks operad $\mathbf{E}_2$ is formal, with the formality isomorphism depending on a choice of Drinfeld associator. Tamarkin formality supplies the operadic change of coordinate. The package H_{GRT} promotes that change of coordinate to the convolution models of a fixed quadratic chiral datum and intertwines their maps to the chiral bar construction. With this package, admissible classical characterisations are coordinates over the associator torsor and their transition maps preserve the quadratic comparison cone.

16.3 THE FOURTEEN CHARTS AND THEIR HOME-COORDINATE STATUS

The atlas has fourteen candidate chart tests. Entries $U_1, \dots, U_{10}$ are the KZ entries at Φ_{KZ} , taken verbatim from Chapter 15 with their home coordinate made explicit. The additional four are stated here as independent propositions at Φ_{AT} , $\Phi_{\text{dR},B}$, Φ_{ell} , and Φ_{Kon} , each with its own comparison complex. The mathematical obligation for every entry is an explicit filtered quasi-isomorphism from its test complex to the finite quadratic comparison cone at its home coordinate.

THEOREM 16.3.1 (*Fourteen admissible characterisations on their home chart*). Type signature: (Open quadrant, finite-stage associator-chart atlas presentation, Beilinson levels 1–2, hypothesis packages: H_{mod} and H_{chart} , consisting for each named home coordinate of a perfect complex $T_{j,N,m}$, a filtered quasi-isomorphism $\alpha_{j,N,m}: T_{j,N,m} \simeq C_{\Phi_{j,N,m}}^q$, and compatible PBW completion; cross-chart equivalence additionally uses H_{GRT}). Let $\mathcal{A}$ be a chiral algebra on X of finite PBW type, and assume the PBW–Artin hypotheses at the finite stages appearing below. The following fourteen predicates are chart tests. On the locus where the named finite-stage comparison complex $T_{\Phi,N,m}$ exists and the maps $T_{\Phi,N,m} \xrightarrow{\sim} C_{\Phi,N,m}^q$ are filtered quasi-isomorphisms compatible with PBW completion, the predicate is equivalent to quadratic chiral Koszulness of $\mathcal{A}$ on its home associator coordinate. On the remaining locus it retains its stated meaning as a candidate condition, and construction of $\alpha_{j,N,m}$ is the precise comparison problem.

(*Home coordinate* Φ_{KZ} , charts U_1 – U_{10}):

- (i) U_1 (*PBW E_2 -collapse*): the PBW spectral sequence of $\tilde{B}^{\text{ch}}(\mathcal{A})$ collapses at E_2 .
- (ii) U_2 (*chiral Koszul morphism*): the quadratic comparison $q_{\mathcal{A}}: \widehat{\mathcal{A}}^i \rightarrow \widehat{B}^{\text{ch}}(\mathcal{A})$ is a quasi-isomorphism, equivalently $p_{\mathcal{A}}: \Omega^{\text{ch}}(\widehat{\mathcal{A}}^i) \rightarrow \mathcal{A}$ is a quasi-isomorphism under H_{CL} .
- (iii) U_3 (*A_{∞} -formality of the KZ model*): the minimal A_{∞} -model of $\mathcal{A}$ at Φ_{KZ} has $m_k = 0$ for $k \geq 3$.
- (iv) U_4 (*shadow-tower formality*): the shadow tower $\Theta_{\mathcal{A}}$ is formal as an L_{∞} -algebra at the Φ_{KZ} base.
- (v) U_5 (*E_2 -formality of chiral Hochschild*): $CH^*(\mathcal{A}, \mathcal{A})$ is E_2 -formal over the KZ model.
- (vi) U_6 (*curve independence*): the bar complex of $\mathcal{A}$ is independent of the curve X within the Deligne–Mumford stratum of $\mathcal{A}$.
- (vii) U_7 (*PBW universality*): the associated graded $R_{\mathcal{A}} = \text{gr}^F \mathcal{A}$ is a polynomial Poisson vertex algebra under $F_{\bullet}$, and the PBW deformation is flat on the finite comparison window. This is the PBW-free chart: freely strongly generated vertex algebras satisfy it; simple quotients and logarithmic orbifold or triplet examples require a separate verification after passage from the ambient algebra.
- (viii) U_8 (*Barr–Beck–Lurie monadicity*): $\mathcal{A} \mapsto \tilde{B}^{\text{ch}}(\mathcal{A})$ is monadic over the category of counital conilpotent factorisation coalgebras.
- (ix) U_9 (*factorisation homology concentration*): $\int_X \mathcal{A}$ is concentrated in the expected factorisation degree (uniform-weight $g = 0$; $g \geq 1$ scalar-lane, Remark 16.3.3).
- (x) U_{10} (*FM boundary acyclicity*): the pullback of $\tilde{B}^{\text{ch}}(\mathcal{A})$ to the boundary strata of $\text{FM}_n(X)$ is acyclic in degrees ≥ 2 .

(*Home coordinate* Φ_{AT} , chart U_{11}):

- (xi) U_{11} (*Lagrangian criterion at Alekseev–Torossian*): the derived intersection of $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$ inside $\mathcal{M}_{\text{comp}}^{\text{AT}}$ has acyclic tangent fibre $\mathbb{T}_{\text{int}}^{\text{AT}}$.

(*Home coordinate* $\Phi_{\text{dR,B}}$, chart U_{12}):

- (xii) U_{12} (*mixed Hodge module purity*): the Hodge–Betti finite-resolution hypotheses hold and each $\tilde{B}_n^{\text{ch}}(\mathcal{A})$ is pure of weight n as a mixed Hodge module.

(*Home coordinate* Φ_{ell} , chart U_{13}):

- (xiii) U_{13} (*genus-one twisted Künneth*): $\tilde{B}^{\text{ch}}(\mathcal{A} \boxtimes_{\text{ell}} \mathcal{A}^!) \simeq \tilde{B}^{\text{ch}}(\mathcal{A}) \boxtimes_{\text{ell}} \tilde{B}^{\text{ch}}(\mathcal{A}^!)$ on $\overline{\mathcal{M}}_{1,n}$.

(*Home coordinate* Φ_{Kon} , chart U_{14}):

- (xiv) U_{14} (*Swiss-cheese homotopy-Koszulity*): the Kontsevich comparison complex for the action of $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ on the pair $(\mathcal{Z}_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A}), \mathcal{A})$ is homotopy-Koszul at every Maurer–Cartan degree.

On an admissible home chart each of $U_1, \dots, U_{14}$ is equivalent to quadratic chiral Koszulness. The KZ-scoped split is the restriction of the completed atlas to the KZ coordinate.

Proof. Fix j . The quasi-isomorphism $\alpha_{j,N,m}: T_{j,N,m} \rightarrow C_{\Phi_{j,N,m}}^q$ identifies acyclicity of the named test with acyclicity of the quadratic comparison cone at every finite window. Theorem 16.2.3(A1) and H_{CL} identify the latter with quadratic chiral Koszulness. Compatibility in N, m and derived Mittag–Leffler give the completed statement. This proves every home-chart implication from the data in H_{chart} .

Under H_{GRT} , the cocycle $\gamma_{g,\Phi,N,m}$ intertwines the quadratic comparison cones at two associator coordinates. Hence the finite acyclicity opens and their completed inverse limits agree under transport. The four supplementary propositions below state concrete packages whose missing mathematical content is precisely the construction of their respective maps $\alpha_{j,N,m}$. $\square$

Remark 16.3.2 (Scope of the PBW-universality chart). Chart U_7 is a sufficient PBW-free test on its admissible home component. A global converse requires comparison maps on every component. Free strong generation supplies the test, as in Proposition 14.1.37. Outside that component, for example for simple quotients with null-vector ideals and for logarithmic triplet or orbifold constructions, the atlas requires a separate bar, determinant, or comparison-complex argument before U_7 can be used as an equivalence.

Remark 16.3.3 (Scope of the uniform-weight tag). Chart U_9 (factorisation homology concentration) refers to the scalar-channel uniform-weight regime at genus $g \geq 1$: the scalar coefficient $\kappa_{\mathrm{ch}}(\mathcal{A})$ controls a single universal Maurer–Cartan datum, and multi-weight corrections $\delta F_g^{\mathrm{cross}}$ are tracked separately (Theorem ??). At $g = 0$ and at the uniform-weight scalar lane for $g \geq 1$, U_9 is a KZ chart test; the full all-weight strengthening lives on the Lagrangian chart U_{II} at Φ_{AT} .

16.3.1 Chart U_{II} : Alekseev–Torossian

PROPOSITION 16.3.4 (*Alekseev–Torossian chart*). [Type signature: Open quadrant; finite AT/Kashiwara–Vergne comparison presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package H_{AT} : H_{mod} , perfectness of the displayed tangent fibre, and a filtered comparison with the quadratic cone.] At the Alekseev–Torossian associator Φ_{AT} [?AT12], fix the finite PBW comparison component on which the Kashiwara–Vergne tangent complex is perfect. Let

$$\mathcal{M}_{\mathcal{A}}, \mathcal{M}_{\mathcal{A}^!} \longrightarrow \mathcal{M}_{\mathrm{comp}}^{\mathrm{AT}}$$

be the two derived formal moduli maps defined by $\mathcal{A}$ and by the Verdier dual algebra $\mathcal{A}^! = (\mathcal{A}^i)^\vee$. At a point x of their derived intersection, set

$$\mathbb{T}_{\mathrm{int},x}^{\mathrm{AT}} = \mathrm{fib}\left(\mathbb{T}_x \mathcal{M}_{\mathcal{A}} \oplus \mathbb{T}_x \mathcal{M}_{\mathcal{A}^!} \longrightarrow \mathbb{T}_x \mathcal{M}_{\mathrm{comp}}^{\mathrm{AT}}\right).$$

Assume H_{AT} supplies compatible filtered quasi-isomorphisms

$$\alpha_{N,m}^{\mathrm{AT}}: \mathbb{T}_{\mathrm{int},x;N,m}^{\mathrm{AT}} \xrightarrow{\sim} C_{\Phi_{\mathrm{AT}},N,m}^q.$$

Then AT transversality $\mathbb{T}_{\mathrm{int},x}^{\mathrm{AT}} \simeq 0$ is equivalent to quadratic chiral Koszulness of $\mathcal{A}$. The assertion applies to the finite comparison component specified by H_{AT} .

Proof. The comparison $\alpha_{N,m}^{\text{AT}}$ identifies vanishing of the tangent fibre with acyclicity of the finite quadratic comparison cone. Compatibility with the PBW tower and derived Mittag–Leffler gives the completed equivalence. Theorem 16.2.3(A1) identifies this acyclicity with quadratic chiral Koszulness under H_{CL} . The Alekseev–Torossian theorem [?AT12] supplies the Kashiwara–Vergne coordinate; construction of $\alpha_{N,m}^{\text{AT}}$ is the additional chiral comparison contained in H_{AT} . $\square$

Remark 16.3.5 (Perfectness as chart coordinate). The package H_{AT} records perfectness of the finite Kashiwara–Vergne tangent complex and the comparison $\alpha_{N,m}^{\text{AT}}$. Thus the AT chart is defined on the component where both pieces of data are available. Extension to a larger deformation ambient is a separate perfectness and comparison problem.

16.3.2 Chart U_{12} : de Rham–Betti

PROPOSITION 16.3.6 (*Hodge–Betti chart*). [Type signature: Open quadrant; finite mixed-Hodge PBW presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package H_{HB} : H_{mod} , a strict mixed-Hodge PBW resolution, and a filtered comparison from its off-weight complex to the quadratic cone.] At the de Rham–Betti associator $\Phi_{\text{dR},\text{B}}$ [?Deligne89], let $\mathcal{A}$ be of finite PBW type with conformal-weight grading and a strict mixed-Hodge PBW resolution of the unit. Let T_N^{HB} be the perfect off-weight complex

$$T_N^{\text{HB}} := \bigoplus_{n \leq N} \bigoplus_{w \neq n} \text{gr}_w^W \bar{B}_n^{\text{ch}}(\mathcal{A}).$$

Assume H_{HB} supplies compatible filtered quasi-isomorphisms

$$\alpha_N^{\text{HB}} : T_N^{\text{HB}} \xrightarrow{\sim} C_{\Phi_{\text{dR},\text{B}},N}^q.$$

Then purity of the bar pieces through stage N is equivalent to the finite quadratic Koszul condition, and the completed equivalence holds under derived Mittag–Leffler convergence.

Proof. Strictness identifies purity through stage N with acyclicity of T_N^{HB} . The map α_N^{HB} identifies this with acyclicity of $C_{\Phi_{\text{dR},\text{B}},N}^q$. Theorem 16.2.3(A1) gives the finite quadratic Koszul criterion, and derived Mittag–Leffler gives the completed statement. Deligne’s de Rham–Betti comparison [?Deligne89] supplies the mixed-Hodge coordinate; the map α_N^{HB} is the chiral comparison obligation encoded by H_{HB} . $\square$

16.3.3 Chart U_{13} : Enriques elliptic

PROPOSITION 16.3.7 (*Enriques elliptic chart*). [Type signature: Open quadrant; finite elliptic KZB comparison presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package H_{ell} : H_{mod} , a perfect Künneth-defect complex, and a filtered comparison with the quadratic cone.] At the Enriques elliptic associator Φ_{ell} [?Enriques14], let $\mathcal{A}$ be of finite PBW type and suppose the elliptic KZB comparison morphism

$$\chi_{N,m}^{\text{ell}} : F_{\leq N} \bar{B}^{\text{ch}}(\mathcal{A} \boxtimes_{\text{ell}} \mathcal{A}^!) \longrightarrow F_{\leq N} \bar{B}^{\text{ch}}(\mathcal{A}) \boxtimes_{\text{ell}} F_{\leq N} \bar{B}^{\text{ch}}(\mathcal{A}^!)$$

has perfect cone $T_{N,m}^{\text{ell}}$. Assume H_{ell} supplies compatible filtered quasi-isomorphisms

$$\alpha_{N,m}^{\text{ell}} : T_{N,m}^{\text{ell}} \xrightarrow{\sim} C_{\Phi_{\text{ell}},N,m}^q.$$

Then the twisted Künneth morphism is a quasi-isomorphism exactly on the finite quadratic Koszul locus, and the completed equivalence holds under derived Mittag–Leffler convergence.

Proof. The cone of $\chi_{N,m}^{\text{ell}}$ is acyclic precisely when the twisted Künneth morphism is a quasi-isomorphism. The map $\alpha_{N,m}^{\text{ell}}$ identifies this cone with the finite quadratic comparison cone, and Theorem 16.2.3(A1) gives the Koszul criterion. Compatibility with the tower gives the completed statement. Enriquez’s elliptic associator [Enriquez14] supplies the KZB coordinate; construction of $\alpha_{N,m}^{\text{ell}}$ is the additional chiral comparison encoded by H_{ell} . $\square$

16.3.4 Chart U_{14} : Kontsevich integral

PROPOSITION 16.3.8 (*Kontsevich integral chart*). [Type signature: Open quadrant; weight-completed Swiss-cheese/chord-diagram comparison presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package H_{Kon} : H_{mod} , a chain-level $\text{SC}^{\text{ch,top}}$ action, convergence, and filtered comparison with the quadratic cone.] At the Kontsevich integral associator Φ_{Kon} [?Kontsevich93], assume the derived-centre pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}), \mathcal{A})$ carries a weight-complete $\text{SC}^{\text{ch,top}}$ action and that the Kontsevich chord-diagram comparison complex $T_{N,m}^{\text{Kon}}$ is perfect. Assume H_{Kon} supplies compatible filtered quasi-isomorphisms

$$\alpha_{N,m}^{\text{Kon}} : T_{N,m}^{\text{Kon}} \xrightarrow{\sim} C_{\Phi_{\text{Kon}}, N, m}^q.$$

On this comparison component, quadratic chiral Koszulness of $\mathcal{A}$ is equivalent to homotopy-Koszulity of that $\text{SC}^{\text{ch,top}}$ comparison complex at every degree of the Maurer–Cartan expansion. On the class M stratum this gives the proposed Kontsevich home coordinate when the same comparison package holds throughout the weight-completed tower.

Proof. Homotopy-Koszulity is acyclicity of $T_{N,m}^{\text{Kon}}$. The map $\alpha_{N,m}^{\text{Kon}}$ identifies this condition with acyclicity of the finite quadratic comparison cone. Theorem 16.2.3(A1) gives quadratic chiral Koszulness, and the convergence clause in H_{Kon} gives the completed assertion. The Kontsevich integral [?Kontsevich93] supplies chord-diagram coordinates; the chain-level $\text{SC}^{\text{ch,top}}$ action and the comparison $\alpha_{N,m}^{\text{Kon}}$ are the additional obligations in H_{Kon} . $\square$

Remark 16.3.9 (*Chart redundancy and the torsor structure*). After H_{chart} is supplied, every admissible comparison complex detects the same quadratic cone. Under H_{GRT} , Theorem 16.2.3(A3) organises these presentations over the associator torsor. The shadow-rank hypotheses of (A5) provide the proposed computational choice on each stratum. The number fourteen records the selected test list; the associator torsor retains its pro-unipotent geometry.

THEOREM 16.3.10 (*Koszulness is GRT_1 -invariant; admissible characterisations are charts*). [Type signature: Open quadrant; quadratic chiral associator-chart presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis packages H_{mod} , H_{chart} , and H_{GRT} .] Under these packages, quadratic chiral Koszulness is preserved by the GRT_1 transport of formality coordinates. Every admissible classical characterisation is a coordinate chart because its test complex is identified with $C_{\Phi, N, m}^q$, and the cocycle $\gamma_{g, \Phi, N, m}$ transports that comparison across associator coordinates.

Proof. The maps $\alpha_{j, N, m}$ identify each chart predicate with acyclicity of its home quadratic cone. The maps $\gamma_{g, \Phi, N, m}$ identify those cones under GRT_1 transport and satisfy the cocycle identity. Theorem 16.2.3(A1) identifies their acyclicity with quadratic chiral Koszulness. Completion follows from the Mittag–Leffler clauses in the three packages. $\square$

16.4 FRONTIER CLOSURES: VIRASORO AND YANGIAN

16.4.1 Virasoro non-circular closure

An independent Virasoro argument can enter through representation theory: a strict mixed-Hodge lift of a Feigin–Fuchs resolution would compute the off-weight complex before the quadratic Koszul criterion is invoked. The following statement records the exact comparison package required for that route.

THEOREM 16.4.1 (*Virasoro Koszulness, non-circular*). [Type signature: Open quadrant; Hodge–Betti finite-PBW presentation of the Virasoro vacuum; Beilinson levels $1 \leftrightarrow 2$; hypothesis package $H_{\text{Vir}, \text{HB}}$: a strict mixed-Hodge lift of the relevant Feigin–Fuchs resolution, its off-weight acyclicity, and the comparison α_N^{HB} of Proposition 16.3.6.] For the Virasoro vertex algebra Vir_c at generic central charge $c \notin \{c_{p,q} : (p, q) \in \mathbb{Z}_{>0}^2, \gcd(p, q) = 1\}$, assume $H_{\text{Vir}, \text{HB}}$. Then the bar cohomology is supported on the quadratic diagonal; equivalently,

$$H^\bullet(T_N^{\text{HB}}(\text{Vir}_c)) = 0 \quad \text{for every finite } N.$$

Consequently $q_{\text{Vir}_c} : \text{Vir}_c^i \rightarrow \bar{B}^{\text{ch}}(\text{Vir}_c)$ is a quasi-isomorphism after PBW completion, so Vir_c is quadratically chirally Koszul.

Proof. The package $H_{\text{Vir}, \text{HB}}$ makes the strict mixed-Hodge resolution a model for $T_N^{\text{HB}}(\text{Vir}_c)$ and supplies its off-weight acyclicity. The comparison α_N^{HB} identifies this complex with $C_{\Phi_{\text{dR}, \text{B}}, N}^q$. Proposition 16.3.6 and derived Mittag–Leffler identify the completed quadratic comparison cone as acyclic. Theorem 16.2.3(A1) then gives the asserted quasi-isomorphism q_{Vir_c} . $\square$

Remark 16.4.2 (*Why this closes the classical circularity*). The logical route is representation-theoretic: Feigin–Fuchs/Kac data $\rightarrow$ strict mixed-Hodge resolution $\rightarrow T_N^{\text{HB}} \rightarrow C_N^q \rightarrow q_{\text{Vir}_c}$. Its unresolved step is the construction of the strict mixed-Hodge lift and of α_N^{HB} for the Virasoro vacuum family. A direct construction of those maps closes the Virasoro branch, with q_{Vir_c} as the Koszul detector and the universal bar–cobar counit as the ambient reconstruction map.

16.4.2 Yangian chart inclusion

The associative Koszulness of the Yangian $Y_{\hbar}(\mathfrak{g})$ for $\mathfrak{g}$ simple uses the Polishchuk–Positselski nonhomogeneous Koszul framework [Positselski11]. The chiral question is whether this Koszulness upgrades to the chiral setting. The moduli reformulation phrases this as a chart inclusion.

THEOREM 16.4.3 (*Yangian chart inclusion*). [Type signature: Open quadrant; associative-to-chiral finite-PBW comparison presentation; Beilinson levels $1 \leftrightarrow 2$; hypothesis package: a finite-PBW chiral avatar, filtered comparison of quadratic cones, representability, Shapovalov-locus reflection, H_{GRT} compatibility, and derived Mittag–Leffler completion.] For the Yangian $Y_{\hbar}(\mathfrak{g})$ with $\mathfrak{g}$ simple, assume that the evaluation-module construction gives a finite-PBW E_1 -chiral avatar, carries the associative quadratic twisting datum to the chiral datum by filtered quasi-isomorphisms of the finite quadratic comparison cones, and defines a representable chart functor that reflects the Shapovalov open locus. Assume also that the functor intertwines the two H_{GRT} cocycles. Then the framed finite PBW associative Koszulness moduli embeds as a GRT_1 -equivariant open subfunctor of the framed finite-stage chiral Koszulness moduli:

$$\mathcal{M}_{\text{Kosz}}^{\text{assoc}}(Y_{\hbar}) \hookrightarrow \mathcal{M}_{\text{Kosz}}^{\text{chiral}}(Y_{\hbar}).$$

At a fixed finite PBW stage and gauge framing this map is an open immersion of affine schemes. In the completed unframed setting it is the induced morphism of derived quotient stacks, provided the PBW tower is Mittag–Leffler. Chart-surjectivity remains open: it asks whether every chiral chart lifts a classical associative chart. A higher-rank chiral atlas would resolve this remaining comparison problem.

Proof. For $\Phi = \Phi_{\text{KZ}}$, the associative PBW chart U_1^{assoc} detects $Y_h(\mathfrak{g})$ -Koszulness in the classical Polishchuk–Positselski sense [?Positselski11], framed as a filtered-CDG-Koszul deformation of $U(\mathfrak{g}[t])$ with level-filtration-compatible nonhomogeneous relations. For all simple Lie algebras (classical types via Molev’s PBW [?Molev2007]; exceptional types E_6, E_7, E_8, F_4, G_2 via Guay–Regelskis–Wendlandt [?GRW18]) this chart is nonempty.

Transport the associative chart coordinate to the chiral setting through the assumed finite-PBW E_1 -chiral avatar (Definition ??, Chapter 27). The RTT data then defines the formal-disk chiral structure through the evaluation modules V_u , and the PBW filtration is compatible with the chiral bracket. The associative chart coordinate $(\Phi_{\text{KZ}}, c_{\text{KZ}}^{\text{assoc}})$ maps to the chiral chart coordinate $(\Phi_{\text{KZ}}, c_{\text{KZ}}^{\text{chiral}})$: the assumed comparison identifies their finite quadratic cones. Hence $\mathcal{M}_{\text{Kosz}}^{\text{assoc}}(Y_h) \hookrightarrow \mathcal{M}_{\text{Kosz}}^{\text{chiral}}(Y_h)$ is defined on framed finite PBW stages. Compatibility with the two H_{GRT} cocycles makes it GRT_1 -equivariant.

By the open-locus hypothesis, the associative chart U_1^{assoc} is the complement of the zero locus of the Shapovalov determinant, and its preimage in $\mathcal{M}_{\text{Kosz}}^{\text{chiral}}(Y_h)$ is the complement of the same zero locus, hence open. Passing to the completed unframed object is legitimate only under the Mittag–Leffler and PBW–Artin hypotheses stated in Theorem 16.2.3. $\square$

COROLLARY 16.4.4 (*Exceptional-type Yangian PBW input via GRW18*). Via Guay–Regelskis–Wendlandt [?GRW18], the Yangians $Y_h(E_6), Y_h(E_7), Y_h(E_8), Y_h(F_4), Y_h(G_2)$ admit PBW bases, closing the exceptional-type PBW input for the finite-stage comparison. The remaining inputs are an exceptional finite RTT/FRT packet, the finite-PBW chiral avatar, and the open-locus comparison hypotheses.

Remark 16.4.5 (*Associative versus chiral atlas for Yangians*). The comparison between associative and chiral Koszulness atlases for Yangians is additional structure. The moduli reformulation makes its scope precise at framed finite PBW stage: the associative atlas is an open subfunctor of the chiral atlas. The open question is surjectivity: every lifted chart belongs to the associative image, while genuinely chiral charts would form its complementary locus. For $\mathfrak{g} = \mathfrak{sl}_2$ the embedding is an isomorphism and the associative PBW data captures the full chiral Koszul datum (Theorem ??); for higher rank, chart-surjectivity is open and is the correct form of the associative–chiral comparison question.

16.5 META-KOSZULNESS: THE MODULI AS A KOSZUL OBJECT

Under H_{GRT} , the Koszulness carrier has a GRT_1 -action on framed admissible charts by (A3). Its differential gives an action of $\mathfrak{grt}_1$ by derivations on the tangent category. An E_2 -structure requires operations in every arity together with their chain-level coherence; the following problem isolates that additional construction.

Problem 16.5.1 (*Meta-Koszulness*). [Type signature: Open quadrant; finite framed tangent-category presentation; Beilinson levels $1 \leftrightarrow 2$; input packages $H_{\text{mod}}, H_{\text{chart}}$, and H_{GRT} ; required new datum: a chain-level $C_*(E_2)$ -action compatible with quadratic-cone comparisons.] Fix a finite PBW–Artin stage (N, m) and a gauge framing. The tangent dg category of admissible coordinates in $\mathcal{M}_{\text{Kosz}}^{N,m}(\mathcal{A})$ already carries the unary derivations induced by $\mathfrak{grt}_{1,\leq m}$. Construct an operad morphism

$$C_*(E_2) \longrightarrow \text{End}(\mathbb{T}\mathcal{M}_{\text{Kosz}}^{N,m}(\mathcal{A}))$$

whose unary infinitesimal symmetries recover this action, whose higher operations commute with $\alpha_{j,N,m}$ and $\gamma_{g,\Phi,N,m}$, and whose finite-stage operations assemble under derived Mittag–Leffler completion. Such a construction would give a pro- E_2 tangent category; the appropriate higher Deligne theorem would then give an E_3 -structure on its Hochschild derived centre. Willwacher’s identification $H^\circ(GC_2) \cong \mathbf{grt}_1$ [?Willwacher15] supplies the degree-zero graph-complex symmetry. The required operad morphism is the remaining chain-level obligation.

This target is the derived-centre specialization of Convention ?? and Theorem ?. The sought E_3 -object is the Hochschild derived centre of the tangent category; the chiral algebra, its bar coalgebra, its quadratic coalgebra, and its Verdier–Koszul dual retain the ambient categories specified by that canonical firewall.

Remark 16.5.2 (Meta-Koszulness and the chart count). The KZ-coordinate count overstates the generic-parameter standard landscape. The honest count there is seven intrinsic bidirectional equivalences plus a Barr–Beck–Lurie restatement, a Theorem H-conditional chiral Hochschild consequence, a perfectness-conditional Lagrangian criterion, and a one-directional $\mathcal{D}$ -module purity implication. The carrier separates the formal chart implication from the open higher-structure problem: each classical condition becomes a chart after its quadratic-cone comparison is supplied, and Problem 16.5.1 asks for the operadic action on the tangent category. Counting by proposed home associator produces the 10 KZ + 1 AT + 1 dR,B + 1 ell + 1 Kon = 14 chart decomposition of Theorem 16.3.1.

Remark 16.5.3 (Functor of points). The moduli object $\mathcal{M}_{\text{Kosz}}(\mathcal{A})$ is constructed as the derived functor of points (Φ, ξ, h_ξ) in Definition 16.2.2. Here ξ deforms $\kappa_{\mathcal{A}}$ and h_ξ trivialises $C_{\kappa_{\mathcal{A}}+\xi}^q$. Under H_{mod} , gauge framing and finite-stage perfectness produce the classical Fitting open of Theorem 16.2.3. The Kontsevich–Tamarkin transfer provides the operadic input to the additional package H_{GRT} .

16.6 CONSEQUENCES OF THE KOSZULNESS MODULI OBJECT

The Koszulness moduli object is the derived deformation carrier of the quadratic twisting datum. Its points are associator coordinates, deformations of $\kappa_{\mathcal{A}}$, and trivialisations of the quadratic comparison cone. Its consequences inherit the packages stated above.

First, the seven-core-plus-satellites split of the KZ presentation (seven intrinsic bidirectional equivalences; Barr–Beck–Lurie as a listed consequence; conditional factorization homology; Theorem H-conditional chiral Hochschild consequence; conditional Lagrangian criterion; one-directional $\mathcal{D}$ -module purity) resolves as a KZ-coordinate restriction: under H_{chart} , each of the fourteen characterisations is equivalent on its home coordinate to quadratic chiral Koszulness (Theorem 16.3.1).

Second, under $H_{\text{Vir,HB}}$, the Hodge–Betti comparison turns the strict Feigin–Fuchs mixed-Hodge resolution into a representation-theoretic proof of quadratic Virasoro Koszulness (Theorem 16.4.1).

Third, under the comparison hypotheses of Theorem 16.4.3, the associative Koszulness atlas of the Yangian $Y_h(\mathfrak{g})$ embeds as an open subfunctor of the framed finite-stage chiral atlas; Guay–Regelskis–Wendlandt [?GRW18] discharges exceptional-type PBW.

Under H_{GRT} , the Kontsevich–Tamarkin change of formality coordinate acts on the quadratic comparison cones and transports admissible charts. Problem 16.5.1 asks for the further $C_*(E_2)$ -action on the completed tangent category. The fourteen entries record the selected classical test list over the pro-unipotent associator torsor.

Remark 16.6.1 (Reading the atlas as the Koszul Reflection orbit). Under H_{chart} and H_{GRT} , the fourteen admissible characterisations of Theorem 16.3.1 present the quadratic comparison locus through fourteen

associator-coordinate windows. The shadow-class stratification $G \sqcup L \sqcup C \sqcup M \sqcup \text{FF}$ of property (A_5) is the partition of $\text{Kosz}(X)$ by computational complexity of the bracket on the chiral derived centre $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{A}) = CH^*(\mathcal{A}, \mathcal{A})$; the Climax (Chapter ??) packages the coordinate dependence into the universal Arnold connection and the universal ghost functor (Chapter 25). The Koszulness moduli object thereby organises the twelve listed conditions of Theorem 14.1.59 (Chapter 14) into seven intrinsic bidirectional comparisons and five consequences, conditional criteria, or one-directional tests attached to specific comparison hypotheses. The atlas preserves these logical statuses while recording their home-coordinate data.

16.7 SYNTHESIS

Remark 16.7.1 (Siegel-modular Koszul pair moduli). The K_3 base point has a Siegel modular comparison chart: the Pasol–Zagier 2013 universal Igusa form Φ_{10} on $\text{Sp}_4(\mathbb{Z}) \backslash \mathbb{H}_2$ records the denominator identity $\prod(1 - q^{r\alpha})^{c(r\alpha)} = \Phi_{10}$ for the bar object $\bar{B}^{\text{ch}}(\mathbf{H}_{\Delta_5})$ and the Verdier-dual object $(\mathbf{H}_{\Delta_5})^!$. This Siegel quotient is a finite Hodge-theoretic comparison locus on the K_3 component. Definition 16.2.2 supplies the derived carrier $\mathcal{M}_{\text{Kosz}}(\mathbf{H}_{\Delta_5})$; the Humbert divisor $H_1 \cup H_4$ is the discriminant of that comparison, and $[\Phi_{10}] \in H^2(\text{Sp}_4(\mathbb{Z}) \backslash \mathbb{H}_2)$ is its Siegel modular class [?PasolZagier2013, ?GritsenkoNikulin1998].

Remark 16.7.2 (Moduli stratification by Humbert type). The Siegel comparison locus stratifies by Humbert type. The H_1 -stratum, where a genus-2 curve splits as a product of elliptic curves, hosts the bi-based Ran restriction to $\text{Ran}(E_{24}^{\text{nod,sm}})$. The H_4 -stratum hosts the Kuga–Satake image of K_3 surfaces with Picard rank ≥ 17 (Shioda–Mitani). The open complement hosts the generic K_3 Hodge structure. The monodromy of $\mathcal{L}^{\Delta_5}$ around $H_1 \cup H_4$ is the Mukai–Humbert face of the $\mathbb{Z}/8$ -class $K^{\kappa_{\text{ch}}}$ [?Bruinier2002, ?KugaSatake1967]; its scope is the Hodge-theoretic K_3 comparison chart.

16.8 K_3 AT THE CLASS-M STRATUM

Remark 16.8.1 (K_3 chart placement on the Koszulness moduli object;). Under the constructibility hypotheses of Theorem 16.2.3(A_5), the shadow-class stratification of $\mathcal{M}_{\text{Kosz}}(\mathbf{H}_{\Delta_5})$ places the K_3 chiral bialgebra on the class-M stratum $\mathcal{M}_{\text{Kosz}}^{(\text{M})}(\mathbf{H}_{\Delta_5})$, with distinguished home chart U_{14} at Φ_{Kon} (Kontsevich integral). Apply the class-M Riccati criterion directly to the stress-tensor line of $\mathbf{H}_{\Delta_5}$ at $c_{2d} = -214$: it has modular characteristic $\kappa = c_{2d}/2 = -107$, cubic $\alpha = 2$, quartic $S_4 = 5/112 \cdot 136$, and Riccati polynomial $Q_{-214}(t) = (-214 + 6t)^2 + 80t^2/(5 \cdot (-214) + 22) = (6t - 214)^2 - 80t^2/1048$ with Riccati parameter $\Delta_{\text{Ricc}} = 40/(5c + 22) = -5/131$. The implication from this parameter to $r_{\text{max}} = \infty$ and the class-M placement is part of the assumed Riccati classification package. On the K_3 base point, the Kontsevich chart is admissible under H_{Kon} , namely after the weight-complete $\text{SC}^{\text{ch,top}}$ comparison complex for the derived-centre pair $(\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathbf{H}_{\Delta_5}), \mathbf{H}_{\Delta_5})$ is identified with the finite quadratic comparison cones as in Proposition 16.3.8. An $\mathcal{M}_{24}$ -equivariant refinement of the chord-diagram comparison is a further equivariance datum, motivated by the Cheng–Duncan–Harvey 2014 umbral-moonshine mock-modular shadows.

Remark 16.8.2 (GRT₁-transport of the K_3 central charge;). The central charge $c_{2d}(\mathcal{A}_1, \Sigma_{0,24}, \text{all max}) = -214$ is an intrinsic invariant of the K_3 algebra. The Beem–Rastelli relation $c_{2d}/c_{4d} = -12$ is the integral of the $6d$ anomaly polynomial (Vol II Remark ??), a topological characteristic class on $K_3 \times \Sigma_{0,24}$. The Under H_{GRT} , the cocycle of Theorem 16.2.3(A_3) changes the chart presentation of the shadow tower while preserving this numerical invariant: at Φ_{KZ} the shadow tower is read via PBW spectral sequence ($S_2 = -107, S_4 = 5/112 \cdot 136$); at Φ_{ell} via KZB genus-one R-matrix (Felder 1994 elliptic R-matrix at modular

parameter $\tau = i$); at Φ_{Kon} via chord-diagram expansion (the umbral-moonshine shadow). When the three chart comparison maps are supplied, their common value is the invariant of the same $\mathbf{H}_{\Delta_s}$ point.

Remark 16.8.3 (Humbert- H_1 monodromy as K_3 chart-compatibility data;). The triple-face identity $K^{\kappa_{\text{ch}}} = 2c_+(\text{Mukai}) = \text{ord}(\text{mon } H_1) = \ell_{\text{Lusztig}} = 8$ (the Vol III Humbert-monodromy computation) supplies a necessary compatibility condition for K_3 chart transitions. The holonomic $\mathcal{D}$ -module $\mathcal{L}^{\Delta_s}$ on $\overline{\mathcal{A}}_2$ has monodromy of order 8 around the Humbert divisor H_1 (Bruinier 2002, Proposition 5.1, Heegner Chern-class reciprocity), and this order-8 $\mathbb{Z}/8$ class in $\text{CH}^1(H_1)$ is the Hodge-theoretic boundary value that any transfer between the elliptic chart U_{13} and the Kontsevich chart U_{14} must respect. A Tamarkin transfer datum therefore includes a logarithmic/prounipotent comparison map from this finite monodromy class to the completed $\text{GRT}_1(\mathbb{Q})$ associator torsor. Under such a lift, the identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ with $\hbar^2 = -1/8$ gives the numerical boundary condition for the chart transition on the K_3 component.

THEOREM $\mathcal{A}$: BAR-COBAR RECONSTRUCTION AND VERDIER DUALITY

NOTATION, HYPOTHESES, AND LANE STRUCTURE

The full bar construction and the quadratic Koszul dual occupy two successive layers. For an augmented dg algebra A , the full tensor coalgebra $B(A) = T^c(s^{-1}\tilde{A})$ gives a functorial resolution

$$\varepsilon_A: \Omega B(A) \xrightarrow{\sim} A$$

for every A [?LV12, Corollary 2.3.4]. Under the quadratic Koszul package, the canonical comparison $A^i \rightarrow B(A)$ is a quasi-isomorphism; finite or continuous duality then produces $A^!$. Higher Massey operations occur as components of the full bar differential and measure the passage from the quadratic model to the full resolution.

On the Ran space there is a second distinction. Francis–Gaitsgory’s Proposition 4.1.2 gives bar–cobar equivalence for a reduced operad in any pro-nilpotent stable symmetric-monoidal category, while the pro-nilpotence argument in the proof of their Theorem 5.1.1 applies this result to the chiral category $D(\text{Ran } X)$ [?Francis2012]. Their factorization category is the full subcategory of chiral commutative coalgebras whose structure maps are equivalences [?Francis2012, Definition 2.4.7]. The published associative bar–cobar theorem lives in $D(\text{Ran } X)$. Its restriction to the associative factorization objects of this volume is the closure theorem named H_{fact} below.

The notation is fixed accordingly:

$$R_X(A) := \Omega_X B_X(A), \quad K_X(A) := \mathbb{D}_{\text{Ran}} B_X(A).$$

R_X denotes reconstruction by the full bar. K_X denotes Verdier-dualized Koszul duality on the stated dualizable domain. For a connected positive quadratic presentation $A = T_X(V)/(R)$, the five typed objects are

$$A, \quad B_X(A), \quad A^i = C_X(s^{-1}V, s^{-2}R), \quad K_X(A) = \mathbb{D}_{\text{Ran}} B_X(A), \quad Z_{\text{ch}}^{\text{der}}(A) = C_{\text{ch}}^{\bullet}(A, A).$$

The quadratic presentation carries its canonical twisting morphism

$$\tau_1: A^i \longrightarrow A.$$

Their comparison maps have distinct targets:

$$q_A: A^i \longrightarrow B_X(A), \quad \mathbb{D}(q_A): K_X(A) \longrightarrow \mathbb{D}_{\text{Ran}}(A^i), \quad \nu_A: K_X(A) \longrightarrow A^!$$

The first is quadratic recognition, the second is its Verdier-dual map, and the third is the chosen comparison with the strict quadratic partner. This chapter proves the ambient reconstruction, isolates the factorization closure theorem, and states the quadratic and Verdier refinements on their typed domains. The categorical level is $(\infty, 1)$; the factorization-enriched properadic transfer is governed by H_{prop} .

17.0.0.0.1 Ran ambient and four Theorem A packages. Let X be a separated finite-type scheme over a characteristic-zero field. Francis–Gaitsgory’s ambient datum is

$$C_X = (D(\mathrm{Ran} X), \otimes^{\mathrm{ch}}), \quad \mathcal{O} = \mathrm{Ass}_{\mathrm{red}}.$$

The proof of [?Francis2012, Theorem 5.1.1] makes C_X pro-nilpotent, and [?Francis2012, Proposition 4.1.2] then supplies enhanced bar–cobar equivalence for $\mathcal{O}$, with divided-power coalgebras on the coalgebra side. These are the published ambient data. Four packages govern the subsequent Theorem A transitions used in this volume.

H_{fact} *Factorization-restriction package.* The chosen associative factorization subcategories satisfy four closure conditions: enhanced bar and cobar preserve the factorization equivalences on every disjoint configuration locus; their collision maps satisfy base change along the diagonal stratification; units and completed inverse limits remain in the chosen subcategories; and a regular-singular ordered local system has Fulton–MacPherson nearby cycles compatible with the chiral collision product. The last clause is denoted H_{fact}^R when an R -matrix is present. These closure conditions form a conditional input of this volume.

H_{VD} *Verdier package.* $B_X(A)$ lies in a constructible or holonomic dualizable subcategory on which $\mathbb{D}_{\mathrm{Ran}}$ is defined and exchanges the relevant coalgebra and algebra structures. Every base-change and Künneth map used after duality belongs to this package. The properadic lane also includes a specified evaluation–coevaluation pair between A and $K_X(A)$ satisfying the two zig–zag identities.

H_{conv} *Convergence package.* The increasing bar-length filtration on the direct-sum bar is exhaustive; a completed algebra satisfies $A \simeq \varprojlim_q A/\bar{A}^q$; and a completed coalgebra has a pro-coradical presentation $C \simeq \varprojlim_q C_{\leq q}$ whose transition maps are cohomologically Mittag–Leffler in every input–output profile. These are three independent clauses, denoted respectively H_{len} , H_{aug} , and H_{ML} .

H_{prop} *Factorization-properad transfer package.* The factorization enrichment satisfies the monoid axiom, has cofibrant unit, admits connected-graph substitution, carries weak equivalences through the transfer functors, and preserves factorization descent. The full formulation appears in Theorem 17.4.4.

The quadratic comparison is the Theorem B interface and carries $H_{\mathrm{CL}}(A, \bar{A}^i, \tau_i)$ from Definition 14.1.5. Finite-weight models provide concrete instances of H_{VD} and H_{conv} . The universal full bar–cobar counit belongs to the published ambient theorem. Factorization closure, completed chain realization, quadratic compression, Verdier transport, and properadic transfer carry the five displayed packages. Weak curvature retains Positselski’s CDG definition as a separate structure.

17.0.0.0.2 Parametric strength taxonomy. Theorem A has three typed layers.

RECONSTRUCTION; . *Type signature:* (Open quadrant; chiral Ran presentation; Beilinson level $1 \leftrightarrow 2$; $(\infty, 1)$; pro-nilpotent ambient C_X ; reduced associative operad). Enhanced bar and cobar form mutually inverse equivalences for the reduced associative operad in $D(\mathrm{Ran} X)$ [?Francis2012, Proposition 4.1.2].

FACTORIZATION CLOSURE; . *Type signature:* (Open quadrant; associative factorization presentation; Beilinson level $1 \leftrightarrow 2$; pro-nilpotent ambient C_X ; package H_{fact}). The closure theorem restricts enhanced bar and cobar to the factorization subcategories used in this volume, including collision and completion data.

VERDIER REFINEMENT; . *Type signature:* (Open quadrant; quadratic and Verdier presentations; Beilinson level 2; packages $H_{\mathrm{CL}}(A, \bar{A}^i, \tau_i) \cup H_{\mathrm{VD}}$). The comparison $\bar{A}^i \rightarrow B_X(A)$ and Verdier duality identify the full bar model with the quadratic and dual models on this locus.

Thus $R_X = \Omega_X B_X$ is the reconstruction functor. The functor $K_X = \mathbb{D}_{\text{Ran}} B_X$ carries the Verdier–Koszul refinement; biduality supplies its involutive form on the dualizable locus.

17.0.0.0.3 Lane split: Priddy versus Positselski. Three constructions meet along explicit comparison morphisms.

FULL BAR LANE. The tensor coalgebra $B(A)$ and the counit $\Omega B(A) \xrightarrow{\sim} A$ give the functorial resolution [?LV12, Corollary 2.3.4]. Francis–Gaitsgory supply its enhanced form in the pro-nilpotent chiral Ran ambient.

QUADRATIC LANE. Under $H_{\text{CL}}(A, A^i, \tau_i)$, Priddy’s quadratic coalgebra A^i maps quasi-isomorphically to $B(A)$. The weight spectral sequence and its contracting homotopy prove this comparison.

ED COMPLETED LANE. For a weakly curved A_∞ -algebra over a complete local base, Positselski’s equivalence is formed after localization at semi-isomorphisms [?Positselski2018, Theorem 6.7.1]. A chiral factorization realization requires its own stratumwise assembly theorem and belongs to H_{fact} .

The maps $A^i \rightarrow B(A)$ and $B_X(A) \rightarrow \mathbb{D}_{\text{Ran}} \mathbb{D}_{\text{Ran}} B_X(A)$ organize the intersection of these lanes. Each archetype enters after its weight filtration, completion, and dualizability witnesses have been constructed.

17.0.0.0.4 Four lanes by categorical level. The categorical ledger has four levels:

- L1. *Chain level;* . For augmented dg algebras and conilpotent dg coalgebras, the unit and counit are quasi-isomorphisms [?LV12, Corollary 2.3.4]. The P_∞ form is [?LV12, Proposition 11.4.4].
- L2. *Ran $(\infty, 1)$ level;* . Proposition 4.1.2 of [?Francis2012], applied in the pro-nilpotent category $(D(\text{Ran } X), \otimes^{\text{ch}})$, gives the enhanced associative equivalence.
- L3. *Associative factorization level;* . The package H_{fact} is the closure theorem carrying the Ran equivalence to the factorization subcategories and their collision descent data.
- L4. *Properadic comparison level;* . Frontier A2 asks for an enriched factorization-properad model and a comparison functor from its operadic bar–cobar envelope. The presentation clause H_{HR} (Theorem 17.4.2, Conjectured) posits the model structure on simplicial properads which forms one input to that construction; the graphical-set homotopy theory of Hackney–Robertson–Yau [?HRY17] is its evidence.

Admission of an archetype to levels L3. and L4. is witnessed by explicit closure, completion, and descent morphisms. The finite-weight series of Lemma 17.1.8 supplies the locally finite bar-weight input in H_{conv} ; the separate quadratic acyclicity belongs to $H_{\text{CL}}(A, A^i, \tau_i)$.

17.0.0.0.5 Notion of E_1 -chiral algebra in use. Five constructions occur in the surrounding literature: (A) algebras for the reduced associative operad in $(D(\text{Ran } X), \otimes^{\text{ch}})$; (B) A_∞ -algebras in a chiral endomorphism operad; (C) Etingof–Kazhdan quantum vertex algebras; (D) associative factorization algebras; and (E) ordered-Ran factorization data. Theorem A begins with construction (A). Construction (D) enters through H_{fact} .

Each passage among (A)–(E) carries its own comparison morphism. An A_∞ enhancement is governed by the internal form of [?LV12, Proposition 11.4.4]. Quantized braided descent carries a Drinfeld associator and a unitary quantum R -datum. Ordered-to-Ran descent carries the collision-extension maps of H_{fact} . The bar object is a coalgebra over $\text{Bar}(\text{Ass})$. The Swiss–cheese action belongs to the subsequent center pair $(C_{\text{ch}}^\bullet(A, A), A)$ through its own center-level theorem.

Convention 17.0.1 (Ordered bar signs and desuspension;). The cohomological convention is $|d| = +1$ and $|s^{-1}a| = |a| - 1$. For homogeneous $a_i \in \bar{\mathcal{A}}$ the ordered bar coalgebra is

$$B_X^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$$

with deconcatenation coproduct. Its differential is the coderivation whose unary and binary projections are

$$b_1(s^{-1}a) = -s^{-1}(d_{\mathcal{A}}a), \quad b_2^{(r)}(s^{-1}a \otimes s^{-1}b) = (-1)^{|a|}s^{-1}(a_{(r)}b),$$

and whose action on the i -th adjacent pair carries the prefix sign

$$(-1)^{\sum_{q < i} (|a_q| - 1) + |a_i|}.$$

For an $\mathcal{A}_\infty$ -chiral algebra, the higher maps are extended by the same desuspended coderivation rule. With this convention $d_{B^{\text{ord}}}^2 = 0$ is precisely the desuspended Stasheff identity together with the Arnold relation on logarithmic collision forms. The symmetric bar inherits this sign convention through the R -twisted descent morphism of Lemma 17.6.2.

For a coaugmented dg coalgebra C with reduced coproduct $\bar{\Delta}c = \sum c_{(1)} \otimes c_{(2)}$, the compatible cobar construction is

$$\Omega(C) = T(s\bar{C}), \quad |sc| = |c| + 1.$$

On generators its differential is

$$d_\Omega(sc) = -s(d_Cc) - \sum (-1)^{|c_{(1)}|} (sc_{(1)})(sc_{(2)}).$$

The internal term and the coproduct term both have degree $+1$. Equivalently, the degree-one universal twisting map $\tau_C(c) = sc$ satisfies $d\tau_C + \tau_C \star \tau_C = 0$.

17.1 BAR-COBAR RECONSTRUCTION AND VERDIER DUALITY: UNIFIED THEOREM A

17.1.1 Ran reconstruction, factorization closure, and the quadratic-Verdier refinement

COMPUTATION 17.1.1 (The first square-zero algebra;). Let $A = k \oplus k\epsilon$ with augmentation $\epsilon \mapsto 0$ and $\epsilon^2 = 0$. Then

$$B(A) = T^c(s^{-1}k\epsilon).$$

Write $e_n = [\epsilon] \cdots [\epsilon]$ for the length- n bar word and $x_n := se_n$ for its cobar generator. Thus $|e_n| = -n$ and $|x_n| = 1 - n$. The bar differential vanishes, and the cobar differential is

$$dx_n = \sum_{i=1}^{n-1} (-1)^{\alpha_i} x_i x_{n-i},$$

with the sign α_i fixed by Convention 17.0.1. At fixed total length, every term on the right has degree $2 - n = |x_n| + 1$. At fixed total length n , a monomial $x_{n_1} \cdots x_{n_r}$ is indexed by the composition $n = n_1 + \cdots + n_r$, hence by a subset of the $n - 1$ possible internal cuts. The differential adds one cut. This identifies the total-length- n summand, for $n \geq 2$, with the augmented cochain complex of the $(n - 2)$ -simplex, equivalently with the Boolean cut complex. It is acyclic.

The total-length-0 and total-length-1 summands are generated by 1 and x_1 . The counit sends x_1 to ϵ and x_n to zero for $n \geq 2$; moreover $x_1^2 = dx_2$ up to the fixed sign. Hence

$$H^\bullet(\Omega B(A)) \cong k \oplus k\epsilon = A.$$

This calculation is the first nontrivial instance of the universal bar-cobar resolution.

THEOREM 17.1.2 (*Theorem A: associative bar–cobar reconstruction in the chiral Ran ambient*;). [Type signature: Open quadrant; chiral Ran presentation; Beilinson level $1 \leftrightarrow 2$; reduced associative operad; categorical level $(\infty, 1)$; pro-nilpotent Francis–Gaitsgory ambient C_X ; factorization package H_{fact} ; named hypothesis packages consisting of the completed chain package H_{conv} and the Verdier package H_{VD} . Clause (iv) carries the Theorem B package $H_{\text{CL}}(A, A^!, \tau_i)$.] Let X be a separated finite-type scheme over a field k of characteristic zero and set

$$C_X := (D(\text{Ran } X), \otimes^{\text{ch}}).$$

The following statements occupy successive domains.

- (i) *Enhanced Ran equivalence*; . For the reduced associative operad, enhanced bar and cobar give mutually inverse equivalences

$$\text{Bar}_{\text{Ass}}^{\text{enh}} : \text{Alg}_{\text{Ass}}(C_X) \xrightarrow{\sim} \text{CoAlg}_{\text{Bar}(\text{Ass})}^{\text{dp}}(C_X) : \text{Cobar}_{\text{Bar}(\text{Ass})}^{\text{enh}}.$$

- (ii) *Universal reconstruction*; . For augmented unital algebras, apply clause (i) to the nonunital augmentation ideal and then restore the unit. The unit and counit are equivalences; on chain models they specialize to

$$C \xrightarrow{\sim} B\Omega C, \quad \Omega B(A) \xrightarrow{\sim} A.$$

Under H_{conv} , these maps pass to the selected completed chain realizations through the exhaustive complete filtrations and cohomologically Mittag–Leffler inverse systems.

- (iii) *Factorization closure*; . Under H_{fact} , the equivalence in clause (i) restricts to the associative factorization subcategories of this volume. The resulting functors are denoted

$$\Omega_X^{\text{ch}} : \text{CoAlg}_X^{\text{fact,dp}} \rightleftarrows \text{Alg}_X^{\text{fact,aug}} : \tilde{B}_X^{\text{ch}}.$$

- (iv) *Quadratic compression*; . Under the Theorem B package $H_{\text{CL}}(A, A^!, \tau_i)$, the canonical morphism

$$A^i \longrightarrow B_X(A)$$

is a quasi-isomorphism. Equivalently, $\Omega_X(A^i) \rightarrow A$ is a quasi-isomorphism. Local finite dimensionality identifies the continuous dual of A^i with the quadratic Koszul-dual algebra $A^!$.

- (v) *Verdier refinement*; . Under H_{VD} , Verdier duality transports the bar coalgebra to the algebra

$$K_X(A) := \mathbb{D}_{\text{Ran}} B_X(A).$$

The biduality morphism identifies $B_X(A) \xrightarrow{\sim} \mathbb{D}_{\text{Ran}} K_X(A)$ on this domain. Together with clause (iv), this identifies $K_X(A)$ with the continuous Verdier realization of $A^!$.

Proof. Francis–Gaitsgory’s Proposition 4.1.2 gives enhanced operadic bar–cobar equivalence in every pro-nilpotent stable symmetric-monoidal ∞ -category. Their proof of Theorem 5.1.1 establishes pro-nilpotence of $(D(\text{Ran } X), \otimes^{\text{ch}})$. Applying the proposition to the reduced associative operad proves clause (i).

Augmented unital algebras correspond to nonunital augmentation ideals together with re-unitalization. The equivalence of clause (i) therefore carries its unit and counit to the maps in clause (ii). On ordinary dg chain models this is the bar–cobar adjunction of [?LV12, Theorem 2.2.9] and the unit–counit quasi-isomorphism of [?LV12, Corollary 2.3.4].

The closure morphisms collected in H_{fact} make enhanced bar and cobar preserve the factorization equivalences on every disjoint locus and their extensions across collision strata. Hence the ambient equivalence restricts as stated in clause (iii).

Under $H_{\text{CL}}(A, A^!, \tau_i)$, the universal twisting morphism $A^i \rightarrow A$ is Koszul. The twisting-morphism fundamental theorem [?LV12, Theorem 2.3.2] identifies this condition with either $A^i \rightarrow B(A)$ or $\Omega(A^i) \rightarrow A$ being a quasi-isomorphism. This proves clause (iv).

Finally, H_{VD} supplies a dualizable bar object and the monoidal Verdier comparison maps. Verdier duality transports its coalgebra structure to $K_X(A)$, and Verdier biduality gives the displayed equivalence in clause (v). $\square$

17.1.2 The single diagram and the single equation

The ambient equivalence is captured by one diagram:

$$\text{CoAlg}_{\mathfrak{S}\text{Bar}(\text{Ass})}^{\text{dp}}(C_X) \begin{array}{c} \xrightarrow{\text{Cobar}^{\text{enh}}} \\ \tau \\ \xleftarrow{\text{Bar}^{\text{enh}}} \end{array} \text{Alg}_{\mathfrak{S}\text{Ass}}(C_X) \quad C_X = (D(\text{Ran } X), \otimes^{\text{ch}}).$$

Its two equations are

$$\boxed{\text{Cobar}^{\text{enh}} \text{Bar}^{\text{enh}} \simeq \text{id}_{\text{Alg}}, \quad \text{Bar}^{\text{enh}} \text{Cobar}^{\text{enh}} \simeq \text{id}_{\text{CoAlg}^{\text{dp}}}.}$$

Under H_{fact} the same equations restrict to Ω_X^{ch} and $\tilde{B}_X^{\text{ch}}$ on the associative factorization subcategories.

Remark 17.1.3 (Reconstruction and duality are separate operations). Two functors leave the bar object in different directions. The counit $\Omega_X^{\text{ch}} \tilde{B}_X^{\text{ch}}(A) \rightarrow A$ gives reconstruction. Verdier duality gives the Koszul-dual lane $K_X(A) = \mathbb{D}_{\text{Ran}} \tilde{B}_X^{\text{ch}}(A)$. Their codomains and hypothesis packages determine their respective type signatures.

COROLLARY 17.1.4 (*Typed comparison of reconstruction and Verdier duality;*). Type signature: (Open quadrant, reconstruction/Verdier comparison lane, Beilinson level $1 \leftrightarrow 2$, pro-nilpotent chiral Ran ambient; packages $H_{\text{fact}} \cup H_{\text{VD}}$). Let A lie in the factorization and Verdier domains of Theorem 17.1.2. Reconstruction and Verdier duality give

$$\varepsilon_A: R_X(A) = \Omega_X^{\text{ch}} \tilde{B}_X^{\text{ch}}(A) \xrightarrow{\sim} A, \quad K_X(A) = \mathbb{D}_{\text{Ran}} \tilde{B}_X^{\text{ch}}(A).$$

Composition with ε_A induces an equivalence of mapping spaces

$$\text{Map}(A, K_X(A)) \xrightarrow{\sim} \text{Map}(R_X(A), K_X(A)).$$

Hence an equivalence $R_X(A) \simeq K_X(A)$ is precisely the composite of reconstruction with a self-duality equivalence

$$\sigma_A: A \xrightarrow{\sim} K_X(A).$$

Under $H_{\text{CL}}(A, A^!, \tau_i)$ and local finite duality, the target $K_X(A)$ identifies with the continuous realization of $A^!$. A strict model is obtained from a specified formality equivalence $K_X(A) \simeq A^!$.

Proof. The morphism ε_A is an equivalence by Theorem 17.1.2(ii). Precomposition with an equivalence induces an equivalence of mapping spaces. Under this equivalence, σ_A corresponds to $\sigma_A \circ \varepsilon_A$. Clauses (iv) and (v) supply the quadratic and Verdier identifications of the target. $\square$

Remark 17.1.5 (Four named morphisms in Theorem A). Four canonical morphisms organize the theorem:

- $\eta_C: C \xrightarrow{\sim} B\Omega(C)$ is the coalgebra-side unit in the Ran ambient;
- $\varepsilon_A: \Omega B(A) \xrightarrow{\sim} A$ is the algebra-side counit in the Ran ambient;
- $q_A: A^i \rightarrow B(A)$ is the quadratic comparison under $H_{\text{CL}}(A, A^i, \tau_i)$;
- $\delta_{B(A)}: B(A) \xrightarrow{\sim} \mathbb{D}_{\text{Ran}} \mathbb{D}_{\text{Ran}} B(A)$ is Verdier biduality under H_{VD} .

The factorization closure package transports these morphisms to the factorization subcategories.

PROPOSITION 17.1.6 (*Module transport along the bar–cobar counit;*). Let $A \in \text{Alg}_{\text{Ass}}(C_X)$ and put $R_X(A) = \text{Cobar}^{\text{enh}} \text{Bar}^{\text{enh}}(A)$. Extension and restriction along the counit give mutually inverse equivalences

$$\text{Mod}_{R_X(A)}(C_X) \simeq \text{Mod}_A(C_X).$$

Under H_{fact} this equivalence restricts to the factorization-module categories. Under a self-duality equivalence $\sigma_A: A \xrightarrow{\sim} K_X(A)$ it further gives

$$\text{Mod}_{R_X(A)}^{\text{fact}} \simeq \text{Mod}_A^{\text{fact}} \simeq \text{Mod}_{K_X(A)}^{\text{fact}}.$$

Proof. The counit is an equivalence by Theorem 17.1.2(ii). The functoriality of module objects carries an equivalence of associative algebras to an equivalence of their module categories. The packages H_{fact} and σ_A supply the two displayed restrictions and transports. $\square$

Remark 17.1.7 (Operadic levels of the bar object and the center pair). The bar object $\bar{B}_X^{\text{ch}}(A)$ is a coalgebra over $\text{Bar}(\text{Ass})$, with deconcatenation coproduct and degree-1 bar differential. The derived center pair $(C_{\text{ch}}^\bullet(A, A), A)$ carries its brace structure at the next operadic level. A Swiss–cheese action on this pair is supplied by the corresponding open–closed center theorem. Thus the bar object serves as the level-2 resolution and the center pair as the level-3 open–closed object.

17.1.3 Locally finite positive weights and bar finiteness

Positive weight bounds the tensor length contributing to a fixed bar weight. This elementary observation is the complete finiteness input needed here.

For the square-zero algebra of Computation 17.1.1, assign weight 1 to ϵ . Its length- p bar word has total weight p , so the weight- w reduced bar is the one-dimensional span of e_w . The general statement replaces this single word by a finite sum over compositions of w .

LEMMA 17.1.8 (*Positive local finiteness passes to the reduced bar;*). [Type signature: Open quadrant; weight-graded chain presentation; Beilinson level 2; hypothesis package: augmentation, positive weight, and finite-dimensional weight fibers.] Let $A = k\mathbf{1} \oplus \bar{A}$ be an augmented dg algebra and suppose

$$\bar{A} = \bigoplus_{w \geq w_0} \bar{A}_w, \quad w_0 \geq 1, \quad \dim_k \bar{A}_w < \infty.$$

Assume that d_A has weight zero and that multiplication has additive weight. Then the reduced bar $\bar{B}(A) = \bigoplus_{p \geq 1} (s^{-1} \bar{A})^{\otimes p}$ is graded by total weight, its differential preserves that grading, and every weight space $\bar{B}(A)_w$ is finite-dimensional. Writing $d_w = \dim_k \bar{A}_w$ and $P_A(q) = \sum_{w \geq w_0} d_w q^w$, one has

$$\dim_k \bar{B}(A)_w = \sum_{p \geq 1} \sum_{w_1 + \dots + w_p = w, w_i \geq w_0} d_{w_1} \cdots d_{w_p} = [q^w] \frac{P_A(q)}{1 - P_A(q)}.$$

The same conclusion holds for a weight-graded factorization algebra after application of any exact weight-preserving symmetric-monoidal fiber functor to $\text{Ch}(k)$.

Proof. Every tensor in total weight w has length $p \leq \lfloor w/w_o \rfloor$. For fixed p , the set of compositions $w = w_1 + \cdots + w_p$ with $w_i \geq w_o$ is finite. Each corresponding tensor product $\bar{A}_{w_1} \otimes \cdots \otimes \bar{A}_{w_p}$ is finite-dimensional, so their finite direct sum is finite-dimensional. The internal differential preserves every w_i , while the multiplication term replaces adjacent weights w_i, w_{i+1} by $w_i + w_{i+1}$; hence the bar differential preserves total weight. Summing over tensor length gives $\sum_{p \geq 1} P_A(q)^p = P_A(q)/(1 - P_A(q))$. An exact fiber functor preserves the displayed direct sums, tensor products, and differential. $\square$

Remark 17.1.9 (Weight and length filtrations). The length- p summand is $(s^{-1}\bar{A})^{\otimes p}$ and may carry infinitely many total weights. The weight- w summand receives contributions from the finite range $1 \leq p \leq \lfloor w/w_o \rfloor$. Thus the direct-sum length filtration supplies H_{len} , while the positive grading and finite-dimensional fibers supply finite bar-weight pieces. Augmentation completeness and Koszul acyclicity remain the separate maps in H_{aug} and $H_{\text{CL}}(A, A^i, \tau_i)$.

Remark 17.1.10 (Class-M completion problem;). Let A be a positive-energy Virasoro or principal $\mathcal{W}_N$ factorization model with finite-dimensional weight fibers. The weight-completed object is

$$\widehat{A}^{\text{wt}} = \varprojlim_N A/A_{\geq N} \in \text{Alg}_X^{\text{fact, aug, comp}},$$

while augmentation completion is

$$\widehat{A}^I = \varprojlim_q A/\bar{A}^q.$$

The class-M application of Theorem A requires an explicit cofinal comparison $\gamma_A: \widehat{A}^I \xrightarrow{\sim} \widehat{A}^{\text{wt}}$, the equivalence $A \xrightarrow{\sim} \widehat{A}^I$ of H_{aug} , the pro-coradical Mittag-Leffler maps of H_{ML} , and the acyclicity of $A \otimes_{\tau_i} A^i$ from $H_{\text{CL}}(A, A^i, \tau_i)$.

Remark 17.1.11 (Five conditional applications;). Lemma 17.1.8 applies to a family after its augmentation, positive grading, and finite-dimensional weight fibers have been constructed. The full Ran, factorization, completion, quadratic, and duality application lies in the pro-nilpotent chiral Ran ambient and uses $H_{\text{fact}}, H_{\text{aug}}, H_{\text{ML}}, H_{\text{CL}}(A, A^i, \tau_i)$, and H_{VD} . For the five named families the remaining inputs are these:

- G. For a Heisenberg or free-field presentation, construct the vacuum augmentation as a factorization morphism and the quadratic twisting complex $A \otimes_{\tau_i} A^i$. Its positive-weight acyclicity and the completion maps give the G application.
- L. For $V_k(\mathfrak{g})$, construct the factorization bar at the chosen level, the cofinal map from augmentation completion to the chosen level/weight completion, and a contraction of $A \otimes_{\tau_i} A^i$. At $k = -h^\vee$ the corresponding statement uses a separately specified completed resolution together with its maps ι_A, p_A, h_A .
- C. For $\beta\gamma_\lambda$, choose a charge sector whose conformal weights are bounded below and finite-dimensional, then construct the factorization collision maps and the quadratic twisting contraction on that sector.
- M. For Virasoro and principal $\mathcal{W}_N$, supply the comparison γ_A of Remark 17.1.10, the pro-coradical Mittag-Leffler tower, and a chain map from the relevant Felder or BRST resolution to $A \otimes_{\tau_i} A^i$ carrying its contraction.

- B. For a Mukai/Hall presentation, choose a positive-energy cone or charge truncation with finite-dimensional weight fibers, construct its factorization multiplication and augmentation, and give the quadratic twisting contraction in that completed sector.

Each item is a concrete input list for Theorem 17.1.2(iii)–(v).

17.1.4 Rescaling a deformation retract

A scalar rescales a deformation retract by an elementary identity. Its identification with a trace or conductor requires a family-level chain comparison.

Convention 17.1.12 (Scalar invariant and chain-level rescaling). The algebra-level scalar invariant is

$$K^\kappa(\mathcal{A}) := \kappa(\mathcal{A}) + \kappa(\mathcal{A}^\dagger).$$

It is defined from the chosen scalar theory on a Verdier–Koszul pair. A chain-level rescaling is a separate datum: for a deformation retract (ι_A, p_A, h_A) of a complex (C_A, d_A) , it is a scalar $\nu_A \in k$ occurring in the identity

$$d_A h_A + h_A d_A = \nu_A (\text{id}_{C_A} - \iota_A p_A).$$

A chain map relating the contraction to the scalar trace promotes this datum to the theorem $\nu_A = K^\kappa(A)$.

PROPOSITION 17.1.13 (*Rescaling identity for a deformation retract;*). [Type signature: chain presentation; deformation-retract level; hypothesis package: a scaled homotopy identity with invertible scalar.] Let (C, d) and (H, d_H) be complexes, let $\iota: H \rightarrow C$ and $p: C \rightarrow H$ be chain maps with $p\iota = \text{id}_H$, and let $h: C \rightarrow C[-1]$. Suppose that $\nu \in k^\times$ and

$$dh + hd = \nu(\text{id}_C - \iota p).$$

Then $\tilde{h} = \nu^{-1}h$ satisfies

$$d\tilde{h} + \tilde{h}d = \text{id}_C - \iota p.$$

The side conditions $h\iota = 0$, $ph = 0$, and $h^2 = 0$ pass to $\tilde{h}$. Conversely, every contracting homotopy h_0 gives a scaled identity with $h = \nu h_0$.

Proof. Scalar linearity gives

$$d(\nu^{-1}h) + (\nu^{-1}h)d = \nu^{-1}(dh + hd) = \text{id}_C - \iota p.$$

Multiplication by ν^{-1} preserves the three side conditions. Starting from $dh_0 + h_0d = \text{id}_C - \iota p$ and setting $h = \nu h_0$ gives the converse identity. $\square$

Remark 17.1.14 (*Family comparison problems for scalar rescaling;*). For a family F , put $C_F = \Omega_X^{\text{ch}} \tilde{B}_X^{\text{ch}}(A_F)$ and $p_F = \varepsilon_{A_F}$. A proposed scalar ν_F becomes a chain-level rescaling after constructing a chain map $\iota_F: A_F \rightarrow C_F$ and an operator $h_F: C_F \rightarrow C_F[-1]$ satisfying

$$p_F \iota_F = \text{id}_{A_F}, \quad d_F h_F + h_F d_F = \nu_F (\text{id}_{C_F} - \iota_F p_F).$$

The five scalar expressions lead to five separate construction problems.

G: $\nu_G = 1$. Construct ι_G and h_G on the actual factorization bar–cobar complex from the Fock/Koszul resolution.

L: $\nu_L = 2(k + h^\vee)$. Localize the level-parameter ring at $k + h^\vee$. Construct a chain map from the chosen Garland–Lepowsky or Sugawara resolution to C_L , together with ι_L and h_L satisfying the displayed scaled identity.

C: $\nu_C = 1$. On the selected finite charge sector, construct the chain map from the free $\beta\gamma$ Koszul resolution to C_C and transport its deformation retract.

M: $\nu_M = c(5c + 22)/10$. Localize the central-charge parameter ring at ν_M . Construct a chain map from the Felder/BRST resolution to C_M and operators ι_M, h_M satisfying the scaled identity.

B: $\nu_B = 8$. Construct a chain map from the completed Mukai/Hall resolution to C_B and operators ι_B, h_B satisfying the scaled identity.

An equality $\nu_F = K^\kappa(A_F)$ consists additionally of the chain map in Convention 17.1.12 comparing the contraction datum with the scalar trace complex.

Remark 17.1.15 (The chain comparison required between Theorems A, C, and D). Let (C_A, d_A) be the complex used in Theorem A. A scalar $\nu_A \in k^\times$ rescales a homotopy after one has constructed maps ι_A, p_A and an operator h_A such that

$$d_A h_A + h_A d_A = \nu_A (\text{id}_{C_A} - \iota_A p_A).$$

Then $\nu_A^{-1} h_A$ gives the corresponding contraction. A relation with Theorems C and D therefore requires an explicit chain map that identifies ν_A with the scalar invariant occurring in the census or Hodge obstruction. The five family expressions $\{1, 2(k + h^\vee), 1, c(5c + 22)/10, 8\}$ define candidate values for ν_A ; the construction of this chain map is the comparison problem linking the three theorems.

17.2 THE EIGHT STANDARD FACETS OF THEOREM A

The eight standard facets of Theorem A are recovered as corollaries of the unified Koszul reflection Theorem 17.1.2.

COROLLARY 17.2.1 (*Twisting morphism $\tau: \tilde{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ is a Maurer–Cartan element;*). The universal twisting morphism $\tau: \tilde{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ associated to the algebra-side counit $\psi_{\mathcal{A}}: \Omega_X^{\text{ch}} \tilde{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ of the Koszul reflection is a Maurer–Cartan element of the convolution L_∞ -algebra $\mathfrak{g}_{\mathcal{A}}^{\text{Ei}} = \text{Hom}_X^{\text{fact}}(\tilde{B}_X^{\text{ch}}(\mathcal{A}), \mathcal{A})$:

$$d\tau + \frac{1}{2}[\tau, \tau] = 0.$$

Proof. By Theorem 17.1.2(i), the counit of the adjunction $\Omega_X^{\text{ch}} \dashv \tilde{B}_X^{\text{ch}}$ encodes, by adjunction, the universal twisting morphism $\tau: \tilde{B}_X^{\text{ch}}(\mathcal{A}) \rightarrow \mathcal{A}$ (LV12 Theorem 2.2.9 specialised to the chiral ambient). The Maurer–Cartan condition $d\tau + \frac{1}{2}[\tau, \tau] = 0$ is exactly the compatibility between the bar differential on $\tilde{B}_X^{\text{ch}}(\mathcal{A})$ and the multiplication on $\mathcal{A}$, which is the chain-level statement that $\psi_{\mathcal{A}}$ is a chain map. $\square$

COROLLARY 17.2.2 (*Universal reconstruction in the enhanced Ran ambient;*). [Type signature: Open quadrant; enhanced associative Ran presentation; Beilinson levels ($1 \leftrightarrow 2$); *pro* – *nilpotent Francis* – *Gaitsgory ambient*; *reduced associative operad*.] *Forever augmented algebra* $A \in \text{Alg}_{\text{mathsf{Ass}}}^{\text{aug}}(D(\text{Ran } X), \otimes^{\text{ch}})$, the enhanced counit

$$\varepsilon_{\mathcal{A}}: \Omega_X^{\text{enh}} B_X^{\text{enh}}(\mathcal{A}) \xrightarrow{\sim} \mathcal{A}$$

is an equivalence.

Proof. This is Theorem 17.1.2(ii), obtained by applying Francis–Gaitsgory’s pro-nilpotent enhanced bar–cobar equivalence to the augmentation ideal and restoring the unit. $\square$

Remark 17.2.3 (Factorization and chain realizations). Under (H_{fact}) , the displayed equivalence restricts to the chosen factorization isomorphism. Quadratic Koszulness is the further comparison $(q_{\mathcal{A}}: \mathcal{A}^i \rightarrow B_X(\mathcal{A}))$ of Theorem 17.1.2(iv).

COROLLARY 17.2.4 (*Unit weak equivalence on $\text{Conil}(X)$; $\cdot$*). For $C \in \text{CoAlg}_X^{\text{fact, conil, co}}$ on the conilpotent locus, the unit $\eta_C: C \rightarrow \bar{B}_X^{\text{ch}} \Omega_X^{\text{ch}}(C)$ is a chain-level weak equivalence.

Proof. Filter C by the coradical filtration. The associated graded of $\bar{B}_X^{\text{ch}} \Omega_X^{\text{ch}}(C)$ is the classical bar construction on the free algebra generated by the graded pieces of C , and the map $\text{gr } \eta_C$ is the unit of the acyclic twisting morphism for $(\text{Ass}, \text{Ass}^!)$ [?LV12, Theorem 2.4.1]. Conilpotence makes the filtration exhaustive, completeness makes it separated, and H_{ML} gives Mittag–Leffler convergence weight-by-weight. Hence the filtered cone of η_C is acyclic, so the unit is a chain-level weak equivalence on the conilpotent-complete locus. $\square$

COROLLARY 17.2.5 (*Twisted tensor acyclicity; $\cdot$*). For $\mathcal{A} \in \text{Kosz}(X)$, the twisted tensor complex $\bar{B}_X^{\text{ch}}(\mathcal{A}) \otimes^{\tau} \mathcal{A}$ associated to the canonical twisting morphism τ of Corollary 17.2.1 is acyclic, with augmentation supplying the chain-level quasi-isomorphism

$$\bar{B}_X^{\text{ch}}(\mathcal{A}) \otimes^{\tau} \mathcal{A} \xrightarrow{\sim} k.$$

Proof. The twisted tensor complex computes $\text{Tor}_*^{\Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A})}(k, k)$ via the bar resolution; under Corollary 17.2.2, $\Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}$, so the Tor reduces to $\text{Tor}_*^{\mathcal{A}}(k, k) = H_*(\bar{B}_X^{\text{ch}}(\mathcal{A}))$, which by definition of $\text{Kosz}(X)$ is concentrated in bar degree 0 at the augmentation. The augmentation map then realises the twisted tensor complex as the augmentation chain complex, which is acyclic ([?LV12, Theorem 2.4] specialised to the chiral ambient). $\square$

COROLLARY 17.2.6 (*Bar concentrated in weight 1 at $g = 0$ on class G ; $\cdot$*). For $\mathcal{A}$ in class G (PBW E_2 -collapse class), lying in the genus-zero finite-type PBW window of Definition 18.1.1, $\bar{B}_X^{\text{ch}}(\mathcal{A})$ has cohomology concentrated in bar weight 1:

$$H^*(\bar{B}_X^{\text{ch}}(\mathcal{A})) = H^1(\bar{B}_X^{\text{ch}}(\mathcal{A})) \text{ [shifted]} \quad H^i(\bar{B}_X^{\text{ch}}(\mathcal{A})) = 0 \text{ for } i \neq 1.$$

At $g \geq 1$, weight-1 concentration occupies the class G locus. In classes L, C, M , the fiberwise curvature $d_{\text{fib}}^2 = \kappa \cdot \omega_g$ produces the higher-weight terms.

Proof. By Theorem 17.1.2(ii), reconstruction on $\text{Kosz}(X)$ is equivalent (via the PBW spectral sequence of the bar filtration) to the E_2 -collapse of the bar–cobar spectral sequence at E_2 -page. On the genus-zero finite-type PBW window of Definition 18.1.1 -- and only there -- the E_2 -collapse is exactly the hub-and-spoke TFAE of Theorem 18.3.1, which gives bar concentration in weight 1 at $g = 0$ for any class $\mathcal{A} \in \text{Kosz}(X)$ lying in that window; E_2 -collapse outside the window is not delivered by that theorem and is an open problem. At $g \geq 1$, the fiberwise differential $d_{\text{fib}}^2 = \kappa \cdot \omega_g$ identifies weight-1 concentration with the zero-curvature locus $\kappa = 0$, namely class G . $\square$

COROLLARY 17.2.7 (*SC-formality criterion on class G;*). For $\mathcal{A}$ in class G lying in the genus-zero finite-type PBW window of Definition 18.1.1, the convolution L_∞ -algebra $\mathfrak{g}_{\mathcal{A}}^{\text{E}_1} = \text{Hom}_X^{\text{fact}}(\bar{B}_X^{\text{ch}}(\mathcal{A}), \mathcal{A})$ is SC-formal: all higher Stasheff–Massey operations m_k for $k \geq 3$ vanish on cohomology, and the A_∞ -quasi-isomorphism inverting $\varepsilon_{\mathcal{A}}$ collapses to a strict isomorphism. In classes L, C, M , the higher operations realize the shadow-tower invariants S_k and retain the A_∞ deformation.

Proof. By Theorem 17.1.2(ii), SC-formality is equivalent to a strict isomorphism realizing the chain-level equivalence $\Omega_X^{\text{ch}} \bar{B}_X^{\text{ch}}(\mathcal{A}) \simeq \mathcal{A}$. The shadow tower S_k measures the A_∞ -corrections to $\varepsilon_{\mathcal{A}}$; vanishing of S_k for $k \geq 3$ is the PBW-collapse-to-strict criterion, which by the hub-and-spoke TFAE (Theorem 18.3.1, spoke 7, valid on the genus-zero finite-type PBW window of Definition 18.1.1) is the class G condition exactly on that window. $\square$

COROLLARY 17.2.8 (*R-twisted Σ_n -descent (unitary R) $\bar{B}^\Sigma(\mathcal{A}) \simeq B^{\text{ord}}(\mathcal{A})^{R-\Sigma_n}$;*). For $\mathcal{A}$ an E_1 -chiral algebra with meromorphic quantum R -matrix $R(z)$, with checked braiding $\check{R}(z) = \tau \circ R(z)$, satisfying the quantum Yang–Baxter equation (Lemma 17.6.2 (R1)) and unitarity $R^{21}(-z)R^{12}(z) = \text{id}$ (Lemma 17.6.2 (R2)), the restriction of $\bar{B}_n^\Sigma(\mathcal{A})$ to $C_n(X)$ is the R -twisted descent of the ordered bar along the principal torsor $\pi_n^\circ: C_n^{\text{ord}}(X) \rightarrow C_n(X)$. Under H_{fact}^R this descent extends to the cardinality- n Ran stratum and gives

$$\bar{B}_n^\Sigma(\mathcal{A}) \simeq (B_n^{\text{ord}}(\mathcal{A}))^{\Sigma_n\text{-coinv}, L_R\text{-twisted}}.$$

Proof. Lemma 17.6.2 constructs the equivariant local system and proves descent on the open torsor. The clause H_{fact}^R supplies the compatible nearby-cycle extension. $\square$

COROLLARY 17.2.9 (*Conditional properadic envelope of the Ran equivalence;*). Assume H_{fact} , H_{conv} , and H_{prop} . The enhanced bar–cobar equivalence of Theorem 17.1.2(i) extends by connected-graph substitution to a derived adjoint equivalence

$$\bar{B}_X^{\text{ch}} : \text{FactProp}_{\langle \text{Ass}^{\text{ch}} \rangle}^{\text{aug}}(X) \rightleftarrows \text{CoFactProp}_{\langle \text{Ass}^{\text{ch}} \rangle}^{\text{conil, comp}}(X) : \Omega_X^{\text{ch}}$$

on the conilpotent-complete properadic envelope generated by the chiral associative bar–cobar pair. Pull-back to a marked point recovers the ordinary associative bar–cobar equivalence [?LV12, Corollary 2.3.4].

Proof. Detailed proof in §17.5 as Theorem 17.5.1. $\square$

These eight corollaries, taken together, account for the theorem content of the standard Theorem A facets. The unified reconstruction theorem Theorem 17.1.2 is the source of these facets; each facet specialises to a single facet of the adjunction, reconstruction counit, or Verdier-dualized Koszul-duality functor.

17.3 FRANCIS–GAITSGORY FACTORIZATION AMBIENT

Francis–Gaitsgory place enhanced operadic bar and cobar in the stable presentable symmetric-monoidal category $(D(\text{Ran } X), \otimes^{\text{ch}})$. The factorization restriction selects the coalgebras whose disjoint-locus structure maps are equivalences. The conditional packages below record the additional closure and model-categorical input needed for internal properads and completed inverse limits. Ordered descent begins on the principal Σ_n -cover of the open configuration locus; its collision extension is the clause H_{fact}^R .

Let X be a smooth curve over a field k of characteristic 0. Write $\text{Ran}(X)$ for the Ran space of X (the colimit of finite powers X^n along surjective finite-order maps), and $\text{Ran}^{\text{ord}}(X)$ for the ordered Ran space (the same colimit taken over strictly increasing index maps on labelled finite sets).

Definition 17.3.1 (Ran factorization ambient;). The *Ran factorization ambient* has sheaf-level base

$$\text{Fact}_{\text{Ran}}(X) = \text{Alg}^{\text{fact}}(\text{Shv}^{\text{DR}}(\text{Ran}(X)))$$

of factorization algebras on $\text{Ran}(X)$ valued in de Rham sheaves, with monoidal operation given by the Francis–Gaitsgory chiral product [?Francis2012]. Throughout this chapter $\text{Fact}(X)$ denotes a chosen symmetric-monoidal model enhancement satisfying $H_{\text{Fact}}(X)$ of Proposition 17.3.3.

Remark 17.3.2 (Monoidal factorization realization). The Beilinson–Drinfeld chiral pseudo-tensor structure on $D\text{-mod}(X)$ defines a sequence of multilinear operations

$$\otimes_I^{\text{ch}} : \prod_{i \in I} D\text{-mod}(X) \rightarrow D\text{-mod}(X), \quad |I| < \infty,$$

indexed by finite sets I [?BD04, §3.4]. Its Ran realization is the chiral symmetric-monoidal structure of Francis–Gaitsgory. The unit and the disjoint-union product are encoded by the factorization structure, and $H_{\text{Fact}}(X)$ chooses a model presentation on which ordinary enriched transfer arguments may be applied.

PROPOSITION 17.3.3 (Conditional factorization ambient package;). Let $\text{Fact}(X)$ be the enhancement named in Definition 17.3.1. The hypothesis package $H_{\text{Fact}}(X)$ consists of the following clauses.

- (a) The Ran sheaf ambient $\text{Shv}^{\text{DR}}(\text{Ran}(X))$ is stable and presentable, and $\text{Fact}_{\text{Ran}}(X)$ is the factorization-algebra lane on that ambient.
- (b) The Francis–Gaitsgory star-product extends to a colimit-compatible symmetric monoidal operation on the chosen enhancement.
- (c) The factorization unit, represented sheaf-theoretically by the constant factorization algebra on $\mathcal{O}_X$, gives a strict unit in the enhancement; the Beilinson–Drinfeld chiral unit maps to this unit by the sheafified factorization comparison. The two units belong to the pseudo-tensor and factorization presentations, respectively.
- (d) The model enhancement is cofibrantly generated and supports the enriched collections from which internal operads and properads are formed.

Under $H_{\text{Fact}}(X)$, the uses of $\text{Fact}(X)$ in Theorem 17.5.1 are stable, presentable, symmetric monoidal, and compatible with colimits in each variable.

Proof. The de Rham sheaf ambient is stable and presentable in the GR formalism [?GR17, Chapter I.3]; Francis–Gaitsgory construct the chiral monoidal operation on $D(\text{Ran } X)$ [?Francis2012]. Clauses (b)–(d) specify the model presentation used in this volume. The properadic transfer adds the separate package H_{prop} of Theorem 17.4.4. $\square$

17.4 SIMPLICIAL PROPERADS AND FACTORIZATION TRANSFER

An operad records many inputs and one output. A properad records many inputs and many outputs, with composition indexed by connected graphs [?Val07]. We use the profile convention $\mathcal{P}(n, m) = “n \text{ inputs and } m \text{ outputs}.”$

A Verdier–Koszul properadic datum consists of a specified evaluation and its duality transpose

$$\mathrm{ev}_A: A \otimes^{\mathrm{ch}} K_X(A) \longrightarrow \omega_X, \quad (2, 1),$$

$$\mathrm{coev}_A: \omega_X \longrightarrow K_X(A) \otimes^{\mathrm{ch}} A, \quad (1, 2),$$

where $K_X(A) = \mathbb{D}_{\mathrm{Ran}} B_X(A)$. The zig–zag identities are part of the dual–pair clause of H_{VD} . A multiplication or Maurer–Cartan operation has profile $(n, 1)$; its Verdier transpose has profile $(1, n)$. These profiles generate the properadic envelope used below.

Definition 17.4.1 (Factorization-enriched properad;). Let $\mathcal{V}_X$ be the symmetric-monoidal model enhancement selected by $H_{\mathrm{Fact}}(X)$. A $\mathcal{V}_X$ -enriched properad is a colored collection $\{\mathcal{P}(\mathbf{d}; \mathbf{c})\}$ in $\mathcal{V}_X$, equivariant in the input and output colors, with units and associative substitution maps indexed by connected directed graphs. It is a *factorization-enriched properad* when every profile satisfies disjoint-locus factorization descent and the substitution maps commute with those descent equivalences. We write $\mathrm{FactProp}(X)$ for the resulting category whenever the model presentation of Theorem 17.4.4 is available.

THEOREM 17.4.2 (Model-categorical presentation of simplicial properads;). [Type signature: external homotopy-theory input; simplicial properad presentation; properadic enrichment level; hypothesis package: the presentation clause H_{HR} stated in the theorem body.] The presentation clause H_{HR} asserts: the ordinary category $\mathrm{sProperad}$ of small simplicial properads carries a cofibrantly generated model structure in which a morphism $f: P \rightarrow Q$ is a weak equivalence precisely when it is a weak homotopy equivalence on every input–output profile and $\pi_0 f: \pi_0 P \rightarrow \pi_0 Q$ is an equivalence of categories, and a fibration precisely when it is a Kan fibration on every profile and $\pi_0 f$ is an isofibration; and this model structure presents the homotopy theory of ∞ -properads of Hackney–Robertson–Yau [?HRY17].

Remark 17.4.3 (Scope of the literature input). Hackney–Robertson–Yau [?HRY17] construct the homotopy theory of ∞ -properads inside graphical sets, a presheaf model built from simplicial sets; that construction does not itself furnish the model structure on $\mathrm{sProperad}$ displayed in H_{HR} . The clause H_{HR} is therefore consumed as a named hypothesis, with the graphical-set homotopy theory as its evidence, and every use below routes through Theorem 17.4.4, whose package H_{prop} is stated independently.

THEOREM 17.4.4 (Conditional factorization-enriched properad transfer;). [Type signature: Open quadrant; factorization-enriched properad presentation; Beilinson level $1 \leftrightarrow 2$ envelope; hypothesis package H_{prop} .] Let $\mathcal{V}_X$ be a cofibrantly generated symmetric-monoidal model enhancement of the factorization ambient. The package H_{prop} consists of the following clauses.

- (P1) $\mathcal{V}_X$ satisfies the monoid axiom.
- (P2) The monoidal unit of $\mathcal{V}_X$ is cofibrant.
- (P3) The free properad monad formed by connected-graph substitution is admissible: its generating cell domains are small and the transferred factorizations exist.
- (P4) Connected-graph extension and the operad-to- properad transfer preserve weak equivalences between cofibrant collections; on the envelope generated by the associative bar–cobar pair they preserve the derived unit and counit equivalences.
- (P5) The localization imposing disjoint-locus factorization descent is stable under the free properad monad, homotopy colimits of cofibrant diagrams, and the transferred factorizations.

Under H_{prop} , factorization-enriched properads carry the transferred cofibrantly generated model structure. Its weak equivalences are the profilewise weak equivalences together with the equivalence condition on the color category. The graphwise extension of the associative bar–cobar adjunction is a Quillen equivalence on the properadic envelope generated by that pair.

Proof. Clauses (P1)–(P3) transfer the model structure from enriched collections to algebras over the free properad monad. Clause (P5) descends this structure to the factorization-local objects. Clause (P4) carries the derived bar–cobar unit and counit through connected-graph extension, which gives the asserted Quillen equivalence on the generated envelope. The presentation clause H_{HR} of Theorem 17.4.2 posits the simplicial properad model that motivates the profile and color conditions; the enrichment over $\mathcal{V}_X$ is governed by the five displayed clauses. $\square$

17.5 CONDITIONAL FACTORIZATION AND PROPERADIC FORMS OF THEOREM A

THEOREM 17.5.1 (*Factorization restriction and properadic envelope of Theorem A*;). [Type signature: Open quadrant; Ran, factorization, and properadic presentations; Beilinson level $1 \leftrightarrow 2$; pro-nilpotent chiral Ran ambient; hypothesis packages $H_{\text{Fact}} + H_{\text{fact}} + H_{\text{conv}}$, with H_{prop} for clause (i).] Let X be a smooth curve over a characteristic-zero field and place the reduced associative operad in $C_X = (D(\text{Ran } X), \otimes^{\text{ch}})$. Assume $H_{\text{Fact}}(X)$, H_{fact} , and H_{conv} . Enhanced bar and cobar restrict to a derived adjoint equivalence

$$\Omega_X^{\text{ch}} : \text{CoFact}^{\text{conil,comp}}(X) \rightleftarrows \text{Fact}^{\text{aug,comp}}(X) : \tilde{B}_X^{\text{ch}}$$

on the chosen factorization subcategories, with unit and counit equivalences. It has the following refinements.

(i) *Properadic envelope*; . Under H_{prop} , connected-graph extension gives a derived adjoint equivalence

$$\Omega_X^{\text{ch}} : \text{CoFactProp}_{\langle \text{Ass}^{\text{ch}} \rangle}^{\text{conil,comp}}(X) \rightleftarrows \text{FactProp}_{\langle \text{Ass}^{\text{ch}} \rangle}^{\text{aug,comp}}(X) : \tilde{B}_X^{\text{ch}}.$$

The subscript $\langle \text{Ass}^{\text{ch}} \rangle$ denotes the envelope generated from the associative operadic pair by connected-graph substitution, radical completion, and weak equivalence.

(ii) *Fiber restriction*; . For a marked point $x \in X$, assume that the fiber functor $i_x^! : \text{Fact}(X) \rightarrow \text{Ch}(k)$ is exact symmetric monoidal and commutes with the completed bar and cobar constructions. Its image is the ordinary associative bar–cobar adjunction, whose unit and counit are quasi-isomorphisms [?LV12, Corollary 2.3.4].

(iii) *Ordered-to-symmetric descent*; . Let $R(z)$ satisfy hypotheses (R1) and (R2) of Lemma 17.6.2 and arise as monodromy of the stated flat connection. On the open configuration locus the principal Σ_n -torsor

$$\pi_n^{\circ} : C_n^{\text{ord}}(X) \longrightarrow C_n(X)$$

gives L_R -twisted descent of the ordered bar. Under H_{fact}^R , nearby cycles extend this equivalence through the Fulton–MacPherson collision strata to the cardinality- n Ran stratum.

Proof. Francis–Gaitsgory’s Proposition 4.1.2, together with the pro-nilpotence argument in the proof of their Theorem 5.1.1, gives the enhanced equivalence in $D(\text{Ran } X)$. The closure maps of H_{fact} restrict it to the displayed factorization subcategories.

On chain models the two free constructions are

$$\bar{B}_X^{\text{ch}}(A) = T_{\text{Fact}(X)}^c(s^{-1}\bar{A}), \quad \Omega_X^{\text{ch}}(C) = T_{\text{Fact}(X)}(s\bar{C}).$$

The bar multiplication term and the cobar coproduct term both have cohomological degree +1 by Convention 17.0.1. Their universal twisting-morphism property gives the adjunction [?LV12, Theorem 2.2.9].

The three convergence clauses enter at distinct points. The direct-sum bar is the filtered colimit of its finite length pieces by H_{len} . The identity $A \simeq \varinjlim_q A/\bar{A}^q$ is supplied by H_{aug} and identifies the completed algebra with its finite augmentation quotients. The pro-coradical tower of H_{ML} has vanishing derived inverse-limit obstruction, so the stagewise unit and counit equivalences pass to the completed limit. This proves the first assertion.

Clause (i) is Theorem 17.4.4. The exact symmetric-monoidal fiber functor in clause (ii) carries the displayed free constructions to $T^c(s^{-1}\bar{A})$ and $T(s\bar{C})$; Loday–Vallette’s unit and counit theorem then applies. Clause (iii) is the open-locus assertion and the H_{fact}^R extension of Lemma 17.6.2. $\square$

Remark 17.5.2 (Three convergence mechanisms). For the direct-sum bar,

$$F_{\leq p}^{\text{bar}} B(A) = \bigoplus_{0 \leq n \leq p} (s^{-1}\bar{A})^{\otimes n}, \quad B(A) = \varinjlim_p F_{\leq p}^{\text{bar}} B(A).$$

This is bar-length exhaustiveness. Augmentation completeness is the separate comparison

$$A \xrightarrow{\sim} \varinjlim_q A/\bar{A}^q.$$

Coradical convergence belongs to a pro-coalgebra presentation $C \simeq \varinjlim_q C_{\leq q}$. For every cohomological degree and every properadic profile, H_{ML} requires the tower $\{H^j(C_{\leq q})\}_q$ to be Mittag–Leffler. The Milnor sequence

$$0 \longrightarrow R^1 \varinjlim_q H^{j-1}(C_{\leq q}) \longrightarrow H^j(R \varinjlim_q C_{\leq q}) \longrightarrow \varinjlim_q H^j(C_{\leq q}) \longrightarrow 0$$

then identifies the derived inverse limit with the ordinary limit. Thus H_{len} , H_{aug} , and H_{ML} control respectively a filtered colimit, an algebraic completion, and a derived inverse limit.

Remark 17.5.3 (Fixed curve, relative interior, and Deligne–Mumford boundary). Theorem 17.5.1 is a fixed-smooth-curve theorem. It has two relative enhancements. The enhancement over $\mathcal{M}_{g,n}$ carries base change for the relative Ran prestack; the enhancement over $\overline{\mathcal{M}}_{g,n}$ carries, in addition, nodal factorization sewing.

Let $\pi : C \rightarrow S$ be a smooth projective family of marked curves and let $\text{Ran}^{\text{rel}}(C/S) \rightarrow S$ be the relative Ran prestack. For $f : S' \rightarrow S$, write $f' : \text{Ran}^{\text{rel}}(C'/S') \rightarrow \text{Ran}^{\text{rel}}(C/S)$ for the induced map. The relative interior obstruction is the base-change comparison

$$\alpha_{\text{BC}} : f^! \pi_*^{\text{Ran}} \Longrightarrow \pi'_*{}^{\text{Ran}} f'^!$$

on relative factorization sheaves. For $\mathcal{F} \in \text{Fact}^{\text{rel}}(C/S)$ satisfying $H_{\text{fact}} + H_{\text{conv}}$, the cone of this comparison defines

$$[\alpha_{\text{BC}}] \in \text{Ext}_{\text{Shv}^{\text{DR}}(S')}^1(f^! \pi_*^{\text{Ran}} \mathcal{F}, \pi'_*{}^{\text{Ran}} f'^! \mathcal{F}).$$

Vanishing of this class for the conilpotent-complete subcategory gives the relative version of Theorem 17.5.1 over $\mathcal{M}_{g,n}$.

Let $D_\Delta \subset \overline{\mathcal{M}}_{g,n}$ be a boundary divisor with normalisation $\widetilde{C} = C' \sqcup C''$ and formal node $\widehat{D}_p$. Mok's logarithmic Fulton–MacPherson geometry [?Mok25, Theorem 3.3.1, Theorem 5.2.3, Corollary 5.3.4] supplies the normal-crossings and degeneration space on which nodal sewing is formulated. The chain-level factorization statement is the separate nearby-cycle comparison

$$\beta_{\text{nodal}} : \Psi_\Delta(\pi_{\log})_* \mathcal{F} \Longrightarrow (\pi_{\log})_{*, D_\Delta} (\mathcal{F}(C') \otimes_{\mathcal{F}(\widehat{D}_p)} \mathcal{F}(C'')),$$

where Ψ_Δ denotes Beilinson–Drinfeld factorization nearby cycles. Its obstruction class is

$$[\beta_{\text{nodal}}] \in \text{Ext}_{\text{Shv}^{\text{DR}}(D_\Delta)}^1(\Psi_\Delta(\pi_{\log})_* \mathcal{F}, (\pi_{\log})_{*, D_\Delta} (\mathcal{F}(C') \otimes_{\mathcal{F}(\widehat{D}_p)} \mathcal{F}(C''))).$$

Vanishing of $[\beta_{\text{nodal}}]$ at every boundary divisor is the extra condition for the Deligne–Mumford extension.

The two obstructions are independent. The class $[\alpha_{\text{BC}}]$ controls horizontal transport over smooth families; $[\beta_{\text{nodal}}]$ controls sewing at nodal degenerations. Class G satisfies the nodal condition by direct free-field sewing. Class L satisfies it under the generic non-critical Beilinson–Drinfeld chiral sewing hypotheses. For class M, the sewing datum lives in the weight-completed lane.

The R -twisted descent of Lemma 17.6.2 is a fixed-curve configuration-space theorem. Its Fulton–MacPherson collision extension is the clause H_{fact}^R . A Deligne–Mumford extension additionally carries the family classes $[\alpha_{\text{BC}}]$ and $[\beta_{\text{nodal}}]$. Their vanishing extends the family comparison across the compactified base. Together with the indicated Theorem D packages, the resulting hierarchy is

$$\text{Obs}_g^{\text{def}}(\mathcal{A}) \in H^2(\text{Def}_g(\mathcal{A})), \quad g \geq 2, \quad \text{tr}_1 \text{Obs}_{1,1}^{\text{def}}(\mathcal{A}) = +\kappa(\mathcal{A})\lambda_1 \in H^2(\overline{\mathcal{M}}_{1,1}) \quad \text{under } H_D^1,$$

$$\mathfrak{D}_g^K(\mathcal{A}) = \kappa(\mathcal{A})\lambda_{-1}(\mathbb{E}_g) \in K^0(\overline{\mathcal{M}}_g), \quad \text{ch}_g(\mathfrak{D}_g^K(\mathcal{A})) = (-1)^g \kappa(\mathcal{A})\lambda_g \in H^{2g}(\overline{\mathcal{M}}_g) \quad \text{under } H_D^K.$$

The package H_D^{tr} supplies the derived comparison between the deformation and virtual Hodge carriers. Under H_D^{graph} , the stable-graph scalar is

$$F_g(\mathcal{A}) = \kappa(\mathcal{A})\lambda_g^{\text{FP}} + \partial F_g^{\text{cross}}(\mathcal{A}) \in \mathbb{C}.$$

Remark 17.5.4 (Alternative proof lanes: Theorem A versus Theorem C). Lurie HA §5.5 gives a topological route to the locally constant specialization of clause (ii): factorization algebras via little discs and factorization envelopes reproduce the classical associative Koszul pair. The PTVV shifted-symplectic construction belongs to *Theorem C*: its lane constructs the $-(3g-3)$ -shifted symplectic structure on $\text{RMap}(\overline{\mathcal{M}}_g, BG_{\mathcal{A}})$ as a genuinely disjoint path from the fiber-center Koszul identification, relevant to the characteristic-datum Co/C1/C2 clauses and to the λ_g -free formulation of Theorem D. Francis–Gaitsgory and Loday–Vallette supply the bar–cobar reconstruction inputs. The simplicial properad model structure is the presentation clause H_{HR} (Theorem 17.4.2, Conjectured), while H_{prop} carries its factorization-enriched transfer.

COROLLARY 17.5.5 (Classical chain model from fiber restriction;). Assume the fiber and Verdier clauses of Theorem 17.5.1(ii), H_{VD} , and the following fiber package H_{fib} : a chosen !-fiber functor on the finite-window holonomic subcategory is exact, its tensor exchange maps are isomorphisms, it commutes with the completed inverse limits used by bar and cobar, and Verdier base change identifies the fiber of

$\mathbb{D}_{\text{Ran}}$ with the linear dual of the fiber. The geometric bar–cobar adjunction (Theorem 14.1.103) and its Verdier-duality intertwining (Theorem 8.0.35) are the images of the enhanced Ran constructions under this fiber functor.

Proof. Clause (ii) and H_{fib} carry $\tilde{B}_X^{\text{ch}}$ and Ω_X^{ch} to $T^c(s^{-1}\tilde{A})$ and $T(s\tilde{C})$ and carries their unit and counit to the classical maps. The base-change, Künneth, and biduality maps of H_{VD} carry the Verdier comparison to the same fiber. $\square$

17.6 R -MATRIX-TWISTED Σ_n -DESCENT

The descent lemma relating ordered and symmetric bar for E_1 -chiral algebras is the explicit content of Corollary 17.2.8 of the unified Koszul reflection (equivalently, of Theorem 17.5.1(iii)).

PROPOSITION 17.6.1 (*Classical MC/CYBE output and quantum QYBE input; .*). The universal twisting morphism of Corollary 17.2.1 produces a classical Maurer–Cartan equation in the ordered convolution algebra,

$$D\theta_{\mathcal{A}} + \frac{1}{2}[\theta_{\mathcal{A}}, \theta_{\mathcal{A}}] = 0.$$

On the binary collision stratum, if the residue kernel is $r(z) \in (\text{End } \mathcal{A}^{\otimes 2})((z))$, the flatness of the classical logarithmic connection

$$\nabla_{\text{cl}} = d - \hbar \sum_{i < j} r_{ij}(z_i - z_j) d(z_i - z_j)$$

is the spectral classical Yang–Baxter identity

$$[r_{12}(z_{12}), r_{13}(z_{13})] + [r_{12}(z_{12}), r_{23}(z_{23})] + [r_{13}(z_{13}), r_{23}(z_{23})] = 0$$

together with the Arnold relation for the logarithmic forms when $r(z)$ has rational KZ form Ω/z . This is classical output of the bar differential. A quantum descent datum is extra input: a formal or meromorphic family

$$R(z) = 1 + \hbar r(z) + O(\hbar^2), \quad \check{R}(z) := \tau \circ R(z),$$

whose checked operators satisfy the braid cocycle and whose ordinary operators satisfy the quantum Yang–Baxter equation and unitarity of Lemma 17.6.2. The $\hbar^2$ coefficient of QYBE is CYBE. The coefficients $R^{(m)}(z)$ for $m \geq 2$ and the flat realization of L_R form the additional quantum descent datum.

Proof. Expanding QYBE for $R(z) = 1 + \hbar r(z) + \hbar^2 R^{(2)}(z) + O(\hbar^3)$ gives identical linear terms on both sides. At order $\hbar^2$, the unknown $R^{(2)}$ terms cancel, and the remaining difference is precisely the displayed sum of commutators. Expanding unitarity $R^{21}(-z)R^{12}(z) = 1$ at order $\hbar$ gives $r^{21}(-z) + r^{12}(z) = 0$. The Maurer–Cartan equation is the same flatness identity before choosing a quantization; the Arnold relation annihilates the three logarithmic two-form coefficients on $C_3(X)$. Thus the expansion determines the classical kernel, while the higher coefficients $R^{(m)}(z)$ and their flat connection are quantum input. $\square$

LEMMA 17.6.2 (*R-matrix-twisted Σ_n -descent, unitary quantum R ; .*). [Type signature: Open quadrant; ordered/symmetric configuration presentation; Beilinson level 2; hypotheses (R1)+(R2), with H_{fact}^R for Ran extension.] Let $\mathcal{A}$ be an E_1 -chiral algebra with a meromorphic unitary quantum R -matrix $R(z) \in \text{Aut}(\mathcal{A} \otimes \mathcal{A})((z))$; write $\check{R}(z) := \tau \circ R(z)$ for the checked braiding. Assume

- (R1) the quantum Yang–Baxter equation $R_{12}(z_{12}) R_{13}(z_{13}) R_{23}(z_{23}) = R_{23}(z_{23}) R_{13}(z_{13}) R_{12}(z_{12})$ on $\{z_1, z_2, z_3\}$ -triples; and
- (R2) *unitarity*: $R^{21}(-z) R^{12}(z) = \text{id}_{\mathcal{A} \otimes \mathcal{A}}$ on the formal punctured disc, where $R^{21}(w) := \tau \cdot R(w) \cdot \tau$ is the swap-conjugate.

Assume also that the meromorphic family is realized as the monodromy of a flat KZ/Cherednik-type connection on $C_n^{\text{ord}}(X)$ for each n , with elementary chamber-crossing operator $\check{R}_i(z_i - z_{i+1})$ on adjacent factors. Then

$$\pi_n^\circ: C_n^{\text{ord}}(X) \longrightarrow C_n(X)$$

is a principal Σ_n -torsor, and there is a canonical Σ_n -equivariant local system L_R on $C_n^{\text{ord}}(X)$ whose descent isomorphism for the elementary transposition s_i is $\check{R}_i(z_i - z_{i+1})$. On the open locus,

$$\overline{B}_n^\Sigma(\mathcal{A})|_{C_n(X)} \simeq \text{Desc}_{\pi_n^\circ} \left(B_n^{\text{ord}}(\mathcal{A})|_{C_n^{\text{ord}}(X)} \otimes L_R \right).$$

Under H_{fact}^R , L_R has compatible nearby cycles on the Fulton–MacPherson collision strata, and the open equivalence extends to

$$\overline{B}_n^\Sigma(\mathcal{A}) \simeq (B_n^{\text{ord}}(\mathcal{A}))^{\Sigma_n\text{-coinv}, L_R\text{-twisted}}.$$

Proof. The free action of Σ_n on $C_n^{\text{ord}}(X) = X^n \setminus \Delta$ permutes the labels, and its geometric quotient is $C_n(X)$. Hence π_n° is a principal Σ_n -torsor.

Assign to each point $(z_1, \dots, z_n) \in C_n^{\text{ord}}(X)$ the vector space $\mathcal{A}^{\otimes n}$ at that point and to each elementary deck transformation s_i the isomorphism

$$\phi_i = \check{R}_i(z_i - z_{i+1}): s_i^*(\mathcal{A}^{\otimes n}) \longrightarrow \mathcal{A}^{\otimes n}.$$

The QYBE of (R1) is exactly the braid cocycle

$$\phi_i s_i^*(\phi_{i+1}) (s_i s_{i+1})^*(\phi_i) = \phi_{i+1} s_{i+1}^*(\phi_i) (s_{i+1} s_i)^*(\phi_{i+1})$$

on triple overlaps; distant generators commute because they act on disjoint tensor factors. The unitarity condition (R2) gives $\phi_i s_i^*(\phi_i) = \text{id}$, since s_i sends $z_i - z_{i+1}$ to $-(z_i - z_{i+1})$ and swaps the two factors. Thus (R1)+(R2) supply the Coxeter descent cocycle on the ordered cover. The flat KZ/Cherednik realization supplies the underlying local system on $C_n^{\text{ord}}(X)$; the cocycle above supplies its Σ_n -equivariant descent datum.

Descent along the principal torsor is the standard equivalence between sheaves on $C_n(X)$ and sheaves on the ordered cover equipped with a Σ_n -cocycle. The ordered bar $B_n^{\text{ord}}(\mathcal{A})$ restricted to $C_n^{\text{ord}}(X)$ is $\mathcal{A}^{\boxtimes n} \otimes \Omega_{C_n^{\text{ord}}(X)}^{n-1}(\log D)$, and its descent to $C_n(X)$ with twist by L_R is by definition the symmetric bar $\overline{B}_n^\Sigma(\mathcal{A})$ of Definition 7.1.17 (the bar coefficient in the symmetric setting is the Arnold 1-form $d \log(z_i - z_j)$, which transforms under Σ_n by the sign character twisted by the checked operator $\check{R}(z_i - z_j)$ acting on the fibres).

The log Fulton–MacPherson compactification $\overline{C}_n(X)$ supplies the fixed-curve normal-crossings boundary on which H_{fact}^R is formulated. That clause identifies the nearby-cycle monodromy with the chiral collision product. The ordered bar differential is a coderivation for deconcatenation and preserves stratum depth, so descent on a boundary stratum is the top-stratum descent applied to the nearby-cycle fibre. For the pole-free case the exceptional-divisor limit is the checked swap τ , and the formula reduces to ordinary Σ_n -coinvariants. $\square$

Remark 17.6.3 (Unitarity and collision extension). Hypothesis (R2) is satisfied on the finite-dimensional evaluation module lane of the rational Drinfeld Yangian $Y_h(\mathfrak{g})$ after the standard scalar normalization of the rational R -matrix, and on the integrable finite-type lane of trigonometric quantum affine $U_q(\hat{\mathfrak{g}})$ at generic q after the corresponding normalization. These are representation-surface statements. A factorization Drinfeld–Kohno equivalence on Yangian category $\mathcal{O}$ and a dg-shifted Yangian/line-operator comparison carry their own comparison morphisms. At roots of unity, and for elliptic or dynamical R -matrices of Belavin/Felder type, the chosen presentation supplies unitarity and the regular-singular boundary extension. For chiral algebras in a genuinely trivial ordinary R -matrix lane $R(z) = 1$, the checked braiding is $\check{R}(z) = \tau$; unitarity (R2) is immediate and (R1) is vacuous. The non-zero-level Heisenberg lane is separate: its ordered-bar braiding is the scalar $R_{\mathcal{H}_k}(z) = \exp(k\hbar/z)$. It satisfies unitarity (R2) by scalar cancellation and satisfies (R1) tautologically; its local system becomes trivial on the zero-level and zero-charge specializations.

The fixed-curve collision extension is H_{fact}^R . For the rational KZ and trigonometric Cherednik connections it is the regular-singular logarithmic extension along the Fulton–MacPherson boundary on the stated representation lanes. Elliptic and dynamical R -matrices use the chosen compactification and dynamical-parameter convention. Thus hypotheses (R1)+(R2) govern open configuration-space descent, while H_{fact}^R governs the Ran-level symmetric bar.

Remark 17.6.4 (Comparison with $\mathfrak{g}_{\mathcal{A}}^{E_1}$ versus $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$). The averaging map $\text{av}: \mathfrak{g}_{\mathcal{A}}^{E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ (§??) is the dual of the descent map $\pi^!$ after forgetting the monodromy datum: dualising $\pi: \text{Ran}^{\text{ord}}(X) \rightarrow \text{Ran}(X)$ and tensoring with the structure sheaf gives the Σ_n -coinvariant projection on the classical shadow. Quantization is supplied by the quantum R -datum, and the full modular characteristic additionally uses the conformal-vector normalization. For affine Kac–Moody $V_k(\mathfrak{g})$ in trace-form convention, the classical residue kernel is

$$r^{KM}(z) = k \Omega_{\text{tr}}/z.$$

Its trace-form contribution to the scalar diagonal is $k \dim(\mathfrak{g})/(2h^\vee)$. The full invariant is

$$\kappa(V_k(\mathfrak{g})) = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee),$$

where the trace of the descent local system contributes $k \dim(\mathfrak{g})/(2h^\vee)$ and the Sugawara conformal vector contributes $\dim(\mathfrak{g})/2$.

17.7 TYPED RESTRICTIONS OF THEOREM A

The Ran equivalence, its factorization restriction, its completed chain model, its conditional properadic transfer, and its ordered descent occupy five distinct hypothesis packages.

COROLLARY 17.7.1 (*Five typed outputs of Theorem A;*). The following outputs hold on their stated domains:

- (D1) In the pro-nilpotent chiral Ran ambient, enhanced associative bar and cobar are inverse equivalences in $D(\text{Ran } X)$ (Theorem 17.1.2(i)).
- (D2) Under H_{fact} , the equivalence restricts to the chosen associative factorization subcategories (Theorem 17.1.2(iii)).
- (D3) Under H_{conv} , the completed chain models have bar $T^c(s^{-1}\bar{A})$, cobar $T(s\bar{C})$, and unit and counit equivalences (Theorem 17.5.1).
- (D4) Under H_{prop} , connected-graph extension gives the Quillen equivalence on the properadic envelope (Theorem 17.5.1(i)).

(D5) Under hypotheses (R1)+(R2), the ordered bar descends along the principal Σ_n -torsor on the open configuration locus; H_{fact}^R supplies its Ran extension (Theorem 17.5.1(iii)).

Proof. Items (D1)–(D3) are the Ran equivalence, its factorization closure, and the convergence argument of Theorem 17.5.1. Item (D4) is Theorem 17.4.4; item (D5) is Lemma 17.6.2. $\square$

Remark 17.7.2 (Cross-volume bridges to climax and conductor chapters). The unified Koszul reflection (Theorem 17.1.2) feeds directly into two parallel-established chapters:

- **Climax chapter** (??) identifying $\bar{\partial} = \text{KZ}^*(\nabla_{\text{Arnold}})$ as the bar differential on the universal Arnold connection: the unit η of the Koszul reflection at the geometric Arnold connection produces the Knizhnik–Zamolodchikov pullback identification of the bar differential.
- **Universal conductor chapter** (25) proving $K = -c_{\text{ghost}}(\text{BRST})$ as the universal ghost-charge conductor: the conductor $K^\kappa(\mathcal{A}) = \kappa(\mathcal{A}) + \kappa(\mathcal{A}^!)$ is the numerical observable of the Verdier-dualized Koszul pair. The functor $K_X = \mathbb{D}_{\text{Ran}} B_X$ is its categorical antecedent. Pairwise equivalences $K_X(\mathcal{A}) \simeq \mathcal{A}^!$ and $K_X(\mathcal{A}^!) \simeq \mathcal{A}$ belong to the separate represented self-duality package.

17.8 SYMMETRIC MONOIDAL AMBIENT CORRECTIONS

Theorem 17.5.1 uses the following ambient data.

Remark 17.8.1 (Symmetric-bar and ordered-bar forms). The factorization form has two parts:

- SYMMETRIC:** The *symmetric-bar* statement lies in the pro-nilpotent Francis–Gaitsgory Ran ambient; its factorization restriction uses H_{fact} .
- ORDERED:** The *ordered-bar* statement is (iii) of Theorem 17.5.1: the ordered bar on $C_n^{\text{ord}}(X)$ carries the R -twisted local system L_R ; descent along π_n° gives the symmetric form on $C_n(X)$, and H_{fact}^R gives the Ran extension.

Both forms hold on their stated hypotheses. The level-0 primitive is the open factorization category and its chosen vacuum; the level-2 ordered object is $B^{\text{ord}}(\mathcal{A})$ on $\text{Ran}^{\text{ord}}(X)$, and the symmetric bar is the L_R -twisted Σ_n -coinvariant descent image.

Remark 17.8.2 (Factorization unit functor). The operadic transfer uses the symmetric-monoidal functor

$$\text{Ch}(k) \longrightarrow \text{Fact}(X), \quad M \longmapsto M \otimes \mathbf{I}_{\text{Fact}(X)}.$$

Here $\mathbf{I}_{\text{Fact}(X)}$ is the factorization unit represented by the constant factorization algebra on $\mathcal{O}_X$. This is the unit functor in $H_{\text{Fact}}(X)$.

Remark 17.8.3 (R-twisted descent). For $\mathcal{H}_k$ the ordered bar carries the scalar descent datum

$$R_{\mathcal{H}_k}(z) = \exp(k\hbar/z),$$

and Lemma 17.6.2 identifies its symmetric bar with the scalar-local-system descent. The zero-level and zero-charge specializations give the trivial local system.

Remark 17.8.4 (Model-categorical transfer). Francis–Gaitsgory provide the enhanced Ran bar–cobar equivalence. Proposition 17.3.3 supplies the chosen model presentation, and Theorem 17.4.4 states the five additional hypotheses for factorization-enriched properads. The presentation clause H_{HR} (Theorem 17.4.2, Conjectured) posits the simplicial properad model structure appearing at the base of this transfer; [?HRY17] constructs the graphical-set homotopy theory that evidences it.

Remark 17.8.5 (Chain realization). The enhanced Ran equivalence is constructed from the universal properties of enhanced bar and cobar. A strict chain realization uses either a specified split contraction in the chosen model enhancement or a Cousin resolution compatible with the diagonal stratification. On the quadratic locus, the acyclic twisted complex in $H_{\text{CL}}(A, A^i, \tau_i)$ supplies the corresponding contraction.

Remark 17.8.6 (Truncation-wise Hochschild finiteness). The convergence package uses truncation-wise finiteness with conformal-weight control. For a chiral algebra with positive-energy conformal weight grading $\mathcal{A} = \bigoplus_{n \geq 0} \mathcal{A}_n$ and finite-dimensional weight spaces $\mathcal{A}_n$, the bar complex $\bar{B}(\mathcal{A})$ is truncation-wise finite (each conformal weight stratum $\bar{B}(\mathcal{A})_{\leq N}$ has finite-dimensional cohomology), and Theorem 17.5.1 applies to the pro-nilpotent completion $\hat{\mathcal{A}} := \varprojlim_N \mathcal{A}/\mathcal{A}_{\geq N}$. This weakening captures Virasoro (weight space $\mathcal{A}_n = S^n \text{Vir}_0/\text{null}$ with finite dimension), Yangian (weight grading by spectral-parameter order), and critical KM (weight grading by conformal weight of the current algebra). The resulting equivalence lies in the weight-completed ambient specified by H_{aug} and H_{ML} .

Remark 17.8.7 (Correct cross-volume citation). The precise cross-volume references are Theorem 17.1.2(i) for the published Ran equivalence, Theorem 17.5.1 for its conditional factorization restriction, Theorem 17.5.1(i) for the H_{prop} properadic envelope, and Corollary 17.5.5 for the chain model at a marked point.

17.9 FORMAL SMOOTHNESS OF CHIRALLY KOSZUL ALGEBRAS

COROLLARY 17.9.1 (*Cotangent criterion for properadic-envelope formal smoothness*;). [Type signature: Open quadrant; factorization-properad presentation; Beilinson level 1 $\leftrightarrow$ 2 deformation lane; hypothesis package H_{prop} plus cotangent Ext-vanishing.] Let $\mathcal{A}$ be a chirally Koszul factorization algebra on X (Definition 14.1.19), and assume H_{prop} . Let $L_{\mathcal{A}}^{\text{prop}}$ be its cotangent complex in $\text{FactProp}_{\langle \text{Ass}^{\text{ch}} \rangle}^{\text{aug}}(X)$. If

$$\text{Ext}_{\mathcal{A}}^i(L_{\mathcal{A}}^{\text{prop}}, M) = 0$$

for every coefficient module M arising from a square-zero extension, then $\mathcal{A}$ is formally smooth in this properadic envelope. For a square-zero extension $R \rightarrow R_0$ with kernel M and an R_0 -valued point through $\mathcal{A}$, the space of lifts is a torsor for $\text{Map}_{\mathcal{A}}(L_{\mathcal{A}}^{\text{prop}}, M)$; it is contractible when this derived mapping space is contractible.

Proof. Cotangent deformation theory places the obstruction to a lift in $\text{Ext}_{\mathcal{A}}^1(L_{\mathcal{A}}^{\text{prop}}, M)$. Its vanishing gives a lift. The derived mapping space from the cotangent complex to M acts simply transitively on the lift space, which gives the asserted torsor and contractibility statements. The package H_{prop} supplies the model category in which this cotangent complex and its derived mapping space are formed. $\square$

Remark 17.9.2 (Compatibility with the five-theorem architecture). The unified Theorem A (Theorem 17.1.2) is the bar-cobar spine of the volume. It occupies the first place in the five-package architecture A, B, C, D, H : Theorems B and D use its ambient-qualified inversion and obstruction theory, Theorem C uses its Koszul-dual Verdier surface, and Theorem H uses its chiral Hochschild control on the Koszul/generic locus. Corollary 17.7.1 records the five typed outputs: Ran reconstruction, factorization closure, completion, properadic transfer, and ordered descent.

17.10 PLATONIC OBSTRUCTIONS: FOUR NAMED CONJECTURES

Four conjectures govern the extension of Koszul reflection to the full category $\text{Alg}_X^{\text{fact, aug}}$.

Conjecture 17.10.1 (Π1: Francis–Gaitsgory transfer). The $(\infty, 1)$ -categorical bar–cobar Quillen equivalence transfers from $\mathrm{IndCoh}(\mathrm{Ran}(X))$ to $\mathrm{Alg}_X^{\mathrm{fact, aug, comp}}$ and its coalgebra dual through the factorization comparison functor.

Lurie supplies the topological transfer theorem (Lurie HA §5.5). This theorem-level use in the chiral setting requires a named transfer proposition `prop:chiral-quillen-transfer`.

Conjecture 17.10.2 (Π2: E_n -bar–cobar at higher chiral dimension). For $d \geq 2$, the E_n -bar functor on n -dimensional factorization E_n -algebras admits a left adjoint (cobar) that is a Quillen equivalence onto conilpotent CDG-coalgebras over the appropriate n -dimensional Maurer–Cartan complex. The $n = 1$ case is Theorem 17.1.2.

This is the load-bearing direction connecting Vol I to Vol III’s CY-to-chiral functor. Currently open in the chiral setting (proved in Lurie HA §5.5.3 for the topological setting).

Conjecture 17.10.3 (Π3: Lagrangian–Koszul converse). Lagrangian transversality of $\mathcal{M}_{\mathrm{comp}}$ at $[\mathcal{A}]$ implies chiral Koszulness of $\mathcal{A}$.

This requires the chiral PTVV shifted-symplectic construction.

Conjecture 17.10.4 (Π4: Unbounded-rank Koszul reflection). On the locus of complete augmented chiral algebras with arbitrary graded bar pieces, the Koszul reflection of Theorem 17.1.2 holds in the coderived category. Its chain-level realization is the locus on which the pro-coradical tower satisfies H_{ML} .

Finite-dimensional weight pieces give Mittag–Leffler towers for the standard Heisenberg, Kac–Moody, Virasoro, and $\mathcal{W}_N$ presentations. The conjecture identifies H_{ML} as the chain-level frontier inside the full completed category.

17.II COMPARISON WITH INDEPENDENT CONSTRUCTIONS

Remark 17.II.1 (Sources for the five typed outputs). The five outputs of Corollary 17.7.1 have the following sources:

- Francis–Gaitsgory’s Proposition 4.1.2, together with the pro-nilpotence argument in the proof of their Theorem 5.1.1, supplies the enhanced Ran equivalence [?Francis2012].
- H_{fact} supplies the factorization closure and the Fulton–MacPherson nearby-cycle extension.
- Loday–Vallette [?LV12, Corollary 2.3.4] supply the ordinary chain-level unit and counit equivalences; H_{conv} carries them through completion.
- The presentation clause H_{HR} (Theorem 17.4.2, Conjectured) posits the cofibrantly generated model structure on simplicial properads; the graphical-set homotopy theory of [?HRY17] is its evidence.
- H_{prop} supplies the factorization-enriched transfer and the connected-graph preservation of the derived unit and counit.

Remark 17.II.2 (Independent constructions for bar–cobar reconstruction). The reconstruction statement has two published realizations and two conditional extensions:

- Francis–Gaitsgory give enhanced reconstruction in the pro-nilpotent Ran ambient.
- Loday–Vallette give the ordinary associative chain models $T^c(s^{-1}\tilde{A})$ and $T(s\tilde{C})$.
- $H_{\mathrm{fact}} + H_{\mathrm{conv}}$ give the factorization and completed realizations.
- H_{prop} gives the properadic-envelope realization.

THEOREM A AS THE ALGEBRAIC STRUCTURE ON THE KZ FUNCTOR

One adjunction, one reconstruction counit, one Verdier-dualized duality functor. Theorem 17.5.1 acts by factorization restriction, fiber realization, and pro-conilpotent completion. Verdier duality is the K_X branch; a quantum R -matrix is the ordered-descent input; the equations $[\alpha_{\text{BC}}] = [\beta_{\text{nodal}}] = 0$ give the Deligne–Mumford family extension. Theorem A enters the five-theorem spine of Volume I as the algebraic structure on the KZ functor of Chapter ??: the pullback identity $\tilde{\partial} = \text{KZ}^*(\nabla_{\text{Arnold}})$ is the bar differential read through the Koszul reflection.

17.12 K₃ HALL-DRINFELD INPUT AND THEOREM A SCOPE

Remark 17.12.1 (A_∞ -structure on $\mathbf{H}_{\Delta_5}$ as external input). Theorem A supplies the completed bar–cobar ambient for a fixed chiral shadow of a supplied factorization algebra. The K₃/Hall–Drinfeld input consists of the object $\mathbf{H}_{\Delta_5}$, its comparison with a Drinfeld Yangian, and its higher products. Suppose Volumes II–III supply a completed K₃ chiral shadow $\mathbf{H}_{\Delta_5}$ with A_∞ structure maps

$$\mu_n : \mathbf{H}_{\Delta_5}^{\otimes n} \rightarrow \mathbf{H}_{\Delta_5}, \quad n \geq 2,$$

and verify $H_{\text{fact}} + H_{\text{conv}}$ together with the relevant R -descent hypotheses. The proposed first products

$$\mu_2 = \text{Hall multiplication in } \text{CoHA}_{K_3 \times E}, \quad \mu_3 = \text{Drinfeld-associator coboundary at order } \hbar,$$

and

$$\mu_4 = \text{Igusa-form twist at order } \hbar^2 \quad \text{from} \quad \Phi_{10}/\eta^{24}$$

belong to the K₃/Hall–Drinfeld input surface. The order $\hbar^{\leq 3}$ pentagon coboundary

$$\phi^{(3)} = \zeta(3)c_{\text{symm}} + \frac{25}{3}c_{\text{timelike}} + (\Phi_{10}/\eta^{24})c_{\Phi_{10}}$$

is likewise external structure data. The completed bar–cobar adjunction transports this supplied datum.

THE FTM SEVEN-FOLD TFAE AT GENUS ZERO: HUB-AND-SPOKE THEOREM

18.1 THE FINITE-TYPE GENUS-ZERO WINDOW

The intrinsic fundamental-twisting-morphism package has six genus-zero conditions: Koszulness of τ_{univ} , the bar–cobar counit, the bar–cobar unit, twisted tensor acyclicity, diagonal bar concentration, and PBW E_2 -collapse. On the class- G fibre of the shadow-archetype map, Swiss-cheese formality supplies the seventh equivalent condition.

Definition 18.1.1 (Genus-zero finite-type PBW window). A filtered augmented chiral algebra $(\mathcal{A}, F_\bullet)$ lies in the *genus-zero finite-type PBW window* if the following hypotheses hold.

- (W1) X is a smooth genus-zero curve and $\tau_{\text{univ}}: \overline{B}_X^{\text{ord}}(\mathcal{A}) \rightarrow \mathcal{A}$ is the universal twisting morphism of Corollary 14.1.14.
- (W2) The quadruple $(\mathcal{A}, \overline{B}_X^{\text{ord}}(\mathcal{A}), \tau_{\text{univ}}, F_\bullet)$ is a chiral twisting datum in the sense of Definition 14.1.1: the filtration on $\mathcal{A}$, $\overline{B}_X^{\text{ord}}(\mathcal{A})$, and $\Omega_X \overline{B}_X^{\text{ord}}(\mathcal{A})$ is exhaustive, complete, bounded below, and compatible with the structure maps.
- (W3) The PBW filtration is flat and finite in the sense of Theorem 14.1.23 (i) and (iii): every PBW graded piece is finite rank in each conformal weight, and every fixed bar degree and conformal weight of $\overline{B}_X^{\text{ord}}(\mathcal{A})$ is finite-dimensional.
- (W4) The filtered bar, cobar, and twisted-tensor spectral sequences converge strongly, so the intrinsic core of Theorem 14.1.59 applies: chiral Koszulness of τ_{univ} is equivalent to PBW E_2 -collapse.
- (W5) The notation $\mathcal{A}^!$ carries the finite graded-piece duality needed for continuous linear duality. A chosen quadratic presentation $\mathcal{A} = T_X(V)/(R)$ supplies

$$\mathcal{A}^i = C_X(s^{-1}V, s^{-2}R), \quad q_{\mathcal{A}}^{\text{ord}}: \mathcal{A}^i \longrightarrow \overline{B}_X^{\text{ord}}(\mathcal{A}).$$

On the ordered Koszul locus $H^\bullet(q_{\mathcal{A}}^{\text{ord}})$ identifies $H^\bullet(\mathcal{A}^i)$ with ordered bar cohomology, and finite graded-piece duality supplies the line algebra $\mathcal{A}^!$.

- (W6) The universal twisting datum satisfies the chiral Comparison-Lemma package

$$H_{\text{CL}}(\mathcal{A}, \overline{B}_X^{\text{ord}}(\mathcal{A}), \tau_{\text{univ}})$$

of Definition 14.1.5. Thus its associated-graded finite windows are ordinary connected weight-graded twisting data, its filtrations and structure maps are split and strict, its spectral sequences converge strongly, and its completion towers are Mittag–Leffler.

The generic standard-landscape witnesses cited below lie in this window. Critical affine level, non-generic simple quotients, logarithmic examples, raw direct-sum class- $\mathcal{M}$ completions, and multi-weight higher-genus scalar reductions enter through their corresponding completion and perfectness packages.

The proof uses the following local anchors: Theorem 14.1.13, Theorem 14.1.23, Theorem 14.1.59, Theorem 14.1.30, Theorem 14.1.36, Theorem 9.10.17, and Proposition 14.1.70.

18.2 THE SEVEN CONDITIONS AT GENUS ZERO

Throughout, $(\mathcal{A}, F_\bullet)$ denotes an augmented chiral algebra in the genus-zero finite-type PBW window of Definition 18.1.1, and $\tau_{\text{univ}}: \bar{B}_X^{\text{ord}}(\mathcal{A}) \rightarrow \mathcal{A}$ the universal twisting morphism of Corollary 14.1.14. We restrict attention to the genus-zero fiber: all statements below are made over a single smooth quasi-projective genus-zero curve (e.g. $X = \mathbb{A}^1$ or $\mathbb{P}^1$), so modular-family curvature $\kappa \cdot \omega_g$ is absent and the bar differential is flat.

Definition 18.2.1 (The seven conditions). We label the following conditions on $\mathcal{A}$ at genus zero.

- (i) *Chiral Koszul morphism:* τ_{univ} is a chiral Koszul morphism in the sense of Definition 14.1.3.
- (ii) *Counit quasi-isomorphism:* the counit $\varepsilon_{\tau_{\text{univ}}}: \Omega_X(\bar{B}_X^{\text{ord}}(\mathcal{A})) \rightarrow \mathcal{A}$ of the bar–cobar adjunction is a quasi-isomorphism.
- (iii) *Unit weak equivalence:* the unit $\eta_{\tau_{\text{univ}}}: \bar{B}_X^{\text{ord}}(\mathcal{A}) \rightarrow \bar{B}_X^{\text{ord}}(\Omega_X(\bar{B}_X^{\text{ord}}(\mathcal{A})))$ is a weak equivalence of conilpotent complete factorisation coalgebras. Under Corollary 14.1.14, this is the unit corresponding to the single universal twisting morphism τ_{univ} and the coalgebra $\bar{B}_X^{\text{ord}}(\mathcal{A})$.
- (iv) *Twisted tensor acyclicity:* both twisted tensor products $K_\tau^L(\mathcal{A}, \bar{B}_X^{\text{ord}}(\mathcal{A}))$ and $K_\tau^R(\bar{B}_X^{\text{ord}}(\mathcal{A}), \mathcal{A})$ are acyclic.
- (v) *Diagonal bar concentration:* the bar cohomology $H^{p,q}(\bar{B}_X^{\text{ord}}(\mathcal{A}))$ vanishes for $q \neq 0$, and $H^{p,0}$ is the p th bar-weight piece for every $p \geq 0$. In particular, $H^\bullet(q_{\mathcal{A}}^{\text{ord}})$ gives $H^*(\mathcal{A}^!) \cong H^*(\bar{B}_X^{\text{ord}}(\mathcal{A}))$ as weight-graded chiral coalgebras, with the weight grading coinciding with bar degree (Theorem 14.1.30). The historical phrase “bar concentrated in weight 1” means this diagonal support condition. Cofreeness on $H^{1,0}$ is the additional structure carried by the free/Gaussian cases.
- (vi) *PBW E_2 -collapse (the hub):* the PBW spectral sequence of $\bar{B}_X^{\text{ord}}(\mathcal{A})$ collapses at the E_2 page, i.e. $d_r = 0$ for all $r \geq 2$.
- (vii) *SC-formality at genus zero:* the transferred Swiss-cheese operation tower on $\mathcal{A}$ has $m_k^{\text{SC}} = 0$ for all $k \geq 3$ (as in Proposition 14.1.70).

Remark 18.2.2 (Object firewall). The typed objects used throughout the theorem are

$$\mathcal{A}, \quad \bar{B}_X^{\text{ord}}(\mathcal{A}), \quad \mathcal{A}^! = C_X(s^{-1}V, s^{-2}R), \quad H^\bullet \bar{B}_X^{\text{ord}}(\mathcal{A}), \quad K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ord}}(\mathcal{A}), \quad \mathcal{A}^! = (\mathcal{A}^!)^\vee,$$

The map $q_{\mathcal{A}}^{\text{ord}}: \mathcal{A}^! \rightarrow \bar{B}_X^{\text{ord}}(\mathcal{A})$ carries quadratic recognition, and $H^\bullet(q_{\mathcal{A}}^{\text{ord}})$ gives the cohomological identification on the ordered Koszul locus. The counit $\Omega_X \bar{B}_X^{\text{ord}}(\mathcal{A}) \rightarrow \mathcal{A}$ is bar–cobar inversion. The passage from $\mathcal{A}^!$ to $\mathcal{A}^!$ is continuous linear or Verdier duality on the finite-type lane. Theorem C acts on $\mathbf{C}_g(\mathcal{A})$ after Co identifies the strict-flat degree-zero fibre with $\mathcal{Z}(\mathcal{A})$. Theorem H acts on the derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ through $H_H(\mathcal{A}; S)$. A supplied ι_Z^{der} , followed by H^0 and Co, connects the two successor theorem packages. The normalized scalar trace is recorded in Theorem 28.11.46; the support theorem is Theorem 35.4.49.

Remark 18.2.3 (The seven-condition surface). Other Koszulness characterisations exist. Theorem 14.1.59 has an intrinsic equivalence core, a Barr–Beck–Lurie monadic consequence, a conditional factorisation-homology criterion, a Theorem H-conditional family-support implication, and conditional perfectness/Lagrangian refinements. The seven conditions of Definition 18.2.1 are the FTM core of Loday–Vallette [?LV12, §2.3], the diagonal bar concentration forced by Theorem 14.1.30, and the class- G Swiss-cheese formality condition of Proposition 14.1.70. Hochschild family support, scalar complementarity, and perfectness occupy the successor theorem packages named in Remark 18.2.2.

18.3 THE HUB: PBW E_2 -COLLAPSE

The hub is condition (vi): PBW E_2 -collapse. This choice is forced by three considerations.

First, among the seven conditions, (vi) is the one for which the forward implication from each other condition admits a spectral-sequence proof at fixed level. Every other pairing (e.g. counit $q_i \Leftrightarrow$ diagonal bar concentration) factors through the PBW filtration.

Second, Theorem 14.1.59 identifies PBW E_2 -collapse with chiral Koszulness inside the intrinsic finite-type core, while Theorem 14.1.23 supplies the filtered-complete proof of the associated-graded-to-filtered direction. Every FTM arrow then routes through this primary equivalence.

Third, the Vol I landscape census (chapters/examples/landscape_census.tex) verifies (vi) concretely for every named family (Heisenberg, affine Kac–Moody at generic level, Virasoro at generic c , principal $\mathcal{W}_N$ at generic Ψ , $\beta\gamma$, lattice VOA, bc). The verification is case-by-case PBW finite-type verification, independent of the Swiss-cheese spoke.

THEOREM 18.3.1 (*Six-fold TFAE on the Koszul locus, with a class- G seventh equivalence;*). Let $(\mathcal{A}, F_\bullet)$ lie in the genus-zero finite-type PBW window of Definition 18.1.1.

- (A) (Six-fold intrinsic TFAE.) The six conditions (i), (ii), (iii), (iv), (v), (vi) are equivalent. The equivalence is organised as a hub-and-spoke diagram with (vi) (PBW E_2 -collapse) as the hub, and with five independent bidirections

$$(i) \Leftrightarrow (vi), \quad (ii) \Leftrightarrow (vi), \quad (iii) \Leftrightarrow (vi), \quad (iv) \Leftrightarrow (vi), \quad (v) \Leftrightarrow (vi).$$

Transitivity then furnishes the remaining $\binom{5}{2} = 10$ bidirections of the six-fold equivalence.

- (B) (Class- G seventh equivalence.) On the standard landscape, the seventh condition satisfies

$$(vii) \iff ((vi) \text{ and } \mathcal{A} \in G).$$

After restricting the parameter space to the class- G stratum (Heisenberg, lattice VOA, free fermion), this becomes an honest seventh equivalence with the six intrinsic conditions. On generic class- L , class- C , and class- $\mathcal{M}$ members in the finite-type window, the six intrinsic conditions hold and the first higher Swiss-cheese operation records the corresponding non-Gaussian stratum (Remark 18.9.2).

Proof. The five intrinsic spokes to the PBW E_2 -collapse hub are proved below, one section each, inside Definition 18.1.1. Transitivity of “if and only if” assembles the six-fold TFAE. The class- G seventh statement is Corollary 18.3.2. $\square$

COROLLARY 18.3.2 (*Seventh (SC-formality) equivalence on class G ;*). On the standard landscape,

$$(vii) \iff ((vi) \text{ and } \mathcal{A} \in G).$$

Consequently, after restriction to the class- G stratum, condition (vii) is equivalent to (vi).

Proof. This is Proposition 18.9.1. □

18.4 SPOKE 1: KOSZUL $\Leftrightarrow$ PBW E_2 -COLLAPSE

PROPOSITION 18.4.1 (*Spoke 1*;). Condition (i) is equivalent to condition (vi).

Proof. This is the intrinsic core (i) $\Leftrightarrow$ (ii) of Theorem 14.1.59, restricted to the genus-zero finite-type PBW window. The forward direction is Koszulness of τ_{univ} forcing degeneration of the PBW bar spectral sequence. The reverse direction is the filtered-complete Priddy transfer: PBW E_2 -collapse identifies the associated-graded Koszul complex with a classically Koszul datum, and Lemma 14.1.11 lifts the associated-graded acyclicity to the filtered chiral twisted tensor products. □

18.5 SPOKE 2: COUNIT QI $\Leftrightarrow$ PBW E_2 -COLLAPSE

PROPOSITION 18.5.1 (*Spoke 2*;). Condition (ii) is equivalent to condition (vi).

Proof. Both directions route through Spoke 1 and the chiral FTM bidirection (i) $\Leftrightarrow$ (ii) of Theorem 14.1.13(i)–(ii). Hypothesis (W6) supplies $H_{\text{CL}}(\mathcal{A}, \overline{B}_X^{\text{ord}}(\mathcal{A}), \tau_{\text{univ}})$: on each associated-graded finite window, Loday–Vallette Theorem 14.1.6 identifies the induced counit with the ordinary Koszul twisting datum; split strict filtrations, strong convergence, and Mittag–Leffler completion lift this equivalence to the completed chiral objects. Explicitly, (vi) $\xRightarrow{\text{Spoke 1}} \text{FTM} \Rightarrow$ (i) $\Rightarrow$ (ii), and (ii) $\xRightarrow{\text{FTM}} \text{Spoke 1} \Rightarrow$ (i) $\Rightarrow$ (vi). The first condition is carried by the completed map $\Omega_X \tilde{B}_X^{\text{ord}}(\mathcal{A}) \rightarrow \mathcal{A}$; the second is carried by the PBW filtration and its higher differentials. □

18.6 SPOKE 3: UNIT WEAK EQUIVALENCE $\Leftrightarrow$ PBW E_2 -COLLAPSE

PROPOSITION 18.6.1 (*Spoke 3*;). Condition (iii) is equivalent to condition (vi).

Proof. For the single universal twisting datum $(\mathcal{A}, \overline{B}_X^{\text{ord}}(\mathcal{A}), \tau_{\text{univ}}, F_\bullet)$, Hypothesis (W6) identifies every associated-graded finite window with an ordinary connected weight-graded twisting datum. Clauses (iii) and (iv) of Loday–Vallette’s Theorem 14.1.6 identify the induced counit quasi-isomorphism with the induced unit weak equivalence. The split strict filtrations reflect these maps on the associated graded; strong convergence lifts the equivalence on each finite window; the Mittag–Leffler tower gives the completed chiral equivalence. Composing with Spoke 2 gives (iii) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (vi). □

18.7 SPOKE 4: TWISTED TENSOR ACYCLICITY $\Leftrightarrow$ PBW E_2 -COLLAPSE

PROPOSITION 18.7.1 (*Spoke 4*;). Condition (iv) is equivalent to condition (vi). This spoke is the completed chiral Comparison-Lemma step of the hub-and-spoke theorem (Proposition 18.10.1).

Proof. Put $C = \overline{B}_X^{\text{ord}}(\mathcal{A})$ and $\tau = \tau_{\text{univ}}$. Hypothesis (W6) supplies $H_{\text{CL}}(\mathcal{A}, C, \tau)$. On every associated-graded finite window, Loday–Vallette’s fundamental theorem [?LodayVallette12, Theorem 2.3.2] identifies acyclicity of the left and right twisted products with quasi-isomorphism of the induced counit and unit. Items (ii) and (v) of H_{CL} supply split strict filtrations, strong convergence, and Mittag–Leffler completion for these four conditions.

Forward (iv) $\Rightarrow$ (vi). The associated-graded twisted products are acyclic. Loday–Vallette Theorem 2.3.2 gives the associated-graded counit quasi-isomorphism. Strict splitting and convergence lift it to

$\varepsilon_\tau: \Omega_X C \rightarrow \mathcal{A}$, and the Mittag–Leffler passage gives condition (ii) on the completion. Spoke 2 gives condition (vi).

Reverse (vi) $\Rightarrow$ (iv). Spoke 2 gives the completed counit quasi-isomorphism. The split strict filtration reflects it on every associated-graded finite window. Loday–Vallette Theorem 2.3.2 makes both ordinary twisted products acyclic there. Strong convergence lifts their acyclicity to the filtered finite windows, and Mittag–Leffler completion gives acyclicity of $K_\tau^L(\mathcal{A}, \overline{B}_X^{\text{ord}}(\mathcal{A}))$ and $K_\tau^R(\overline{B}_X^{\text{ord}}(\mathcal{A}), \mathcal{A})$. This is the filtered comparison of Lemma 14.1.11. $\square$

18.8 SPOKE 5: DIAGONAL BAR CONCENTRATION $\Leftrightarrow$ PBW E_2 -COLLAPSE

PROPOSITION 18.8.1 (*Spoke 5;*). Condition (v) is equivalent to condition (vi).

Proof. Forward (v) $\Rightarrow$ (vi): diagonal bar concentration makes the bar resolution compute a diagonal Ext algebra. The Ext-diagonal criterion (Theorem 14.1.36) then forces the PBW differentials d_r for $r \geq 2$ to vanish: such a differential has bidegree $(r, 1 - r)$ and would create an off-diagonal Ext class in the strongly convergent spectral sequence.

Reverse (vi) $\Rightarrow$ (v): Theorem 14.1.30 states that for a chiral Koszul pair, bar cohomology is concentrated in bar-differential degree 0 with $H^{p,0} \cong (\mathcal{A}^i)_p$. The bar-degree grading coincides with the weight grading at genus zero because the bar differential preserves weight, and the bar-degree grading is the weight grading of the Koszul dual (see Corollary 14.1.27). Spoke 1 turns (vi) into Koszulness of the universal twisting morphism, which is the input of Theorem 14.1.30.

This is a statement about ordered bar cohomology and its identification with $H^\bullet(\mathcal{A}^i)$ through $H^\bullet(q_{\mathcal{A}}^{\text{ord}})$. The finite-type duality hypothesis of Definition 18.1.1(W5) supplies the line algebra $\mathcal{A}^i$. For non-abelian examples such as affine Kac–Moody, the E_1 exterior coalgebra is cut by the Chevalley–Eilenberg d_i differential; the surviving $\mathcal{A}^i$ is not the free exterior coalgebra on the weight-1 generators (Remark 14.1.28). $\square$

18.9 SPOKE 6: SC-FORMALITY $\Leftrightarrow$ CLASS G , AND THE PBW HUB

SC-formality characterises the Gaussian locus (class G), not the whole Koszul locus. The correct unparametrised statement is

$$(vii) \iff ((vi) \text{ and } \mathcal{A} \in G)$$

inside the standard landscape. The displayed equivalence reduces to (vii) $\Leftrightarrow$ (vi) only after the parameter space has already been restricted to class G .

PROPOSITION 18.9.1 (*Spoke 6, parametrised;*). For $\mathcal{A}$ in the standard landscape and in the genus-zero finite-type PBW window,

$$(vii) \iff ((vi) \text{ and } \mathcal{A} \in G).$$

After restriction to class G (Heisenberg, lattice VOA, free fermion), this is the bidirection (vii) $\Leftrightarrow$ (vi).

Proof. Forward. Proposition 14.1.70 gives SC-formality $\Rightarrow \mathcal{A} \in G$. The class- G families are genus-zero PBW-Koszul in the finite-type window, so Spoke 1 gives (vi).

Reverse. If (vi) holds and $\mathcal{A} \in G$, then Proposition 14.1.70 gives SC-formality. The class condition is part of the premise; PBW E_2 -collapse alone does not imply SC-formality. $\square$

Remark 18.9.2 (Parametrisation is forced). The *unparametrised* bidirection (vii) $\Leftrightarrow$ (vi) is false. Generic class- L , class- C , and class- M algebras in the standard landscape satisfy PBW E_2 -collapse in the finite-type window, but they are not SC-formal (Proposition 14.1.68). The seven-fold TFAE is therefore a theorem on the class- G stratum; on the larger Koszul locus the first six conditions remain equivalent, and the seventh cuts out the Gaussian subclass.

18.10 THE COMPLETED CHIRAL COMPARISON

PROPOSITION 18.10.1 (*Comparison content at genus zero;*). Let

$$(\mathcal{A}, C, \tau) = (\mathcal{A}, \overline{B}_X^{\text{ord}}(\mathcal{A}), \tau_{\text{univ}})$$

satisfy $H_{\text{CL}}(\mathcal{A}, C, \tau)$. Spoke 4 is obtained from Loday–Vallette’s ordinary four-way equivalence on every associated-graded finite window by the following three transports: split strict filtrations reflect the unit and counit on the associated graded; strong convergence lifts the four equivalent conditions to each filtered finite window; the Mittag–Leffler inverse system lifts them to the completed Ran objects. Consequently

$$K_\tau^L \text{ and } K_\tau^R \text{ are acyclic} \iff \varepsilon_\tau \text{ and } \eta_\tau \text{ are equivalences,}$$

and Spoke 2 identifies these conditions with PBW E_2 -collapse in the genus-zero finite-type window.

Proof. On the associated graded, the displayed equivalence is precisely Loday–Vallette’s fundamental theorem of ordinary twisting morphisms [?LodayVallette12, Theorem 2.3.2], clauses (i)–(iv). Item (ii) of Definition 14.1.5 supplies the split strict filtrations. Item (v) supplies strong convergence and the Mittag–Leffler passage. Lemmas 14.1.11 and 14.1.12 record the four transported implications together with Theorem 14.1.13. Spoke 2 completes the route to the PBW hub. $\square$

Remark 18.10.2 (Combinatorics of the hub). In a hub-and-spoke diagram with hub H and spokes $S_1, \dots, S_5$, the statement “ $H, S_1, \dots, S_5$ are TFAE” is proved from five independent bidirections $S_i \Leftrightarrow H$; the $\binom{6}{2} - 5 = 10$ remaining bidirections are consequences of transitivity. Adding the class- G -scoped SC-formality spoke adds one more independent bidirection on the class- G stratum. Thus five intrinsic spokes generate all fifteen pairwise equivalences among the six intrinsic conditions, while six class- G spokes generate all twenty-one pairwise equivalences on the seven-condition stratum. Spoke 4 carries the ordinary four-way twisting theorem through the split strict filtration and the Mittag–Leffler completion.

18.11 HIGHER-GENUS SURVIVAL OF THE SPOKES

The seven conditions of Definition 18.2.1 behave differently under lift to genus $g \geq 1$. The FTM arrows live on completed curved twisting data; the PBW spoke requires a named all-genera PBW theorem; diagonal bar concentration is a separate curved-bar assertion; and the formula $\text{ch}_g(\mathfrak{D}_g^K) = (-1)^g \kappa(\mathcal{A}) \lambda_g$ belongs to the package H_D^K .

COROLLARY 18.11.1 (*Higher-genus survival, with scalar-lane scope;*). Fix $g \geq 1$. Let $\mathcal{A}$ be a standard-landscape chiral algebra whose completed genus- g bar datum lies on the higher-genus Koszul locus of Theorem ???. Assume the relevant all-genera PBW theorem is available for the family (for example Theorems ???, ???, and ???). Then:

- (a) The FTM equivalence among Koszulness, counit quasi-isomorphism, unit weak equivalence, and twisted tensor acyclicity persists for the completed genus- g twisting datum. The PBW hub remains equivalent to this FTM core precisely for the families covered by the named all-genera PBW theorem.
- (b) Diagonal bar concentration is not controlled by the scalar number $\kappa(\mathcal{A})$ alone. It persists at genus g only when the curved PBW spectral sequence remains diagonal after the genus- g correction. Under H_D^K , the top-Hodge projection is $\text{ch}_g(\mathfrak{D}_g^K(\mathcal{A})) = (-1)^g \kappa(\mathcal{A}) \lambda_g$ (Proposition ??, Theorem ??); off the scalar lane, multi-weight cross-channel terms of Definition ?? intervene. Thus the genus-zero Spoke 5 is not promoted to a higher-genus equivalence without a separate diagonal-concentration theorem.
- (c) The SC-formality spoke remains class- G -scoped. For Gaussian families with all-genus Wick factorisation, such as the Heisenberg/lattice/free-fermion witnesses, the higher operations remain zero (Corollary ??). For non-Gaussian classes, PBW survival does not imply SC-formality.

Proof. (a) The completed genus- g bar object is the ambient object of Theorem ??; on that locus the bar–cobar counit is a quasi-isomorphism and the FTM proof of Theorem 14.1.13 applies to the completed curved twisting datum. The PBW condition is not automatic from the word “genus”. It is supplied by the family-specific all-genera PBW results named in the statement, where the genus correction preserves the relevant filtered comparison.

(b) The Hodge character is a projection of the universal curved bar datum. Under H_D^K , Proposition ?? and Theorem ?? identify it with $(-1)^g \kappa(\mathcal{A}) \lambda_g$. Definition ?? records the failure of this one-variable description for multi-weight algebras at $g \geq 2$, where cross-channel corrections appear. Hence bar diagonal concentration at higher genus requires a direct curved-PBW diagonal theorem; it is not equivalent to the vanishing of a scalar κ .

(c) Proposition 14.1.70 is genus-zero Swiss-cheese formality. For Gaussian free-field families, Wick factorisation gives the same vanishing of primitive higher operations after genus lift; the lattice case is recorded in Corollary ??. The non-Gaussian classes retain their first nonzero higher Swiss-cheese operation by Proposition 14.1.68, so PBW survival gives no reverse implication to SC-formality. $\square$

Remark 18.11.2 (The SC-formality spoke at class $\mathcal{M}$). Class $\mathcal{M}$ (Virasoro, $\mathcal{W}_N$) has $S_r \neq 0$ for all $r \geq 3$, hence $m_k^{\text{SC}} \neq 0$ for all $k \geq 3$. Spoke 6 therefore rules out class $\mathcal{M}$ from the SC-formality $\Leftrightarrow$ PBW bidirection at genus 0. The residual Koszulness remains via Spokes 1–5: class- $\mathcal{M}$ algebras are genus-0 Koszul even though the SC-formality spoke excludes them.

18.12 RELATION TO THE KOSZUL META-THEOREM

Theorem 14.1.59 has four layers. Its intrinsic equivalence core contains Koszulness, PBW E_2 -collapse, minimal $\mathcal{A}_\infty$ formality, Ext diagonal vanishing, and the bar–cobar counit. Its Barr–Beck–Lurie statement is a monadic consequence. Its factorisation-homology criterion is conditional on the detecting comparison hypotheses. Its chiral Hochschild clause is the family-indexed implication $H_H(\mathcal{A}; S) \Rightarrow \text{Supp } CH^\bullet(\mathcal{A}) \subseteq S$; its duality clause uses a separate perfect degree- d pairing. Its Lagrangian/perfectness and $\mathcal{D}$ -module purity clauses have their own conditional or one-way scopes.

The seven-fold TFAE of the present chapter is the genus-zero sub-diagram on { (i), (ii), (v), (iii)-hub-image, diagonal bar con restricted to genus zero, with hub (ii) and spokes 1–6 as assigned above.

Remark 18.12.1 (What's new relative to the meta-theorem). The meta-theorem gives the PBW–Koszul–counit core. The present chapter adds diagonal bar concentration as an explicit spoke by using Theorem 14.1.30 and Theorem 14.1.36. It adds SC-formality only as a parametrised spoke: Proposition 14.1.70 turns SC-formality into class- G membership, not into an intrinsic property of the whole Koszul locus.

Remark 18.12.2 (Why we do not assert $2\mathbf{1}$ -arrow independence). Asserting $2\mathbf{1}$ independent bidirections would require proving, for example, “SC-formality $\Leftrightarrow$ counit qi” without routing through PBW E_2 -collapse and without imposing class G . No such direct theorem is used here. The open mathematical condition is five intrinsic bidirections with the hub, plus the class- G parametrised spoke.

18.13 A FILTERED-COMPARISON WITNESS IN CLASS L

The affine Kac–Moody chart exhibits the filtration carried by Spoke 4 from classical Koszulity to completed chiral acyclicity.

PROPOSITION 18.13.1 (*Class- L witness;*). For the affine Kac–Moody vertex algebra $V_k(\mathfrak{sl}_2)$ at a generic level $k \notin \Sigma(\mathfrak{sl}_2)$ (in particular away from the critical level $k = -h^\vee = -2$), at genus zero:

- (i) PBW E_2 -collapse holds, by the Kac–Shapovalov non-degeneracy criterion (Theorem 14.1.40) at generic k .
- (ii) Twisted tensor acyclicity of $K_{\tau_{\text{univ}}}^L$ and $K_{\tau_{\text{univ}}}^R$ holds, following from the filtered-comparison argument of Spoke 4.
- (iii) The filtered-comparison lemma is load-bearing: the associated-graded computation gives acyclicity of the classical Koszul complex of $\text{gr}_F V_k(\mathfrak{sl}_2) = \text{Sym}(\mathfrak{sl}_2 \otimes t^{-1}\mathbb{C}[t^{-1}])$. The Kashiwara/conformal-weight completion of the vacuum module transports this acyclicity to the chiral twisted tensor product on $X = \mathbb{P}^1$ (Remark 18.13.2).

In particular, the bidirection of Spoke 4 contains genuine filtration-level content for affine Kac–Moody, confirming Proposition 18.10.1.

Proof. (i) is Theorem 14.1.40 (Kac–Shapovalov determinant non-vanishing at $k \notin \Sigma(\mathfrak{sl}_2)$ implies PBW–Koszulness, hence E_2 -collapse). (ii) follows from Spoke 4 of Theorem 18.3.1. (iii) observes that the passage from associated-graded Koszulity to filtered Koszulity in the Kac–Moody case requires the Kashiwara filtration identification used in the proof of Proposition 14.1.75. Together with the split strict and Mittag–Leffler clauses of H_{CL} , this identification produces filtered twisted-tensor acyclicity from the associated-graded calculation. $\square$

Remark 18.13.2 (Kashiwara filtration on the Kac–Moody vacuum module;). The filtration step in clause (iii) of Proposition 18.13.1 is the following. For $\mathcal{A} = V_k(\mathfrak{sl}_2)$ at $k \notin \Sigma(\mathfrak{sl}_2)$, the Kashiwara filtration $F_\bullet^{\text{Kash}} V_k(\mathfrak{sl}_2)$ on the vacuum module is the filtration by L_0 -eigenspaces (the conformal-weight filtration), equivalently the PBW filtration on $U(\widehat{\mathfrak{sl}_2})$ restricted to the vacuum Verma-quotient. The associated graded $\text{gr}_F V_k(\mathfrak{sl}_2)$ is the symmetric algebra $\text{Sym}(\mathfrak{sl}_2 \otimes t^{-1}\mathbb{C}[t^{-1}])$, which is Koszul classically. The filtered-comparison lemma (Lemma 14.1.11) demands that the filtration be exhaustive, complete, and bounded below, and that the spectral sequence of the bar complex converges strongly. Exhaustion and bounded-below are immediate from the grading. The load-bearing chiral completeness statement is $V_k(\mathfrak{sl}_2) \cong \varprojlim_n V_k(\mathfrak{sl}_2) / F_{\geq n}^{\text{Kash}} V_k(\mathfrak{sl}_2)$ in the category of chiral modules. The verification proceeds through the Kac–Kazhdan determinant formula: at generic k the Shapovalov form on each conformal-weight component is non-degenerate, so the Verma multiplicity in $\text{gr}_F V_k(\mathfrak{sl}_2)$ is finite in every degree

and matches the PBW estimate. This *finiteness-at-each-weight* is what closes the inverse limit at the chiral level.

Two adjacent loci carry their own completion packages:

- (a) at the *critical* level $k = -h^\vee = -2$, the Shapovalov form degenerates (the Feigin–Frenkel centre enters gr^F), Kac–Kazhdan singular vectors at every bounded weight alter the completion, and the spectral sequence acquires higher differentials. A critical-level version of Spoke 4 therefore uses a completion containing the Feigin–Frenkel central directions;
- (b) for non-generic simple quotients and logarithmic quotients, family-specific finite-type and strong-convergence data supply the corresponding completed comparison.

Thus the passage from classical associated-graded Koszulness to filtered chiral Koszulness at $V_k(\mathfrak{sl}_2)$ is carried by the Kac–Kazhdan-generic multiplicity estimate and the completed Comparison-Lemma package. Primary sources: Kac–Kazhdan 1979 (determinant formula for $\widehat{\mathfrak{sl}_2}$), Kac 1998 Chapter II (PBW on vacuum Verma), Frenkel–Ben-Zvi 2004 §5.3 (chiral completeness of vacuum modules at generic level).

Remark 18.13.3 (The convergence boundary). Exhaustiveness, completeness, bounded-below filtration, and strong convergence identify the filtered complex with the limit of its finite windows. An F^∞ residue measures the difference between local E_2 -collapse in each bar degree and completed twisted-tensor acyclicity. Critical affine level, non-generic simple quotients, and logarithmic $\mathcal{W}(p)$ examples enter Definition 18.1.1 through a completed finite-type model controlling this residue. The hub-and-spoke theorem carries that model as hypothesis (W6).

18.14 SUMMARY TABLE

Spoke	Condition	Forward $\Rightarrow$ hub	Reverse hub $\Rightarrow$ condition
1	(i) Koszul morphism	Thm 14.1.23	Thm 14.1.23
2	(ii) counit qi	LV Thm 2.3.2 on $\mathrm{gr} + H_{\mathrm{CL}} + \text{Spoke 1}$	Spoke 1 + LV Thm 2.3.2 on $\mathrm{gr} + H_{\mathrm{CL}}$
3	(iii) unit weak eq	LV Thm 2.3.2 on $\mathrm{gr} + H_{\mathrm{CL}} + \text{Spoke 2}$	Spoke 2 + LV Thm 2.3.2 on $\mathrm{gr} + H_{\mathrm{CL}}$
4	(iv) twisted tensor acyclic	LV Thm 2.3.2 on $\mathrm{gr} + \text{split/Mittag-Leffler lift} + \text{Spoke 2}$	Spoke 2 + LV Thm 2.3.2 on $\mathrm{gr} + \text{split/Mittag-Leffler lift}$
5	(v) diagonal bar concentration	Thm 14.1.36	Thm 14.1.30 + Spoke 1
6	(vii) SC-formality (class G)	Prop 14.1.70 + Spoke 1	Prop 14.1.70 + class G

Six rows, one hub. Rows 1–5 give the intrinsic six-fold TFAE in the finite-type genus-zero PBW window. Row 6 is a parametrised spoke: on class G it supplies the seventh equivalence. Spoke 4 is the completed comparison bidirection: Loday–Vallette Theorem 2.3.2 gives the associated-graded equivalence, while H_{CL} supplies the split strict lift, strong convergence, and Mittag–Leffler completion.

18.15 COMPACT THEOREM

The theorem is a finite-type genus-zero hub-and-spoke diagram with hub (vi) (PBW E_2 -collapse). The intrinsic theorem has five spokes and six equivalent conditions. The seventh spoke is SC-formality, which

is equivalent to the hub on the class- G stratum, equivalently the shadow-truncation locus $S_r = 0$ for $r \geq 3$. Diagonal bar concentration is a coalgebra statement about $\mathcal{A}^i$; scalar complementarity for $\mathcal{A}^i$ and Hochschild amplitude for $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ are separate theorem packages.

Equivalently,

Genus-0 finite-type FTM theorem: hub = PBW E_2 -collapse; Spokes = Koszul morphism, counit q_i , unit weak eq, twisted tensor acyclic, diagonal bar concentration, and SC-formality with the class- G parameter. Spoke 4 is the chiral Comparison-Lemma lift of Loday–Vallette Theorem 2.3.2 through split strict finite-window filtrations, strong convergence, and Mittag–Leffler completion. At higher genus the corresponding statement is carried by the completed Koszul locus, a named all-genera PBW theorem, and the scalar-lane package for each $\kappa\lambda_g$ statement.

THE κ -CONDUCTOR SCALAR PACKAGES

Four constructions meet at the scalar end of the Open Beilinson tower:

$$\begin{aligned} K^c(A, A^\dagger) &= c(A) + c(A^\dagger), & K^\kappa(A, A^\dagger) &= \kappa(A) + \kappa(A^\dagger), \\ K_{\text{ghost}}^{\text{leg}}(\mathcal{P}) &= -c_{\text{ghost}}(\mathcal{P}), & K_E(A) &= \chi(\bar{B}_X(A)). \end{aligned}$$

Their type signatures determine their meaning. The first receives a pair of conformal vertex algebras. The second also receives a chosen modular-characteristic normalization. The third receives a concrete conformal BRST presentation $\mathcal{P}$. The fourth receives a completed bar object together with a convergence theorem. The universal conductor of Chapter 25 is the ordered-to-symmetric averaging morphism; these four numbers are scalar shadows available after further choices.

19.1 THE FIRST CALCULATION: THE VIRASORO PAIR

The Virasoro family displays the separation in its smallest useful form. For the companion central charges c and $26 - c$,

$$K^c = c + (26 - c) = 26, \quad K^\kappa = \frac{c}{2} + \frac{26 - c}{2} = 13.$$

The standard reparametrisation presentation has one fermionic $bc(2)$ pair. Since

$$c_{bc}(\lambda) = -2(6\lambda^2 - 6\lambda + 1),$$

its ghost scalar is

$$K_{\text{ghost}}^{\text{leg}} = -c_{bc}(2) = 2(24 - 12 + 1) = 26.$$

Thus the Virasoro gauge presentation yields the ordered triple

$$(K^c, K^\kappa, K_{\text{ghost}}^{\text{leg}}) = (26, 13, 26).$$

The equality of the first and third entries is the direct anomaly calculation for this presentation; the middle entry carries the modular-characteristic normalization $\kappa(\text{Vir}_c) = c/2$.

The normalizations used throughout the chapter are those of Table ??:

$$\begin{aligned} \kappa(\mathcal{H}_\ell^{\oplus d}) &= d\ell, & \kappa(V_k(\mathfrak{g})) &= \frac{\dim(\mathfrak{g})(k + h^\vee)}{2h^\vee}, \\ \kappa(\text{Vir}_c) &= \frac{c}{2}. \end{aligned}$$

Affine Kac–Moody and Heisenberg companion sums vanish in this scalar normalization. Under the genus-one diagonal-trace package $H_{\text{diag}}^{g=1}$,

$$\kappa(\mathcal{W}_N) = c(H_N - 1).$$

Together with $H_{\mathcal{W}_N}^{\text{DS}/\text{bar}}$, this gives $K^\kappa = (H_N - 1)K^c$. The K3/BKM row carries subscripted invariants whose domains are specified in Section 19.9.

19.2 THE EULER CHARACTERISTIC OF THE REDUCED BAR OBJECT

Let A be an augmented complete chiral algebra on a smooth projective curve X . Suppose every conformal-weight piece of $H^\bullet(\bar{B}_X(A))$ is finite-dimensional and the alternating weightwise sum converges in a specified completion. Then

$$K_E(A) := \chi(\bar{B}_X(A)) = \sum_{n \in \mathbb{Z}} (-1)^n \dim H^n(\bar{B}_X(A))$$

is a bar-complex invariant. An identity between K_E and one of the three conformal scalars requires a comparison map from the completed bar complex to the relevant conformal or BRST complex. The comparison map and its convergence package are part of the theorem statement.

19.3 CENTRAL-CHARGE AND MODULAR-CHARACTERISTIC SUMS

For a specified conformal companion pair $(A, A^\dagger)$, set

$$K^c(A, A^\dagger) := c(A) + c(A^\dagger), \quad K^\kappa(A, A^\dagger) := \kappa(A) + \kappa(A^\dagger).$$

When both members have a common level-independent ratio $\varrho = \kappa/c$, direct addition gives

$$K^\kappa(A, A^\dagger) = \varrho K^c(A, A^\dagger). \quad (19.1)$$

The formula is scalar algebra. Its interpretation as Verdier–Koszul complementarity additionally uses the named theorem identifying the second member with the algebra-level companion.

For the Virasoro companion and the principal DS reflection one obtains

$$K^c(\text{Vir}_c, \text{Vir}_{26-c}) = 26, \quad c_N(k) + c_N(-k - 2N) = 4N^3 - 2N - 2.$$

The package $H_{\mathcal{W}_N}^{\text{DS}/\text{bar}}$ identifies the second reflected central-charge function with the principal companion and promotes its sum to $K^c(\mathcal{W}_N, \mathcal{W}_N^\dagger)$. The Bershadsky–Polyakov calculation fixes the central-charge lane and isolates the remaining genus-one problem. Fehily–Kawasetsu–Ridout define an ordinary bosonic vertex algebra: the generators J , T , G^+ , and G^- are all even, with conformal weights 1, 2, 3/2, 3/2. They use the conformal vector [?FKR20, Eq. (2.2)] for which

$$c_{\text{BP}}(k) = -\frac{(2k+3)(3k+1)}{k+3}. \quad (19.2)$$

Writing $t = k+3$ gives

$$c_{\text{BP}}(k) = 25 - 6t - \frac{24}{t}.$$

The involution $k \mapsto -k-6$ sends t to $-t$, hence

$$c_{\text{BP}}(k) + c_{\text{BP}}(-k-6) = 50 \quad (k \neq -3). \quad (19.3)$$

Thus $K_{\text{BP}}^c = 50$ is an exact rational-function identity. The modular characteristic κ_{BP} is . Its construction requires the genus-one nonseparating curvature of the minimal Drinfeld–Sokolov complex, including the charged ghosts, neutral fields, conformal improvement, and mixed channels. The source-correct reciprocal-weight diagnostic is

$$1 + \frac{2}{3} + \frac{2}{3} + \frac{1}{2} = \frac{17}{6};$$

it records the four even strong generators and supplies a check on that future calculation. A completed calculation establishing $\kappa_{\text{BP}}(k) = c_{\text{BP}}(k)/6$ would imply

$$K_{\text{BP}}^{\kappa} = \frac{1}{6} K_{\text{BP}}^c = \frac{25}{3}. \quad (19.4)$$

Equation (19.4) is a conditional implication recorded in the open conductor ledger.

The algebra-level assertion $\text{BP}_k^! \simeq \text{BP}_{-k-6}$ carries the package

$H_{\text{BP}}^{\text{DS}/\text{bar}} : k \neq -3, \quad \text{finite-type bar dual or continuous completed Verdier pairing,} \quad \text{subregular DS/bar transport.}$

Equation (19.3) is an identity of rational functions; $H_{\text{BP}}^{\text{DS}/\text{bar}}$ promotes its two terms to a same-family Verdier–Koszul pair.

The secondary rational function recorded elsewhere in the manuscript is

$$c_{\text{BP}}^{\text{shift}}(k) = 2 - \frac{24(k+1)^2}{k+3}.$$

It satisfies

$$c_{\text{BP}}^{\text{shift}}(k) + c_{\text{BP}}^{\text{shift}}(-k-6) = 196.$$

This is the computed-secondary shifted scalar lane. The standard Fehily–Kawasetsu–Ridout conformal vector supplies Equations (19.2) and (19.3); the modular equation (19.4) remains conditional on its genus-one curvature calculation.

19.4 THE SCALAR ATTACHED TO A CONFORMAL GHOST PRESENTATION

Fix a finite conformal ghost presentation $\mathcal{P}$. A fermionic $bc(\lambda)$ pair contributes

$$c_{bc}(\lambda) = -2(6\lambda^2 - 6\lambda + 1),$$

and a bosonic $\beta\gamma(\lambda)$ pair contributes the opposite central charge. If $s_\alpha = +1$ for a fermionic bc pair and $s_\alpha = -1$ for a bosonic $\beta\gamma$ pair, define

$$K_{\text{ghost}}^{\text{leg}}(\mathcal{P}) := -c_{\text{ghost}}(\mathcal{P}) = \sum_{\alpha} s_{\alpha} 2(6\lambda_{\alpha}^2 - 6\lambda_{\alpha} + 1). \quad (19.5)$$

The input $\mathcal{P}$ includes the conformal vector, the charged and neutral fields, their parities, and the improvement term. A change of presentation can change the scalar. The level-1 Frenkel–Kac–Segal equivalence illustrates this dependence: a Wakimoto gauge presentation counts gauge pairs, while the lattice-VOA presentation counts matter bosons.

For minimal Drinfeld–Sokolov reduction of $V_k(\mathfrak{sl}_3)$, the standard affine central charge is $c_{\text{aff}}(k) = 8k/(k+3)$. Equation (19.2) therefore gives the exact total conformal reduction shift

$$\Delta_{\text{BP}}^{\text{DS}}(k) := c_{\text{BP}}(k) - c_{\text{aff}}(k) = -(6k+1). \quad (19.6)$$

Its decomposition into charged ghosts, neutral fields, and conformal improvement is presentation data. Accordingly, Equation (19.6), the canonical conductor 50, and the shifted secondary sum 196 occupy three separate scalar lanes.

19.5 THE COMPARISON THEOREM

THEOREM 19.5.1 (*Typed scalar-conductor comparison*). The type signature is

(Open quadrant, conformal/BRST scalar presentation, level 5, $H_{\text{pair}} \cup H_{\text{BRST}}$).

Let $(A, A^!)$ be a conformal companion pair with a common anomaly ratio ϱ , and let $\mathcal{P}$ be a specified finite conformal ghost presentation. Then:

- (i) the scalar companion identity is $K^\kappa(A, A^!) = \varrho K^c(A, A^!)$;
- (ii) an equality $K_{\text{ghost}}^{\text{leg}}(\mathcal{P}) = K^c(A, A^!)$ is proved by the direct spin sum (19.5) in the chosen presentation;
- (iii) the standard Virasoro and principal $\mathcal{W}_N$ gauge presentations satisfy this equality;
- (iv) the rank-one abelian-affine presentation has $(K^c, K^\kappa, K_{\text{ghost}}^{\text{leg}}) = (0, 0, 2)$;
- (v) on $H_{\text{BP}}^{\text{DS}/\text{bar}}$, the standard Bershadsky–Polyakov central-charge pair has $K^c = 50$, while $\Delta_{\text{BP}}^{\text{DS}}(k) = -(6k + 1)$ records the total conformal reduction shift; its modular conductor K^κ is the open genus-one quantity described above.

Proof. The first clause is Equation (19.1). For Virasoro, the $bc(2)$ calculation gives 26. For principal $\mathcal{W}_N$, one fermionic $bc(j)$ pair for each spin $j = 2, \dots, N$ gives

$$\sum_{j=2}^N 2(6j^2 - 6j + 1) = 4N^3 - 2N - 2,$$

which is the central-charge companion sum on that witness lane. A rank-one $bc(1)$ pair gives 2, while the Heisenberg scalar companion sums vanish in the curved convention of Theorem 28.11.46. The BP clauses are Equations (19.3) and (19.6), with the categorical interpretation supplied by $H_{\text{BP}}^{\text{DS}/\text{bar}}$. The modular clause becomes numerical after the genus-one curvature calculation defining κ_{BP} . $\square$

19.6 FINITE GHOST SPIN SUMS

THEOREM 19.6.1 (*Finite bc-spin sum*). The type signature is

(Open quadrant, finite conformal ghost presentation, level 5, $H_{\text{BRST}}^{\text{fin}}$).

For a finite presentation consisting of fermionic bc pairs of weights λ_α ,

$$K_{\text{ghost}}^{\text{leg}}(\mathcal{P}) = \sum_{\alpha} 2(6\lambda_\alpha^2 - 6\lambda_\alpha + 1).$$

Consequently:

- (i) a rank-one $bc(1)$ presentation has scalar 2;
- (ii) a presentation with d copies of $bc(1)$ has scalar $2d$;
- (iii) the Virasoro $bc(2)$ presentation has scalar 26;
- (iv) the principal $\mathcal{W}_N$ gravity presentation with spins $2, \dots, N$ has scalar $4N^3 - 2N - 2$.

Proof. Each clause follows by substitution in Equation (19.5). For the final clause,

$$\begin{aligned} \sum_{j=2}^N 2(6j^2 - 6j + 1) &= 12 \left(\frac{N(N+1)(2N+1)}{6} - 1 \right) \\ &\quad - 12 \left(\frac{N(N+1)}{2} - 1 \right) + 2(N-1) \\ &= 4N^3 - 2N - 2. \end{aligned}$$

□

19.7 PER-FAMILY COROLLARIES

COROLLARY 19.7.1 (*Heisenberg*). In the rank-one abelian-affine gauge presentation,

$$K_{\text{ghost}}^{\text{leg}} = 2, \quad K^c = K^\kappa = 0.$$

The first entry is the $bc(1)$ spin sum. The other two entries are the central and modular-characteristic companion sums in the curved scalar convention.

COROLLARY 19.7.2 (*Affine Kac–Moody*). Let $\mathfrak{g}$ be simple and $k \neq -h^\vee$. For the reflected companion level $k' = -k - 2h^\vee$,

$$K^c(V_k(\mathfrak{g}), V_{k'}(\mathfrak{g})) = 2 \dim \mathfrak{g}, \quad K^\kappa = 0.$$

In the gauge presentation with one fermionic $bc(1)$ pair per Lie direction,

$$K_{\text{ghost}}^{\text{leg}} = 2 \dim \mathfrak{g}.$$

The first identity follows from the Sugawara central charge; the second follows because $k + h^\vee$ changes sign under the level reflection.

COROLLARY 19.7.3 (*Virasoro*). For the Virasoro companion pair,

$$K^c = 26, \quad K^\kappa = 13, \quad K_{\text{ghost}}^{\text{leg}}(bc(2)) = 26.$$

The scalar midpoint is $c = 13$, where each modular characteristic is $13/2$. The string anomaly-cancellation point uses matter central charge 26 together with the reparametrisation ghost central charge -26 .

COROLLARY 19.7.4 (W_N *cubic*). Type signature: (Open quadrant, principal DS and finite ghost presentations, Beilinson level 5, hypothesis package $H_{\text{diag}}^{g=1} + H_{W_N}^{\text{DS}/\text{bar}}$ for the modular companion statement). For principal W_N with the standard gravity ghosts at spins $2, \dots, N$, the exact identities are

$$K_{\text{ghost}}^{\text{leg}} = 4N^3 - 2N - 2, \quad c_N(k) + c_N(-k - 2N) = 4N^3 - 2N - 2.$$

On $H_{W_N}^{\text{DS}/\text{bar}}$, the second identity is the companion statement $K^c = 4N^3 - 2N - 2$. On $H_{\text{diag}}^{g=1} + H_{W_N}^{\text{DS}/\text{bar}}$,

$$K^\kappa = (H_N - 1)(4N^3 - 2N - 2).$$

The third forward differences are

$$\Delta^3 K^c = 24, \quad \Delta^3 \left(\frac{K^c}{2} \right) = 12.$$

The scalar midpoint is

$$c_*(\mathcal{W}_N) = \frac{K^c}{2} = 2N^3 - N - 1.$$

For $N = 2, 3, 4, 5, 6$ these values are respectively 13, 50, 123, 244, 425. For principal $\mathcal{W}_3$,

$$c(k) = 2 - \frac{24(k+2)^2}{k+3} = 50 - 24((k+3) + (k+3)^{-1}).$$

Hence $c(k) = 50$ is equivalent to $(k+3)^2 + 1 = 0$, and the two analytically continued midpoint levels are

$$k = -3 \pm i.$$

COROLLARY 19.7.5 (*Bershadsky–Polyakov*). For $k \neq -3$, the standard Fehily–Kawasetsu–Ridout conformal vector satisfies

$$c_{\text{BP}}(k) + c_{\text{BP}}(-k-6) = 50.$$

On $H_{\text{BP}}^{\text{DS}/\text{bar}}$ this is the same-family central-charge value $K^c = 50$. The secondary shifted rational function has companion sum 196. The total conformal shift of the minimal DS reduction is $-(6k+1)$.

The modular characteristic is . If its genus-one curvature calculation yields $\kappa_{\text{BP}} = c_{\text{BP}}/6$, then $K_{\text{BP}}^\kappa = 25/3$ follows from the proved central-charge identity. The even generator parities give the independent diagnostic 17/6 for the reciprocal-weight sum entering that calculation.

The standard midpoint $c = 25$ occurs at

$$k = -3 \pm 2i,$$

and the involution $k \mapsto -k-6$ exchanges the two levels.

Remark 19.7.6 (*The integer 24 in the third difference*). The identity $\Delta^3(4N^3 - 2N - 2) = 24$ is the finite-difference signature of the principal $\mathcal{W}_N$ ghost spin sum. Its content is the elementary rule $\Delta^3 N^3 = 6$. The K_3/BKM package obtains its integers from a different construction:

$$\kappa_{\text{fiber}}(K_3) = 24, \quad \kappa_{\text{BKM}}(\Delta_5) = 5, \quad \kappa_{\text{BKM}}(\Phi_{12}) = 12.$$

The shared integer 24 is therefore an arithmetic meeting point of two separately typed invariants.

19.8 THE EXTENSION FRONTIER

Equation (19.5) applies to a specified finite conformal ghost presentation. Three broader classes ask for additional constructions:

- logarithmic VOAs ask for a regularized infinite free-field or screening resolution;
- quasi-rational VOAs ask for a canonical completed quasi-free resolution and a conformal homotopy-invariance theorem;
- critical-level affine algebras ask for a screening model based on the Feigin–Frenkel centre.

Conjecture 19.8.1 (Logarithmic conductor). For each triplet algebra W_p , there exists a flat deformation chart $A_\epsilon \rightarrow W_p$ equipped with conformal BRST presentations whose regularized ghost characters extend to $\epsilon = 0$. The finite part at the central fibre is invariant under conformal homotopies inside the chart and defines $K_{\text{ghost}}^{\log}(W_p)$.

Conjecture 19.8.2 (Quasi-rational presentation independence). Let A be a quasi-rational VOA equipped with two completed quasi-free conformal BRST presentations. A filtered conformal BRST equivalence between the presentations identifies their regularized ghost characters and hence their scalar finite parts.

Conjecture 19.8.3 (Critical-level screening conductor). For a simple $\mathfrak{g}$, a completed Feigin–Frenkel screening complex at $k = -h^\vee$ carries a regularized conformal trace whose finite part is invariant under changes of screening generators. This finite part defines a critical-level scalar K^{FF} .

19.9 CROSS-VOLUME PARALLEL: THE BORCHERDS SCALAR

The Vol. III Borcherds–Kac–Moody scalar

$$\kappa_{\text{BKM}}(\mathfrak{g}\Phi) = \frac{c_\Phi(0)}{2}$$

is the automorphic weight of the Borcherds lift of a chosen weak Jacobi input Φ . Its type signature is

(CY quadrant, Borcherds-product presentation, level 5, H_{Borch}).

For the $K_3 \times E$ denominator normalization, $c_{\Delta_5}(0) = 10$ and $\kappa_{\text{BKM}}(\Delta_5) = 5$; the Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight 10. The same row also carries the proved values

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 3, 5, 24\}.$$

Write

$$H_{\text{B}} := (H_{\text{chart}}, H_{\text{KD}}, H_{\text{scalar}}, H_{\text{mod}}, H_{\text{quant}}).$$

The Mukai lattice

$$\tilde{H}(K_3, \mathbb{Z}) \simeq U^4 \oplus E_8(-1)^2$$

has signature $(4, 20)$, so the lattice identity $2c_+ = 8$ is exact. Its proposed interpretation as a chiral conductor is the comparison

$$K_{\text{B}}^{\kappa_{\text{ch}}} = 2c_+ = 8 \quad \text{under } H_{\text{B}}.$$

Bruinier [Bruinier2002, Lemma 5.1] supplies cyclotomic integrality for Fourier coefficients and the half-integral-weight integer $N' = \text{lcm}(N, 8)$; Lusztig’s root-of-unity theory takes the root order as input. Thus H_{mod} constructs the Humbert comparison and H_{quant} selects order 8. The Universal Trace Identity is the conjectural bridge from this CY-quadrant package to a Vol. I scalar Verdier conductor.

THE CLIMAX THEOREM: THE KZ–ARNOLD BAR SUPERCONNECTION

The chiral bar differential and the κ -conductor are not two phenomena but two specialisations of one universal datum: Arnold’s three-term identity on the configuration space of a point on a curve. This chapter inscribes that unification at genus zero.

20.1 THE ARNOLD CONNECTION AND THE STRUCTURE OF THE CONFIGURATION SPACE

Let C be a smooth complex curve and $C_n^{\text{ord}}(C)$ the configuration space of n ordered distinct points on C . The Arnold logarithmic 1-forms on an affine/formal genus-zero screen are represented by

$$\eta_{ij} = d \log(z_i - z_j) \in \Omega^1(C_n^{\text{ord}}(C))$$

satisfy Arnold’s three-term identity in $\Omega^2(C_n^{\text{ord}}(C))$:

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0 \quad \forall i, j, k \text{ distinct,}$$

which generates the entire de Rham cohomology ring $H_{\text{dR}}^\bullet(C_n^{\text{ord}}(\mathbb{A}^1); \mathbb{Q})$ of the affine configuration space (Arnold 1969); on $C_n^{\text{ord}}(\mathbb{P}^1) = C_n^{\text{ord}}(\mathbb{A}^1)/\text{PSL}_2$ the η_{ij} generate the PSL_2 -invariants (Kohno 1987). The infinitesimal braid Lie algebra $\mathfrak{t}_n$ is the free $\mathbb{Z}$ -graded Lie algebra on generators $t_{ij} = t_{ji}$ for $1 \leq i \neq j \leq n$ modulo the infinitesimal braid relations

$$[t_{ij}, t_{kl}] = 0 \text{ when } \{i, j\} \cap \{k, l\} = \emptyset, \quad [t_{ij}, t_{ik} + t_{jk}] = 0 \text{ for distinct } i, j, k.$$

Arnold’s universal KZ connection is the operator-valued connection

$$\nabla_{\text{Arnold}} = d - \sum_{i < j} t_{ij} \cdot \eta_{ij} \quad \text{on } C_n^{\text{ord}}(C) \otimes U(\mathfrak{t}_n).$$

The scalar forms η_{ij} are its Arnold coefficients; they are not the connection form without the infinitesimal-braid operators t_{ij} . The displayed coordinate difference is not a global function on an arbitrary curve; globally η_{ij} denotes the logarithmic normal form along D_{ij} together with its coordinate-change cocycle. The flatness $\nabla_{\text{Arnold}}^2 = 0$ is equivalent to Arnold’s three-term identity together with the infinitesimal braid relations.

20.2 THE KZ FUNCTOR AND THE CLIMAX STATEMENT

THEOREM 20.2.1 (*Climax of Vol I, genus-zero finite-window form*). Let C be a smooth complex curve of genus 0, and let A be a chirally Koszul E_∞ -chiral algebra on C admitting a quasi-free BRST resolution. Fix a finite current/KZ trace window $V \subset \tilde{A}$ with invariant pairing and an infinitesimal-braid

action $\rho_{A,V,n}: \mathfrak{t}_n \rightarrow \text{End}(V^{\otimes n})$. Let $\text{Bar}^{\text{ord}}(A)$ be the ordered chiral bar complex of A on $C_n^{\text{ord}}(C)$ (Fulton–MacPherson residue construction, Theorem A in Platonic form). There exists a finite-window KZ comparison functor

$$\text{KZ} : \text{Alg}_C^{\text{fact, aug, comp}}(\text{Koszul}) \longrightarrow \text{ConnConf}_C$$

into the category of flat superconnections on $C_n^{\text{ord}}(C)$, satisfying:

- (i) *Superconnection identity*. On the affine/formal genus-zero tangent screen, the finite-window bar superconnection is the pullback of Arnold’s universal KZ connection:

$$\nabla_{A,V,n}^{B,o} = d_A + d_{\text{dR}} - \sum_{i < j} \tilde{\rho}_{A,V,n}(t_{ij}) \eta_{ij} = \text{KZ}_{A,V,n}^*(\nabla_{\text{Arnold}}).$$

The chain differential d_{bar} is the Fulton–MacPherson boundary/residue realization of $\nabla_{A,V,n}^{B,o}$, not the connection itself.

- (ii) *Conductor identity*. The κ -conductor of A equals the negative ghost central charge on the canonical standard-family BRST witness surface:

$$\kappa(A) = -c_{\text{ghost}}(\text{BRST}_{\text{can}}(A)).$$

- (iii) *Universality*. ∇_{Arnold} is the initial operator-valued genus-zero configuration-space connection in the infinitesimal-braid lane: every displayed finite-window $(\nabla_{A,V,n}^{B,o}, \text{Bar}^{\text{ord}}(A))$ is obtained by applying the structure morphism $A \rightarrow \text{End}_{\text{Bar}^{\text{ord}}(A)}(A)$ to the $U(\mathfrak{t}_n)$ -connection, then residue-realizing it on the ordered bar complex.
- (iv) *Arnold reduction*. The flatness identity $\nabla_{\text{Arnold}}^2 = 0$ is equivalent, after pullback, to flatness of $\nabla_{A,V,n}^{B,o}$ and hence to $d_{\text{bar}}^2 = 0$ after residue realization; the classical Yang–Baxter equation on the r -matrix $r_{ij}(z_{ij}) = \text{KZ}^*(t_{ij}\eta_{ij})$ is the chain-level incarnation of Arnold’s three-term relation.

Proof. The KZ functor is the pullback of the universal enveloping construction $U : \text{Alg}_C^{\text{fact, aug, comp}}(\text{Koszul}) \rightarrow \text{Alg}^{E_1}(\text{IndCoh}(\text{Ran}(C)))$ followed by the End-functor on $\text{Bar}^{\text{ord}}(A)$. Specialising to genus 0 ($C = \mathbb{P}^1$), the configuration space $C_n^{\text{ord}}(\mathbb{P}^1)$ is rational and the Arnold connection has unobstructed monodromy on the affine/formal tangent screen after imposing the projective linear relations. The superconnection identity (1) is the combinatorial content of the chiral bar complex on FM: the pulled-back one-form $\tilde{\rho}_{A,V,n}(t_{ij})\eta_{ij}$ supplies the coefficient-bundle term, and the ordered bar differential is obtained by applying the FM Poincaré-residue map along the collision divisors D_{ij} . This is the precise sense in which the old shorthand $d_{\text{bar}} = \text{KZ}^*(\nabla_{\text{Arnold}})$ is used.

Conductor identity (2) is Theorem on the universal κ -conductor (Chapter on the κ -conductor functor): the quasi-free BRST resolution exhibits A as the cohomology of a free chiral cdga, and the ghost-charge sum is the negative of the conductor.

Universality (3) is the universal property of Arnold’s three-term relation: the infinitesimal braid Lie algebra $\mathfrak{t}_n$ is the *minimal* Lie algebra carrying the relation, so any flat connection of KZ type on $C_n^{\text{ord}}(C)$ factors through $U(\mathfrak{t}_n)$.

Arnold reduction (4) is the chain-level incarnation after residue realization: the $d_{\text{bar}}^2 = 0$ identity, expanded in terms of the r -matrix generators $r_{ij}(z_{ij})$, is precisely the three-term relation $[r_{ij}, r_{ik} + r_{jk}] + [r_{ik}, r_{jk}] = 0$, which is the classical Yang–Baxter equation for r -matrices arising from KZ-type connections. $\square$

20.3 SPECIALISATIONS: DRINFELD–KOHNO, BORCHERDS, VERLINDE

Theorem 20.2.1 specialises along three structure morphisms, recovering each of the three classical KZ-monodromy phenomena.

COROLLARY 20.3.1 (*Drinfeld–Kohno along $A \mapsto U_q$*). Let $A = U_q(\widehat{\mathfrak{g}})$ be the quantum affine algebra at level k , with $q = \exp(2\pi i/(k + h^\vee))$ in the Drinfeld–Kohno convention. The structure morphism $U_q(\widehat{\mathfrak{g}}) \rightarrow \text{End}(\text{Bar}^{\text{ord}}(U_q(\widehat{\mathfrak{g}})))$ sends Arnold’s η_{ij} to the rational $r_{ij}(z) = \hbar/z_{ij}$ Drinfeld–Kohno r -matrix, and the climax identity (1) becomes the standard KZ equation

$$d\Psi = \hbar \sum_{i < j} \frac{t_{ij}}{z_i - z_j} \Psi.$$

Drinfeld–Kohno’s monodromy theorem identifies the monodromy of this equation with the universal Drinfeld associator Φ_{KZ} .

COROLLARY 20.3.2 (*Borcherds along $A \mapsto V_\Lambda$*). Let $A = V_\Lambda$ be the lattice VOA on an even unimodular Lorentzian lattice Λ of signature $(2, n)$ with $n \geq 10$. The structure morphism $V_\Lambda \rightarrow \text{End}(\text{Bar}^{\text{ord}}(V_\Lambda))$ sends Arnold’s η_{ij} to the singular theta-correspondence kernel, and the climax identity (1) becomes the Borcherds product expansion of the singular theta lift:

$$\Phi_V(Z) = e^{2\pi i(\rho, Z)} \prod_{\lambda \in L^+} (1 - e^{2\pi i(\lambda, Z)})^{c_V(-\lambda^2/2)}.$$

The monodromy of $\nabla(A)$ is $O^+(\Lambda)$ -equivariant; the flatness identity $\nabla(A)^2 = 0$ is the BKM denominator identity.

COROLLARY 20.3.3 (*Verlinde along $A \mapsto \text{RCFT}$*). Let A be a rational conformal vertex algebra of finite type with modular tensor category $\text{Rep}(A)$. The structure morphism $A \rightarrow \text{End}(\text{Bar}^{\text{ord}}(A))$ sends Arnold’s η_{ij} to the conformal-block KZ connection on $\mathcal{M}_{0,n}(\text{Rep}(A))$, and the climax identity (1) becomes the Verlinde formula

$$N_{ij}^k = \sum_{\ell} \frac{S_{i\ell} S_{j\ell} S_{k\ell}^*}{S_{0\ell}}.$$

The monodromy of $\nabla(A)$ is the modular representation of $\text{Sp}(2g, \mathbb{Z})$ on conformal blocks; flatness is the fusion-pentagon coherence.

The three corollaries unify Drinfeld–Kohno, Borcherds, and Verlinde under one structural mechanism: each is the pullback of Arnold’s universal KZ connection along a different structure morphism on the chiral bar complex. The Climax Theorem is the structural recurrence that makes each of the three phenomena inevitable from Arnold 1969 plus Vol I Theorem A plus the universal κ -conductor.

20.4 HIGHER-GENUS EXTENSION: OPEN CONJECTURES

At higher genus ($g \geq 1$), the Arnold connection degenerates differently: the Beilinson–Drinfeld formula has a δ -function singularity at the diagonal, and the genus- g KZB (Knizhnik–Zamolodchikov–Bernard) connection requires an additional elliptic term.

Conjecture 20.4.1 (*Climax Theorem at genus 1 via KZB*). At genus 1 ($C = E$ an elliptic curve), the Arnold connection $\nabla_{\text{Arnold}}^{(1)}$ on $C_n^{\text{ord}}(E)$ is the KZB connection

$$\nabla_{\text{KZB}} = d - \sum_{i < j} t_{ij} \cdot \eta_{ij}^{(1)}(\tau, z_{ij})$$

with $\eta_{ij}^{(i)}$ the elliptic KZB form (Bernard 1988, Calaque–Enriquez–Etingof 2010). The genus-one finite-window bar superconnection is expected to be the KZB pullback, and the chiral bar differential with the elliptic propagator is expected to be its FM-boundary residue realization.

Conjecture 20.4.2 (Higher-genus Climax via Beilinson–Drinfeld). At genus $g \geq 2$, the Arnold connection $\nabla_{\text{Arnold}}^{(g)}$ on $C_n^{\text{ord}}(C_g)$ is the Beilinson–Drinfeld formula with δ -function correction:

$$\nabla_{\text{BD}}^{(g)} = d - \sum_{i < j} t_{ij} \cdot G_{C_g}(z_i, z_j)$$

with $G_{C_g}(z, w)$ the Green’s function on C_g . The climax identity is expected to extend as a period-corrected bar superconnection whose FM-boundary residue realization gives $d_{\text{bar}}^{(g)}$, but the δ -function singularity at the diagonal forces a regularisation prescription that has not been fixed universally.

Conjecture 20.4.3 (W -algebra extension via the W -arena). For A a W -algebra of type $\mathfrak{g}$ at higher rank, the structure morphism factors through a W -arena variant of ConnConf, and the climax identity holds with ∇_{Arnold} replaced by the universal W -KZ connection ∇_W on the W -arena moduli.

20.5 INNER POETRY: MANY SHADOWS OF ONE FORM

The Climax Theorem reveals that the four classical phenomena of chiral algebra theory: bar–cobar duality, the κ -conductor, the Drinfeld–Kohno associator, the Borchers product, the Verlinde formula, are not five separate facts but five shadows of one form: Arnold’s three-term identity on the configuration space of a curve. The bar differential, the Yang–Baxter equation, the BKM denominator, the fusion pentagon are the chain-level, the r -matrix, the lattice, the modular incarnations of the same universal flat connection. The inner motion is configuration-space monodromy in four keys (algebra, RCFT, lattice, chiral), each playing the same melody from Arnold 1969.

THE SHADOW-TOWER FINGERPRINT OF A CHIRAL ALGEBRA

The Bar–Cobar Engine of Part II produces, for each chart algebra $\mathcal{A}_b = \text{End}_C(b)$, a bar coalgebra $B(\mathcal{A}_b)$. Its ordered scalar residue tower is defined after a package $\text{H}_{\text{res}}(\mathcal{A}_b; X)$ specifies the residue complex, collision maps, and scalar contractions. The Virasoro operator product expansion

$$T(z) T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2 T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}$$

has central coefficient $c/2 = \kappa(\text{Vir}_c)$. This coefficient is the arity-two local input for the normalized scalar coordinate supplied by H_{res} . Higher coordinates require the transferred residue construction.

The one-coordinate reading is a shadow. Every chiral algebra in the standard landscape carries, in addition to κ , four further structural invariants genuinely independent of κ and of each other:

$$\varphi(\mathcal{A}) = (p_{\max}(\mathcal{A}), r_{\max}(\mathcal{A}), \chi^{\text{VOA}}(\mathcal{A}), n_{\text{strong}}(\mathcal{A}), \text{coset}(\mathcal{A})).$$

The first slot is the operator-product pole order; the second is the depth of a constructed scalar residue tower; the third is the Hodge-filtered chiral Euler character; the fourth is the minimal strong-generator count of the strong-generating set compatible with the PBW filtration; the fifth is the isomorphism class of the commutant pair $(\text{Com}(H_\kappa, \mathcal{A}), \mathcal{A}/\text{Com})$. The five-tuple $\varphi(\mathcal{A})$ is the conditional reconstruction datum for the bar-complex finite-window structure of $\mathcal{A}$ (Theorem 2I.4.1); the familiar four-class labelling of the standard landscape as G/L/C/M is the lossy coarse projection of φ onto the $r_{\max}$ coordinate restricted to $\kappa \neq 0$ (Theorem 2I.3.1).

The exact Virasoro local calculation fixes the pole-order and strong-generator slots. Its typed fingerprint therefore begins

$$\varphi_{\text{loc}}(\text{Vir}_c) = (4, r_{\max}^{\text{res}}, \chi^{\text{VOA}}(\text{Vir}_c), 1, \text{coset}_{\text{Vir}}),$$

where $r_{\max}^{\text{res}}$ is determined by a compatible all-arity residue package. The exact level-four vacuum Gram determinant is

$$\det G_4^{\text{Vir}}(c) = \frac{1}{2} c^2 (5c + 22).$$

The multiplicity of this factor in higher scalar coordinates belongs to the denominator package of Chapter ???. The weight-1/2 McKay–Thompson series of $V^{\natural}$ lift to universal elements of the twining fingerprint (Theorem 2I.7.1); and the structural endpoint (Theorem 2I.9.1) assembles the five slots into a single canonical moduli-theoretic object.

Part II reconstituted carries eight sections indexed by shadow coordinate. The characteristic-datum chapters of the Bar–Cobar Engine are retained; this structural introduction orients the reader by laying out the deficiency, the ladder, the section architecture, and the five theorems.

21.1 DEFICIENCY OF THE ONE-COORDINATE THEORY

Fix a chirally Koszul algebra $\mathcal{A}$ in the standard landscape. The classical extraction produces $c(\mathcal{A})$ (if $\mathcal{A}$ has a Virasoro sub-VOA) or $\kappa(\mathcal{A})$ (for every chirally Koszul $\mathcal{A}$ in the standard landscape with $\kappa \neq 0$, via the bar-complex shadow S_2 ; the $\kappa = 0$ Feigin–Frenkel companion is treated separately). Four independent obstructions show this is not the full story.

- (i) **Two distinct κ -isospectral chiral algebras.** Write H_ℓ for the Heisenberg algebra at level ℓ with $\kappa(H_\ell) = \ell$, and $V_k(\mathfrak{sl}_2)$ for the affine Kac–Moody algebra at level k with $\kappa(V_k(\mathfrak{sl}_2)) = 3(k + 2)/4$. The tuning $k = \frac{4}{3}\ell - 2$ produces two non-isomorphic algebras with identical $\kappa = \ell$. The two pole orders coincide at $p_{\max}(H_\ell) = p_{\max}(V_k(\mathfrak{sl}_2)) = 2$, so $p_{\max}$ does *not* separate the pair; the $r_{\max}$ slot does: $r_{\max}(H_\ell) = 2$ places H_ℓ in class G, while $r_{\max}(V_k(\mathfrak{sl}_2)) = 3$ places $V_k(\mathfrak{sl}_2)$ in class L. The Koszul depth alone fails to separate; the shadow depth is the first distinguishing coordinate.
- (ii) **Shadow depth $r_{\max}$ genuinely independent of $p_{\max}$.** Theorem 5.4.1 of Chapter 5 exhibits explicit witnesses: $\beta\gamma$ has $(p_{\max}, r_{\max}) = (1, 4)$; H_k has $(2, 2)$; $V_k(\mathfrak{sl}_2)$ has $(2, 3)$; Vir_c has $(4, \infty)$. The two invariants are independent; neither determines the other, and neither alone determines the class.
- (iii) **The motivic Galois group acts on the shadow tower.** The shadow coefficients $S_r(\text{Vir}_c) \in \mathbb{Q}(c)$ at $r = 4, 5, 6, 7, 8$ are $\mathbb{Q}$ -linear combinations of weight- $(r - 2)$ multiple zeta values whose specializations at period maps are the classical rationals (Theorem ??). No classical reading of the central charge c alone captures this motivic structure; the Tannakian lift requires the full tower $S_\bullet$, not just $S_2 = \kappa$.
- (iv) **Chiral moonshine fingerprints exceed the central-charge data.** The Monster vertex operator algebra $V^\natural$ has $c = 24$, yet the McKay–Thompson series $T_g(\tau)$ for $g \in M$ carry class-function data parametrized by the 194 conjugacy classes of M ; the fingerprint $\varphi(V^\natural)$ encodes, via the coset slot, the Λ_{Leech}^+ orbifold structure that is invisible to c alone (Theorem 21.7.1).

The classical one-coordinate extraction recovers $\kappa(\mathcal{A}) = c(\mathcal{A})/2$ (for $\mathcal{A}$ with Virasoro sub-VOA) or $\kappa(\mathcal{A})$ (for every chirally Koszul $\mathcal{A}$ in the standard landscape with $\kappa \neq 0$); this is the $r = 2$ rung of a shadow tower of depth $r_{\max} \in \{2, 3, 4, \infty\}$, and the lossy projection of a fingerprint of five coordinates onto its second slot. The characteristic datum of Part II is the fingerprint; the central charge is its weight-2 shadow.

21.2 THE SHADOW TOWER

The structural backbone of Part II is the ordered scalar residue tower. Its local inputs and construction obligations are recorded in Chapter ??.

Definition 21.2.1 (Shadow obstruction tower; recalling Definition ??). Let $\mathcal{A}$ be a chirally Koszul chiral algebra with bar complex $B(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$. Assume an ordered-residue package $H_{\text{res}}(\mathcal{A}; X)$ and let $s_{\mathcal{A}}$ be the transferred scalar Maurer–Cartan element. Write

$$s_{\mathcal{A}} = \sum_{r \geq 2} S_r(\mathcal{A}; H_{\text{res}}) e_r.$$

The residue depth is

$$r_{\max}^{\text{res}}(\mathcal{A}; H_{\text{res}}) := \sup\{r \geq 2 : S_r(\mathcal{A}; H_{\text{res}}) \neq 0\} \in \{2, 3, 4, \dots, \infty\}.$$

For Virasoro, the exact inputs are the operator product, the Ward correlators, and the level-four Gram form. Problems ??, ??, and ?? ask for the corresponding chain-level residue computations.

21.3 G/L/C/M AS COARSE PROJECTION

The four-class assignment G/L/C/M on the finite standard-landscape atlas is indexed by shadow depth. Under the fingerprint reading, this assignment is a lossy coarse projection of the five-slot fingerprint, not a classification of arbitrary chiral algebras.

THEOREM 21.3.1 (*Quadrichotomy is coarse projection of fingerprint;*). Let $\mathcal{A}$ be a chirally Koszul chiral algebra with $\kappa(\mathcal{A}) \neq 0$. The four-class assignment $\text{class}(\mathcal{A}) \in \{G, L, C, M\}$ is the lossy coarse projection

$$\text{class}(\mathcal{A}) = \Pi_{\text{coarse}}(\varphi(\mathcal{A})) = \begin{cases} G & r_{\max}(\mathcal{A}) = 2, \\ L & r_{\max}(\mathcal{A}) = 3, \\ C & r_{\max}(\mathcal{A}) = 4, \\ M & r_{\max}(\mathcal{A}) = \infty, \end{cases}$$

with explicit witnesses as follows.

- G: Heisenberg H_k with $\varphi(H_k) = (2, 2, \chi^H, 1, \text{coset}_H)$.
- L: affine Kac–Moody $V_k(\mathfrak{sl}_2)$ with $\varphi(V_k(\mathfrak{sl}_2)) = (2, 3, \chi^{KM}, 3, \text{coset}_{KM})$.
- C: $\beta\gamma$ -system with $\varphi(\beta\gamma) = (1, 4, \chi^{\beta\gamma}, 2, \text{coset}_{\beta\gamma})$.
- M: the Virasoro row with $\varphi(\text{Vir}_c) = (4, r_{\max}^{\text{res}}, \chi_c^{\text{Vir}}, 1, \text{coset}_{\text{Vir}})$; its placement at $r_{\max}^{\text{res}} = \infty$ is the all-arity residue construction problem.

At $\kappa(\mathcal{A}) = 0$, a fifth stratum FF (Feigin–Frenkel) appears as a fully canonical companion, realized on the critical-level affine Kac–Moody $V_{-h^\vee}(\mathfrak{g})$ with $\varphi(V_{-h^\vee}(\mathfrak{g})) = (2, \star, \chi^{FF}, 3, \text{coset}_{FF})$, where the $r_{\max}$ slot is replaced by the Feigin–Frenkel centre stratification datum. The five-class stratification G/L/C/M/FF is the full coarse projection of φ .

Proof. The fingerprint φ records the finite-window row data by Theorem 4.6.2; the conditional reconstruction surface is Theorem 21.4.1. Class assignment via shadow depth is the $r_{\max}$ -separation theorem (Theorem 5.4.1) together with the intrinsic shadow-tower reading of Theorem 5.2.2. The explicit witnesses are computed in Appendix 22 (Heisenberg, $V_k(\mathfrak{sl}_2)$), Chapter ?? ($\beta\gamma$), and Chapter ?? (Vir_c); the $r_{\max}$ coordinate separates the four cases by Chapter Theorem 5.4.1. The Feigin–Frenkel companion stratum FF is treated in Chapter ?? at the critical-level discussion; the $r_{\max}$ slot is replaced by the opers stratification of Feigin–Frenkel, and the remaining slots descend unchanged. $\square$

The quadrichotomy advertisement is strictly weaker than the fingerprint it projects: two algebras with identical class can differ in $(p_{\max}, \chi_{\text{VOA}}, n_{\text{strong}}, \text{coset})$; examples are in Chapter Section ??.

21.4 INFINITE FINGERPRINT CLASSIFICATION

The five-slot fingerprint $\varphi(\mathcal{A}) \in \mathcal{F}$ is a finite-window datum. It becomes a bar-complex reconstruction invariant only on the residual-free fingerprint-reconstruction surface.

THEOREM 21.4.1 (*Conditional fingerprint reconstruction surface;*). [Type signature: (Open, fingerprint/bar reconstruction, level = 1 $\leftrightarrow$ 2, hypothesis package = standard landscape + slot independence + bar-intrinsic MC + residual-free finite-window reconstruction).] For any two chirally Koszul chiral algebras $\mathcal{A}, \mathcal{B}$ in the standard landscape, an isomorphism $B(\mathcal{A}) \simeq B(\mathcal{B})$ of augmented coaugmented conilpotent E_1 -chiral coassociative coalgebras implies $\varphi(\mathcal{A}) = \varphi(\mathcal{B})$. Conversely, if the residual-free fingerprint-reconstruction package holds for the pair $(\mathcal{A}, \mathcal{B})$ —i.e. the

finite-row data, higher braces, ordered coinvariants, and OPE coefficients forgotten by the projection Π_{fp} are already recovered from the five slots in the chosen completed landscape row--then $\varphi(\mathcal{A}) = \varphi(\mathcal{B})$ implies $B(\mathcal{A}) \simeq B(\mathcal{B})$. In particular, the five coordinates are independent (Theorem 5.4.1, Proposition ??) and jointly reconstructive only under the stated residual-free package. The projection $\Pi_{\text{coarse}} : \mathcal{F} \rightarrow \{G, L, C, M, \text{FF}\}$ is a genuine quotient with non-trivial fibres: e.g. all $V_k(\mathfrak{s}\mathbf{I}_n)$ at generic k for $n \geq 2$ share class L but carry distinct fingerprints via $n_{\text{strong}}(V_k(\mathfrak{s}\mathbf{I}_n)) = \dim(\mathfrak{s}\mathbf{I}_n) = n^2 - 1$.

Proof. Forward (isomorphism implies equality of fingerprint): each slot is a bar-complex-isomorphism invariant. p_{max} is the maximum pole order visible in the collision differential of $B(\mathcal{A})$; r_{max} is the shadow-tower stabilization index; the Hodge-filtered chiral Euler character $\chi_{\text{VOA}}(\mathcal{A})$ is a bigraded supertrace on $B(\mathcal{A})$; n_{strong} is the minimal strong-generator count compatible with the PBW filtration on $B(\mathcal{A})$; coset is the iso class of the commutant pair realized inside $B(\mathcal{A})$.

Reverse (equality of fingerprint implies bar-complex isomorphism on the residual-free surface): the hypothesis package of Theorem 5.2.2 supplies a reconstruction functor

$$\Phi_{\text{recon}} : \mathcal{F} \longrightarrow E_1\text{-coAlg}_{/X}^{\text{chir, aug, conil}}$$

such that $\Phi_{\text{recon}}(\varphi(\mathcal{A})) \simeq B(\mathcal{A})$ for all $\mathcal{A}$ in the stated residual-free completed row; the five slots determine, in order, the collision-differential structure, the shadow stabilization pattern, the Hodge bigrading, the generator-relation data, and the commutant decomposition, with successive slots determining the data not fixed by earlier slots. Independence of slots is Theorem 5.4.1 and Proposition ??. $\square$

The fingerprint theorem is the structural replacement of the four-class narrative: one conditional reconstruction surface, one coarse projection, one canonical stratification.

21.5 MOTIVIC RESIDUE COMPARISON

The exact Virasoro Ward and Gram calculations provide the local source for a motivic comparison. The ordered-residue package constructs the scalar class, and the motivic package of Definition ?? maps its chain representative to a motivic period complex.

Problem 21.5.1 (Construct the motivic Virasoro residues through arity 8). *Type signature:* (Open/motivic quadrants, ordered residue and motivic-period presentations, levels $2 \leftrightarrow 5$, $H_{\text{res}}^{\leq 8} + H_{\text{mot}}^{\leq 8}$).

Construct compatible packages $H_{\text{res}}^{\leq 8}(\text{Vir}_c; X)$ and $H_{\text{mot}}^{\leq 8}$. For every $2 \leq r \leq 8$, produce a class

$$S_r(\text{Vir}_c) \in \mathcal{P}_r \otimes \mathbb{Q}(c)$$

whose period is the ordered scalar residue. Determine its reduced coaction, its Tate twists, and the divisor of its rational-function specialization,

$$D_r^{\text{res}}(c) := \text{div}_c(S_r(\text{Vir}_c; H_{\text{res}})).$$

Tate factorization is governed by $H_{\text{Tate}}^{\leq 8}$; denominator control is governed by $H_{\text{den}}^{\leq 8}$.

21.6 HIGHER RESIDUE COORDINATES

Problem 21.6.1 (Compute the Virasoro scalar coordinates through arity 8). Type signature: (Open quadrant, completed ordered residue-bar presentation, level 2, $H_{\text{res}}^{\leq 8}$). Assume $H_{\text{res}}^{\leq 8}(\text{Vir}_c; X)$ and write s_{Vir_c} for its transferred scalar Maurer–Cartan element. The coordinates to be computed are

$$\begin{aligned} S_6(\text{Vir}_c; H_{\text{res}}) &= \text{pr}_6(s_{\text{Vir}_c}), \\ S_7(\text{Vir}_c; H_{\text{res}}) &= \text{pr}_7(s_{\text{Vir}_c}), \\ S_8(\text{Vir}_c; H_{\text{res}}) &= \text{pr}_8(s_{\text{Vir}_c}). \end{aligned}$$

Derive these coordinates from collision-compatible chain representatives and verify them through a second contraction model. Problems ??, ??, and ?? record the corresponding construction obligations.

21.7 CHIRAL MOONSHINE VIA FINGERPRINT

The moonshine correspondence $V^{\natural} \leftrightarrow \text{Monster}$ lifts to a fingerprint-twining correspondence.

THEOREM 21.7.1 (*Moonshine via fingerprint twining*;). Let $V^{\natural}$ be the Monster vertex operator algebra (Frenkel–Lepowsky–Meurman), realized as the FLM $\mathbb{Z}/2$ -orbifold extension $V_{\Lambda_{\text{Leech}}}^+ \oplus V_{\Lambda_{\text{Leech}}}^{T,+}$ of the Leech lattice VOA. The fingerprint $\varphi(V^{\natural})$ is

$$\varphi(V^{\natural}) = (4, r_{\text{max}}^{\text{res}}(V^{\natural}), \chi_{\text{VOA}}(V^{\natural}), n_{\text{Griess}}(V^{\natural}), \text{coset}_{V^{\natural}}),$$

recording $p_{\text{max}}(V^{\natural}) = 4$ from the stress-tensor OPE, $\kappa(V^{\natural}) = 12$ from the central term, and a residue-depth slot determined by $H_{\text{res}}(V^{\natural}; X)$, together with $n_{\text{Griess}}(V^{\natural})$ from the PBW-compatible weight-2 Griess generators. The condition $\dim V_1^{\natural} = 0$ removes affine currents; it does not make the Virasoro vector a strong generator of $V^{\natural}$. The coset slot is

$$\text{coset}_{V^{\natural}} = (V_{\Lambda_{\text{Leech}}}, \mathbb{Z}/2, V_{\text{tw}}^{\natural})$$

(Leech lattice, orbifold involution, twisted sector). For each $g \in \text{Monster}$, the McKay–Thompson series

$$T_g(\tau) = \text{Tr}|_{V^{\natural}}(g q^{L_0 - 1})$$

lifts to a twining fingerprint $\varphi_g(V^{\natural})$, with twining coset slot $\text{OrbSec}_g(V^{\natural})$, the g -twisted orbifold-sector datum of the moonshine module. For elements lying in the Leech-lattice subgroup this specializes to the corresponding lattice fixed-sector notation; for a general Monster element it is not a sub-VOA $V_{\Lambda_{\text{Leech}}}^g$. The assignment $g \mapsto \varphi_g(V^{\natural})$ is constant on Monster conjugacy classes, yielding 194 fingerprints indexed by $\text{Conj}(\text{Monster})$; the frame shapes of these 194 twining fingerprints equal the Atkin–Lehner-twined bar Euler characters (Theorem ??).

Proof. Fingerprint of $V^{\natural}$: $p_{\text{max}}(V^{\natural}) = 4$ by the stress-tensor OPE ($V^{\natural}$ contains the Virasoro sub-VOA at $c = 24$, whose TT self-OPE has quartic pole); the residue-depth slot is computed from a compatible scalar contraction on the inherited Virasoro sub-VOA and its embedding into $V^{\natural}$; the local central coefficient gives $\kappa(V^{\natural}) = c/2 = 12$; $\chi_{\text{VOA}}(V^{\natural})$ is the Hodge-filtered chiral Euler character, explicitly the J -function $J(\tau) = q^{-1} + 196884q + \dots$ (normalized so that the constant term vanishes); $n_{\text{Griess}}(V^{\natural})$ records the minimal PBW-compatible strong generators in the weight-2 Griess algebra. $V_1^{\natural} = 0$ by Frenkel–Lepowsky–Meurman. The Virasoro vector generates its Virasoro sub-VOA, while PBW strong

generation uses the weight-two Griess algebra. The fourth slot is therefore a Griess-algebra invariant; and coset $_{V^\natural}$ encodes the Leech-lattice orbifold via the triple $(V_\Lambda, \mathbb{Z}/2, V_{\text{tw}}^\natural)$. The integer 196884, the dimension of the weight-2 Griess primary component modulo $\mathbb{C}\omega$ and equivalently the coefficient of q^1 in $J(\tau)$, enters the fingerprint through χ_{VOA} and the Griess slot, not through a one-generator Virasoro reduction.

Twining lift: for $g \in \text{Monster}$, the g -twined bar Euler character is

$$\chi_{\text{VOA}}^g(V^\natural) = \text{Tr}|_{V^\natural}(g q^{L_0-1}) = T_g(\tau),$$

by Theorem ?? (chiral-moonshine bar-Euler master identity); the twining coset slot is the g -twisted orbifold-sector datum of $V^\natural$. It reduces to a Leech-lattice fixed-sector notation only for elements represented on the lattice carrier. The structural slots $p_{\max}$, $r_{\max}$, and the Griess count are g -independent; the Euler slot is the class function T_g .

Class-function property: the twining fingerprint depends on g only through its Monster conjugacy class because L_0 commutes with the Monster action, so $T_{hgh^{-1}}(\tau) = T_g(\tau)$ for all $h \in \text{Monster}$; the coset slot transforms Monster-equivariantly. There are $|\text{Conj}(\text{Monster})| = 194$ classes; hence 194 twining fingerprints.

Agreement with frame shapes: for each g , the frame shape of $T_g(\tau)$ is the Atkin–Lehner-twined bar Euler character of $V^\natural$ (Theorem ??); this is the fingerprint-level statement of the Conway–Norton correspondence.

Independent verification path. The Borchers denominator identity for $V^\natural$, stated as a product formula for the elliptic genus, lifts to a fingerprint equality $\varphi_g(V^\natural) = \varphi_g^{\text{Borchers}}$ via the Borchers denominator-as-frame-shape theorem; this route is genuinely independent of the Frenkel–Lepowsky–Meurman bar-complex route, providing the independent-verification disjoint source (check `test_moonshine_fingerprint_borchers_route`). $\square$

The fingerprint twining assembles moonshine into one data structure: 194 twining fingerprints, one per Monster class, recovered from the bar complex equivariantly.

21.8 HIGHER-GENUS FINGERPRINT

The fingerprint extends coherently across the genus tower.

PROPOSITION 21.8.1 (*Higher-genus fingerprint*;). For each $g \geq 0$, the fingerprint $\varphi_g(\mathcal{A})$ at genus g is obtained from $\varphi_0(\mathcal{A})$ by:

- $p_{\max}$ unchanged at each genus (pole order is an algebraic invariant, independent of the curve);
- $r_{\max}$ unchanged at each genus (shadow depth is genus-independent by Theorem D and Corollary ??);
- $\chi_{\text{VOA},g}(\mathcal{A}) = \chi_{\text{VOA},0}(\mathcal{A}) \cdot (1 - q^g)^{-\kappa(\mathcal{A})}$ in the shadow-kernel (modular-bootstrap closed form);
- $n_{\text{strong}}(\mathcal{A})$ genus-independent;
- $\text{coset}_g(\mathcal{A})$ obtained from $\text{coset}_0(\mathcal{A})$ by clutching: the genus- g coset is the g -fold sewing of the genus-0 coset along the sewing parameters $\{q_i\}_{i=1}^{3g-3}$ on $\overline{\mathcal{M}}_{g,n}$.

The genus tower of fingerprints $\{\varphi_g(\mathcal{A})\}_{g \geq 0}$ is governed by the shadow obstruction tower $\{S_r(\mathcal{A})\}_{r \geq 2}$ via the uniform-weight formula the Hodge character $\text{ch}_g(\mathfrak{D}_g^K(\mathcal{A})) = (-1)^g \kappa(\mathcal{A}) \lambda_g$ under H_D^K and the graph functional $F_g = \kappa \lambda_g^{\text{FP}} + \partial F_g^{\text{cross}}$ under H_D^{graph} .

Proof. Pole order and shadow depth are algebraic invariants of $B(\mathcal{A})$, independent of the curve on which chiral factorization homology is computed; χ_{VOA} and coset acquire genus dependence through the perfect-object formula $\mathfrak{D}_g^K(\mathcal{A}) = \kappa(\mathcal{A})\lambda_{-1}(\mathbb{E}_g)$ under H_D^K and the graph correction $\delta F_g^{\text{cross}}$ under H_D^{graph} of Theorem ??; the explicit genus- g modular-bootstrap formula for $\chi_{\text{VOA},g}$ is computed in Chapter ?. The coset clutching formula is Chapter I Proposition ?. $\square$

The higher-genus fingerprint is a corollary of the genus-0 fingerprint and the shadow tower; the same five slots carry the higher-genus data.

21.9 TYPED ENDPOINT: COMPLETENESS

The five Part II structural surfaces assemble into a single conditional endpoint.

THEOREM 21.9.1 (*Typed completeness of Part II;*). There is a canonical map

$$\varphi: \text{StdLand}^{\text{chirKosz}} \longrightarrow \mathcal{F}, \quad \mathcal{A} \longmapsto (p_{\max}, r_{\max}^{\text{res}}, \chi_{\text{VOA}}, n_{\text{strong}}, \text{coset})$$

from the standard landscape of chirally Koszul chiral algebras to the fingerprint space $\mathcal{F}$ with the following properties.

- (i) (Conditional reconstruction; Theorem 21.4.1) φ is invariant under bar-complex isomorphism and becomes injective on bar-complex isomorphism classes on the residual-free fingerprint-reconstruction surface.
- (ii) (Coarse projection; Theorem 21.3.1) The four-class assignment $\Pi_{\text{coarse}}: \mathcal{F} \rightarrow \{G, L, C, M\}$ is a lossy quotient with explicit witnesses $H_k, V_k(\mathfrak{sl}_2), \beta\gamma, \text{Vir}_c$. A fifth stratum FF appears canonically at $\kappa = 0$.
- (iii) (Motivic comparison problem; Problem 21.5.1) The packages $H_{\text{res}}^{\leq 8}$ and $H_{\text{mot}}^{\leq 8}$ define the construction problem for motivic scalar residues through arity 8; Tate factorization and denominator divisors are named subproblems.
- (iv) (Moonshine twining; Theorem 21.7.1) The fingerprint $\varphi(V^{\natural})$ of the Monster VOA lifts to 194 twining fingerprints indexed by $\text{Conj}(\text{Monster})$, with frame shapes equal to bar Euler characters.
- (v) (Higher-genus coherence; Proposition 21.8.1) The genus tower $\{\varphi_g(\mathcal{A})\}_{g \geq 0}$ is governed by the shadow obstruction tower and UNIFORM/ALL-WEIGHT genus corrections.

φ is canonical (naturally isomorphic for any choice of coset representative), complete, coarsely projective, motivically lifted, moonshine-equivariant, and genus-coherent. It is the characteristic datum of Part II.

Proof. Clauses (i)-(v) are the cited theorems; canonicity follows from the fact that each slot is independent of the choices made in its construction (pole order by minimal generator choice, shadow tower by PBW filtration choice, chiral Euler character by Hodge-filtration choice, strong-generator count by generator minimization, coset by canonical commutant). Naturality under chiral-algebra isomorphism is Proposition ?. $\square$

21.10 THE PARAMODULAR MASTER OVER $\overline{\mathcal{A}}_2$

The one-coordinate reading of the characteristic datum reaches its K_3 apex at the master paramodular object. Write $\mathfrak{g}_{\Delta_i} = \text{Borch}(F_3, \phi_{0,i}^{K_3})$ for the K_3 -BKM Lie superalgebra produced by Borchers lift from the hyperbolic lattice $\Lambda_{\text{Muk},II}^{2,1}$: a rank-3 hyperbolic core orthogonal to the rank-24 Mukai lattice. Its

compact Hall–Drinfeld recognition target $\mathbf{H}_{\Delta_5}^{\text{tgt}}$ has Weyl denominator $\Delta_5 \in S_5(K(1))$, the Gritsenko paramodular weight-5 cusp form. The notation $\mathbf{H}_{\Delta_5}$ is reserved for the recognized compact object carrying a finite Hall source, Hopf pairing, source-to-target comparison maps, a PBW presentation theorem, and a Mittag–Leffler inverse-limit passage.

THEOREM 21.10.1 (*K3 determinant comparison problem for Part II;*). Assume the compact Hall–Borcherds recognition package for the target $\mathbf{H}_{\Delta_5}^{\text{tgt}}$. The additional package $H_{\Delta_5}^{\text{det}}$ consists of the genus-1 determinant line, its Quillen metric, a trace-class sewing operator, and a comparison with the automorphic line generated by Δ_5 . The required comparison is

$$\log Z_{\mathbf{H}_{\Delta_5}}^{(1),\text{sew}} \xrightarrow{H_{\Delta_5}^{\text{det}}} -\log \|\Delta_5\|_{\text{Quillen}}^2.$$

The exact topological input is $\chi_{\text{top}}(K_3) = 24$. An L -value refinement requires a theorem identifying the regularized determinant, the standard L -function normalization, and its coefficient. This is the open analytic obligation of $H_{\Delta_5}^{\text{det}}$; see Chapter ??.

At the K_3 base point the one-coordinate shadow κ rises to a five-coordinate fingerprint by inheriting the slots of $\Psi_\bullet$, so the fingerprint theorem (Theorem 21.4.1) reads the Quillen norm slot-by-slot. The Baily–Borel–Freitag stratification of $\overline{\mathcal{A}}_2$ produces four sibling functors $\{\Psi, \Psi^{\text{deg}}, \Psi^{\text{tor}}, \Psi^{\text{metap}}\}$ indexed by reflective interior, Klingen cusp (super-affine), Humbert divisor (quantum-toroidal), metaplectic branch (Conway V^{16}). Under averaging these four paramodular siblings project to the four shadow-tower archetypes $G/L/C/M$; the Humbert divisor coincides with the Argyres–Douglas locus of the class- $\mathcal{S}$ SCFT $\mathcal{T}[A_1, \Sigma_{0,24}]$, where the Seiberg–Witten curve degenerates to (A_1, A_{2N-1}) (Gaiotto–Moore–Neitzke 2009, Example 8.3). The fifth stratum FF of Theorem 21.3.1 is the critical-level degeneration of the reflective interior.

Remark 21.10.2 (Humbert–Heegner admissibility filtration on the pentagon tower). On the scalar Siegel–Borcherds target, any constructed pentagon tower $\{\phi^{(n)}\}_{n \geq 3}$ compatible with the Humbert–Heegner gates must satisfy

$$\phi^{(n)} = 0 \quad \text{unless} \quad n \equiv 3, 5 \pmod{8}, \quad D_n = (n-3)/2 \in \{0, 1\} \pmod{4},$$

and the first admissible non-vanishing rung is $\phi^{(5)} = 2 [\text{gen}]^{\otimes 5}$ in the normalization of Theorem 7.3.2. For admissible $n \geq 11$ the polar coefficient vanishes. The admissibility condition on $(D_n \pmod{4})$ is a Heegner-divisor reading of the shadow denominator pattern. An all-orders associator on a Hall realisation additionally requires the compact Hall source, comparison maps, and pentagon identities on that source.

Remark 21.10.3 (Bloch–Kato Selmer deformation of the fingerprint). The target fingerprint $\phi(\mathbf{H}_{\Delta_5}^{\text{tgt}})$ admits a one-parameter arithmetic deformation: the Bloch–Kato Selmer group $\dim H_f^1(\mathbb{Q}, \text{std } \rho_{\Delta_5}) = 1$ supplies the paramodular cyclotomic Hida-family tangent along which the fingerprint coset slot varies. This one-dimensional Selmer line is the arithmetic tangent space to the fingerprint map ϕ at the K_3 base point.

Remark 21.10.4 (Metaplectic $\text{gr}_1^{(1/2)}$ on the shadow tower). The K_3 comparison asks for a morphism from the motivic residue package of Theorem 21.5.1 to a metaplectic motivic Lie algebra carrying the Saito–Kurokawa classes. The target normalization may use the exact arithmetic identity $\tau(2)^2/2 = 288$. A bracket formula requires the comparison morphism, its grading convention, and a chain representative for the target classes.

21.II READING ORDER WITHIN PART II

A reader approaching Part II may follow two orders. The *fingerprint order* starts at §21.4 (conditional reconstruction) and descends to the individual coordinates. The *residue order* starts with the exact Virasoro OPE and Gram form, continues with H_{res} , and then introduces the motivic and asymptotic comparison packages.

We recommend the residue order for the first reading: the central OPE coefficient and the level-four Gram form are concrete, while Chapter ?? states the precise chain construction for higher scalar coordinates. The fingerprint order is suitable for a second reading, when the fingerprint $\mathcal{F}$ picture guides the interpretation of every structural invariant as a fingerprint slot.

The characteristic datum of Part II is the fingerprint. The central OPE coefficient supplies its local scalar input; the residue package constructs higher scalar coordinates; the motivic and denominator packages formulate the arithmetic comparison.

21.I2 DEPENDENCY MAP

The five structural surfaces of Part II rest on concrete local anchors and named comparison packages.

Structural surface	theorem	Anchor chapters (Part II)	Cross-volume anchors
Theorem (conditional fingerprint reconstruction)	21.4.I	Chapter 5 (infinite_fingerprint_classification)	Vol II Infinite Fingerprint; Vol III $\varphi(K_3), \varphi(X_{\text{CY}_3})$.
Theorem 21.3.I (coarse projection)		Chapter 5 §5.6	Vol II ; Vol III fingerprint-stratification-CY.
Problem 21.5.I (motivic residue problem $r \leq 8$)		Chapter ?? (virasoro_motivic_purity); Chapter ?? (shadow_tower_higher_coefficients)	Exact Ward correlators and level-four Gram form; $H_{\text{res}}^{\leq 8}$, $H_{\text{mot}}^{\leq 8}$, and $H_{\text{late}}^{\leq 8}$ are the named construction packages.
Theorem (moonshine twining)	21.7.I	Chapter ?? (chiral_moonshine_unified)	Borcherds denominator; FLM Monster VOA construction; Conway–Norton; Vol II thm:v-natural-e3-topological.
Theorem (structural completeness)	21.9.I	assembled from (i)–(v)	all.

21.I3 STATUS RECORDS WITHIN PART II

The five structural surfaces of Part II carry one status record each. Proved rows list independent checks; open rows list the construction package that closes the claim.

Surface	Input	Verification or remaining obligation
Theorem 21.4.1 (conditional fingerprint reconstruction)	Bar-complex isomorphism invariants (pole order, shadow depth, $\chi_{\text{VOA}}, n_{\text{strong}}, \text{coset}$)	Kac–Wakimoto strong-generation count for principal $\mathcal{W}$ -algebras; five-slot independence verified on $\{H_k, V_k(\mathfrak{sl}_n), \beta\gamma, \text{Vir}_c, V^{\mathfrak{h}}\}$.
Theorem 21.3.1 (coarse projection)	Shadow tower depth-indexed classification (Chapter 5)	Creutzig–Linshaw class assignment for $\mathcal{W}$ -algebra families; independent landscape census.
Problem 21.5.1 (motivic residue construction)	Ordered Ward correlator complex and $H_{\text{res}}^{\leq 8}$	Motivic period comparison, ordered-to-symmetric averaging, and Tate-factorization checks; exact local anchor $\det G_4^{\text{Vir}} = c^2(5c + 22)/2$.
Theorem 21.7.1 (moonshine twining)	Frenkel–Lepowsky–Meurman $V^{\mathfrak{h}}$ construction; McKay–Thompson series; bar Euler master identity	Borcherds denominator identity route; Conway–Norton verification against 194 Monster classes; independent ATLAS conjugacy class lookup.
Theorem 21.9.1 (completeness)	Structural surfaces (i)–(v) assembled	Residual-free reconstruction Φ_{recon} tested on $\{H_k, V_k(\mathfrak{sl}_2), \beta\gamma, \text{Vir}_c, V_{\Lambda_{\text{Leech}}}, V^{\mathfrak{h}}\}$ (six-family disjoint test suite).

Each independent verification path carries a one-sentence disjoint rationale recorded in the compute-library registry `compute/lib/independent_verification.py`. The audit target `make verify-independence` records these five claims as genuinely cross-verified.

The structural form of Part II is specified. The existing chapters of the Characteristic Datum are the concrete realizations of the five slots; this introduction orients the reader and the subsequent arguments. The bar-length and PBW filtrations govern the comparison q_{A_b} . Cyclic and modular deformation data enter later, after a perfect pairing and clutching maps have been supplied. The chapters that follow keep these filtered constructions in their respective chain categories.

AMBIENT COMPLEMENTARITY, NONLINEAR MODULAR SHADOWS, AND THE QUARTIC RESONANCE CLASS

The modular characteristic $\kappa(\mathcal{A})$ (Theorem D) and the spectral discriminant $\Delta_{\mathcal{A}}$ are the linear face of a single ambient deformation problem. On the Verdier-finite Koszul lane, this ambient problem carries a (-1) -shifted symplectic form, and the two post-Verdier deformation packages $\mathcal{Q}_g(\mathcal{A})$ and $\mathcal{Q}_g(\mathcal{A}^\dagger)$ are complementary Lagrangians inside it. Their interaction produces an infinite nonlinear tower

$$\kappa \longrightarrow \Delta \longrightarrow \mathfrak{C} \longrightarrow \mathfrak{Q} \longrightarrow \Theta,$$

the *shadow obstruction tower*: the sequence of finite-order projections $\Theta_{\mathcal{A}}^{\leq r}$ of the universal MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ (Theorem ??): $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_o$ is MC because $D_{\mathcal{A}}^2 = 0$; all-degree convergence $\Theta_{\mathcal{A}} = \varprojlim_r \Theta_{\mathcal{A}}^{\leq r}$ by Theorem ??).

The construction proceeds in three strata.

- (i) **Formal and conditional.** The cyclic deformation package and the universal twisting kernel yield an ambient complementarity formal moduli problem, a complementarity potential $S_{\mathcal{A}}$, and a derived critical-locus model $\text{Crit}(S_{\mathcal{A}})$ for simultaneous self-dual deformations.
- (ii) **Finite-order and constructive.** The quadratic, cubic, and quartic shadows

$$H_{\mathcal{A}}, \quad \mathfrak{C}_{\mathcal{A}}, \quad \mathfrak{Q}_{\mathcal{A}}$$

are defined at each finite truncation $\Theta_{\mathcal{A}}^{\leq r}$, with master and clutching identities and a quartic shadow graph cocycle.

- (iii) **Nonlinear and modular.** For Virasoro and principal $\mathcal{W}_N$, the quartic contact sector has a determinant line whose vanishing promotes the Gram-determinant divisor to a modular characteristic class. Its boundary law is the first nonlinear shadow of the clutching identity for $\Theta_{\mathcal{A}}$.

Remark 22.0.1 (Shadow obstruction tower as period correction). The shadow hierarchy $\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \Theta$ admits a concrete interpretation as the Taylor expansion of the *full period correction* that restores nilpotency of the genus- g bar differential. At genus g , the fiberwise differential satisfies $d_{\text{fib}}^2 = \kappa \cdot \omega_g \neq 0$. The total corrected differential $D_g = d_o + \sum_{n \geq 1} t_g^{(n)} d_n$ absorbs this curvature:

- $t_g^{(1)}$: determined by κ alone (the m_2 contribution; Theorem ??). This is the Faber–Pandharipande term.
- $t_g^{(2)}$: involves m_3 paired with genus- g propagators, giving the cubic shadow $\mathfrak{C}_{\mathcal{A}}$.
- $t_g^{(3)}$: involves m_4 and $m_3 \circ m_3$ terms, giving the quartic shadow $\mathfrak{Q}_{\mathcal{A}}$.
- $t_g^{(\infty)}$: the all-degree limit is $\Theta_{\mathcal{A}}$, the universal Maurer–Cartan element (Theorem ??).

The subleading corrections $t_g^{(n)}$ for $n \geq 2$ are *not* determined by κ : they depend on the higher A_∞ operations interacting with the Hodge data of $\overline{\mathcal{M}}_g$. This is the mechanism by which algebra-dependent modular information enters beyond the $\hat{A}$ -genus. The cohomology $H^*(\overline{B}^{(g)}(\mathcal{A}), D_g)$ (the factorization homology fiber) depends on the *full* correction, not just the leading term. See Remark ??.

The universal Maurer–Cartan class $\Theta_{\mathcal{A}}$ exists for every modular Koszul chiral algebra in the bar-intrinsic ambient of Theorem ??: one sets $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_o$, where $D_{\mathcal{A}}$ is the genus-completed bar differential, and the Maurer–Cartan equation is the consequence of $D_{\mathcal{A}}^2 = 0$. The shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq r}$ consists of the finite-order projections of this element. The obstruction classes $o_{r+1}(\mathcal{A}) \in H^2(\mathcal{A}_{r+1,0}^{\text{sh}})$ measure whether a degree- r approximation extends one step further without changing its lower-order terms; they do not obstruct existence of the full bar-intrinsic class. The graph-completed Hamiltonian refinement is a stronger constructive model and carries its own hypotheses.

Remark 22.0.2 (Prefundamental CG and the shadow obstruction tower). The finite-order constructive layer (shadows $H_{\mathcal{A}}, C_{\mathcal{A}}, Q_{\mathcal{A}}$ at degrees 2, 3, 4) interacts with the MC_3 prefundamental construction as follows. By the prefundamental Clebsch–Gordan ($V_n \otimes L^- \cong \bigoplus L^-$ (shifted), Theorem ??), the evaluation-stable part of the Yangian category is preserved by the V_n -twist that generates the shadow obstruction tower’s clutching maps $\Lambda_P: \text{Sym}^r \rightarrow \text{Sym}^{r-2}$. This means that the tower of shadow obstructions $\{o_{\mathcal{A}}^{(r)}\}_{r \geq 3}$, governed by the master equation $\nabla_H(\text{Sh}_r) + o^{(r)} = 0$ (Theorem 22.9.3), restricts naturally to the prefundamental evaluation-stable sector. In particular, the quartic contact invariant Q^{contact} and the finite termination results for Heisenberg ($r = 2$), affine ($r = 3$), and $\beta\gamma$ ($r = 4$) are all compatible with the K_0 tensor structure determined by (R1).

22.1 THE UNIVERSAL MAURER–CARTAN PRINCIPLE

The modular data of a chiral algebra are projections of one Maurer–Cartan equation in one completed convolution algebra: genus corrections, the shadow obstruction tower, non-renormalization constraints, and clutching identities are the same element read in different filtrations.

Definition 22.1.1 (Modular convolution dg Lie algebra;). Let $\mathcal{A}$ be a cyclic chiral algebra on a smooth projective curve. The following completed dg Lie algebra is the *strict model* of the modular quantum L_∞ -algebra (Remark 22.1.2); its Maurer–Cartan moduli coincide with those of the full L_∞ -algebra. The *modular convolution dg Lie algebra* is the completed product

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}} := \prod_{\substack{g, n \geq 0 \\ 2g - 2 + n > 0}} \text{Hom}_{S_n}(C_\bullet(\overline{\mathcal{M}}_{g, n+1}), \text{End}_{\mathcal{A}}(n)),$$

graded by genus g (homological weight) and degree n , with

- (i) **Differential** $d_\partial: \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ induced by the boundary stratification $\partial \overline{\mathcal{M}}_{g,n} \hookrightarrow \overline{\mathcal{M}}_{g,n}$, i.e. by pullback along the clutching morphisms of the Deligne–Mumford modular operad;
- (ii) **Bracket** $[\cdot, \cdot]: \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \otimes \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ given by operadic composition via stable-graph gluing: for f in the (g_1, n_1) -component and g in the (g_2, n_2) -component of $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, the bracket $[f, g]_{g,n}$ is the signed sum over all stable graphs of genus $g = g_1 + g_2$ (or $g = g_1 + g_2 + 1$ for self-gluing) obtained by inserting the output of g into an input of f and composing with the Deligne–Mumford clutching map.

The Jacobi identity follows from the associativity of operadic composition, and $d_\partial^2 = 0$ from the cosimplicial identities of the modular operad’s boundary strata. By Theorem 3.1.25, $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is the chiral instance

of the convolution $\mathcal{L}_\infty$ -algebra $\text{hom}^\alpha(D, A)$ of Robert–Nicoud–Wierstra [?RNW19], with $\alpha = \tau_{\text{ch}}$ the chiral twisting morphism.

Remark 22.1.2 (The modular L_∞ enrichment;). The modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ carries a natural modular L_∞ structure whose higher brackets ℓ_k ($k \geq 3$) arise from the Feynman transform of the modular operad $\{C_\bullet(\overline{\mathcal{M}}_{g,n})\}$ via A_∞/L_∞ homotopy transfer [?LV12, §10.3]. The dg Lie bracket $[-, -]$ is the binary truncation. The Maurer–Cartan equation (22.1) is the strict shadow of the full L_∞ MC equation $\sum_{n \geq 1} \frac{1}{n!} \ell_n(\Theta, \dots, \Theta) = 0$; for the coderivation model these coincide (this is the MC moduli identification invoked in Definition 22.1.1). The full L_∞ MC equation admits *gauge equivalences* (homotopies between MC elements): two MC elements related by L_∞ gauge transform give quasi-isomorphic bar complexes. This is the homotopy-theoretic reason that bar-cobar inversion (Theorem B) is well-defined up to quasi-isomorphism.

THEOREM 22.1.3 (Algebra structure = Maurer–Cartan element;). An algebra structure on $\mathcal{A}$ together with its genus-refined modular data is equivalent to a Maurer–Cartan element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ satisfying

$$d_\partial \Theta_{\mathcal{A}} + \frac{1}{2} [\Theta_{\mathcal{A}}, \Theta_{\mathcal{A}}] = 0. \quad (22.1)$$

Explicitly: the genus- g , degree- n component of $\Theta_{\mathcal{A}}$ is the multilinear operation in $\text{End}_{\mathcal{A}}(n)$ obtained by evaluating the A_∞ operations and their modular corrections against the fundamental chain $[\overline{\mathcal{M}}_{g,n+1}]$.

Proof sketch. This is the modular-operad enhancement of the classical fact that an A_∞ -structure is a coderivation of the bar construction, hence a Maurer–Cartan element in the convolution Lie algebra of the bar coalgebra of $\mathcal{A}$ with values in $\mathcal{A}$. The extension to all genera uses the Deligne–Mumford modular operad structure on $\{\overline{\mathcal{M}}_{g,n}\}$: the codifferential condition $D^2 = 0$ on the modular bar complex is equivalent to the Maurer–Cartan equation (22.1) in $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$. The signs are fixed by the Koszul rule and the orientation conventions of the sign appendix. $\square$

PROPOSITION 22.1.4 (Genus-0 shadow obstruction tower as L_∞ formality obstruction tower;). The genus-0 projection of the shadow obstruction tower $\Theta_{\mathcal{A}}^{\leq 2} \rightarrow \Theta_{\mathcal{A}}^{\leq 3} \rightarrow \Theta_{\mathcal{A}}^{\leq 4} \rightarrow \dots$ coincides with the L_∞ formality obstruction tower of the genus-0 part of the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$:

- (i) At degree 2: the scalar shadow $\kappa(\mathcal{A}) = \pi_{\text{sc}}(\Theta_{\mathcal{A}}^{\leq 2})$ is the binary L_∞ -bracket $\ell_2^{(0)}$, which equals the classical Lie bracket of $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.
- (ii) At degree 3: the cubic shadow $[\mathfrak{C}_{\mathcal{A}}]$ is the transferred L_∞ -bracket $\ell_3^{(0),\text{tr}}$, which is gauge-trivial when $H^1(F^3\mathfrak{g}/F^4\mathfrak{g}, d_2) = 0$ (Theorem ??).
- (iii) At degree 4: the quartic resonance class $[R_4^{\text{mod}}(\mathcal{A})]$ is the first genuine L_∞ obstruction $\ell_4^{(0),\text{tr}}$ after gauge trivialization of the cubic.
- (iv) The genus-0 termination stage $r_{\text{max}}(\mathcal{A})$ equals both the A_∞ -depth $d_\infty(\mathcal{A})$ and the L_∞ -formality level $f_\infty(\mathcal{A})$ (Theorem ??).
- (v) The positive-genus corrections to the full shadow obstruction tower are carried by the quantum operations $\ell_n^{(g)}$ and the BV loop terms; they are not part of the classical genus-0 formality obstruction tower.

Proof. The degree filtration $F^r \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ on the modular convolution algebra induces an obstruction tower on the space of MC elements. The shadow $\Theta_{\mathcal{A}}^{\leq r}$ is by definition the projection of the bar-intrinsic MC element $\Theta_{\mathcal{A}} := D_{\mathcal{A}} - d_0$ (Theorem 22.1.3) to $F^{\leq r} \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.

At degree 2, the MC equation reduces to the Jacobi identity for $\ell_2^{(o)}$; its scalar trace is $\kappa(\mathcal{A})$. At degree 3, the obstruction to lifting $\Theta_{\mathcal{A}}^{\leq 2}$ to $\Theta_{\mathcal{A}}^{\leq 3}$ lives in $H^2(F^3\mathfrak{g}_{\mathcal{A}}^{\text{mod}}/F^4\mathfrak{g}_{\mathcal{A}}^{\text{mod}}, d_2)$, which is the same cohomology group controlling the transferred L_{∞} -bracket $\ell_3^{(o), \text{tr}}$. The gauge triviality theorem (Theorem ??) identifies the vanishing of H^1 in the same graded piece as the condition for removability.

At degree 4, after gauge-trivializing the cubic term, the residual obstruction class in $H^2(F^4\mathfrak{g}_{\mathcal{A}}^{\text{mod}}/F^5\mathfrak{g}_{\mathcal{A}}^{\text{mod}}, d_2)$ is the canonical quartic $[R_4^{\text{mod}}(\mathcal{A})]$. This is exactly the transferred bracket $\ell_4^{(o), \text{tr}}$ of the homotopy transfer from $(V_{\mathcal{A}}, d_2, \ell_2^{(o)})$ to its cohomology, the standard formula for the first non-trivial L_{∞} massey product after a formal bracket.

These three genus-0 identifications are proved at degrees 2, 3, 4 by Proposition ??, which establishes the coincidence of the shadow obstruction tower with the L_{∞} formality obstruction tower at each degree by direct comparison of the graph-sum formulae with the homotopy transfer formulae. The equality $r_{\max} = d_{\infty} = f_{\infty}$ extends this to all degrees by Theorem ??. The positive-genus terms belong to the quantum L_{∞} structure and the BV loop operator, so they form a parallel correction layer rather than part of the classical formality obstruction tower. $\square$

Remark 22.1.5 (Termination as the new content; genus-0 curve geometry). The identification of the genus-0 shadow obstruction tower with the L_{∞} formality obstruction tower is structural: the homological perturbation lemma (HPL) produces a transferred L_{∞} -algebra on any retract, and the transferred brackets ℓ_r^{tr} always exist. The genuinely new content of Proposition 22.1.4 is the *termination* phenomenon: the transferred L_{∞} -algebra terminates at degree $r_{\max}(\mathcal{A})$, meaning $\ell_r^{\text{tr}} = 0$ for all $r > r_{\max}$. This is a consequence of the shadow obstruction tower analysis (Theorem ??), not the HPL itself. The HPL is agnostic about termination; it produces infinitely many brackets in general. What forces termination is the specific structure of the modular convolution algebra: the vanishing of obstruction classes $o^{(r+1)}(\mathcal{A})$ in $H^2(F^{r+1}\mathfrak{g}_{\mathcal{A}}^{\text{mod}}/F^{r+2}\mathfrak{g}_{\mathcal{A}}^{\text{mod}}, d_2)$ for $r > r_{\max}$, which reflects the OPE complexity of $\mathcal{A}$.

Two aspects of this deserve emphasis. First, even the degree-2 projection $\kappa(\mathcal{A})$ already depends on curve geometry: the averaging map av gives the Σ_2 -coinvariant operator class of the meromorphic collision kernel $K_{\mathcal{A}}^{\text{coll}}(z)$ on the Fulton–MacPherson compactification $\overline{C}_2(X)$. This is not “Koszul duality over a point”; the formal-disk restriction that recovers the classical theory is *data* (a homotopy retract of $\overline{C}_2(X) \rightarrow D^{\times}$ from the global configuration space to the punctured disk), not a tautological identification. Second, the higher-degree transferred brackets ℓ_r^{tr} for $r \geq 3$ use the Arnold forms $\eta_{ij} = d \log(z_i - z_j)$ on $\overline{C}_r(X)$ and the boundary stratification of $\overline{\mathcal{M}}_{0, r+1}$ (the Stasheff associahedron K_{r+1}); the termination analysis takes place within this genus-0 curve geometry, not over a point.

PROPOSITION 22.1.6 (Five-component decomposition;). Expanding $\Theta_{\mathcal{A}}$ by genus and boundary type yields

$$\Theta_{\mathcal{A}} = \Theta^{\text{tree}} + \Theta^{\text{sew}} + \hbar \Theta^{\text{loop}} + \Theta^r + \Theta^{\text{bdry}},$$

and the Maurer–Cartan equation (22.1) decomposes into five interlocking pieces:

- (1) **Genus 0, tree-level:** the $d_{A_{\infty}}$ piece: the transferred A_{∞} operations $\{m_n\}_{n \geq 2}$;
- (2) **Genus 0, self-gluing:** the d_{sew} piece: self-gluing of genus-0 operations (the cyclic A_{∞} constraint);
- (3) **Genus $g \geq 1$, non-separating:** the $\hbar \Delta$ piece: BV contraction, the genus-raising operator;
- (4) **Spectral:** the d_r piece: the line-operator twist by $r(z)$;
- (5) **Boundary strata:** the d_{bdry} piece: clutching maps along $\partial \overline{\mathcal{M}}_{g, n}$.

In particular, the total differential $D = d_{A_{\infty}} + d_{\text{sew}} + \hbar \Delta + d_r$ is *not* five independent structures assembled by fiat. It is the single equation (22.1) expanded by stratum.

In the three-pillar framework (§??): pieces (1)–(2) carry the Pillar B convolution sL_∞ structure (Theorem 3.1.25); piece (3) is the BV operator from the modular operad boundary; pieces (4)–(5) encode the Pillar C log-FM collision geometry, with the planted-forest differential d_{pf} arising as the tropical skeleton of $\overline{\text{FM}}_n(C|D)$ (Theorem ??). Pillar A (the Ch_∞ structure) governs the L_∞ coherence that makes $D^2 = 0$ hold despite these five terms interacting nontrivially.

Proof. Stratify $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ by genus and partition the boundary strata of $\overline{\mathcal{M}}_{g,n}$ into separating, non-separating, and tree-level. The Maurer–Cartan equation is additive in genus and boundary type; projecting onto each stratum yields the five terms. The BV operator Δ arises from the non-separating node stratum $\delta_{\text{irr}}: \overline{\mathcal{M}}_{g-1,n+2} \rightarrow \overline{\mathcal{M}}_{g,n}$, which raises genus by 1. $\square$

THEOREM 22.1.7 (*Shadow obstruction tower from MC evaluation;*). The shadow hierarchy $\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \Theta$ is the evaluation of $\Theta_{\mathcal{A}}$ on specific moduli classes:

- (i) $\kappa(\mathcal{A}) = \langle \Theta_{\mathcal{A}}, \Theta_{\mathcal{A}} \rangle$ paired with $[\overline{\mathcal{M}}_{1,1}]$ (the fundamental class of genus-1 moduli);
- (ii) $\Delta_{\mathcal{A}} = \text{spectral data of } \Theta_{\mathcal{A}}|_{\overline{\mathcal{M}}_{1,2}}$ (restriction to 2-pointed genus 1);
- (iii) $\mathfrak{C}_{\mathcal{A}} = \Theta_{\mathcal{A}}|_{\overline{\mathcal{M}}_{0,4}}$ (quartic genus-0 boundary stratum);
- (iv) $\mathfrak{Q}_{\mathcal{A}} = \text{the contact term of } \Theta_{\mathcal{A}} \text{ on } \overline{\mathcal{M}}_{0,5}$ (quintic boundary);
- (v) the full $\Theta_{\mathcal{A}}$ is the universal Maurer–Cartan element itself.

Proof. Each shadow is by definition the value of the genus-refined multilinear data on an explicit cycle representative in $H_*(\overline{\mathcal{M}}_{g,n})$. Item (i) is Theorem D specialized to genus 1; items (ii)–(iv) are the definitions of $\Delta_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}}$ from the shadow calculus developed below. The hierarchy $\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \Theta$ is the filtration of $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ by degree: each shadow is the next Taylor coefficient of the single element $\Theta_{\mathcal{A}}$. $\square$

COROLLARY 22.1.8 (*Standard-family evaluations of the universal class;*). For each standard family (Heisenberg, affine Kac–Moody, Virasoro, $\mathcal{W}_3$, Yangian), the specific formulas (κ values, shadow obstruction tower data, genus corrections) computed in the example chapters are obtained by evaluating $\Theta_{\mathcal{A}}$ on explicit cycle representatives in $H_*(\overline{\mathcal{M}}_{g,n})$. The family-specific input is the OPE or RTT presentation used to construct $\mathcal{A}$; once that algebra object is fixed, the shadow formulas are projections of the same universal class.

Proof. Theorem 22.1.7 identifies each named shadow as the value of $\Theta_{\mathcal{A}}$ on its boundary stratum. The example chapters compute the same evaluations after substituting the corresponding OPE or RTT presentation of $\mathcal{A}$. Evaluation of a Maurer–Cartan element on a fixed cycle commutes with this substitution. $\square$

Remark 22.1.9 (*One equation*). The modular convolution dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is the organizing structure. The quantum master equation, graph sums, genus tower, non-renormalization constraints, and shadow projections are the same Maurer–Cartan element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ after projection to the corresponding quotient.

22.2 THE GOVERNING QUESTION FROM FIRST PRINCIPLES

The linear complementarity identity

$$Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^!) \cong C_g(\mathcal{A}).$$

is the trace shadow of a formal moduli problem carrying a shifted symplectic structure, with the two dual deformation packages as Lagrangians. The first-principles datum consists of:

- (1) a cyclic deformation complex for $\mathcal{A}$,
- (2) a cyclic deformation complex for $\mathcal{A}^\dagger$,
- (3) a universal twisting kernel relating the two,
- (4) a cyclic pairing turning the total deformation problem into a shifted symplectic formal moduli problem.

This is exactly the geometric shape suggested by the chiral bar–cobar formalism. The bar–cobar kernel is not auxiliary notation; it is the object whose deformations simultaneously remember the deformation of $\mathcal{A}$, the deformation of $\mathcal{A}^\dagger$, and the compatibility between them.

22.3 AMBIENT COMPLEMENTARITY FROM FIRST PRINCIPLES

Definition 22.3.1 (Ambient complementarity datum). Let $\mathcal{A} = T_X(V)/(R)$ be a modular Koszul chiral algebra on a smooth projective curve, let $\mathcal{A}^\dagger = C_X(s^{-1}V, s^{-2}R)$ be its presentation coalgebra, and let

$$q_{\mathcal{A}}: \mathcal{A}^\dagger \longrightarrow \overline{B}_X(\mathcal{A}), \quad K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}} \overline{B}_X(\mathcal{A}), \quad \nu_{\mathcal{A}}: K_X(\mathcal{A}) \longrightarrow \mathcal{A}^\dagger$$

be the quadratic, Ran–Verdier, and chosen-pair data. The package H_{CL} makes $q_{\mathcal{A}}$ a quasi-isomorphism, while the finite or completed pair package makes $\nu_{\mathcal{A}}$ an equivalence. An *ambient complementarity datum* consists of:

- (i) two cyclic deformation complexes

$$L_{\mathcal{A}} := \text{Def}_{\text{cyc}}(\mathcal{A}), \quad L_{\mathcal{A}^\dagger} := \text{Def}_{\text{cyc}}(\mathcal{A}^\dagger),$$

viewed as filtered complete cyclic L_∞ -algebras;

- (ii) a completed kernel object

$$K_{\mathcal{A}} := (\mathcal{A}^\dagger \widehat{\otimes} \mathcal{A})[1]$$

with differential twisted by the universal twisting kernel;

- (iii) a Maurer–Cartan element

$$\tau_{\mathcal{A}} \in \text{MC}(\mathcal{A}^\dagger \widehat{\otimes} \mathcal{A})$$

representing the Verdier-dual form of the canonical bar–cobar twisting morphism $\mathcal{A}^\dagger \rightarrow \mathcal{A}$;

- (iv) linearizations of the kernel in the two deformation directions,

$$\nabla_{\mathcal{A}}: L_{\mathcal{A}} \rightarrow K_{\mathcal{A}}, \quad \nabla_{\mathcal{A}^\dagger}: L_{\mathcal{A}^\dagger} \rightarrow K_{\mathcal{A}};$$

- (v) a degree -1 cyclic pairing on the total complex

$$L_{\mathcal{A}} \oplus K_{\mathcal{A}} \oplus L_{\mathcal{A}^\dagger}$$

for which the kernel differential is skew-adjoint.

Definition 22.3.2 (Ambient complementarity tangent complex). Given an ambient complementarity datum, define the *ambient complementarity tangent complex*

$$T_{\text{comp}}(\mathcal{A}) := \text{fib}\left(\nabla_{\mathcal{A}} - \nabla_{\mathcal{A}^\dagger}: L_{\mathcal{A}} \oplus L_{\mathcal{A}^\dagger} \longrightarrow K_{\mathcal{A}}\right).$$

A tangent vector in $T_{\text{comp}}(\mathcal{A})$ is therefore a first-order deformation of $\mathcal{A}$, a first-order deformation of $\mathcal{A}^!$, and a first-order deformation of the universal kernel, constrained by the linearized Maurer–Cartan equation.

THEOREM 22.3.3 (*Ambient complementarity in tangent form;*). Assume an ambient complementarity datum exists for $\mathcal{A}$. Then:

- (i) the complex $T_{\text{comp}}(\mathcal{A})$ carries a canonical nondegenerate pairing of degree -1 ;
- (ii) the one-sided tangent complexes

$$T_{\mathcal{A}} := \text{fib}(\nabla_{\mathcal{A}} : L_{\mathcal{A}} \rightarrow K_{\mathcal{A}}), \quad T_{\mathcal{A}^!} := \text{fib}(\nabla_{\mathcal{A}^!} : L_{\mathcal{A}^!} \rightarrow K_{\mathcal{A}})$$

are isotropic inside $T_{\text{comp}}(\mathcal{A})$;

- (iii) if the pairing on $L_{\mathcal{A}} \oplus K_{\mathcal{A}} \oplus L_{\mathcal{A}^!}$ is perfect and bar–cobar duality identifies the normal complex of one side with the shifted dual tangent complex of the other, then $T_{\mathcal{A}}$ and $T_{\mathcal{A}^!}$ are complementary Lagrangians in $T_{\text{comp}}(\mathcal{A})$.

Proof. The degree -1 pairing on $T_{\text{comp}}(\mathcal{A})$ is induced from the cyclic pairing on the direct sum by passage to the homotopy fiber. Because the total differential is skew-adjoint, the pairing descends to cohomology and is compatible with the differential.

For the one-sided tangent complex $T_{\mathcal{A}}$, the pullback of the ambient pairing reduces to the quadratic term in the differentiated Maurer–Cartan equation for the universal kernel. That quadratic term vanishes because the Maurer–Cartan equation is exactly the isotropy condition for the graph of the one-sided variation. The same argument applies to $T_{\mathcal{A}^!}$.

If the cyclic pairing is perfect and bar–cobar duality identifies the normal complex of one side with the shifted dual tangent complex of the other, maximal isotropy follows: the two sides are opposite polarizations of a single symplectic deformation problem. $\square$

THEOREM 22.3.4 (*Ambient complementarity as a shifted symplectic formal moduli problem;* (see Theorem ??)). Assume the tangent complex $T_{\text{comp}}(\mathcal{A})$ integrates to a filtered complete cyclic L_{∞} -algebra presenting a formal moduli problem

$$\mathcal{M}_{\text{comp}}(\mathcal{A}).$$

Then $\mathcal{M}_{\text{comp}}(\mathcal{A})$ carries a canonical (-1) -shifted symplectic structure, and the one-sided deformation problems of $\mathcal{A}$ and of $\mathcal{A}^!$ define Lagrangian maps

$$\mathcal{M}_{\mathcal{A}} \longrightarrow \mathcal{M}_{\text{comp}}(\mathcal{A}) \longleftarrow \mathcal{M}_{\mathcal{A}^!}.$$

The genus- g complementarity complex is the linear shadow of this picture.

Remark 22.3.5 (*Why the theorem is stronger than additive complementarity*). An additive splitting can always be faked by eigenspace decompositions, arbitrary direct sums, or linear identities. The ambient theorem is harder to fake because it requires:

- (i) a single deformation problem rather than two unrelated ones,
- (ii) a shifted symplectic pairing on that problem,
- (iii) isotropicity of the one-sided packages,
- (iv) maximality of the isotropicity,

(v) compatibility with clutching, factorization, and duality.

The last item is decisive: the theorem is not only about tangent complexes at one point, but about a modular geometry stable under the basic operations of the theory.

22.3.1 Cotangent normal form and the complementarity potential

THEOREM 22.3.6 (*Shifted cotangent normal form*;). Let $\mathcal{M}$ be a pointed (-1) -shifted symplectic formal moduli problem, and let

$$i_+ : \mathcal{L}_+ \rightarrow \mathcal{M}, \quad i_- : \mathcal{L}_- \rightarrow \mathcal{M}$$

be pointed Lagrangian maps through the base point. Assume the induced tangent map

$$T_0 \mathcal{L}_+ \oplus T_0 \mathcal{L}_- \xrightarrow{\sim} T_0 \mathcal{M}$$

is a quasi-isomorphism. Then there exists a pointed formal symplectomorphism

$$(\mathcal{M}, i_+) \simeq (T^*[-1]\mathcal{L}_+, \text{o-section})$$

under which $\mathcal{L}_-$ becomes the graph of a closed degree-zero one-form

$$\alpha_+ \in \Omega^1(\mathcal{L}_+)^{\circ}.$$

In the pointed formal neighborhood this one-form is exact:

$$\alpha_+ = dS_+$$

for a degree-zero formal function S_+ , unique up to an additive constant.

Proof. Because i_+ is Lagrangian, the normal complex of $\mathcal{L}_+$ in $\mathcal{M}$ is canonically identified with $T^*[-1]\mathcal{L}_+$. Formally along $\mathcal{L}_+$, the symplectic neighborhood theorem gives a pointed equivalence with the shifted cotangent bundle. Under this identification, $\mathcal{L}_+$ becomes the zero section. Since $\mathcal{L}_-$ is complementary to the zero section, it is the graph of a one-form α_+ . The graph of a one-form in a cotangent bundle is Lagrangian if and only if the one-form is closed, because the pullback of the canonical symplectic form is exactly $d\alpha_+$. In a pointed formal neighborhood every closed one-form is exact, which produces S_+ . $\square$

Definition 22.3.7 (*Complementarity potential*). Assume the ambient complementarity formal moduli problem exists. The formal function

$$S_{\mathcal{A}} \in \widehat{\mathcal{O}}(\mathcal{M}_{\mathcal{A}})^{\circ}$$

produced by Theorem 22.3.6 for the pair

$$\mathcal{L}_+ = \mathcal{M}_{\mathcal{A}}, \quad \mathcal{L}_- = \mathcal{M}_{\mathcal{A}^!}$$

is called the *complementarity potential* of the Koszul pair $(\mathcal{A}, \mathcal{A}^!)$.

PROPOSITION 22.3.8 (*Legendre duality of the two potentials*;). Assume the ambient complementarity formal moduli problem exists. Let $S_{\mathcal{A}}$ and $S_{\mathcal{A}^!}$ be the complementarity potentials constructed from the two cotangent charts centered at $\mathcal{M}_{\mathcal{A}}$ and $\mathcal{M}_{\mathcal{A}^!}$. Then $S_{\mathcal{A}}$ and $S_{\mathcal{A}^!}$ are formal Legendre transforms of one another.

Proof. The two functions generate the same formal Lagrangian subspace of the same shifted symplectic ambient moduli problem, viewed from the two opposite cotangent charts. The coordinate change between these two charts is the formal Legendre transform. $\square$

PROPOSITION 22.3.9 (*Legendre duality of cubic tensors;*). Let $H_{\mathcal{A}}$ be the complementarity Hessian. Then the cubic shadows of $\mathcal{A}$ and $\mathcal{A}^!$ are related by formal Legendre duality:

$$\mathfrak{C}_{\mathcal{A}^!}(p, p, p) = -\mathfrak{C}_{\mathcal{A}}(H_{\mathcal{A}}^{-1}p, H_{\mathcal{A}}^{-1}p, H_{\mathcal{A}}^{-1}p).$$

More generally, at quartic order the Legendre transform gives

$$S_{\mathcal{A}}^{\vee}(p) = \frac{1}{2}H_{\mathcal{A}}^{-1}(p, p) - \frac{1}{6}\mathfrak{C}_{\mathcal{A}}(H_{\mathcal{A}}^{-1}p, H_{\mathcal{A}}^{-1}p, H_{\mathcal{A}}^{-1}p) + O(p^4).$$

Since $S_{\mathcal{A}}^{\vee} = S_{\mathcal{A}^!}$, the cubic shadow on the dual side is the Hessian-transported negative of the cubic shadow on the primal side.

Proof. Write $S_{\mathcal{A}}(x) = \frac{1}{2}H_{\mathcal{A}}(x, x) + \frac{1}{6}\mathfrak{C}_{\mathcal{A}}(x, x, x) + O(x^4)$. The critical point of $\langle p, x \rangle - S_{\mathcal{A}}(x)$ is $x = H_{\mathcal{A}}^{-1}p + O(p^2)$. Substituting into the Legendre formula and collecting through cubic order yields the displayed identity. $\square$

THEOREM 22.3.10 (*Derived critical locus of self-dual deformations;*). Assume the ambient complementarity formal moduli problem exists. Then there is a canonical equivalence

$$\mathcal{M}_{\mathcal{A}} \times_{\mathcal{M}_{\text{comp}}(\mathcal{A})}^h \mathcal{M}_{\mathcal{A}^!} \simeq \text{Crit}(S_{\mathcal{A}}).$$

Simultaneous deformations of $\mathcal{A}$ and $\mathcal{A}^!$ preserving complementarity are governed by the derived critical locus of the complementarity potential.

Proof. In the cotangent normal form of Theorem 22.3.6, one Lagrangian is the zero section and the other is the graph of $dS_{\mathcal{A}}$. Their derived intersection is by definition the derived zero locus of $dS_{\mathcal{A}}$, which is the derived critical locus of $S_{\mathcal{A}}$. $\square$

PROPOSITION 22.3.11 (*Criterion for fake complementarity;*). In the cotangent chart centered at $\mathcal{M}_{\mathcal{A}}$, the following are equivalent.

- (i) The dual Lagrangian $\mathcal{M}_{\mathcal{A}^!}$ is linear.
- (ii) The complementarity potential $S_{\mathcal{A}}$ is quadratic.
- (iii) The derived critical locus $\text{Crit}(S_{\mathcal{A}})$ is controlled entirely by its Hessian complex, with no higher nonlinear operations.

Consequently, the first obstruction to fake complementarity is the first nonzero higher jet of $S_{\mathcal{A}}$ beyond its quadratic part.

Proof. In the cotangent chart, $\mathcal{M}_{\mathcal{A}^!}$ is the graph of $dS_{\mathcal{A}}$. The graph is linear if and only if $dS_{\mathcal{A}}$ is linear, hence if and only if $S_{\mathcal{A}}$ is quadratic. When $S_{\mathcal{A}}$ is quadratic, its critical locus is cut out by a linear differential and is therefore governed by the Hessian complex alone. Conversely, any cubic or higher term in $S_{\mathcal{A}}$ produces a nonlinear contribution to $dS_{\mathcal{A}}$ and therefore to the critical locus. $\square$

22.4 FINITE-ORDER NONLINEAR SHADOW CALCULUS

The full universal class $\Theta_{\mathcal{A}}$ globalizes the entire modular deformation theory (Theorem ??). Its first visible jets are accessible before the full globalization.

Definition 22.4.1 (Degree shadows of the universal class). By the bar-intrinsic construction (Theorem ??), the universal Maurer–Cartan class

$$\Theta_{\mathcal{A}} \in \text{MC}(\text{Def}_{\text{cyc}}(\mathcal{A}) \widehat{\otimes} \mathbb{G}_{\text{mod}}),$$

exists for every modular Koszul chiral algebra, where $\mathbb{G}_{\text{mod}}$ denotes the completed modular coefficient ring. In a cyclic minimal model the class determines a Hamiltonian modular master potential

$$\mathfrak{S}_{\mathcal{A}} = \sum_{r \geq 2} \frac{1}{r!} \text{Sh}_r(\Theta_{\mathcal{A}}),$$

where $\text{Sh}_r(\Theta_{\mathcal{A}})$ denotes the homogeneous degree- r Taylor coefficient on the tangent space of the minimal model. We call $\text{Sh}_r(\Theta_{\mathcal{A}})$ the *degree- r shadow* of the universal class.

Remark 22.4.2 (Quadratic, cubic, and quartic shadows as degree-2, 3, and 4 pieces). Since the universal class $\Theta_{\mathcal{A}}$ exists (Theorem ??), the three tensors

$$H_{\mathcal{A}}, \quad \mathfrak{C}_{\mathcal{A}}, \quad \mathfrak{Q}_{\mathcal{A}}$$

are nothing but the first three nontrivial shadows of $\Theta_{\mathcal{A}}$:

$$H_{\mathcal{A}} = \text{Sh}_2(\Theta_{\mathcal{A}}), \quad \mathfrak{C}_{\mathcal{A}} = \text{Sh}_3(\Theta_{\mathcal{A}}), \quad \mathfrak{Q}_{\mathcal{A}} = \text{Sh}_4(\Theta_{\mathcal{A}}).$$

The entire finite-order theory developed below is therefore the visible degree- ≤ 4 face of the universal Maurer–Cartan class.

22.4.1 Quadratic, cubic, and quartic shadows

Setup 22.4.3 (Finite-dimensional cyclic slice). Fix a finite-dimensional graded subspace

$$V_{\mathcal{A}} \subset H^*(\text{Def}_{\text{cyc}}(\mathcal{A}), \ell_1)$$

closed under all transferred operations needed through quartic order. Assume that the cyclic pairing restricts to a nondegenerate quadratic form on $V_{\mathcal{A}}$; write

$$H_{\mathcal{A}}: V_{\mathcal{A}} \xrightarrow{\sim} V_{\mathcal{A}}^*[-1]$$

for the induced Hessian, and let $P_{\mathcal{A}} := H_{\mathcal{A}}^{-1}$ denote the propagator.

Definition 22.4.4 (Shadow jets;). The *quadratic*, *cubic*, and *quartic* shadows of $\mathcal{A}$ on $V_{\mathcal{A}}$ are the tensors determined by the Taylor expansion

$$S_{\mathcal{A}}^{\leq 4}(x) = \frac{1}{2} H_{\mathcal{A}}(x, x) + \frac{1}{3!} \mathfrak{C}_{\mathcal{A}}(x, x, x) + \frac{1}{4!} \mathfrak{Q}_{\mathcal{A}}(x, x, x, x).$$

Equivalently, if $(V_{\mathcal{A}}, \ell_n^{\text{tr}})$ is the transferred cyclic minimal model, then

$$\begin{aligned} \mathfrak{C}_{\mathcal{A}}(x, y, z) &:= \sum_{\text{cyc}} \langle x, \ell_2^{\text{tr}}(y, z) \rangle, \\ \mathfrak{Q}_{\mathcal{A}}(x_1, x_2, x_3, x_4) &:= \sum_{\text{cyc}} \langle x_1, \ell_3^{\text{tr}}(x_2, x_3, x_4) \rangle. \end{aligned}$$

Define the quartic obstruction

$$\mathfrak{o}_{\mathcal{A}}^{(4)} := \frac{1}{2} \{\mathfrak{C}_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}\}_{H_{\mathcal{A}}},$$

where the bracket is the Hamiltonian bracket induced by the propagator $P_{\mathcal{A}}$.

THEOREM 22.4.5 (*Quartic shadow master equations;*). Assume the truncated Hamiltonian $S_{\mathcal{A}}^{\leq 4}$ satisfies the classical master equation modulo quintic terms:

$$\{S_{\mathcal{A}}^{\leq 4}, S_{\mathcal{A}}^{\leq 4}\}_{H_{\mathcal{A}}} = O(5).$$

Then the shadow jets satisfy

$$\{H_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}\}_{H_{\mathcal{A}}} = 0, \quad (22.2)$$

$$\{H_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}}\}_{H_{\mathcal{A}}} + \mathfrak{o}_{\mathcal{A}}^{(4)} = 0. \quad (22.3)$$

Equivalently, if one writes

$$\nabla_{H_{\mathcal{A}}}(X) := \{H_{\mathcal{A}}, X\}_{H_{\mathcal{A}}},$$

then

$$\nabla_{H_{\mathcal{A}}} \mathfrak{C}_{\mathcal{A}} = 0, \quad \nabla_{H_{\mathcal{A}}} \mathfrak{Q}_{\mathcal{A}} + \mathfrak{o}_{\mathcal{A}}^{(4)} = 0.$$

Proof. Expand the master equation by homogeneous degree. The cubic term is exactly (22.2); the quartic term is exactly (22.3). No other contributions occur through quartic order. $\square$

Construction 22.4.6 (*Separating sewing product*). Let $P_{\mathcal{A}} = H_{\mathcal{A}}^{-1}$ be the propagator. For symmetric tensors $\alpha \in \text{Sym}^p(V_{\mathcal{A}}^*)$ and $\beta \in \text{Sym}^q(V_{\mathcal{A}}^*)$, define the *single-edge sewing product*

$$\alpha \star_{P_{\mathcal{A}}} \beta \in \text{Sym}^{p+q-2}(V_{\mathcal{A}}^*)$$

by contracting one leg of α with one leg of β using $P_{\mathcal{A}}$ and symmetrizing over the remaining external legs. This is the tensor-level realization of separating clutching by one internal edge.

THEOREM 22.4.7 (*Separating boundary recursion through quartic order;*). Since the shadow jets are the degree- ≤ 4 projections of the bar-intrinsic MC element $\Theta_{\mathcal{A}}$ (Theorem ??), which satisfies the modular clutching identity, on every separating clutching map ξ one has

$$\xi^* H_{\mathcal{A}} = H_{\mathcal{A}} \star_{P_{\mathcal{A}}} H_{\mathcal{A}}, \quad (22.4)$$

$$\xi^* \mathfrak{C}_{\mathcal{A}} = H_{\mathcal{A}} \star_{P_{\mathcal{A}}} \mathfrak{C}_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} \star_{P_{\mathcal{A}}} H_{\mathcal{A}},$$

$$\xi^* \mathfrak{Q}_{\mathcal{A}} = H_{\mathcal{A}} \star_{P_{\mathcal{A}}} \mathfrak{Q}_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} \star_{P_{\mathcal{A}}} \mathfrak{C}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}} \star_{P_{\mathcal{A}}} H_{\mathcal{A}}. \quad (22.5)$$

Proof. These are the degree-2, degree-3, and degree-4 components of the clutching identity for the universal class:

$$\xi^*(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}} \star \Theta_{\mathcal{A}}.$$

At quartic order only the three displayed contractions survive. $\square$

22.4.2 The quartic shadow graph cocycle

Definition 22.4.8 (*Quartic shadow graph complex*). Let $\mathcal{G}_{\mathcal{A}}^{\leq 4}$ denote the completed span of stable graphs whose vertices are decorated as follows:

- (i) a 2-valent vertex is decorated by the Hessian $H_{\mathcal{A}}$,
- (ii) a 3-valent vertex is decorated by the cubic tensor $\mathfrak{C}_{\mathcal{A}}$,
- (iii) a 4-valent vertex is decorated by the quartic tensor $\mathfrak{Q}_{\mathcal{A}}$,
- (iv) every internal edge is contracted with the propagator $P_{\mathcal{A}}$.

Let d_{graph} be the differential obtained by summing over separating edge insertions together with the internal differential induced by the Hamiltonian bracket with $H_{\mathcal{A}}$.

Construction 22.4.9 (*The quartic shadow cocycle*). Define

$$\Theta_{\mathcal{A}}^{\leq 4} := H_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}} \in \mathcal{G}_{\mathcal{A}}^{\leq 4}.$$

THEOREM 22.4.10 (*Finite-order realization of the universal class;*). The element $\Theta_{\mathcal{A}}^{\leq 4}$ is a cocycle in $\mathcal{G}_{\mathcal{A}}^{\leq 4}$ if and only if the quartic shadow master equations (22.2)–(22.3) and the separating boundary recursion (22.4)–(22.5) hold.

Proof. The graph differential on the one-vertex generators reproduces the three sewing terms of Theorem 22.4.7; the Hamiltonian part of the differential reproduces Theorem 22.4.5. Matching homogeneous degrees 2, 3, and 4 yields the claim. $\square$

Remark 22.4.11 (*Tree terms versus obstruction terms*). There are two different quartic descendants of a cubic tensor $\mathfrak{C}$.

- (i) The *tree term*

$$T_{\mathfrak{C}} := \mathfrak{C} \star_P \mathfrak{C}$$

records the quartic geometry created by sewing two cubic vertices with one propagator.

- (ii) The *quartic obstruction*

$$J_{\mathfrak{C}} := \frac{1}{2} \{ \mathfrak{C}, \mathfrak{C} \}_H$$

records the Hamiltonian failure of a quartic primitive to exist.

These two contractions are conceptually different. In particular, a family can have nontrivial quartic boundary geometry even when the quartic obstruction vanishes.

22.4.3 The quartic shadow envelope

Definition 22.4.12 (*Primary–composite quartic shadow envelope*). Let $\mathcal{A}$ be strongly generated by primaries

$$W^{(d_1)}, \dots, W^{(d_r)}, \quad d_1 < \dots < d_r.$$

The *primary–composite quartic shadow envelope* is the graded vector space

$$E_{\mathcal{A}}^{[4]} := V_{\text{prim}} \oplus V_{\text{comp}},$$

where

$$V_{\text{prim}} := \bigoplus_{i=1}^r \mathbb{C} e_i$$

is the span of the strong generators and V_{comp} is the span of all quasi-primary projections

$$\Pi_{\text{qp}}(\cdot W^{(d_i)} W^{(d_j)} \cdot)$$

that occur in the singular or regular parts of pairwise OPEs of strong generators. It is the minimal envelope on which the quartic shadow calculus closes.

PROPOSITION 22.4.13 (*Quartic closure of the shadow envelope*;). The local quartic shadow differential and the quartic separating sewing recursion preserve $E_{\mathcal{A}}^{[4]}$.

Proof. Through quartic order, every local one-vertex contribution comes from a single pairwise OPE of strong generators. Such an OPE can produce only another strong generator, its descendants, or a normal-ordered bilinear composite. After quasi-primary projection, descendants are absorbed into the strong-generator/composite span. No trilinear composite is needed before quintic order. The boundary terms are obtained by gluing either two cubic vertices or one quartic vertex with one propagator, so they also remain in the same envelope. $\square$

22.5 THE THREE PRIMITIVE NONLINEAR ARCHETYPES

The quartic shadow calculus isolates three primitive patterns of nonlinear behavior in the standard low-rank families.

- (i) *Gaussian*: no nonlinear jet survives through quartic order. OPE is abelian: output is vacuum and derivatives of inputs. Shadow depth ≤ 2 .
- (ii) *Lie/tree*: a cubic tensor is present, the quartic obstruction vanishes, and quartic nonlinearity appears first on the boundary as a tree term. OPE creates new fields (root vertex operators), but no generator has a direct self-loop ($a \notin a_{(k)}a$). Shadow depth 3.
- (iii) *Contact/quartic*: the cubic tensor vanishes on the chosen slice, and the first nonlinear local term is quartic. OPE is abelian but a weight deformation activates the quartic shadow. Shadow depth 4.

A fourth pattern, *mixed/infinite* ($r_{\text{max}} = \infty$), arises when a strong generator belongs to its own self-OPE: $T_{(1)}T = 2T$ for Virasoro. This direct self-referentiality drives an infinite $\mathcal{A}_\infty$ cascade (Proposition ??). At higher rank, lattice vertex algebras achieve finite depths 5, 6, 7, $\dots$ through independent cusp forms in $M_{r/2}$ (Theorem ??). We compute the three low-rank patterns in the frame families.

22.5.1 Heisenberg

THEOREM 22.5.1 (*Heisenberg exact linearity*;). On the Heisenberg deformation line one has

$$\mathfrak{C}_{\mathcal{H}} = 0, \quad \mathfrak{d}_{\mathcal{H}}^{(4)} = 0, \quad \mathfrak{Q}_{\mathcal{H}} = 0.$$

Equivalently,

$$\Theta_{\mathcal{H}}^{\leq 4} = H_{\mathcal{H}}.$$

Proof. On the Heisenberg line the deformation problem is governed by a constant Poisson structure and the corresponding Moyal quantization is exact at first order. On the bar side, no higher operations m_n with $n \geq 3$ appear on this slice. Therefore the transferred binary and ternary nonlinear operations vanish, and hence so do the cubic and quartic shadow tensors. $\square$

COROLLARY 22.5.2 (*Gaussian boundary law;*). For the Heisenberg family the separating boundary recursion is purely Gaussian:

$$\xi^* H_{\mathcal{H}} = H_{\mathcal{H}} \star H_{\mathcal{H}}, \quad \xi^* \mathfrak{C}_{\mathcal{H}} = 0, \quad \xi^* \mathfrak{Q}_{\mathcal{H}} = 0.$$

Proof. Theorem 22.5.1 gives $\mathfrak{C}_{\mathcal{H}} = \mathfrak{Q}_{\mathcal{H}} = 0$. The separating boundary map is multiplicative for the binary Gaussian class, hence the only surviving boundary term is the convolution square of $H_{\mathcal{H}}$. $\square$

Remark 22.5.3 (Class G is not “classical Koszul duality over a point”). The Gaussian class G (shadow depth 2, $\Delta = 0$) is sometimes described as the stratum where “chiral Koszul duality reduces to classical Koszul duality.” This is imprecise. In class G the shadow tower terminates at degree 2 *on the curve*: the ordered collision kernel $K_{\mathcal{A}}^{\text{coll}}(z)$ has rank one, its homotopy coinvariant $q_2(K_{\mathcal{A}}^{\text{coll}})$ remains an operator class, and the normalized integral $\tau_{\mathcal{A},2}^{\text{res}} q_2(K_{\mathcal{A}}^{\text{coll}}) = \kappa$ is taken on $\overline{C}_2(X)$. The the bar differential uses the Arnold form $\eta = d \log(z_1 - z_2)$. The coincidence with the classical theory is mediated by the formal-disk restriction $\overline{C}_n(X) \rightarrow D^\times$, which is a homotopy retract carrying nontrivial data (the retraction depends on choosing a local coordinate on the curve). The formal disk is not a point; $\mathbb{P}^1$ has nontrivial global topology (the exceptional divisors of $\overline{C}_n(\mathbb{P}^1)$ are not contractible); and “Koszul duality over $\mathbb{P}^1$ reduces to Koszul duality over a point” is false without the retract data. Class G is the simplest stratum of the *chiral* theory, not a return to the classical one.

Remark 22.5.4 (Derived center interpretation: Gaussian class). In the chiral derived center $\mathcal{Z}_{\text{ch}}^{\text{der}}(\mathcal{H}_k)$ (Definition ??), the Gaussian archetype manifests as follows: the open/closed quartic resonance class $\mathfrak{R}_4^{\text{oc}}(\mathcal{H}_k) = 0$ (Theorem ??(i)), so the cochain-level closed sector has only the Gaussian quadratic shadow on this Heisenberg slice. This is a statement about the transferred open–closed shadow of the derived center, not an assertion that every bulk theory attached to the boundary is quadratic. The completed modular Koszul datum $\Pi_X^{\text{oc}}(\mathcal{H}_k)$ reduces to the linear holographic transform $\mathbb{H}_X(\mathcal{H}_k)$ of §??.

22.5.2 Affine $\widehat{\mathfrak{sl}}_2$

Definition 22.5.5 (Strict current-level sector). For the affine current algebra $\widehat{\mathfrak{sl}}_{2,k}$, let

$$V_{\text{aff}} := \mathfrak{sl}_2[1] \oplus \mathbb{C} K[1]$$

be the strict current-level sector generated by the current algebra and the level direction.

THEOREM 22.5.6 (*Affine cubic normal form;*). On the strict current-level sector one has

$$\mathfrak{C}_{\text{aff}}(x, y, z) = \kappa(x, [y, z]), \quad \mathfrak{p}_{\text{aff}}^{(4)} = 0.$$

Consequently there exists a quartic gauge in which

$$\mathfrak{Q}_{\text{aff}} = 0, \quad \Theta_{\text{aff}}^{\leq 4} = H_{\text{aff}} + \mathfrak{C}_{\text{aff}}.$$

Proof. The simple pole in the current algebra OPE is the Lie bracket, and the double pole is the invariant bilinear form. Therefore the cubic Hamiltonian on the strict sector is the cyclic Lie Hamiltonian

$$\frac{1}{6} \kappa(a, [a, a]).$$

The Hamiltonian self-bracket of this cubic term is the Jacobiator, which vanishes identically. Thus the quartic obstruction vanishes. Through quartic order one may therefore choose the minimal gauge in which no local quartic vertex remains. $\square$

COROLLARY 22.5.7 (*Boundary-generated quartic nonlinearity;*). Even though the local quartic vertex vanishes on the strict current-level sector, the quartic boundary shadow is generally nonzero:

$$\xi^* \mathfrak{Q}_{\text{aff}} = \mathfrak{C}_{\text{aff}} \star_{P_{\text{aff}}} \mathfrak{C}_{\text{aff}}.$$

Explicitly,

$$(\mathfrak{C}_{\text{aff}} \star_{P_{\text{aff}}} \mathfrak{C}_{\text{aff}})(x_1, x_2, x_3, x_4) = \frac{1}{k_{\text{eff}}} \sum_{\text{channels}} \kappa([x_i, x_j], [x_k, x_\ell]),$$

where k_{eff} is the normalization of the Hessian on the strict sector.

Proof. Apply the quartic boundary recursion with $\mathfrak{Q}_{\text{aff}} = 0$. The displayed formula is the definition of sewing two cubic current vertices with one propagator. $\square$

CONJECTURE 22.5.8 (*Critical-level emergence;*). For affine Kac–Moody $\widehat{\mathfrak{g}}_k$, assume the ambient complementarity package exists. At the critical level $k = -h^\vee$, the quadratic/Hessian shadow vanishes:

$$H_{\widehat{\mathfrak{g}}_{-h^\vee}} = 0,$$

while the cubic shadow survives:

$$\mathfrak{C}_{\widehat{\mathfrak{g}}_{-h^\vee}}(x, y, z) = \kappa(x, [y, z]).$$

The complementarity potential is therefore cubic at leading order:

$$S_{\widehat{\mathfrak{g}}_{-h^\vee}}(a) = \frac{1}{6} \kappa(a, [a, a]) + O(a^4).$$

REMARK 22.5.9 (*Critical-level leading term*). The quadratic shadow is governed by the shifted-level factor $k + h^\vee$, hence it vanishes at the critical level. The simple-pole current bracket remains in the OPE, so the first nonzero homogeneous term on the strict current sector is the Lie-theoretic cubic tensor.

CONJECTURE 22.5.10 (*Critical self-duality as Maurer–Cartan;*). At the critical level, the derived self-intersection of the two modular Lagrangians has leading critical equation

$$[a, a] = 0.$$

The cubic truncation of the derived critical locus is the Maurer–Cartan locus for the underlying Lie bracket.

REMARK 22.5.11 (*Critical cubic equation*). Differentiating the critical-level cubic action gives $dS(a) = \frac{1}{2} [a, a] + O(a^3)$. Its cubic critical-locus truncation is

$$\{a : [a, a] = 0\},$$

the Maurer–Cartan locus for the underlying Lie bracket.

REMARK 22.5.12 (*Critical level is purely nonlinear*). The critical level is not “more linear” than generic level; it is the opposite. At the critical level, complementarity becomes purely nonlinear at leading order, connecting complementarity geometry to critical-level representation theory (the Feigin–Frenkel center).

REMARK 22.5.13 (*Derived center interpretation: Lie/tree class*). In the chiral derived center, the cubic shadow $\mathfrak{C}_{\text{aff}} \in \mathcal{Z}^1$ is a degree-1 Gerstenhaber algebra element (a bulk derivation), and the quartic contact vanishes in the standard gauge: $[\mathfrak{Q}_{\text{aff}}^{\text{ct}}] = 0$ in $\mathcal{Z}^2$. The open/closed quartic resonance class reduces to the tree correction: $\mathfrak{R}_4^{\text{oc}}(\widehat{\mathfrak{g}}_k) = [\mathfrak{C} \star_P \mathfrak{C}] \in \mathcal{Z}^2$ (Theorem ??(ii)). This is the trace of cubic graviton exchange across a boundary node.

22.5.3 The $\beta\gamma$ system

Definition 22.5.14 (Weight/contact slice). Let $V_{\beta\gamma}$ be the minimal cyclic slice containing both the standard conformal-weight class-C family and the internal weight-changing class η . Write L_C for the standard-family class-C direction and $L_{wc} = \mathbb{C}\eta$ for the rank-one weight-changing line.

THEOREM 22.5.15 (*$\beta\gamma$ quartic birth;*). On the standard conformal-weight class-C direction L_C one has

$$\mathfrak{C}_{\beta\gamma}|_{L_C} = 0, \quad \mathfrak{d}_{\beta\gamma}^{(4)}|_{L_C} = 0, \quad \mathfrak{Q}_{\beta\gamma}|_{L_C} = -\frac{5}{12}u^4,$$

where u is the standard conformal-weight coordinate. Equivalently, the first nonzero nonlinear standard-family shadow is quartic rather than cubic, and the scalar tower is

$$S_2 = 6\lambda^2 - 6\lambda + 1, \quad S_3 = 0, \quad S_4 = -\frac{5}{12}, \quad S_r = 0 \quad (r \geq 5).$$

On the internal weight-changing line, writing η for its generator,

$$\mathfrak{Q}_{\beta\gamma}(\eta, \eta, \eta, \eta) = \mu_{\beta\gamma}, \quad \mu_{\beta\gamma} := \langle \eta, m_3(\eta, \eta, \eta) \rangle.$$

This scalar is zero by Corollary 22.5.16.

Proof. The class-C scalar values are the standard conformal-weight $\beta\gamma_\lambda$ values recorded in Proposition ?? and in the landscape census: the mixed simple-pole OPE gives no scalar cubic coefficient, while the transferred modular contact term is the constant $S_4 = -5/12$ and the tower terminates for $r \geq 5$. Since $\mathfrak{C}_{\beta\gamma}|_{L_C} = 0$, the quartic obstruction $\frac{1}{2}\{\mathfrak{C}, \mathfrak{C}\}_H$ vanishes on that lane. Restricting the same quartic functional to $L_{wc} = \mathbb{C}\eta$ gives the scalar $\mu_{\beta\gamma}$. $\square$

COROLLARY 22.5.16 (*Weight-changing projection of the quartic contact;*). On the weight-changing line of the $\beta\gamma$ system,

$$\mu_{\beta\gamma} := \langle \eta, m_3(\eta, \eta, \eta) \rangle = 0.$$

Thus the rank-one weight-changing projection of the quartic contact class vanishes. This is not the class-C scalar coefficient $S_4 = -5/12$ of the standard conformal-weight family.

Proof. Two independent arguments. (1) Homotopy transfer: the transferred bracket satisfies $m_2(\eta, \eta) = 0$ (the Maurer–Cartan equation on the one-dimensional weight-changing subspace is linear), so $m_3(\eta, \eta, \eta) = 0$ by the A_∞ relation $m_3 = m_2 \circ (h \otimes \text{id}) \circ m_2 + \dots$ applied to the vanishing binary input. (2) Rank-one abelian rigidity (Theorem 22.5.19): the weight-changing line is a one-dimensional cyclic subspace with vanishing higher brackets. Computational verification: `compute/lib/betagamma_quartic_contact.py`. $\square$

COROLLARY 22.5.17 (*Pure contact boundary law;*). On the weight/contact slice of $\beta\gamma$ one has

$$\xi^* \mathfrak{Q}_{\beta\gamma} = H_{\beta\gamma} \star_{P_{\beta\gamma}} \mathfrak{Q}_{\beta\gamma} + \mathfrak{Q}_{\beta\gamma} \star_{P_{\beta\gamma}} H_{\beta\gamma}.$$

There is no cubic tree contribution.

Proof. Apply the quartic boundary recursion with $\mathfrak{C}_{\beta\gamma} = 0$. $\square$

THEOREM 22.5.18 (*Primitive nonlinear archetype trichotomy*;). Through quartic order, the three frame families realize the three primitive nonlinear archetypes:

(i) Heisenberg is Gaussian:

$$\Theta_{\mathcal{H}}^{\leq 4} = H_{\mathcal{H}}.$$

(ii) Affine $\widehat{\mathfrak{sl}}_2$ is of Lie/tree type:

$$\Theta_{\text{aff}}^{\leq 4} = H_{\text{aff}} + \mathfrak{C}_{\text{aff}},$$

with quartic boundary term generated by $\mathfrak{C}_{\text{aff}} \star \mathfrak{C}_{\text{aff}}$.

(iii) The $\beta\gamma$ system is of contact/quartic type:

$$\Theta_{\beta\gamma}^{\leq 4}|_{L_C} = H_{\beta\gamma}|_{L_C} - \frac{5}{12} u^4,$$

with quartic boundary term propagated from the local quartic vertex.

Proof. The three cases follow from the explicit shadow computations: Heisenberg shadow Gaussianity (Theorem 22.5.1), affine cubic normal form (Theorem 22.5.6), and $\beta\gamma$ quartic birth (Theorem 22.5.15). $\square$

THEOREM 22.5.19 (*Rank-one abelian rigidity*;). Let $L \subset V_{\mathcal{A}}$ be a one-dimensional cyclic subspace on which all transferred higher brackets vanish:

$$\ell_n^{\text{tr}}|_L = 0 \quad (n \geq 2).$$

Then the restriction of the complementarity potential to L is exactly quadratic. In particular, complementarity on L is formally fake.

Proof. On such a line the cyclic action expansion collapses to its quadratic Hessian part: every higher jet $\text{Sh}_r(\Theta_{\mathcal{A}})|_L$ for $r \geq 3$ involves at least one factor of some ℓ_n^{tr} with $n \geq 2$, and all vanish. $\square$

Remark 22.5.20 (Uniform explanation of linear examples). Theorem 22.5.19 explains uniformly why the Heisenberg level line and the explicit $\beta\gamma$ weight-changing line are both formally linear: in each case the deformation lies on a one-dimensional sector with vanishing higher brackets. The class-C $\beta\gamma$ witness is instead the standard conformal-weight family, where the scalar quartic $S_4 = -5/12$ survives and the tail vanishes for $r \geq 5$.

Remark 22.5.21 (Derived center interpretation: contact class). In the chiral derived center, the class-C standard-family lane has $\mathfrak{C}_{\beta\gamma} = 0$ and $[\mathfrak{D}_{\beta\gamma}^{\text{ct}}] = [-5/12] \cdot u^4 \in \mathcal{Z}^2$, so the tree correction vanishes and the quartic contact class is the sole contributor to $\mathfrak{R}_4^{\text{oc}}$. On the weight-changing line, rank-one abelian rigidity (Corollary 22.5.16) collapses this class to zero: $\mathfrak{R}_4^{\text{oc}}(\beta\gamma)|_{\text{wt-line}} = 0$ (Theorem ??(iii)). The contact depth $r_{\text{max}} = 4$ is a stratum phenomenon, not a bulk gravitational invariant.

22.6 MIXED CUBIC–QUARTIC FAMILIES: VIRASORO AND PRINCIPAL $\mathcal{W}_N$

The three primitive archetypes are not the end of the story. Virasoro and principal $\mathcal{W}_N$ introduce the first genuinely mixed families, in which cubic and quartic nonlinearities coexist already at the first nontrivial level.

22.6.1 A universal cubic sector for strong generators

THEOREM 22.6.1 (*Universal gravitational cubic tensor*;). Let $\mathcal{A}$ be strongly generated by Virasoro-primary fields

$$W^{(2)} = T, W^{(d_2)}, \dots, W^{(d_r)}$$

of conformal weights $2, d_2, \dots, d_r$. On the primary slice with coordinates $x_2, x_{d_2}, \dots, x_{d_r}$ dual to the strong generators, the cubic shadow contains the universal summand

$$\mathfrak{C}_{\mathcal{A}}^{\text{grav}} = 2x_2^3 + \sum_{i \geq 2} d_i x_2 x_{d_i}^2.$$

Proof. Each $W^{(d_i)}$ is Virasoro-primary of weight d_i , so

$$T_{(1)} W^{(d_i)} = d_i W^{(d_i)}.$$

For T itself this gives $T_{(1)} T = 2T$. The cyclic cubic tensor is obtained by pairing the output of this action with the quadratic pairing and then symmetrizing the three legs. This produces exactly the stated universal cubic terms. $\square$

22.6.2 Virasoro

Definition 22.6.2 (*Virasoro quartic shadow envelope*). Let

$$\Lambda_{\text{Vir}} := TT : -\frac{3}{10} \partial^2 T.$$

The Virasoro quartic shadow envelope is

$$E_{\text{Vir}}^{[4]} := \mathbb{C} \langle T, \Lambda_{\text{Vir}} \rangle.$$

THEOREM 22.6.3 (*Virasoro mixed shadow theorem*;). On $E_{\text{Vir}}^{[4]}$ one has

$$H_{\text{Vir}} = \frac{c}{2} x^2, \quad \mathfrak{C}_{\text{Vir}} = 2x^3, \quad \mathfrak{Q}_{\text{Vir}}^{\text{contact}} \neq 0.$$

Equivalently,

$$\Theta_{\text{Vir}}^{\leq 4} = H_{\text{Vir}} + \mathfrak{C}_{\text{Vir}} + \mathfrak{Q}_{\text{Vir}}^{\text{contact}}.$$

Proof. The quadratic term is the quartic pole of the TT OPE,

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \dots.$$

The cubic term is the conformal-weight channel

$$T_{(1)} T = 2T,$$

which is the rank-one case of Theorem 22.6.1. The regular term $: TT :$ is not quasi-primary, but its corrected quasi-primary projection is Λ_{Vir} , which therefore contributes a genuine one-vertex quartic contact term. $\square$

THEOREM 22.6.4 (*Explicit Virasoro quartic contact coefficient;*). The quartic contact coefficient of the Virasoro shadow envelope is

$$\mathfrak{Q}_{\text{Vir}}^{\text{contact}} = \frac{10}{c(5c + 22)}.$$

This is the first non-abelian Ring 2 shadow coefficient computed in closed form.

Proof. *Step 1* (Quasi-primary Gram matrix). The vacuum-module states at level 4 are $|1\rangle = L_{-4}|0\rangle$ and $|2\rangle = L_{-2}^2|0\rangle$, with Gram matrix

$$G = \begin{pmatrix} 5c & 3c \\ 3c & c(c + 8)/2 \end{pmatrix}$$

computed from $[L_4, L_{-4}] = 8L_0 + 5c$, $\langle 0|L_4 L_{-2}^2|0\rangle = 3c$, and $\langle 0|L_{-2}^2 L_{-2}^2|0\rangle = c(c + 8)/2$.

Step 2 (Quasi-primary projection). The condition $L_1 \Lambda_{\text{Vir}} = 0$ determines $\Lambda = L_{-2}^2|0\rangle - a L_{-4}|0\rangle$ with $a = 3/5$ (from $L_1 L_{-2}^2|0\rangle = 3L_{-3}|0\rangle$ and $L_1 L_{-4}|0\rangle = 5L_{-3}|0\rangle$).

Step 3 (BPZ norm).

$$\langle \Lambda|\Lambda\rangle = G_{22} - 2a G_{12} + a^2 G_{11} = \frac{c(c + 8)}{2} - \frac{6}{5} \cdot 3c + \frac{9}{25} \cdot 5c = \frac{c(5c + 22)}{10}.$$

Step 4 (Contact coefficient). The TT OPE at level 0 (regular part) contains Λ_{Vir} with coefficient 1 (by definition of normal ordering: TT : and the projection to Λ). The quartic contact coefficient is therefore $1/\langle \Lambda|\Lambda\rangle = 10/[c(5c + 22)]$.

Computational verification: `compute/lib/virasoro_quartic_contact.py` (28 tests). $\square$

Remark 22.6.5 (*Quartic jet of $\Theta_{\mathcal{A}}$*). The quartic contact coefficient $\mathfrak{Q}_{\text{Vir}}^{\text{contact}} = 10/[c(5c + 22)]$ is the degree-4 Taylor jet of the complementarity potential S_{Vir} around the scalar $\kappa(\text{Vir}_c) = c/2$. Together with the scalar κ (degree 2) and the cubic $\mathfrak{C} = 2$ (degree 3), it provides the first three terms of the Taylor expansion of Θ_{Vir} .

The singular locus $c(5c + 22) = 0$ consists of:

- (a) $c = 0$: the uncurved point where $\kappa = 0$ (Corollary 22.6.6);
- (b) $c = -22/5$: the Lee–Yang value $c_{5,2} = 1 - 6 \cdot 9/10 = -22/5$, where the Kac determinant at level 4 vanishes and Λ becomes null.

The formula is well-defined and positive for all non-degenerate generic $c > 0$.

COROLLARY 22.6.6 (*Cubic-leading Virasoro at the uncurved point;*). At $c = 0$ the quadratic term of the Virasoro shadow vanishes while the cubic term survives:

$$H_{\text{Vir}} = 0, \quad \mathfrak{C}_{\text{Vir}} \neq 0.$$

Hence the leading complementarity potential is cubic, with quartic contact correction.

Proof. Theorem 22.6.3 gives $H_{\text{Vir}} = 0$ on the mixed slice and leaves the cubic tensor nonzero. Substitution gives the displayed potential. $\square$

Remark 22.6.7 (Derived center interpretation: mixed class). The mixed archetype is the first where the derived center carries irreducibly nonlinear gravitational data. In $\mathcal{Z}^2$, both the quartic contact class $[\mathfrak{Q}_{\text{Vir}}^{\text{ct}}] = [10/(c(5c + 22))] \cdot x^4$ and the tree correction $[\mathfrak{C}_{\text{Vir}} \star_{P_{\text{Vir}}} \mathfrak{C}_{\text{Vir}}]$ are nonzero, so $\mathfrak{H}_4^{\text{oc}}(\text{Vir}_c) \neq 0$ for generic c (Theorem ??(iv)). The poles at $c = 0$ and $c = -22/5$ (null-state divisor) are the first instances where the boundary shadow obstruction tower degenerates. The nonvanishing quintic obstruction $o_{\text{Vir}}^{(5)} = \{\mathfrak{C}, \mathfrak{Q}\}_H \neq 0$ forces the full Gerstenhaber algebra on $\mathcal{Z}^*$ to be non-formally-generated: no finite truncation of the shadow obstruction tower captures the complete boundary-holographic partition function. For the $\mathcal{W}_3$ algebra, the full contact determinant has the additional weight-6 factor $2c - 1$; the rank-one Ξ_W visible norm does not have this factor (Proposition 22.6.11). Thus $c = 1/2$ is detected only by the full composite sector, while $c = -22/5$ is already visible in the Virasoro weight-4 block.

22.6.3 The prototype higher-spin family $\mathcal{W}_3$

Definition 22.6.8 ($\mathcal{W}_3$ quartic shadow envelope). Let T and W denote the strong generators of $\mathcal{W}_3$, let

$$\Lambda =: TT : -\frac{3}{10} \partial^2 T$$

be the weight-4 quasi-primary composite, and let Λ_2, Λ_3 denote the two weight-6 quasi-primary composites extracted from the regular part of the $W-W$ OPE. Define

$$E_{\mathcal{W}_3}^{[4]} := \mathbb{C}\langle T, W, \Lambda, \Lambda_2, \Lambda_3 \rangle.$$

THEOREM 22.6.9 ($\mathcal{W}_3$ mixed-shadow normal form;). On $E_{\mathcal{W}_3}^{[4]}$ one has

$$H_{W_3} = \frac{c}{2} t^2 + \frac{c}{3} w^2, \quad \mathfrak{C}_{W_3}^{\text{grav}} = 2t^3 + 3tw^2.$$

The quartic contact sector is nonzero and contains:

- (i) a weight-4 contact channel through Λ , with coefficient proportional to $\frac{16}{22+5c}$;
- (ii) a weight-6 contact channel through the quasi-primary square of W and the composites Λ_2, Λ_3 .

In particular,

$$\Theta_{W_3}^{\leq 4} = H_{W_3} + \mathfrak{C}_{W_3} + \mathfrak{Q}_{W_3}^{\text{contact}}$$

is genuinely mixed cubic–quartic.

Proof. The diagonal Hessian comes from the leading self-poles

$$T_{(3)}T = \frac{c}{2}, \quad W_{(5)}W = \frac{c}{3}.$$

The universal cubic term is Theorem 22.6.1 specialized to the weights 2 and 3. The nonlinear $W-W$ OPE produces the weight-4 quasi-primary Λ with coefficient $16/(22 + 5c)$ and also yields the weight-6 quasi-primary composites through the regular part. These are local quartic contact vertices. $\square$

Definition 22.6.10 (Primary quartic resonance divisor for $\mathcal{W}_3$). Let

$$\Xi_W := \Pi_{\text{qp}}(: W^2 :)$$

be the quasi-primary square of the spin-3 generator. The *primary quartic resonance divisor* of $\mathcal{W}_3$ is the vanishing locus of the rank-one Gram pairing of Ξ_W .

PROPOSITION 22.6.11 (*Visible quartic resonance factor for $\mathcal{W}_3$;*). The rank-one visible norm of $\Xi_W = \Pi_{\text{qp}}(: W^2 :)$ is

$$\langle \Xi_W(z), \Xi_W(w) \rangle = \frac{2c(875c^3 + 110975c^2 + 112880c - 1931508)}{315(5c + 22)^2(z - w)^{12}},$$

whose cubic numerator is irreducible over $\mathbb{Q}$ and is nonzero at $c = 1/2$. Hence the visible rank-one Ξ_W norm does not detect the factor $2c - 1$; that factor belongs to the full weight-6 contact block in Theorem 22.6.13.

Proof. The displayed norm is the rank-one Gram entry of the quasi-primary projection $\Pi_{\text{qp}}(: W^2 :)$. Let

$$p(c) = 875c^3 + 110975c^2 + 112880c - 1931508.$$

The polynomial is primitive over $\mathbb{Z}$. Modulo 17 it becomes

$$p(c) \equiv 8c^3 + 16c^2 + 15 \pmod{17},$$

and this cubic has no root in $\mathbb{F}_{17}$; hence p is irreducible over $\mathbb{Q}$. Finally $p(1/2) = -14777719/8 \neq 0$, so the visible rank-one norm does not contain the factor $2c - 1$. $\square$

REMARK 22.6.12 (*Visible versus full quartic resonance*). The rank-one visible norm of Ξ_W and the full contact determinant are different invariants. The visible norm records one quasi-primary line in the regular WW sector. The full quartic resonance divisor is the determinant of the block sum $G_4 \oplus G_6$ and therefore sees the weight-4 Virasoro block together with the complete weight-6 composite block.

THEOREM 22.6.13 (*Full $\mathcal{W}_3$ quartic Gram determinant;*). The contact quartic bundle for $\mathcal{W}_3$ decomposes into weight blocks $Q_{\mathcal{W}_3}^{\text{ct}} = Q_4 \oplus Q_6$, where $Q_4 = \langle \Lambda \rangle$ (weight 4) and $Q_6 = \langle \Lambda_2, \Lambda_3 \rangle$ (weight 6 quasi-primary composites from the regular WW sector). The Gram form is block-diagonal: $G_{\mathcal{W}_3}^{\text{ct}} = \text{diag}(G_4, G_6)$.

- (i) **Weight-4 block.** $G_4 = \langle \Lambda, \Lambda \rangle = \frac{c(5c+22)}{10}$. *Proof.* Represent $\Lambda =: TT : - \frac{3}{10} \partial^2 T$ as the state $L_{-2}^2 |0\rangle - \frac{3}{5} L_{-4} |0\rangle$ in the vacuum Verma module. The level-4 Shapovalov form on $\{L_{-4} |0\rangle, L_{-2}^2 |0\rangle\}$ has Gram matrix $\begin{pmatrix} 5c & 3c \\ 3c & c(c+8)/2 \end{pmatrix}$. Direct computation:

$$\langle \Lambda | \Lambda \rangle = \frac{c(c+8)}{2} - \frac{6}{5} \cdot 3c + \frac{9}{25} \cdot 5c = \frac{c(5c+22)}{10}.$$

This is the weight-4 part of the quartic resonance data. The rank-one visible norm of Proposition 22.6.11 is a separate weight-6 line and does not carry the factor $2c - 1$.

- (ii) **Full determinant.** On the smooth modular interior, the full quartic resonance divisor is

$$R_{4,g,n}^{\text{mod},o}(\mathcal{W}_3) = 3 [c=0] + [2c-1=0] + 2 [5c+22=0].$$

The triple multiplicity at $c = 0$ comes from weight 4 contributing one power and weight 6 contributing two. The double multiplicity at $5c + 22 = 0$ comes from both blocks. The simple multiplicity at $2c - 1 = 0$ is visible only in the weight-6 block (it is invisible from the Virasoro weight-4 channel alone).

Proof. Part (i) is verified by the explicit level-4 Shapovalov computation above. For part (ii), the Kac determinant of the $\mathcal{W}_3$ algebra at level 6 contributes factors $c^2(2c-1)(5c+22)$ to the weight-6 Gram block $\det G_6$. The full determinant is $\det G^{\text{ct}} = G_4 \cdot \det G_6$, whose vanishing locus gives the stated multiplicity count. The factor $(2c-1)$ at $c = 1/2$ detects the $\mathcal{W}_3$ degeneration invisible from Λ alone. $\square$

22.6.4 Principal $\mathcal{W}_N$

Definition 22.6.14 (Principal quartic shadow envelope). For principal $\mathcal{W}_N$ with strong generators

$$W^{(2)} = T, W^{(3)}, \dots, W^{(N)},$$

let $E_{\mathcal{W}_N}^{[4]}$ be the primary-composite quartic shadow envelope generated by the strong generators together with all quasi-primary bilinears

$$\Pi_{\text{qp}}(: W^{(r)} W^{(s)} :) \quad (2 \leq r \leq s \leq N)$$

that occur in pairwise OPEs.

THEOREM 22.6.15 (*Diagonal Hessian and universal cubic sector for principal $\mathcal{W}_N$;).* On the primary slice of principal $\mathcal{W}_N$ with coordinates $x_2, \dots, x_N$ one has

$$H_{\mathcal{W}_N} = \sum_{s=2}^N \frac{c}{s} x_s^2, \quad \mathfrak{E}_{\mathcal{W}_N}^{\text{grav}} = 2x_2^3 + \sum_{s=3}^N s x_2 x_s^2.$$

Proof. The diagonal Hessian comes from the leading self-poles

$$W_{(2s-1)}^{(s)} W^{(s)} = \frac{c}{s},$$

while distinct conformal weights contribute no vacuum cross-term. The universal cubic sector is Theorem 22.6.1. $\square$

THEOREM 22.6.16 (*Nonvanishing of contact quartics for principal $\mathcal{W}_N$;).* For every principal $\mathcal{W}_N$ with $N \geq 3$, the contact quartic sector is nonzero:

$$\mathfrak{Q}_{\mathcal{W}_N}^{\text{contact}} \neq 0.$$

Proof. For each $s \geq 3$, the field $W^{(s)}$ has nonzero two-point function and nonzero leading self-pole. Its normal-ordered square therefore has a nontrivial quasi-primary projection

$$\Lambda_s := \Pi_{\text{qp}}(: W^{(s)} W^{(s)} :),$$

which belongs to the quartic shadow envelope. These quasi-primary squares contribute local quartic contact terms. $\square$

COROLLARY 22.6.17 (*Principal $\mathcal{W}_N$ is mixed cubic-quartic;).* For every principal $\mathcal{W}_N$ with $N \geq 3$ and generic parameter,

$$\Theta_{\mathcal{W}_N}^{\leq 4} = H_{\mathcal{W}_N} + \mathfrak{E}_{\mathcal{W}_N}^{\text{grav}} + \mathfrak{E}_{\mathcal{W}_N}^{\text{hs}} + \mathfrak{Q}_{\mathcal{W}_N}^{\text{contact}},$$

with both the cubic and the quartic local sectors nonzero.

Proof. The cubic sector is nonzero by Theorem 22.6.15. The contact quartic sector is nonzero by Theorem 22.6.16. $\square$

22.7 FROM GRAM DETERMINANTS TO A MODULAR QUARTIC RESONANCE CLASS

We promote the quartic resonance divisor from a polynomial in the parameter to a modular characteristic class. The central idea is simple. A Gram determinant depends on a choice of basis, but its determinant line does not. The correct modular invariant is therefore not the determinant function itself but the determinant *section* of a canonical line bundle. Its vanishing is the resonance locus. The clutching law for this section is the first nonlinear shadow of the clutching identity for $\Theta_{\mathcal{A}}$.

22.7.1 The determinant line of the contact quartic sector

Definition 22.7.1 (Generic quartic-regular parameter locus). Let $\mathcal{A}$ be a family of strongly generated chiral algebras depending algebraically on a parameter u (for example level or central charge). Let $B_{\mathcal{A}}^{\circ}$ denote the maximal Zariski-open locus on which the ranks of all weight-graded contact quartic spaces are locally constant. All bundles below are defined over $\overline{\mathcal{M}}_{g,n} \times B_{\mathcal{A}}^{\circ}$.

Definition 22.7.2 (Weight-graded contact quartic bundle). Let

$$\mathcal{E}_{g,n}^{[4]}(\mathcal{A})$$

denote the quartic shadow local system obtained by transporting the fiberwise envelope $E_{\mathcal{A}}^{[4]}$ along the factorization family over $\overline{\mathcal{M}}_{g,n} \times B_{\mathcal{A}}^{\circ}$. For each total conformal weight d , let

$$\mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}) \subset \mathcal{E}_{g,n}^{[4]}(\mathcal{A})$$

be the locally free subsheaf generated by zero-internal-edge quasi-primary bilinear composites of total weight d . Put

$$\mathcal{E}_{g,n}^{\text{ct}}(\mathcal{A}) := \bigoplus_d \mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}).$$

For each d , let $\mathcal{U}_{g,n}^{(d)}$ denote the tautological modular line in which weight- d two-point functions transform.

Remark 22.7.3 (About the tautological lines). The precise expression for $\mathcal{U}_{g,n}^{(d)}$ depends on the chosen presentation of the factorization theory; it is the standard modular line attached to a weight- d quasi-primary insertion. The determinant construction below is independent of any trivialization of these lines. In genus 0 and after choosing the standard coordinate trivialization, the determinant section becomes an honest polynomial in the parameter.

Construction 22.7.4 (Gram determinant line;). For each weight d , let

$$q_{g,n}^{(d)}(\mathcal{A}) : \mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}) \otimes \mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}) \longrightarrow \mathcal{U}_{g,n}^{(d)}$$

be the symmetric bilinear form given by the genus- (g, n) two-point function on the contact quartic sector. Set

$$\mathcal{L}_{4,g,n}^{\text{res}}(\mathcal{A}) := \bigotimes_d \left((\det \mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}))^{-\otimes 2} \otimes (\mathcal{U}_{g,n}^{(d)})^{\otimes r_d} \right), \quad (22.6)$$

where $r_d := \text{rk}(\mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}))$. The determinant of the weight- d Gram form defines a section

$$\det q_{g,n}^{(d)}(\mathcal{A}) \in \Gamma\left(\overline{\mathcal{M}}_{g,n} \times B_{\mathcal{A}}^{\circ}, (\det \mathcal{E}_{g,n}^{\text{ct},d}(\mathcal{A}))^{-\otimes 2} \otimes (\mathcal{U}_{g,n}^{(d)})^{\otimes r_d}\right).$$

Their tensor product is the *quartic resonance section*

$$s_{4,g,n}^{\text{res}}(\mathcal{A}) := \bigotimes_d \det q_{g,n}^{(d)}(\mathcal{A}) \in \Gamma(\overline{\mathcal{M}}_{g,n} \times B_{\mathcal{A}}^{\circ}, \mathcal{L}_{4,g,n}^{\text{res}}(\mathcal{A})).$$

Definition 22.7.5 (Modular quartic resonance class;). The *modular quartic resonance class* of $\mathcal{A}$ in genus (g, n) is the Cartier divisor class

$$\mathfrak{R}_{4,g,n}^{\text{mod}}(\mathcal{A}) := \text{div}(s_{4,g,n}^{\text{res}}(\mathcal{A})) \in \text{Pic}(\overline{\mathcal{M}}_{g,n} \times B_{\mathcal{A}}^{\circ}).$$

PROPOSITION 22.7.6 (Basis independence and specialization;). The section $s_{4,g,n}^{\text{res}}(\mathcal{A})$ and its divisor class are independent of every choice of local basis of the contact quartic bundle. When $g = n = 0$ and the tautological lines are trivialized in the standard coordinate chart, the zero locus of $s_{4,0,0}^{\text{res}}(\mathcal{A})$ is exactly the Gram-determinant resonance divisor of the quartic contact sector.

Proof. Under a basis change by a matrix A , the Gram matrix transforms by

$$G \mapsto A^T G A.$$

Therefore its determinant transforms by the square of the determinant of A , which is precisely compensated by the determinant-line factor in (22.6). Thus the determinant section is basis-independent. In genus 0 and in a trivializing coordinate chart, the tautological lines become trivial and the determinant section becomes the ordinary Gram determinant. $\square$

Remark 22.7.7 (Why this is a characteristic class). The resonance divisor is now attached to a canonical line bundle on the modular parameter space, not to a chosen matrix. It is functorial under isomorphisms of the family, stable under change of basis, and intrinsic to the factorization transport of the contact quartic sector. This is why it deserves to be called a modular characteristic class.

22.7.2 The tree bundle and the first nonlinear boundary correction

Definition 22.7.8 (Cubic tree bundle along a separating boundary). Let

$$\xi: \overline{\mathcal{M}}_{g_1, n_1+1} \times \overline{\mathcal{M}}_{g_2, n_2+1} \longrightarrow \overline{\mathcal{M}}_{g,n}$$

be a separating clutching map. The *cubic tree bundle*

$$\mathcal{T}_{3,\xi}(\mathcal{A}) \subset \xi^* \mathcal{E}_{g,n}^{[4]}(\mathcal{A})$$

is the locally free image of the one-edge sewing map generated by the cubic shadow:

$$\mathfrak{C}_{\mathcal{A}} \star_{P_{\mathcal{A}}} \mathfrak{C}_{\mathcal{A}}.$$

Its determinant line and determinant section are defined exactly as in Construction 22.7.4; write

$$\mathfrak{T}_{3,\xi}(\mathcal{A}) := \text{div}(s_{3,\xi}^{\text{tree}}(\mathcal{A}))$$

for the resulting divisor class.

Remark 22.7.9 (Interpretation of the tree class). The class $\mathfrak{T}_{3,\xi}(\mathcal{A})$ is the boundary contribution created purely by sewing cubic vertices. It vanishes whenever the cubic shadow vanishes on the chosen slice. It is the first boundary term that cannot be seen in the quadratic theory.

THEOREM 22.7.10 (*Boundary filtration of the quartic envelope*;). On a separating boundary stratum there is a natural increasing filtration

$$0 \subset F^0 \subset F^1 = \xi^* \mathcal{E}_{g,n}^{[4]}(\mathcal{A})$$

by internal-edge number such that the associated graded object splits canonically as

$$\mathrm{gr} \xi^* \mathcal{E}_{g,n}^{[4]}(\mathcal{A}) \cong p_1^* \mathcal{C}_{g_1, n_1+1}^{\mathrm{ct}}(\mathcal{A}) \oplus p_2^* \mathcal{C}_{g_2, n_2+1}^{\mathrm{ct}}(\mathcal{A}) \oplus \mathcal{T}_{3,\xi}(\mathcal{A}),$$

where p_1 and p_2 are the two projections.

Proof. At quartic order a vertex on the boundary can have either zero internal edges or one internal edge. Zero internal edges give the contact quartic sectors transported from the two components. One internal edge joining two cubic vertices gives the tree sector. No higher-edge contribution appears before quintic order. This yields the stated filtration and splitting on the associated graded. $\square$

THEOREM 22.7.11 (*Clutching law for the modular quartic resonance class*;). Let $\mathcal{A}$ be a strongly generated modular Koszul family over $B_{\mathcal{A}}^0$. Along a separating clutching map ξ one has the divisor identity

$$\xi^* \mathfrak{R}_{4,g,n}^{\mathrm{mod}}(\mathcal{A}) = p_1^* \mathfrak{R}_{4,g_1,n_1+1}^{\mathrm{mod}}(\mathcal{A}) + p_2^* \mathfrak{R}_{4,g_2,n_2+1}^{\mathrm{mod}}(\mathcal{A}) + \mathcal{T}_{3,\xi}(\mathcal{A}). \quad (22.7)$$

In words: the boundary restriction of the quartic resonance class is the sum of the two contact resonance classes from the components together with a new tree correction generated by the cubic shadow.

Proof. By Theorem 22.7.10, the associated graded of the pulled-back quartic envelope splits into the two contact bundles and the cubic tree bundle. The quartic clutching formula

$$\xi^* \mathfrak{Q}_{\mathcal{A}} = H_{\mathcal{A}} \star \mathfrak{Q}_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} \star \mathfrak{C}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}} \star H_{\mathcal{A}}$$

shows that, on the associated graded, the Gram pairing is block-upper-triangular with diagonal blocks given by the two contact pairings and the tree pairing. The determinant section therefore factors:

$$\mathrm{gr} \xi^* s_{4,g,n}^{\mathrm{res}}(\mathcal{A}) = p_1^* s_{4,g_1,n_1+1}^{\mathrm{res}}(\mathcal{A}) \otimes p_2^* s_{4,g_2,n_2+1}^{\mathrm{res}}(\mathcal{A}) \otimes s_{3,\xi}^{\mathrm{tree}}(\mathcal{A}).$$

Taking divisors yields (22.7). $\square$

REMARK 22.7.12 (*Logarithmic FM origin of the clutching law*). The clutching law of Theorem 22.7.11 is the algebraic shadow of Mok's degeneration formula [?Mok25, Corollary 5.3.4]. Concretely:

- The separating clutching map ξ corresponds to a semistable degeneration $C \rightarrow B$ with separating node: the log-FM special-fibre component is a proper birational modification of the product $\overline{\mathrm{FM}}_{n_1+1}(Y_1|D_1) \times \overline{\mathrm{FM}}_{n_2+1}(Y_2|D_2)$ of smaller log-FM spaces on the two components.
- The contact quartic class $\mathfrak{R}_{4,g_i,n_i+1}^{\mathrm{mod}}$ on each component is the degree-4 residue along boundary strata of the corresponding log-FM factor.
- The tree correction $\mathcal{T}_{3,\xi}(\mathcal{A})$ arises from the birational modification relating the product of log-FM factors to the actual irreducible component of the special fibre; it is the contribution of the node's log structure.
- The non-separating clutching law (Theorem 22.10.3) similarly corresponds to degeneration along non-separating nodes; the genus loop $\Lambda_P: \mathrm{Sym}^r \rightarrow \mathrm{Sym}^{r-2}$ is the algebraic trace of the log-FM self-gluing.

The five-component differential $D_{\mathcal{A}}$ on the ambient algebra reflects the five types of codimension-1 boundary stratum of $\overline{\text{FM}}_n(C|D_{\text{nodes}})$.

THEOREM 22.7.13 (*The first nonlinear shadow of $\Theta_{\mathcal{A}}$;*). The bar-intrinsic MC element $\Theta_{\mathcal{A}}$ (Theorem ??) satisfies the modular clutching identity

$$\xi^*(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}} \star \Theta_{\mathcal{A}}.$$

The clutching law (22.7) for the modular quartic resonance class is exactly the degree-4 contact-plus-tree shadow of that identity.

Proof. The quartic resonance section is defined from the zero-internal-edge part of the degree-4 shadow, namely the contact quartic sector. The extra divisor term $\mathfrak{T}_{3,\xi}(\mathcal{A})$ is defined from the one-internal-edge part of the same degree, namely the cubic tree sector. The quartic clutching formula is precisely the degree-4 component of the universal clutching identity for $\Theta_{\mathcal{A}}$. Passing to determinant sections on the contact and tree blocks yields (22.7). $\square$

COROLLARY 22.7.14 (*Family-by-family boundary behavior;*). The modular quartic resonance class behaves as follows in the model families.

(i) **Heisenberg**. Both the contact and tree pieces vanish through quartic order:

$$\mathfrak{R}_{4,g,n}^{\text{mod}}(\mathcal{H}) = 0, \quad \mathfrak{T}_{3,\xi}(\mathcal{H}) = 0.$$

(ii) **Affine $\widehat{\mathfrak{sl}}_2$** . On the strict current-level sector the contact quartic class vanishes in the minimal gauge, while the boundary tree class may be nonzero:

$$\mathfrak{R}_{4,g,n}^{\text{mod}}(\widehat{\mathfrak{sl}}_{2,k}) = 0, \quad \mathfrak{T}_{3,\xi}(\widehat{\mathfrak{sl}}_{2,k}) \neq 0 \text{ in general.}$$

(iii) **$\beta\gamma$** . On the weight/contact slice the tree class vanishes and only the contact class survives:

$$\mathfrak{T}_{3,\xi}(\beta\gamma) = 0, \quad \mathfrak{R}_{4,g,n}^{\text{mod}}(\beta\gamma) \text{ propagates additively along the boundary.}$$

(iv) **Virasoro and principal $\mathcal{W}_N$** . Both the contact resonance class and the cubic tree correction are generically nonzero, so the quartic boundary law is genuinely mixed.

Proof. The Heisenberg, affine, and $\beta\gamma$ assertions are the family-wise computations above. The Virasoro and principal $\mathcal{W}_N$ assertion is the mixed case of Theorem 22.7.11. $\square$

Remark 22.7.15 (*Why the quartic resonance class is new*). The scalar characteristic $\kappa(\mathcal{A})$ and the spectral characteristic $\Delta_{\mathcal{A}}$ detect linear and spectral information. The class $\mathfrak{R}_{4,g,n}^{\text{mod}}(\mathcal{A})$ is different in kind. It records the failure of the contact quartic sector to remain nondegenerate, and its boundary correction is quadratic in the cubic shadow. It is therefore the first genuinely nonlinear Picard-valued characteristic of the theory.

22.8 EXTENDED CHARACTERISTIC PACKAGES

Definition 22.8.1 (Nonlinear modular characteristic package). For a modular Koszul family $\mathcal{A}$ on the quartic-regular locus, define the *nonlinear modular characteristic package*

$$\mathfrak{X}_{\mathcal{A}}^{\leq 4} := \left(H_{\mathcal{A}}, [\mathfrak{C}_{\mathcal{A}}], \mathfrak{o}_{\mathcal{A}}^{(4)}, \mathfrak{R}_{4,\bullet}^{\text{mod}}(\mathcal{A}), \{\mathfrak{T}_{3,\xi}(\mathcal{A})\}_{\xi} \right).$$

The *extended modular characteristic package* is

$$\widetilde{C}_{\mathcal{A}} := (\kappa(\mathcal{A}), \Delta_{\mathcal{A}}, \Pi_{\mathcal{A}}, \mathfrak{X}_{\mathcal{A}}^{\leq 4}, \Theta_{\mathcal{A}}),$$

where the final term is included only on the locus where the full universal class exists.

PROPOSITION 22.8.2 (*Functoriality and duality through quartic order;*). Through quartic order, the package $\mathfrak{X}_{\mathcal{A}}^{\leq 4}$ is functorial in morphisms of modular Koszul families and is exchanged under Koszul/Verdier duality by the Legendre transform of the complementarity potential.

Proof. Functoriality of the cyclic deformation complex induces functoriality of the transferred operations and hence of the shadow tensors. The determinant-line construction of the resonance class is intrinsic and therefore functorial. Legendre duality exchanges the two complementary cotangent charts, so it exchanges the cubic, quartic, and resonance data accordingly. $\square$

Remark 22.8.3 (The nonlinear modular characteristic hierarchy). The modular invariants of the theory organize into a hierarchy of increasing nonlinear depth:

$$\underbrace{\kappa(\mathcal{A})}_{\text{scalar}} \longrightarrow \underbrace{\Delta_{\mathcal{A}}}_{\text{spectral}} \longrightarrow \underbrace{[\mathfrak{C}_{\mathcal{A}}], \mathfrak{o}_{\mathcal{A}}^{(4)}, [\mathfrak{Q}_{\mathcal{A}}]}_{\text{nonlinear shadows}} \longrightarrow \underbrace{\Theta_{\mathcal{A}}}_{\text{universal class}}.$$

The scalar characteristic $\kappa(\mathcal{A})$ and the spectral characteristic $\Delta_{\mathcal{A}}$ are proved. The nonlinear shadow classes $[\mathfrak{C}_{\mathcal{A}}]$ and $[\mathfrak{Q}_{\mathcal{A}}]$ are the degree-3 and degree-4 visible coefficients of the universal class, computable on any family where the cyclic deformation package is available through the relevant order. The quartic obstruction $\mathfrak{o}_{\mathcal{A}}^{(4)} = \frac{1}{2}\{\mathfrak{C}_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}\}$ controls whether the cubic globalization extends to quartic order.

The primary nonlinear modular characteristic class is $[\mathfrak{C}_{\mathcal{A}}]$. It is a cocycle for the Hessian-twisted differential $\nabla_{H_{\mathcal{A}}}$ by Theorem 22.4.5, and its cohomology class is a canonical modular invariant. It is the first genuinely nonlinear characteristic class of the modular homotopy theory.

THEOREM 22.8.4 (*Full resonance tower;*). For each degree $r \geq 4$ there exists a modular resonance class

$$\mathfrak{R}_{r,\bullet}^{\text{mod}}(\mathcal{A}) \in \text{Pic}(\overline{\mathcal{M}}_{\bullet}) \times B_{\mathcal{A}}^{\circ}$$

constructed from the determinant line of the zero-internal-edge degree- r contact sector, with clutching law given by the degree- r shadow of the identity

$$\xi^*(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}} \star \Theta_{\mathcal{A}}.$$

The quartic resonance class is the first nontrivial case.

Proof. Existence. The bar-intrinsic construction (Theorem ??) produces $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ at all degrees. The degree- r projection $\Theta_{\mathcal{A}}^{(r)} \in \text{Hom}_{\Sigma_r}(C_*(\overline{\mathcal{M}}_{g,r}), \text{End}_{\mathcal{A}}(r))$ is well-defined for each $r \geq 2$.

The zero-internal-edge contact sector $\mathcal{C}_{g,n}^{\text{ct},(r)}(\mathcal{A})$ is a finite-rank sub-bundle of the degree- r cyclic deformation envelope (finite-dimensionality at each conformal weight follows from strong generation of $\mathcal{A}$; the conformal-weight grading is bounded below). The determinant line and resonance section of Definition 22.12.6 are therefore well-defined, yielding $\mathfrak{R}_{r,\bullet}^{\text{mod}}(\mathcal{A}) \in \text{Pic}(\overline{\mathcal{M}}_\bullet \times B_{\mathcal{A}}^\circ)$ for all $r \geq 4$.

Clutching law. Theorem 22.12.7. □

Remark 22.8.5 (Nonlinear characteristic tower). The nonlinear characteristic tower has four layers.

- (i) The quadratic theory is the proved scalar and shifted-symplectic complementarity package.
- (ii) The cubic and quartic theory is the first nonlinear shadow, visible already in explicit families.
- (iii) The modular quartic resonance class is the first Picard-valued nonlinear characteristic.
- (iv) The full universal class $\Theta_{\mathcal{A}}$ is the common Maurer–Cartan source of these shadows; its graph-completed Hamiltonian lift is the additional conjectural refinement.

The universal class is not merely a source of scalar shadows. It is the generator of Gaussian propagators, cubic tree vertices, quartic contact vertices, and the resonance classes measuring their degeneration.

22.9 HIGHER-DEGREE SHADOW PROPAGATION

The quartic shadow calculus of §22.4 stops at degree 4. But the master equation is a truncation of a universal recursive structure governing all degrees. We prove the general degree- r equations and draw structural consequences.

22.9.1 The all-degree master equation

Definition 22.9.1 (Degree- r shadow jet). For $r \geq 2$, define the *degree- r shadow jet* on the cyclic slice $V_{\mathcal{A}}$ by

$$\text{Sh}_r(\mathcal{A})(x_1, \dots, x_r) := \sum_{\text{cyc}} \langle x_1, \ell_{r-1}^{\text{tr}}(x_2, \dots, x_r) \rangle.$$

Write $S_{\mathcal{A}}^{\leq r} := \sum_{k=2}^r \frac{1}{k!} \text{Sh}_k(\mathcal{A})$ for the truncated complementarity potential through degree r .

Definition 22.9.2 (Degree- r obstruction;). For $r \geq 4$, define the *degree- r obstruction*

$$\mathfrak{o}_{\mathcal{A}}^{(r)} := \sum_{\substack{p+q=r+2 \\ 3 \leq p \leq q}} c_{p,q} \{ \text{Sh}_p(\mathcal{A}), \text{Sh}_q(\mathcal{A}) \}_{H_{\mathcal{A}}},$$

where $c_{p,q} = 1$ if $p < q$ and $c_{p,p} = \frac{1}{2}$, and the bracket is the single-edge sewing contraction of Construction 22.4.6. The first cases are

$$\begin{aligned} \mathfrak{o}_{\mathcal{A}}^{(4)} &= \frac{1}{2} \{ \mathfrak{C}_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}} \}_{H_{\mathcal{A}}}, & (\text{quartic}) \\ \mathfrak{o}_{\mathcal{A}}^{(5)} &= \{ \mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}} \}_{H_{\mathcal{A}}}, & (\text{quintic}) \\ \mathfrak{o}_{\mathcal{A}}^{(6)} &= \frac{1}{2} \{ \mathfrak{Q}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}} \}_{H_{\mathcal{A}}} + \{ \mathfrak{C}_{\mathcal{A}}, \text{Sh}_5(\mathcal{A}) \}_{H_{\mathcal{A}}}. & (\text{sextic}) \end{aligned}$$

THEOREM 22.9.3 (All-degree master equation;). Assume the complementarity potential $S_{\mathcal{A}}$ satisfies the classical master equation $\{S_{\mathcal{A}}, S_{\mathcal{A}}\}_{H_{\mathcal{A}}} = 0$ in the completed degree filtration. Then for every $r \geq 3$, the shadow jets satisfy

$$\nabla_{H_{\mathcal{A}}} \text{Sh}_r(\mathcal{A}) + \mathfrak{o}_{\mathcal{A}}^{(r)} = 0, \tag{22.8}$$

where $\nabla_{H_{\mathcal{A}}} := \{H_{\mathcal{A}}, \cdot\}_{H_{\mathcal{A}}}$ and $\mathfrak{o}_{\mathcal{A}}^{(r)}$ is the degree- r obstruction of Definition 22.9.2. When $r = 3$ the obstruction sum is empty and the equation reads $\nabla_{H_{\mathcal{A}}} \mathfrak{C}_{\mathcal{A}} = 0$.

Proof. Write

$$S_{\mathcal{A}} = H_{\mathcal{A}} + \sum_{m \geq 3} \text{Sh}_m(\mathcal{A})$$

in the completed symmetric algebra on the chosen cyclic slice, with the conventional factorial normalization absorbed into the tensor bracket. A single-edge Hamiltonian contraction lowers homogeneous degree by two:

$$\deg\{\alpha_p, \beta_q\}_{H_{\mathcal{A}}} = p + q - 2.$$

The degree- r part of $\frac{1}{2}\{S_{\mathcal{A}}, S_{\mathcal{A}}\}_{H_{\mathcal{A}}} = 0$ therefore receives contributions only from ordered pairs (p, q) with $p + q = r + 2$. The two ordered linear terms $(2, r)$ and $(r, 2)$ combine, after the factor $\frac{1}{2}$, to

$$\{H_{\mathcal{A}}, \text{Sh}_r\}_{H_{\mathcal{A}}} = \nabla_{H_{\mathcal{A}}} \text{Sh}_r.$$

All remaining terms have $p, q \geq 3$ and hence involve only lower-degree shadows. Thus the degree- r component is

$$\{H_{\mathcal{A}}, \text{Sh}_r\}_{H_{\mathcal{A}}} + \sum_{\substack{p+q=r+2 \\ 3 \leq p \leq q}} c_{p,q} \{\text{Sh}_p, \text{Sh}_q\}_{H_{\mathcal{A}}} = 0,$$

where the remaining terms comprise $\mathfrak{o}_{\mathcal{A}}^{(r)}$. The coefficient $c_{p,q}$ is the automorphism factor of the one-edge two-vertex graph: if $p < q$, the ordered pairs (p, q) and (q, p) both occur and the prefactor $\frac{1}{2}$ gives $c_{p,q} = 1$; if $p = q$, there is one diagonal unordered graph and the prefactor remains $c_{p,p} = \frac{1}{2}$. The completion is used only to make the infinite sum meaningful; every degree- r equation is finite. At $r = 3$ the obstruction sum is empty; at $r = 4$ one recovers Theorem 22.4.5. $\square$

COROLLARY 22.9.4 (*The quintic master equation;*). At degree 5,

$$\nabla_{H_{\mathcal{A}}} \text{Sh}_5(\mathcal{A}) + \{\mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}}\}_{H_{\mathcal{A}}} = 0.$$

The quintic shadow is determined by the cubic and quartic shadows up to a cocycle of $\nabla_{H_{\mathcal{A}}}$.

Proof. Set $r = 5$ in (22.8). The obstruction sum has $p + q = 7$ with $3 \leq p \leq q$, giving only $(p, q) = (3, 4)$ with $c_{3,4} = 1$. $\square$

22.9.2 Quintic behavior of the model families

THEOREM 22.9.5 (*Quintic shadow for the three frame families;*). Through quintic order:

- (i) **Heisenberg.** $\mathfrak{C}_{\mathcal{H}} = \mathfrak{Q}_{\mathcal{H}} = 0$, so $\mathfrak{o}_{\mathcal{H}}^{(5)} = 0$ and $\text{Sh}_5(\mathcal{H}) = 0$.
- (ii) **Affine $\widehat{\mathfrak{sl}}_2$.** $\mathfrak{Q}_{\text{aff}} = 0$ in minimal gauge, so $\mathfrak{o}_{\text{aff}}^{(5)} = 0$ and $\text{Sh}_5(\text{aff}) = 0$.
- (iii) **$\beta\gamma$ system.** On the standard conformal-weight class-C lane, $S_3 = 0$ and $S_4 = -5/12$, so $\mathfrak{o}_{\beta\gamma}^{(5)} = 0$ and $S_5(\beta\gamma_\lambda) = 0$. On the internal weight-changing line, rank-one abelian rigidity (Theorem 22.5.19) gives $\text{Sh}_r(\beta\gamma)|_{L_{\text{wc}}} = 0$ for all $r \geq 2$.

Proof. Each case follows from Corollary 22.9.4 and the vanishing established in Theorems 22.5.1, 22.5.6, and 22.5.15. $\square$

THEOREM 22.9.6 (*The Virasoro quintic is forced;*). On the Virasoro quartic shadow envelope $E_{\text{Vir}}^{[4]}$, the quintic obstruction is generically nonzero:

$$\mathbf{o}_{\text{Vir}}^{(5)} = \{\mathfrak{C}_{\text{Vir}}, \mathfrak{Q}_{\text{Vir}}^{\text{contact}}\}_{H_{\text{Vir}}} \neq 0 \quad \text{for generic } c.$$

Consequently $\text{Sh}_5(\text{Vir}) \neq 0$ generically: the Virasoro shadow obstruction tower does not terminate at quartic order.

Proof. The gravitational cubic is $\mathfrak{C}_{\text{Vir}} = 2x^3$ and the contact quartic is $\mathfrak{Q}_{\text{Vir}}^{\text{contact}} = Q_0 x^4$ with $Q_0 = 10/[c(5c + 22)] \neq 0$ for generic c . Their single-edge sewing contraction on the one-generator primary line with propagator $P = 2/c$ produces a nonzero rank-5 tensor proportional to Q_0/c . $\square$

THEOREM 22.9.7 (*Finite termination for primitive archetypes;*). For the three frame families, the shadow obstruction tower terminates at finite degree.

- (i) **Heisenberg:** $\text{Sh}_r(\mathcal{H}) = 0$ for all $r \geq 3$. The tower is exactly Gaussian.
- (ii) **Affine $\widehat{\mathfrak{sl}}_2$ (strict sector, minimal gauge):** $\text{Sh}_r(\text{aff}) = 0$ for $r \geq 4$.
- (iii) **$\beta\gamma$ (standard conformal-weight class-C lane):** $S_3 = 0$, $S_4 = -5/12$, and $S_r = 0$ for $r \geq 5$. The internal weight-changing line is a stricter rank-one degeneration with $\text{Sh}_r|_{L_{\text{wc}}} = 0$ for all $r \geq 2$.

In contrast, Virasoro has $\text{Sh}_5 \neq 0$ (Theorem 22.9.6); over $\mathbb{Q}(c)$ the leading Laurent coefficient of each S_r is nonzero (Theorem ??), so the universal scalar tower is infinite. A fixed value of c imposes the corresponding specialization non-cancellation.

Proof. For each primitive archetype, finite termination follows from vanishing of all obstruction sources at the relevant degree. For the Heisenberg, all higher brackets vanish. For affine $\widehat{\mathfrak{sl}}_2$, the Jacobiator vanishes and the quartic gauge freedom absorbs all remaining terms. For the standard $\beta\gamma_\lambda$ family, the landscape census gives the class-C values $S_3 = 0$, $S_4 = -5/12$, and $S_r = 0$ for $r \geq 5$; on the internal weight-changing line Theorem 22.5.19 gives the stronger vanishing of every shadow.

For Virasoro, Theorem 22.9.6 gives $\text{Sh}_5 \neq 0$, and Theorem ?? gives a nonzero leading Laurent coefficient for every higher S_r . Hence no finite truncation contains the universal scalar shadow tower over $\mathbb{Q}(c)$. $\square$

Remark 22.9.8 (*The Virasoro shadow obstruction tower is the first infinite one*). Theorem 22.9.7 gives the structural divide: Gaussian terminates at degree 2, Lie/tree at degree 3, and the standard $\beta\gamma_\lambda$ contact lane at degree 4. The weight-changing $\beta\gamma$ line is a lower-dimensional degeneration of the contact lane, not the class-C witness. Virasoro, the first mixed family, has a non-polynomial complementarity potential over the function field. This is the mechanism by which the Virasoro modular package carries strictly more information than the $\hat{A}$ -genus.

22.9.3 The all-degree separating boundary recursion

THEOREM 22.9.9 (*All-degree separating boundary recursion;*). Since the shadow jets are projections of the bar-intrinsic MC element $\Theta_{\mathcal{A}}$ (Theorem ??), which satisfies the modular clutching identity, for every $r \geq 2$ and every separating clutching map ξ ,

$$\xi^* \text{Sh}_r(\mathcal{A}) = \sum_{\substack{p+q=r+2 \\ p, q \geq 2}} \text{Sh}_p(\mathcal{A}) \star_{P_{\mathcal{A}}} \text{Sh}_q(\mathcal{A}). \quad (22.9)$$

Proof. This is the degree- r component of $\xi^*(\Theta_{\mathcal{A}}) = \Theta_{\mathcal{A}} \star \Theta_{\mathcal{A}}$. $\square$

COROLLARY 22.9.10 (*Quintic separating boundary recursion*;). At degree 5:

$$\xi^* \text{Sh}_5(\mathcal{A}) = H_{\mathcal{A}} \star \text{Sh}_5(\mathcal{A}) + \mathfrak{C}_{\mathcal{A}} \star \mathfrak{Q}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}} \star \mathfrak{C}_{\mathcal{A}} + \text{Sh}_5(\mathcal{A}) \star H_{\mathcal{A}}.$$

Proof. Set $r = 5$ in (22.9); the pairs with $p + q = 7$ and $p, q \geq 2$ are $(2, 5), (3, 4), (4, 3), (5, 2)$. $\square$

22.10 THE GENUS LOOP OPERATOR AND NON-SEPARATING CLUTCHING

The separating clutching keeps genus constant and distributes shadow legs across two components. The non-separating clutching increases genus by one by identifying two marked points. Its action on the shadow obstruction tower *traces out* two shadow legs, converting higher-degree genus-0 data into lower-degree genus-1 corrections. This is the mechanism by which the modular homotopy theory goes beyond the $\hat{A}$ -genus.

22.10.1 Definition and basic properties

Definition 22.10.1 (*The genus loop operator*;). Let $V_{\mathcal{A}}$ be a finite-dimensional cyclic slice with propagator $P_{\mathcal{A}} = H_{\mathcal{A}}^{-1}$. The *genus loop operator* is the linear map

$$\Lambda_{P_{\mathcal{A}}} : \text{Sym}^r(V_{\mathcal{A}}^*) \longrightarrow \text{Sym}^{r-2}(V_{\mathcal{A}}^*)$$

defined by contracting over all $\binom{r}{2}$ pairs of symmetric legs with the propagator:

$$(\Lambda_{P_{\mathcal{A}}} \alpha)(x_1, \dots, x_{r-2}) := \sum_{1 \leq s < t \leq r} \sum_{i,j} \alpha(x_1, \dots, \widehat{x}_s, \dots, \widehat{x}_t, \dots, e_i, e_j) P_{\mathcal{A}}^{ij},$$

where $\{e_i\}$ is any basis of $V_{\mathcal{A}}$ and $P_{\mathcal{A}}^{ij}$ are the components of the propagator. For a symmetric tensor this is $\binom{r}{2}$ times the single-pair contraction.

PROPOSITION 22.10.2 (*Basic properties of the genus loop operator*;). Let $d := \dim V_{\mathcal{A}}$.

- (i) $\Lambda_{P_{\mathcal{A}}}(H_{\mathcal{A}}) = d$.
- (ii) $\Lambda_{P_{\mathcal{A}}}(\mathfrak{C}_{\mathcal{A}}) \in V_{\mathcal{A}}^*$ is a linear form on $V_{\mathcal{A}}$.
- (iii) $\Lambda_{P_{\mathcal{A}}}(\mathfrak{Q}_{\mathcal{A}}) \in \text{Sym}^2(V_{\mathcal{A}}^*)$ is a rank-2 tensor defining a correction to the Hessian at the next genus.

Proof. Immediate from Definition 22.10.1. $\square$

22.10.2 Non-separating clutching of the shadow obstruction tower

THEOREM 22.10.3 (*Non-separating clutching law for the shadow obstruction tower*;). Along the non-separating clutching map $\xi_{\text{ns}} : \overline{\mathcal{M}}_{g-1, n+2} \rightarrow \overline{\mathcal{M}}_{g, n}$, the one-vertex associated graded of the refined Mok filtration satisfies

$$\text{gr } \xi_{\text{ns}}^*(\text{Sh}_r^{(g)}) = \Lambda_{P_{\mathcal{A}}}(\text{Sh}_{r+2}^{(g-1)}),$$

where the leading term traces two legs of the genus- $(g-1)$ shadow at degree $r+2$. The full non-separating identity includes mixed sewing and planted-forest correction terms and is conditional on the signed log-FM residue-pushforward cocomposition.

Proof. On the one-vertex associated graded, the non-separating clutching identity for the universal class reads $\xi_{\text{ns}}^* \Theta_{\mathcal{A}}^{(g)} = \Lambda_{P_{\mathcal{A}}}(\Theta_{\mathcal{A}}^{(g-1)})$. Expanding both sides in the degree filtration: the degree- r component of the left side is $\text{Sh}_r^{(g)}$, while the degree- r component of $\Lambda_P(\Theta_{\mathcal{A}}^{(g-1)})$ is $\Lambda_P(\text{Sh}_{r+2}^{(g-1)})$ since Λ_P lowers degree by 2. $\square$

COROLLARY 22.10.4 (*Genus-1 Hessian correction from genus-0 quartic shadow;*). In the one-vertex sector, the genus-1 correction to the Hessian is

$$\delta H_{\mathcal{A}}^{(1)} = \Lambda_{P_{\mathcal{A}}}(\mathfrak{Q}_{\mathcal{A}}^{(0)}).$$

This is a rank-2 tensor determined entirely by the genus-0 quartic shadow and the propagator.

Proof. Set $g = 1$ and $r = 2$ in the one-vertex associated graded statement of Theorem 22.10.3. $\square$

Remark 22.10.5 (*Why this goes beyond the $\hat{A}$ -genus*). The scalar modular characteristic $\kappa(\mathcal{A})$ is the trace of the genus-0 Hessian. The genus-1 Hessian correction $\delta H^{(1)} = \Lambda_P(\mathfrak{Q}^{(0)}) \in \text{Sym}^2(V_{\mathcal{A}}^*)$ is a rank-2 tensor, not determined by κ .

22.10.3 Explicit genus loop for the model families

THEOREM 22.10.6 (*Genus loop operator on the model families;*). In the one-vertex sector:

- (i) **Heisenberg.** $\delta H_{\mathcal{H}}^{(1)} = 0$. The modular invariants at all genera are determined by κ alone.
- (ii) **Affine $\widehat{\mathfrak{sl}}_2$.** $\delta H_{\text{aff}}^{(1)} = 0$ (since $\mathfrak{Q}_{\text{aff}} = 0$), and the cubic loop also vanishes:

$$\Lambda_{P_{\text{aff}}}(\mathfrak{C}_{\text{aff}}) = 0.$$

This is because the structure constants f_{ab}^c are antisymmetric while the propagator P^{ab} is symmetric, so their contraction vanishes identically.

- (iii) **$\beta\gamma$ system.** $\Lambda_P(\mathfrak{C}_{\beta\gamma}) = 0$, but the quartic loop gives a Hessian correction proportional to $(2/c)\mathfrak{Q}_{\beta\gamma}(\eta, \eta, \cdot, \cdot)$.
- (iv) **Virasoro.** Both loops are nonzero. On the primary line with $H = (c/2)x^2$, $\mathfrak{C} = 2x^3$, $\mathfrak{Q}^{\text{contact}} = Q_0 x^4$ where $Q_0 = 10/[c(5c + 22)]$:

$$\begin{aligned} \Lambda_P(\mathfrak{C}_{\text{Vir}})(x) &= \frac{12}{c} x, \\ \delta H_{\text{Vir}}^{(1)} &= \frac{120}{c^2(5c + 22)} x^2. \end{aligned}$$

The genus-1 loop ratio is $\rho_{\text{Vir}}^{(1)} = \delta H^{(1)}/H^{(0)} = 240/[c^3(5c + 22)]$. It is not part of the scalar linear Hodge tower $\kappa\lambda_g$; it is a nonlinear shadow invariant.

Proof. (i) follows from $\mathfrak{C}_{\mathcal{H}} = \mathfrak{Q}_{\mathcal{H}} = 0$: every one-loop nonlinear contraction has a cubic or quartic vertex, and no such vertex exists on the Heisenberg slice.

For (ii), $\mathfrak{C}_{\text{aff}}(x, y, z) = \kappa(x, [y, z])$ is cyclically symmetric by ad-invariance. The genus loop contracts two slots with the symmetric propagator $P^{ab} = (1/k_{\text{eff}})(\kappa^{-1})^{ab}$. Since $[e_a, e_b]^c = f_{ab}^c$ is antisymmetric in (a, b) while $(\kappa^{-1})^{ab}$ is symmetric, the contraction $\sum_{a,b} f_{ab}^c (\kappa^{-1})^{ab} = 0$, giving $\Lambda_P(\mathfrak{C}_{\text{aff}}) = 0$.

For (iii) and (iv), the one-generator primary line has $P = 2/c$. For a symmetric rank- r tensor $\alpha_0 x^r$ on a one-dimensional space, $\Lambda_P(\alpha_0 x^r) = \binom{r}{2} P \alpha_0 x^{r-2}$. Thus $\Lambda_P(2x^3) = 3 \cdot (2/c) \cdot 2 \cdot x = 12x/c$, and $\Lambda_P(Q_0 x^4) = 6 \cdot (2/c) \cdot Q_0 x^2 = 12Q_0 x^2/c = 120x^2/[c^2(5c + 22)]$. $\square$

Remark 22.10.7 (The modular invariant ratio). Define the *genus-1 loop ratio* $\rho_{\mathcal{A}}^{(1)} := \Lambda_P(\mathfrak{Q}_{\mathcal{A}})/H_{\mathcal{A}}$. For the Virasoro, $\rho_{\text{Vir}}^{(1)} = 240/[c^3(5c + 22)]$, a nontrivial function of c . Two algebras with the same κ but different $\rho^{(1)}$ are distinguished by the modular homotopy theory even though their $\hat{A}$ -genera agree.

22.10.4 The modular shadow characteristic

Definition 22.10.8 (The full modular shadow characteristic). For a modular Koszul chiral algebra $\mathcal{A}$ with cyclic slice $V_{\mathcal{A}}$, define

$$\mathbf{ch}_{\text{mod}}(\mathcal{A}; \hbar) := \sum_{g \geq 0} \hbar^g \sum_{r \geq 2} \frac{1}{r!} \text{Sh}_r^{(g)}(\mathcal{A}).$$

Its graph-evaluated scalar trace is

$$\text{tr}_{\text{graph}}(\mathbf{ch}_{\text{mod}}) = \sum_g \hbar^g F_g^{\text{sc}}(\mathcal{A}), \quad F_g^{\text{sc}}(\mathcal{A}) = \kappa(\mathcal{A}) \lambda_g^{\text{FP}},$$

which is the $\hat{A}$ -genus tower. Under H_D^K , the corresponding class-valued output is $\text{obs}_g^{\text{Hdg}} = (-1)^g \kappa(\mathcal{A}) \lambda_g$.

THEOREM 22.10.9 (*The modular invariant hierarchy beyond $\hat{A}$;*). Let $\mathcal{A}$ be a modular Koszul chiral algebra whose shadow obstruction tower does not terminate at quadratic order. Then $\mathbf{ch}_{\text{mod}}(\mathcal{A}; \hbar)$ carries strictly more information than $\kappa(\mathcal{A})$. Specifically:

- (i) If $\mathfrak{C}_{\mathcal{A}} \neq 0$, the cubic shadow class is a non-scalar modular invariant, and $\Lambda_P(\mathfrak{C}_{\mathcal{A}})$ gives a canonical linear form not determined by κ .
- (ii) If $\mathfrak{Q}_{\mathcal{A}} \neq 0$, the genus-1 Hessian correction $\delta H^{(1)} = \Lambda_P(\mathfrak{Q}_{\mathcal{A}})$ is a tensorial modular invariant invisible to κ .
- (iii) The derived ratio $\rho_{\mathcal{A}}^{(1)} = \Lambda_P(\mathfrak{Q}_{\mathcal{A}})/H_{\mathcal{A}}$ distinguishes algebras with identical $\hat{A}$ -genera.

Proof. Suppose $\kappa(\mathcal{A}) = \kappa(\mathcal{A}')$ but the quartic shadows differ. Then $\Lambda_P(\mathfrak{Q}_{\mathcal{A}}) \neq \Lambda_P(\mathfrak{Q}_{\mathcal{A}'})$ and $\rho_{\mathcal{A}}^{(1)} \neq \rho_{\mathcal{A}'}^{(1)}$: the nonlinear modular characteristic distinguishes the two algebras. $\square$

Remark 22.10.10 (Summary of the invariant hierarchy). The modular invariant hierarchy:

$$\underbrace{\kappa(\mathcal{A})}_{\text{scalar}} \longrightarrow \underbrace{\Delta_{\mathcal{A}}}_{\text{spectral}} \longrightarrow \underbrace{[\mathfrak{C}_{\mathcal{A}}], [\mathfrak{Q}_{\mathcal{A}}]}_{\text{nonlinear shadows}} \longrightarrow \underbrace{\Lambda_P(\mathfrak{Q}_{\mathcal{A}})}_{\text{genus loop}} \longrightarrow \underbrace{\Theta_{\mathcal{A}}}_{\text{universal class}}.$$

The first three levels are genus-0 data. The genus loop correction is the first genuinely higher-genus modular invariant. The universal class unifies all levels on the stated completed tower.

22.II A UNIFIED SUMMARY THEOREM

THEOREM 22.II.1 (*Ambient complementarity and nonlinear modular shadows;*). Let $\mathcal{A}$ be a modular Koszul family on a quartic-regular parameter locus, and suppose the cyclic deformation package is available through quartic order on a chosen cyclic slice. Then:

- (i) the finite-order deformation theory is governed by a quartic shadow cocycle

$$\Theta_{\mathcal{A}}^{\leq 4} = H_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}};$$

(ii) its local behavior is controlled by the master equations

$$\nabla_{H_{\mathcal{A}}} \mathfrak{C}_{\mathcal{A}} = 0, \quad \nabla_{H_{\mathcal{A}}} \mathfrak{Q}_{\mathcal{A}} + \frac{1}{2} \{ \mathfrak{C}_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}} \} = 0;$$

(iii) its separating-boundary behavior is controlled by the recursion

$$\xi^* \mathfrak{Q}_{\mathcal{A}} = H_{\mathcal{A}} \star \mathfrak{Q}_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} \star \mathfrak{C}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}} \star H_{\mathcal{A}};$$

(iv) Heisenberg, affine $\widehat{\mathfrak{sl}}_2$, and $\beta\gamma$ realize the Gaussian, Lie/tree, and contact/quartic archetypes respectively;

(v) Virasoro and principal $\mathcal{W}_N$ are the first genuinely mixed cubic–quartic families;

(vi) the determinant line of the contact quartic sector carries a canonical modular section whose divisor is the quartic resonance class

$$\mathfrak{R}_{4,g,n}^{\text{mod}}(\mathcal{A}),$$

and whose clutching correction is the cubic tree divisor $\mathfrak{T}_{3,\xi}(\mathcal{A})$;

(vii) since the full universal class $\Theta_{\mathcal{A}}$ exists (Theorem ??), this clutching correction is the first nonlinear modular shadow of its universal clutching identity;

(viii) the shadow obstruction tower extends to all degrees: the all-degree master equation $\nabla_{H_{\mathcal{A}}} \text{Sh}_r + \mathfrak{o}^{(r)} = 0$ governs Sh_r for every $r \geq 3$, with the primitive archetypes terminating (Gaussian at 2, Lie/tree at 3, contact at 4) while the Virasoro tower is infinite over $\mathbb{Q}(c)$ by the leading Laurent calculation;

(ix) the genus loop operator $\Lambda_P : \text{Sym}^r \rightarrow \text{Sym}^{r-2}$ implements non-separating clutching on the shadow obstruction tower, and the genus-1 Hessian correction $\delta H_{\mathcal{A}}^{(1)} = \Lambda_P(\mathfrak{Q}_{\mathcal{A}}^{(0)})$ is the first tensorial modular invariant beyond the $\hat{A}$ -genus;

(x) for the Virasoro, $\delta H_{\text{Vir}}^{(1)} = 120/[c^2(5c + 22)] \cdot x^2$, and the loop ratio $\rho_{\text{Vir}}^{(1)} = 240/[c^3(5c + 22)]$ distinguishes algebras invisible to κ .

Proof. Parts (i)–(iii) are Theorems 22.4.5, 22.4.7, and 22.4.10. Part (iv) is Theorem 22.5.18. Part (v) is Theorems 22.6.3 and 22.6.16 together with Corollary 22.6.17. Part (vi) is Construction 22.7.4 and Definition 22.7.5. Part (vii) is Theorems 22.7.11 and 22.7.13. Part (viii) is Theorems 22.9.3 and 22.9.7. Parts (ix) and (x) are Theorem 22.10.3, Corollary 22.10.4, and Theorem 22.10.6. $\square$

Remark 22.11.2 (Clutching and Verdier compatibility). The universal class $\Theta_{\mathcal{A}}$ is constructed by the bar-intrinsic construction (Theorem ??). The exact all-degree Picard law still requires the signed log-FM residue-pushforward cocomposition and the Verdier compatibility of the graph-completed Hamiltonian lift. The finite-order nonlinear layer already has invariant content: the genus loop operator converts quartic contact data into genus-1 Hessian corrections that no scalar invariant can see, and the quartic resonance class is the first modular characteristic detecting nonlinear complementarity.

22.12 THE GRAPH-COMPLETED FEYNMAN TRANSFORM

The finite-order shadow calculus of the preceding sections captures the degree- ≤ 4 face of the universal Maurer–Cartan class $\Theta_{\mathcal{A}}$, which exists by the bar-intrinsic construction (Theorem ??). The next question is not *existence* (that is settled) but *refinement*: can one upgrade the abstract MC element to a *graph-completed Hamiltonian modular master action* that organizes the vertex-by-vertex computational content? This section constructs the natural carrier object for such a refinement, states the resulting conjecture, and introduces three new geometric avatars.

22.12.1 The modular chiral Feynman transform

Definition 22.12.1 (Modular chiral Feynman transform;). Define the *modular chiral Feynman transform* of $\mathcal{A}$ by

$$\mathfrak{F}_{\text{mod}}(\mathcal{A}) := \prod_{g,n} \prod_{\Gamma \in \Gamma_{g,n}^{\text{st}}} \left(H^\bullet(\overline{\mathcal{M}}_\Gamma) \otimes \text{Or}(\Gamma) \otimes \bigotimes_{v \in V(\Gamma)} \text{CoDer}_{\text{val}(v)}^{\text{cyc}}(\widehat{B}_X(\mathcal{A})) \right)_{\text{Aut}(\Gamma)},$$

where $\Gamma_{g,n}^{\text{st}}$ is the set of stable graphs of type (g, n) , $\overline{\mathcal{M}}_\Gamma$ is the stratum of $\overline{\mathcal{M}}_{g,n}$ indexed by Γ , $\text{Or}(\Gamma)$ is the orientation line, and $\text{CoDer}_{\text{val}(v)}^{\text{cyc}}$ denotes cyclic coderivations of valence $\text{val}(v)$.

It carries three commuting differentials:

$$d_{\text{mod}} = d_{\text{int}} + d_{\text{split}} + d_{\text{edge}},$$

where:

- d_{int} is the internal cyclic-coderivation differential;
- d_{split} expands vertices via transferred L_∞ -operations;
- d_{edge} inserts and contracts internal edges by the Hessian propagator.

Remark 22.12.2 (Why the Feynman transform upgrades the bar-intrinsic element). The bar-intrinsic construction produces $\Theta_{\mathcal{A}}$ as an abstract MC element. The Feynman transform upgrades this to a *Hamiltonian* MC element by resolving three structural requirements for the graph-completed refinement: (1) a cyclic structure on bar coderivations; (2) the completed tensor product with tautological coefficients; (3) a clutching-compatible graph-sum representation. In $\mathfrak{F}_{\text{mod}}(\mathcal{A})$:

- cyclicity is built into the vertex labels,
- completion is the graph-number/bar-length/weight filtration,
- clutching is the edge-insertion differential d_{edge} .

Conjecture 22.12.3 (Graph-completed Hamiltonian refinement;). The bar-intrinsic MC element $\Theta_{\mathcal{A}}$ (Theorem ??) admits a canonical *Hamiltonian* lift to a group-like element

$$\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{F}_{\text{mod}}(\mathcal{A}))$$

in the Feynman transform, whose projections recover the entire modular characteristic hierarchy:

- (i) graph scalar trace: $\text{tr}_{\text{graph}}(\Theta_{\mathcal{A}}) = \sum_{g \geq 1} \kappa(\mathcal{A}) \lambda_g^{\text{FP}}$;
- (ii) one-vertex projection: $H_{\mathcal{A}} + \mathfrak{C}_{\mathcal{A}} + \mathfrak{Q}_{\mathcal{A}} + \cdots$;
- (iii) determinant shadow: the full resonance tower $\mathfrak{R}_{r,g,n}^{\text{mod}}(\mathcal{A})$ for all $r \geq 4$;
- (iv) Legendre duality shadow: $\Theta_{\mathcal{A}^\dagger} = \Theta_{\mathcal{A}}^\vee$.

The existence of $\Theta_{\mathcal{A}}$ is a theorem; what remains conjectural is whether the abstract MC element lifts to a graph-completed Hamiltonian modular master action in $\mathfrak{F}_{\text{mod}}(\mathcal{A})$.

22.12.2 The complementarity Legendrian

Definition 22.12.4 (Complementarity Legendrian;). Given the complementarity potential $S_{\mathcal{A}}$ of Definition 22.3.7, define its 1-jet lift

$$\Lambda_{\mathcal{A}} := j^1 S_{\mathcal{A}} \subset J^1(\mathcal{M}_{\mathcal{A}}) \simeq T^*[-1]\mathcal{M}_{\mathcal{A}} \times \mathbb{A}^1.$$

This is the *complementarity Legendrian*.

Remark 22.12.5 (Three virtues of the Legendrian lift). The Legendrian $\Lambda_{\mathcal{A}}$ achieves three things simultaneously:

- (i) it removes the additive-constant ambiguity in $S_{\mathcal{A}}$;
- (ii) it turns Legendre duality into a *contact* transformation;
- (iii) it gives a geometric origin for the resonance tower: the degree- r resonance loci are the discriminants of the *front projection* of $\Lambda_{\mathcal{A}}$ restricted to the degree- r contact sector.

In this language:

- $\kappa(\mathcal{A})$ is the quadratic front curvature;
- $\Delta_{\mathcal{A}}$ is the spectral branch discriminant;
- $\mathfrak{R}_4^{\text{mod}}(\mathcal{A})$ is the first contact-front singularity divisor.

22.12.3 The full resonance tower

Definition 22.12.6 (Degree- r contact bundle and resonance class;). For every degree $r \geq 4$, define the zero-internal-edge degree- r contact bundle

$$\mathcal{C}_{g,n}^{\text{ct},(r)}(\mathcal{A}) \subset \mathcal{E}_{g,n}^{[r]}(\mathcal{A})$$

and its determinant line

$$\mathcal{L}_{r,g,n}^{\text{res}}(\mathcal{A}) := \bigotimes_d \left((\det \mathcal{C}_{g,n}^{\text{ct},(r),d}(\mathcal{A}))^{-2} \otimes (\mathcal{U}_{g,n}^{(d)})^{r_{d,r}} \right).$$

The degree- r resonance class is

$$\mathfrak{R}_{r,g,n}^{\text{mod}}(\mathcal{A}) := \text{div}(s_{r,g,n}^{\text{res}}(\mathcal{A})).$$

The quartic class of Definition 22.7.5 is the first case.

THEOREM 22.12.7 (*Associated-graded all-degree boundary law for the resonance tower;).* For every $r \geq 4$ and every separating clutching map ξ ,

$$\xi^* \mathfrak{R}_{r,g,n}^{\text{mod}}(\mathcal{A}) \equiv p_1^* \mathfrak{R}_{r,g_1,n_1+1}^{\text{mod}}(\mathcal{A}) + p_2^* \mathfrak{R}_{r,g_2,n_2+1}^{\text{mod}}(\mathcal{A}) + \sum_{p+q=r+2} \mathfrak{T}_{\xi}^{(p,q)}(\mathcal{A}) \pmod{F_{\text{Mok}}^{\geq 2}}, \quad (22.10)$$

where $\mathfrak{T}_{\xi}^{(p,q)}(\mathcal{A})$ is the determinant divisor of one-edge sewings of degree- p and degree- q vertices. The exact Picard-valued all-degree law requires the refined Mok-type contributions in depth at least 2 and is conditional on the log-FM residue-pushforward cocomposition. The quartic case ($r = 4$, with only the $(3, 3)$ tree term) is Theorem 22.7.11.

Proof. The argument generalises the quartic proof (Theorem 22.7.11) from degree 4 to arbitrary degree r , using the same three ingredients: Mok's degeneration formula, the internal-edge filtration, and determinant factorisation.

Step 1: Boundary filtration at degree r . Fix a separating clutching map ξ corresponding to a semistable degeneration $Y_1 \cup_D Y_2$ with r marked points distributed as $I = I_1 \sqcup I_2$. By Mok's degeneration formula [?Mok25, Corollary 5.3.4], the irreducible components of the special fibre of $\text{FM}_r(W/B)$ along ξ are indexed by rigid combinatorial types ρ [?Mok25, Definition 4.7.1]: planted forests whose associated polyhedron μ_{ρ} is a vertex. Each rigid type has a well-defined *depth* (Definition ??): the number of internal

edges in the planted forest crossing the node. This induces an increasing filtration on the pulled-back degree- r contact envelope:

$$\mathfrak{o} = F^{-1} \subset F^0 \subset F^1 \subset \dots \subset F^{\lfloor r/2 \rfloor} = \xi^* \mathcal{C}_{g,n}^{[r]}(\mathcal{A}),$$

where F^k is spanned by rigid types of depth $\leq k$.

Step 2: Identification of the associated graded. The associated graded decomposes by depth:

- (A) *Depth 0* (pure types, $r+0$ or $0+r$): all r points on one component, no edges crossing the node. These contribute the pulled-back contact sectors $p_j^* \mathcal{C}_{g_j, n_j+1}^{\text{ct}, (r)}(\mathcal{A})$.
- (B) *Depth 1* (split types with a single crossing edge): points distributed as $|I_1| + |I_2|$ with $|I_1|, |I_2| \geq 1$ and no further FM bubbling. The component $\text{FM}_r(W/B)(\rho)$ is a modification of $\text{FM}_{|I_1|+1}(Y_1|D_1) \times \text{FM}_{|I_2|+1}(Y_2|D_2)$ (one extra point at the node on each side). This contributes a one-edge sewing of an degree- $(|I_1|+1)$ vertex to a degree- $(|I_2|+1)$ vertex. Summing over splits $p + q = r + 2$ yields the tree correction $\bigoplus_{p+q=r+2} \mathcal{T}_{\xi}^{(p,q)}(\mathcal{A})$.
- (C) *Depth ≥ 2* (nontrivial planted trees with ≥ 2 crossing edges): these rigid types lie in the higher Mok filtration. The present statement records the quotient modulo their contribution; proving that they do not alter the exact Cartier divisor class is a separate refined determinant-line obligation.

Step 3: Determinant factorisation. On the associated graded gr_F , the Gram pairing of the degree- r contact envelope is block-diagonal with respect to the depth decomposition (A)–(B), since the depth-0 sector has no internal edges crossing the node while the depth-1 sector has exactly one. The determinant section of $\xi^* \mathcal{L}_{r,g,n}^{\text{res}}(\mathcal{A})$ therefore factors on gr_F as

$$\text{gr } \xi^* \mathcal{L}_{r,g,n}^{\text{res}}(\mathcal{A}) = p_1^* s_{r,g_1,n_1+1}^{\text{res}}(\mathcal{A}) \otimes p_2^* s_{r,g_2,n_2+1}^{\text{res}}(\mathcal{A}) \otimes \bigotimes_{p+q=r+2} t_{\xi}^{(p,q)}(\mathcal{A}).$$

Taking divisors on the associated graded and then projecting modulo $F_{\text{Mok}}^{\geq 2}$ yields (22.10). No exact Picard-valued statement is asserted beyond this quotient without the missing refined Mok determinant-line calculation. $\square$

22.12.4 The complementarity phase function

Definition 22.12.8 (Nonlinear phase index). Define the *nonlinear phase index*

$$\nu_{\text{nl}}(\mathcal{A}, u) := \min\{r \geq 3 : \text{Sh}_r(\Theta_{\mathcal{A},u}) \neq \mathfrak{o}\},$$

with the convention $\nu_{\text{nl}} = \infty$ when all nonlinear shadows vanish.

THEOREM 22.12.9 (*Nonlinear phase of the standard families;*). The nonlinear phase indices of the five model families are:

- (i) Heisenberg: $\nu_{\text{nl}} = \infty$.
- (ii) Affine $\widehat{\mathfrak{sl}}_2$ generic strict current sector: $\nu_{\text{nl}} = 3$.
- (iii) Affine critical level $k = -h^\vee$: $\nu_{\text{nl}} = 3$, but the quadratic part vanishes, so the cubic term becomes leading.
- (iv) $\beta\gamma$ standard conformal-weight class-C lane: $\nu_{\text{nl}} = 4$; the internal weight-changing line has $\nu_{\text{nl}} = \infty$.
- (v) Virasoro and principal $\mathcal{W}_N$: $\nu_{\text{nl}} = 3$ with mixed quartic resonance.

Proof. The definition of ν_{nl} asks for the first nonzero finite-window projection of $\Theta_{\mathcal{A}}$ in degree at least 3. Theorem 22.5.1 gives no nonlinear projection for the Heisenberg lane. Theorem 22.5.6 identifies the generic affine strict-current cubic as the first nonzero nonlinear projection. Conjecture 22.5.8 supplies the same cubic first term at critical level after the quadratic Hessian vanishes. Theorem 22.5.15 places the first standard conformal-weight $\beta\gamma$ nonlinear projection in degree 4, while the internal weight-changing line has no such projection in the finite window. Theorem 22.6.3 gives the Virasoro cubic first term and the quartic resonance; the principal $\mathcal{W}_N$ case follows from Theorem 22.6.15 and Corollary 22.6.17. $\square$

Remark 22.12.10 (The phase index as a wall-crossing function). The nonlinear phase index $\nu_{\text{nl}}(\mathcal{A}, u)$ is a constructible function on parameter space, measuring the degree at which complementarity becomes genuinely nonlinear. Its jump loci are the walls of the *resonance scattering diagram* of §22.13.2.

22.12.5 The nonlinear spectral-branch stack

Definition 22.12.11 (Nonlinear spectral-branch stack;). The *nonlinear spectral-branch stack* of $\mathcal{A}$ is a stack

$$\mathfrak{B}_{\mathcal{A}}^{\text{nl}}$$

whose truncations record:

- (i) branch eigenvalues at degree 2 (the spectral discriminant $\Delta_{\mathcal{A}}$);
- (ii) contact degeneracies at degree 4 (the quartic resonance class);
- (iii) higher-degree front singularities for $r \geq 5$.

$\Delta_{\mathcal{A}}$ records where quadratic transport branches collide, while $\mathfrak{R}_r^{\text{mod}}$ records where nonlinear contact sectors lose rank. Both live in a single branch-resonance geometry.

Remark 22.12.12 (Conceptual outcome: graph-completed shifted-contact geometry). The unification is

Koszul duality + Verdier duality + curvature + clutching $\implies$ graph-completed shifted-contact geometry.

The object that governs the entire nonlinear modular theory is not only $\Theta_{\mathcal{A}}$, nor only $\mathcal{S}_{\mathcal{A}}$, but the triple

$$(\Theta_{\mathcal{A}}, \Lambda_{\mathcal{A}}, \{\mathfrak{R}_r^{\text{mod}}\}_{r \geq 4}),$$

namely: a graph-completed Hamiltonian master element, its Legendrian geometric avatar, and the full tower of Picard-valued nonlinear resonance shadows.

22.13 POLARIZED RESONANCE SCATTERING

The Feynman transform carries one-color vertex labels. The next structural upgrade replaces the one-color Maurer–Cartan problem by a *polarized bipartite machine* in which complementarity becomes a graph-theoretic selection rule.

22.13.1 The polarized modular graph algebra

Definition 22.13.1 (Polarized modular graph algebra;). Let $\text{Def}^{\pm}(\mathcal{A})$ denote the two complementary polarized pieces of the cyclic deformation problem, corresponding to $\mathcal{A}$ and $\mathcal{A}^!$.

The *polarized modular graph algebra* is the completed vector space

$$\mathcal{G}_{\text{mod}}^{\pm}(\mathcal{A})$$

spanned by stable graphs satisfying:

- (1) every vertex is coloured by + or −,
- (2) every internal edge joins opposite colours,
- (3) a +-vertex carries a cyclic operation from $\text{Def}^+(\mathcal{A})$,
- (4) a --vertex carries a cyclic operation from $\text{Def}^-(\mathcal{A})$,
- (5) each graph is weighted by tautological/modular coefficient data from $R\Gamma(\overline{\mathcal{M}}_{g,n})$.

The differential is

$$d = d_{\text{int}} + d_{\text{split}} + d_{\text{clutch}} + d_{\text{edge}},$$

where d_{clutch} inserts boundary degenerations and d_{edge} contracts a mixed propagator along an opposite-colour edge.

THEOREM 22.13.2 (*Bipartite complementarity principle*;). Same-colour internal-edge contractions vanish identically in $\mathcal{G}_{\text{mod}}^\pm(\mathcal{A})$. Equivalently, complementarity is not merely a direct-sum decomposition; it is a *selection rule*: only opposite-polarization propagators contribute to the full nonlinear theory.

Proof. This is a restatement of the bipartite vanishing theorem (Theorem 22.14.1): the Lagrangian isotropy $\langle V^+, V^+ \rangle = 0 = \langle V^-, V^- \rangle$ forces the same-colour blocks of the propagator to vanish, so every internal-edge contraction within a single colour is zero. $\square$

Conjecture 22.13.3 (*Polarized universal class*;). There exists a canonical Maurer–Cartan element

$$\Theta_{\mathcal{A}}^\pm \in \text{MC}(\mathcal{G}_{\text{mod}}^\pm(\mathcal{A}))$$

whose projections recover the entire hierarchy: scalar trace $\Rightarrow \kappa(\mathcal{A})\lambda_g$, branch determinant $\Rightarrow \Delta_{\mathcal{A}}$, one-vertex degree- r sector $\Rightarrow$ the shadow tensors $H_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}}, \dots$, contact determinant sector $\Rightarrow \mathfrak{R}_{r,g,n}^{\text{mod}}(\mathcal{A})$, and genus-summed semiclassical action $\Rightarrow$ the complementarity potential and its higher corrections.

22.13.2 *The resonance scattering diagram*

Definition 22.13.4 (*Resonance wall locus*). Let

$$\mathcal{W}_{\mathcal{A}} := \{\Delta_{\mathcal{A}} = 0\} \cup \bigcup_{r \geq 4} |\mathfrak{R}_r^{\text{mod}}(\mathcal{A})|$$

be the total nonlinear wall locus in parameter space.

Definition 22.13.5 (*Resonance scattering diagram*;). The resonance scattering diagram

$$\mathfrak{Scat}(\mathcal{A})$$

has walls given by the irreducible components of $\mathcal{W}_{\mathcal{A}}$, and wall functions given by the gauge transport automorphisms induced by the polarized class $\Theta_{\mathcal{A}}^\pm$.

Interpretation:

- $\Delta_{\mathcal{A}}$ detects the quadratic spectral walls,
- $\mathfrak{R}_r^{\text{mod}}$ detect the genuinely nonlinear walls,
- chamber transport is governed by graph sums in $\mathcal{G}_{\text{mod}}^\pm(\mathcal{A})$.

This explains how different theories may sit on the same spectral sheet while differing nonlinearly: identical Δ , different scattering data.

22.13.3 The complementarity schober

Definition 22.13.6 (Complementarity schober;). The complementarity schober

$$\mathfrak{Sch}(\mathcal{A}) \rightarrow B_{\mathcal{A}}^{\circ}$$

is the constructible sheaf of categories whose fibre over a chamber is the category of polarized quantizations of that chamber, and whose wall-crossing functors are induced by the scattering automorphisms of $\mathfrak{Scat}(\mathcal{A})$.

Remark 22.13.7 (Why a schober rather than a scattering diagram). A discriminant polynomial is too coarse: it records *which* theories degenerate, but not *how* they mutate. A schober remembers the mutation data. This is the correct categorified replacement for saying that “the same discriminant supports different chiral theories.”

22.13.4 The modular state

Definition 22.13.8 (Modular state;). Choose one polarization, say the $+$ -side. Quantize $\Theta_{\mathcal{A}}^{\pm}$ to an operator $\widehat{\Theta}_{\mathcal{A}}$ on the Fock space of the polarized deformation theory. The *modular state* is a section

$$\Psi_{\mathcal{A}}$$

satisfying the quantum master equation

$$\widehat{\Theta}_{\mathcal{A}} \Psi_{\mathcal{A}} = 0.$$

Semiclassically,

$$\Psi_{\mathcal{A}} \sim \exp\left(\sum_{g \geq 0} \hbar^{2g-2} F_g(\mathcal{A})\right).$$

Remark 22.13.9 (Local normal forms for the modular state). The nonlinear shadows acquire the following conjectural microlocal normal forms:

- Heisenberg: Gaussian,
- affine $\widehat{\mathfrak{sl}}_2$: Airy-type,
- $\beta\gamma$: Pearcey-type,
- Virasoro / principal $\mathcal{W}_N$: mixed catastrophe type.

The conjectural assertion is that the shadow obstruction tower determines the singularity type of $\Psi_{\mathcal{A}}$, so the archetype trichotomy of Theorem 22.5.18 becomes a classification of polarized modular states by catastrophe type.

22.14 BIPARTITE NONLINEAR TOWER

The constructions of §22.12–§22.13 yield a bipartite hierarchy of theorems and conjectures, ordered by structural depth.

THEOREM 22.14.1 (*Bipartite vanishing theorem;).* Same-polarization internal edges vanish identically in the polarized graph algebra $\mathcal{G}_{\text{mod}}^{\pm}(\mathcal{A})$. Thus every nontrivial nonlinear correction is represented by a bipartite stable graph.

Proof. The complementarity datum (Theorem 22.3.6) furnishes a Lagrangian decomposition $V_{\mathcal{A}} = V^+ \oplus V^-$ of the cyclic slice with respect to the cyclic pairing $\langle -, - \rangle$. Isotropy of each summand means $\langle V^+, V^+ \rangle = 0 = \langle V^-, V^- \rangle$, so in the adapted basis the pairing matrix has the off-diagonal block form

$$\langle -, - \rangle = \begin{pmatrix} 0 & B \\ B^t & 0 \end{pmatrix}, \quad B: V^+ \xrightarrow{\sim} (V^-)^*[-1].$$

The propagator $P_{\mathcal{A}} = H_{\mathcal{A}}^{-1} \in V_{\mathcal{A}} \otimes V_{\mathcal{A}}$ is the formal inverse of this pairing. Block inversion gives

$$P_{\mathcal{A}} = \begin{pmatrix} 0 & (B^t)^{-1} \\ B^{-1} & 0 \end{pmatrix},$$

so $P^{++} = 0 = P^{--}$. Every internal edge in the graph algebra is contracted by $P_{\mathcal{A}}$. An edge joining two vertices of the same colour contributes the P^{++} or P^{--} block, which vanishes. Therefore the only graphs with nonzero weight are those whose internal edges all join opposite colours, i.e. bipartite stable graphs. $\square$

Conjecture 22.14.2 (Quartic lift theorem;). The shadow package $H_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}}$ is precisely the zero-internal-edge truncation of $\Theta_{\mathcal{A}}^{\pm}$ through degree 4.

Remark 22.14.3 (Quartic lift on standard archetypes). The zero-internal-edge truncation of $\Theta_{\mathcal{A}}^{\pm}$ through degree 4 has been verified to reproduce the shadow package $(\mathcal{H}_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}})$ for all four standard archetype families:

- (i) Heisenberg (G, depth 2, $\mathfrak{Q} = 0$): the propagator is scalar, and the graph sum terminates at the single binary graph.
- (ii) Affine (L, depth 3, $\mathfrak{Q} = 0$): the cubic shadow is the Lie bracket $\mathfrak{C} = f_c^{ab}$, and all quartic bipartite graphs cancel by the Jacobi identity.
- (iii) $\beta\gamma$ (C, depth 4, $\mathfrak{Q}$ canonical): the quartic contact invariant $\mu_{\beta\gamma} = 0$ on the weight-changing line (Corollary 22.5.16), while the quartic class on the diagonal is the canonical residue of the $\beta\gamma$ system.
- (iv) Virasoro (M, depth ∞ , $Q_{\text{Vir}}^{\text{contact}} = 10/[c(5c + 22)]$): the quartic slice matches, and the nonvanishing quintic obstruction (Theorem 22.9.6) confirms that higher-degree bipartite graphs contribute.

The bipartite vanishing theorem (Theorem 22.14.1) ensures that only mixed-polarization propagators contribute, reducing the graph enumeration from $|\text{Gr}_{0,4}^{\text{st}}|$ to $|\text{Gr}_{0,4}^{\pm, \text{conn}}|$.

Conjecture 22.14.4 (Resonance wall-crossing theorem;). The spectral discriminant $\Delta_{\mathcal{A}}$ is constant under scattering within a fixed sheet, while the resonance tower records the nonlinear wall-crossing corrections.

Conjecture 22.14.5 (Quantization theorem;). A choice of polarization produces a modular state $\Psi_{\mathcal{A}}$ whose semiclassical expansion recovers the genus tower and whose singular support is the complementarity Legendrian front.

Remark 22.14.6 (Finite graph computation). The finite graph model has five required components:

- (1) a finite-dimensional cyclic L_{∞} model with two polarizations,
- (2) the mixed propagator P^{+-} and the vanishing blocks $P^{++} = P^{--} = 0$,
- (3) the connected graph weights for Heisenberg, affine $\widehat{\mathfrak{sl}}_2$, $\beta\gamma$, and Virasoro,

- (4) the quartic resonance class as the first contact determinant,
- (5) the wall functions of $\mathfrak{Scat}(\mathcal{A})$.

These data turn complementarity from a theorem about decomposition into a theorem about *transport, wall-crossing, and quantization*.

Construction 22.14.7 (Bipartite graph algebra as L_∞ truncation). The polarized graph algebra $\mathcal{G}_{\text{mod}}^\pm(\mathcal{A})$ admits a canonical identification with the tree-level truncation of the L_∞ -algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$:

- (i) Each bipartite graph $\Gamma \in \text{Gr}_{0,r}^{\pm, \text{conn}}$ with zero internal edges corresponds to a tree-level r -ary L_∞ bracket $\ell_r^{(\circ)}$. The correspondence sends the graph weight $W_\Gamma(P^{+-}, m_\bullet)$, contracted using only the off-diagonal propagator $P^{+-} = (B^t)^{-1} \in V^+ \otimes V^-$ (Theorem 22.14.1), to the r -ary homotopy transfer bracket.
- (ii) The Lagrangian decomposition $V_{\mathcal{A}} = V^+ \oplus V^-$ with off-diagonal propagator P^{+-} implements the homotopy transfer:

$$\ell_r^{\text{tr}} = \sum_{\text{binary trees } T \text{ with } r \text{ leaves}} W_T(P^{+-}, m_\bullet),$$

where the sum is over planar binary trees, each internal vertex carries an OPE coefficient m_k , and each internal edge is contracted by P^{+-} . This is the standard homological perturbation lemma applied to the Lagrangian splitting.

- (iii) For finite-depth algebras (classes G, L, C), the truncation $\Theta_{\leq r_{\text{max}}}^\pm = \Theta^\pm$ is exact: no bipartite graphs with internal edges contribute beyond degree r_{max} . The tree-level L_∞ -algebra is then *formal*: it is L_∞ -quasi-isomorphic to its cohomology with the transferred brackets $\ell_2^{\text{tr}}, \dots, \ell_{r_{\text{max}}}^{\text{tr}}$. For class M (Virasoro, $\mathcal{W}_N$), the tower is infinite and the graph algebra receives contributions at every degree.

The shadow–formality identification (Proposition ??) is the degree-by-degree verification of this correspondence at degrees 2, 3, 4. Proposition 22.14.4 upgrades it to the full genus-0 obstruction tower; positive-genus corrections are carried separately by the quantum layer.

Construction 22.14.8 (Exchange diagram: quartic from cubic sewing). The one-edge bipartite graphs in $\text{Gr}_{0,4}^{\pm, \text{conn}}$ compute the boundary quartic class from cubic sewing:

$$[R_4^{\text{mod}}(\mathcal{A})]_{\text{exch}} = [C_A *_{P^{+-}} C_A]$$

where $C_A *_{P^{+-}} C_A$ denotes the cubic shadow contracted through the mixed propagator P^{+-} . For class L algebras (affine, $r_{\text{max}} = 3$), this exchange vanishes and $R_4^{\text{mod}} = 0$. For class C algebras ($\beta\gamma$, $r_{\text{max}} = 4$), the exchange is the *sole* source of quartic data.

Remark 22.14.9 (What shadow data is consumed by the Bridge Theorem). The Bridge Theorem (Remark ??; Theorem ??) consumes shadow data at exactly two projections of the universal MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$:

- (i) *The propagator* $r(z) = \tau|_{\deg 2}$ (*genus-0, degree-2 MC projection*). This is the degree-2 slice of $\Theta_{\mathcal{A}}$: the degree-2, genus-0 component of the graph sum (Definition ??), with a single internal edge carrying the bar propagator. It gives $k \cdot 1/z$ in the Heisenberg/free case (and 0 for $\beta\gamma$, whose simple-pole OPE is absorbed by $d \log$) and $k\Omega_{\text{tr}}/z$ in the affine $\widehat{\mathfrak{g}}_k$ case (Propositions ?? and ??): at $k = 0$ both propagators vanish, consistent. The higher-degree shadows (cubic $\mathfrak{C}$, quartic $\mathfrak{Q}$, resonance tower $\mathfrak{R}_\bullet^{\text{mod}}$) are degree-3, 4, $\dots$ projections of the same MC element; they do *not* enter the genus-0 bridge statement but become relevant at the modular completion level (Conjecture ??).

- (ii) *The curvature $\kappa(\mathcal{A})$ (genus-1, degree-0 MC trace).* The scalar curvature is $\kappa(\mathcal{A}) = \text{tr}(\Theta_{\mathcal{A}}|_{g=1})$: the genus-1, degree-0 component of the universal MC element. It controls the genus-1 deformation of the dg-shifted Yangian and the obstructedness of the bridge at higher genus via $d^2 = \kappa \cdot \omega_1$ (Theorem ??).

CG consequence. The nonlinear shadow obstruction tower $(\kappa \rightarrow \Delta \rightarrow \mathfrak{C} \rightarrow \mathfrak{Q} \rightarrow \dots)$ is the degree filtration of the single MC element $\Theta_{\mathcal{A}}$. The Bridge Theorem consumes only the degree-2 and degree-0 slices ($r(z)$ and κ). The tower is therefore a valuable parallel construction (it computes successively finer projections of the same universal object), but it is **not a prerequisite** for the bridge. The higher shadows become prerequisites only when the construction reaches the modular completion: the all-genera stable-graph Yang–Baxter equation (Conjecture ??), which requires the full MC element $\Theta_{\mathcal{A}}$ at all degrees.

Remark 22.14.10 (The extended modular invariant hierarchy). The full hierarchy, extended by the constructions of this appendix, is

$$\underbrace{\kappa(\mathcal{A})}_{\text{scalar}} \longrightarrow \underbrace{\Delta_{\mathcal{A}}}_{\text{spectral}} \longrightarrow \underbrace{(H_{\mathcal{A}}, \mathfrak{C}_{\mathcal{A}}, \mathfrak{Q}_{\mathcal{A}})}_{\text{Hamiltonian jets}} \longrightarrow \underbrace{\mathfrak{R}_{\bullet}^{\text{mod}}(\mathcal{A})}_{\text{resonance tower}} \longrightarrow \underbrace{\Lambda_{\mathcal{A}}}_{\text{Legendrian}} \longrightarrow \underbrace{\Theta_{\mathcal{A}}}_{\text{master element}}.$$

Every earlier level is a shadow of every later level. The graph-completed master element is the source of all of them.

Remark 22.14.11 (Factorization envelope and the shadow obstruction tower). The factorization envelope ([?BD04, §3.7], [?CG17]; see also Vicedo [?Vic25]) provides a functorial genus-0 machine: from a Lie conformal algebra one constructs a factorization algebra whose associated vertex algebra is the enveloping vertex algebra. The shadow obstruction tower of this appendix supplies the higher-genus completion. That is, the ideal object attached to a cyclically admissible Lie conformal algebra L (Definition ??) is not merely the genus-0 factorization algebra $\text{Fact}_X(L)$, but the full modular Koszul datum $\Pi_X(L)$ (Construction ??), in which all shadows $(\kappa, \Delta, \mathfrak{C}, \mathfrak{Q}, \Theta)$ are successive projections of a single universal Maurer–Cartan element $\Theta_L \in \text{MC}(\text{Def}_{\text{cyc}}(L) \hat{\otimes} \mathbb{G}_{\text{mod}})$.

For the archetype families computed in this appendix:

- *Heisenberg* collapses to its scalar shadow: $\Theta_L \sim \kappa(L)\lambda + \text{exact}$, $\mathfrak{R}_4^{\text{mod}}(L) = 0$. This is the rank-one atom.
- *Affine $\widehat{\mathfrak{g}}_k$* : the first true spectral example. The branch operator T_L^{br} is nontrivial, giving a genuine discriminant.
- *Virasoro*: the first example where the scalar shadow is insufficient and the quartic resonance class $\mathfrak{R}_4^{\text{mod}}$ carries essential content.
- *Principal $\mathcal{W}_N$* : the expectation is $\Theta_{\mathcal{W}_N} = H_{Q_{\text{DS}}}^0(\Theta_{V_k(\mathfrak{g}) \otimes \mathcal{F}_{\text{gh}}})$, turning Drinfeld–Sokolov reduction into a functor on modular Koszul datums. Reduction should commute with shadow-taking: the shadow obstruction tower of $\mathcal{W}_N$ should be the BRST-reduced image of the full current-plus-ghost tower.

The abstract mechanism behind these predictions is the cubic gauge triviality theorem (Theorem ??): whenever $H^1(F^3 \mathfrak{g}_{\mathcal{A}}^{\text{mod}} / F^4 \mathfrak{g}_{\mathcal{A}}^{\text{mod}}, d_2) = 0$, the cubic shadow is gauge-trivial and the quartic resonance class is the canonical representative of the first nonlinear cohomology class. This is the abstract reason the first nonlinear shadow is quartic, and for independent sums all shadows factor (Proposition ??).

22.15 REDUCED-WEIGHT WINDOWS AND FINITE-DIMENSIONAL BAR CONTROL

The shadow obstruction tower of the preceding sections is organized by degree: the degree- r shadow jet $\text{Sh}_r(\mathcal{A})$ probes the universal MC element $\Theta_{\mathcal{A}}$ at r external legs. A complementary organizational principle is the *reduced-weight filtration* on the bar complex itself, which turns the infinite-generator completion problem into a sequence of finite-dimensional dg computations. This is the constructive backbone of the MC₄ construction (Theorem 9.1.28): the coefficient-stability criterion (Theorem 9.1.50) reduces convergence to stabilization on finite windows, and the present section provides those windows explicitly.

22.15.1 Reduced weight and finite-dimensional slices

Definition 22.15.1 (Reduced weight;). Let $\mathcal{A} = \omega_X \oplus \tilde{\mathcal{A}}$ be a conformally graded augmented chiral A_∞ -algebra with $\tilde{\mathcal{A}} = \bigoplus_{h \geq 2} \mathcal{A}[h]$, each $\mathcal{A}[h]$ finite-dimensional, satisfying the *conformal estimate*

$$\text{wt}(\mu_r(a_1, \dots, a_r)) \leq \sum_{i=1}^r \text{wt}(a_i) - (r - 1) \quad (22.11)$$

for all $r \geq 2$ and homogeneous elements $a_i \in \tilde{\mathcal{A}}$. Define the *reduced weight* of a homogeneous element $a \in \mathcal{A}[h]$ by

$$\rho(a) := \text{wt}(a) - 1 = h - 1 \geq 1,$$

and the reduced weight of a bar monomial $sa_1 | \cdots | sa_\ell \in \bar{B}(\mathcal{A})$ by

$$\rho(sa_1 | \cdots | sa_\ell) := \sum_{i=1}^{\ell} \rho(a_i) = \sum_{i=1}^{\ell} (\text{wt}(a_i) - 1).$$

Since every letter has $\rho(a_i) \geq 1$, every bar monomial has $\rho \geq \ell$ (its bar length).

THEOREM 22.15.2 (Reduced-weight finiteness;). For every $q \geq 0$, the *exact reduced-weight slice*

$$B_{\rho(q)}(\mathcal{A}) := \text{span}\{sa_1 | \cdots | sa_\ell \mid \rho(sa_1 | \cdots | sa_\ell) = q\}$$

is finite-dimensional, and the completed bar differential is filtration-nonincreasing:

$$b(B_{\rho(\leq q)}(\mathcal{A})) \subseteq B_{\rho(\leq q)}(\mathcal{A}), \quad B_{\rho(\leq q)}(\mathcal{A}) := \bigoplus_{j=0}^q B_{\rho(j)}(\mathcal{A}).$$

Hence the *reduced-weight completed bar complex*

$$\widehat{B}_\rho(\mathcal{A}) := \prod_{q \geq 0} B_{\rho(q)}(\mathcal{A})$$

is a well-defined separated complete curved dg coalgebra with automatic continuity of the differential.

Proof. Finite-dimensionality. Every letter sa_i in a bar monomial of total reduced weight q has $\rho(a_i) \geq 1$ and $\sum_i \rho(a_i) = q$, so the bar length satisfies $\ell \leq q$ and each letter has $\text{wt}(a_i) = \rho(a_i) + 1 \leq q + 1$. Since $\mathcal{A}[h]$ is finite-dimensional for each h , the number of available letters is bounded by $\sum_{h=2}^{q+1} \dim \mathcal{A}[h]$. The number of words of length $\ell \leq q$ from this finite alphabet is finite, so $B_{\rho(q)}(\mathcal{A})$ is finite-dimensional.

Filtration compatibility. A coderivation term of the bar differential replaces r consecutive letters $a_{j_1}, \dots, a_{j_r}$ by the single letter $\mu_r(a_{j_1}, \dots, a_{j_r})$. By the conformal estimate (22.11), the reduced weight of the output is

$$\rho(\mu_r(a_{j_1}, \dots, a_{j_r})) = \text{wt}(\mu_r(a_{j_1}, \dots, a_{j_r})) - 1 \leq \sum_{k=1}^r \text{wt}(a_{j_k}) - (r-1) - 1 = \sum_{k=1}^r \rho(a_{j_k}) - (r-1).$$

Since $r \geq 2$, the change in total reduced weight is

$$\rho(\text{output letter}) - \sum_{k=1}^r \rho(a_{j_k}) \leq -(r-1) \leq -1 < 0.$$

Therefore the bar differential is strictly filtration-decreasing on each coderivation component, hence filtration-nonincreasing on the total differential. Continuity of the differential on the completed product $\widehat{B}_\rho(\mathcal{A})$ is then automatic: each projection to a finite slice factors through finitely many lower slices. $\square$

Definition 22.15.3 (Finite q -window). For each $q \geq 0$, define the *finite q -window*

$$K_q(\mathcal{A}) := B_{\rho(\leq q)}(\mathcal{A}) = \bigoplus_{j=0}^q B_{\rho(j)}(\mathcal{A}).$$

By Theorem 22.15.2, $K_q(\mathcal{A})$ is a finite-dimensional dg coalgebra (with the restricted bar differential), and the completed bar complex is the inverse limit $\widehat{B}_\rho(\mathcal{A}) = \varprojlim_q K_q(\mathcal{A})$.

THEOREM 22.15.4 (Window locality;). The finite q -window $K_q(\mathcal{A})$ depends only on the A_∞ operations $\{\mu_r\}$ restricted to fields of conformal weight $\leq q+1$. No field of conformal weight $> q+1$ can enter either the basis of $K_q(\mathcal{A})$ or its differential.

Proof. By Definition 22.15.1, every bar letter sa in $K_q(\mathcal{A})$ has $\rho(a) \leq q$, hence $\text{wt}(a) = \rho(a) + 1 \leq q+1$. So the basis of $K_q(\mathcal{A})$ involves only fields of weight $\leq q+1$. For the differential: the bar coderivation applies μ_r to r letters already in the window, producing a letter of weight $\text{wt}(\mu_r) \leq \sum_i \text{wt}(a_i) - (r-1) \leq q+1$. No field of higher weight can be produced, and no higher-weight field enters as an input (since all inputs are already in the window). $\square$

COROLLARY 22.15.5 (Exact stabilization;). For a genuine weight-truncation tower $\mathcal{A}_{\leq N} := \mathcal{A} / \bigoplus_{h>N} \mathcal{A}[h]$, one has a canonical isomorphism

$$K_q(\mathcal{A}_{\leq N}) \cong K_q(\mathcal{A}) \quad \text{for all } N \geq q+1.$$

The infinite-generator problem is thereby killed exactly: a reduced-weight- q computation stabilizes at stage $N = q+1$.

Proof. By Theorem 22.15.4, $K_q(\mathcal{A})$ depends only on fields of weight $\leq q+1$. For $N \geq q+1$, the truncation $\mathcal{A}_{\leq N}$ agrees with $\mathcal{A}$ on all such fields, hence the q -windows are canonically identified as dg coalgebras. $\square$

22.15.2 Stabilization defect and the MC₄ obstruction

The exact stabilization (Corollary 22.15.5) says that each finite window K_q eventually sees no new fields. The next question is finer: does the *differential* on K_q stabilize as one passes through the stage tower? The defect measures this, and its cohomology class is the first obstruction to MC₄ convergence.

Definition 22.15.6 (Stabilization defect). Fix a stage tower $\mathcal{A}_{\leq N}$ and a reduced-weight window q . For $N \geq q + 1$, the underlying vector spaces of the q -window are canonically identified: $K_q(\mathcal{A}_{\leq N}) \cong V_q$ (Corollary 22.15.5). Let $d_{q,N} \in \text{End}(V_q)$ denote the differential on the q -window at stage N . Define the *stabilization defect*

$$\delta_{q,N} := d_{q,N+1} - d_{q,N} \in \text{End}^1(V_q).$$

Since both $d_{q,N}$ and $d_{q,N+1}$ square to zero (or to the same curvature, at genus $g \geq 1$), one has

$$[d_{q,N}, \delta_{q,N}] + \delta_{q,N}^2 = 0,$$

so $\delta_{q,N}$ is a Maurer–Cartan deformation of $d_{q,N}$ in the dg Lie algebra $(\text{End}(V_q), [d_{q,N}, -])$.

Definition 22.15.7 (First stabilization obstruction). The *first stabilization obstruction* at stage N and window q is the cohomology class

$$\mathfrak{o}_{q,N} := [\delta_{q,N}] \in H^1(\text{End}(V_q), [d_{q,N}, -]).$$

If $\mathfrak{o}_{q,N} = 0$, the first-order defect is gauge-removable: there exists $\gamma \in \text{End}^0(V_q)$ such that $\delta_{q,N} = [d_{q,N}, \gamma] + O(\delta^2)$. Higher-order defects live in explicit higher cohomology groups of the same endomorphism complex.

Remark 22.15.8 (From topological convergence to finite linear algebra). Definitions 22.15.6 and 22.15.7 convert the MC₄ convergence problem from “prove that the bar differential converges in a huge topological dg coalgebra” into a sequence of finite-dimensional checks: at each reduced-weight window q and each truncation stage N , compute a finite matrix $(\delta_{q,N})$, compute its cohomology (the H^1 of the endomorphism complex), and test whether the defect class vanishes. When $\mathfrak{o}_{q,N} = 0$ for all q and all sufficiently large N , the coefficient-stability criterion (Theorem 9.1.50) applies and the completed bar-cobar homotopy equivalence (Theorem 9.1.28) is established.

For the standard families:

- *Heisenberg and affine $\widehat{\mathfrak{g}}_k$* : finitely generated, so V_q stabilizes trivially and $\delta_{q,N} = 0$ for $N \gg 0$.
- $\beta\gamma$: one generator per conformal weight, so $\dim V_q = p(q)$ (number of partitions of q). Stabilization holds by the rank-one abelian rigidity (Theorem 22.5.19).
- *Virasoro and $\mathcal{W}_N$* : infinite towers with one primitive per weight. The stabilization defect $\delta_{q,N}$ is a finite matrix (of size $\dim V_q$) whose entries are explicit polynomial functions of c (resp. c and the central charges of the higher-spin currents). The MC₄ frontier reduces to showing $[\delta_{q,N}] = 0$ for these explicit matrices.

22.15.3 Multi-variable shadow obstruction tower

For a chiral algebra $\mathcal{A}$ with $\dim H_{\text{cyc}}^2(\mathcal{A}) = r$ and basis $\{\eta_1, \dots, \eta_r\}$, the shadow at degree n is a degree- n polynomial $\text{Sh}_n \in \text{Sym}^n(H_{\text{cyc}}^2)$ in deformation coordinates $(x_1, \dots, x_r)$.

Definition 22.15.9 (Kappa matrix and propagator;). Define the *kappa matrix* $\kappa_{ij} = \langle \phi_i, \phi_j \rangle_{\max}$, the leading pole coefficient of the two-point function between the quasi-primary fields ϕ_i and ϕ_j dual to η_i and η_j . On the Koszul locus, κ is nondegenerate. Set $P = \kappa^{-1}$. The *multi-variable H-Poisson bracket* is

$$\{f, g\}_H = \sum_{i,j=1}^r \frac{\partial f}{\partial x_i} P_{ij} \frac{\partial g}{\partial x_j}. \quad (22.12)$$

The input shadows are:

- Sh_2 : the quadratic form κ (i.e. $\text{Sh}_2 = \sum_{i,j} \kappa_{ij} x_i x_j$);
- Sh_3 : cubic, from the OPE structure constants $C_{ijk} = \langle \phi_i, \ell_2^{\text{tr}}(\phi_j, \phi_k) \rangle$;
- Sh_4 : quartic, from quasi-primary exchange and the quartic contact invariant.

The master equation (Theorem 22.9.3) generates Sh_n for $n \geq 5$:

$$\nabla_H(\text{Sh}_n) + o^{(n)} = 0, \quad o^{(n)} = \sum_{\substack{j+k=n+2 \\ 3 \leq j \leq k}} \frac{1}{1 + \delta_{jk}} \{\text{Sh}_j, \text{Sh}_k\}_H.$$

LEMMA 22.15.10 (Euler inversion;). The H -covariant derivative satisfies $\nabla_H = 2E$, where $E = \sum_i x_i \partial / \partial x_i$ is the Euler operator. On homogeneous polynomials of degree n , ∇_H is invertible with $\nabla_H^{-1}(g) = g/(2n)$. In particular, each Sh_n is uniquely determined by the lower-order shadows.

Proof. The covariant derivative is $\nabla_H(f) = \{\text{Sh}_2, f\}_H$ where $\text{Sh}_2 = \sum_{i,j} \kappa_{ij} x_i x_j$. By (22.12),

$$\nabla_H(f) = \sum_{i,j,k,\ell} (\partial_{x_i} \text{Sh}_2) P_{ij} (\partial_{x_j} f) = \sum_{i,j,k} 2\kappa_{ik} x_k P_{ij} \partial_{x_j} f = 2 \sum_{j,k} \delta_{kj} x_k \partial_{x_j} f = 2 \sum_j x_j \partial_{x_j} f = 2E(f),$$

using $\sum_i \kappa_{ik} P_{ij} = \delta_{kj}$. For $f \in \text{Sym}^n$: $E(f) = n f$, so $\nabla_H^{-1}(g) = g/(2n)$. $\square$

Example 22.15.11 ($\mathcal{W}_3$ multi-variable shadow;). The algebra $\mathcal{W}_3$ has two generators: T (conformal weight 2) and W (conformal weight 3), giving deformation coordinates (x_T, x_W) with

$$\kappa = \begin{pmatrix} c/2 & 0 \\ 0 & c/3 \end{pmatrix}, \quad P = \kappa^{-1} = \begin{pmatrix} 2/c & 0 \\ 0 & 3/c \end{pmatrix}.$$

The kappa matrix is diagonal because T and W have different conformal weights, so the leading pole in $\langle T, W \rangle$ vanishes. The gravitational cubic (Theorem ??) gives $\text{Sh}_3 = 2x_T^3 + 3x_T x_W^2$ (coefficient $d_W = 3$ from $T_{(1)}W = 3W$). The unique weight-4 quasi-primary $\Lambda = :TT: - \frac{3}{10} \partial^2 T$ mediates the quartic shadow through three channels:

$$Q_{TTTT} = \frac{10}{c(5c+22)}, \quad Q_{TTWW} = \frac{160}{c(5c+22)^2}, \quad Q_{WWWW} = \frac{2560}{c(5c+22)^3}.$$

The W - W - Λ coupling is $C_{WW,\Lambda} = \alpha = 16/(5c+22)$, extracted from $W_{(1)}W$ at pole order $h_W + h_W - h_\Lambda = 2$. Each pair of W -legs contributes one factor of α , yielding the *denominator filtration*: $2k$ W -legs $\Rightarrow (5c+22)^{1+k}$ in the denominator.

W -charge conservation (the $\mathbb{Z}/2$ symmetry $W \mapsto -W$) forces only even powers of x_W in every Sh_n . Consequently $\text{Sh}_n|_{x_T=0} = 0$ for odd n (Corollary 22.15.22).

The Virasoro subalgebra $\langle T \rangle$ is OPE-closed, so Theorem 22.15.20 gives $\text{Sh}_n(\mathcal{W}_3)|_{x_W=0} = \text{Sh}_n(\text{Vir})$ through all degrees (verified computationally through degree 9).

Remark 22.15.12 (Multi-channel mixing). The degree-6 non-autonomy of the shadow obstruction tower on the diagonal is governed by the propagator variance δ_{mix} (Proposition ??), a Cauchy–Schwarz gap that vanishes at curvature-proportionality loci where the quartic gradient is proportional to the curvature vector. For $\mathcal{W}_3$, the mixing polynomial $P(c) = 25c^2 + 100c - 428$ satisfies $\delta_{\text{mix}} = 1280 P^2 / [c^3(5c+22)^6]$.

PROPOSITION 22.15.13 (Kac-shadow singularity principle;). For a chiral algebra $\mathcal{A}$ in the Virasoro or $\mathcal{W}_N$ family, the denominator of $\text{Sh}_n(\mathcal{A})$, expressed as a rational function of the central charge c , divides a product of Kac determinant factors $\det M_m(c, 0)$ for $m \leq 2 \max_i(h_i)$, where h_i are the conformal weights of the generators. In particular, the singularity locus of the shadow obstruction tower is *independent of the degree n* : it is determined entirely by the quasi-primary exchange spectrum at the input degrees 2, 3, 4. For the Virasoro algebra, the exact denominator bound is $c^{n-3}(5c+22)^{\lfloor (n-2)/2 \rfloor}$ for $n \geq 4$, saturated through degree 11 by the closed forms and verified computationally through degree 32.

Proof. The denominators of Sh_n enter through three mechanisms.

Source (i): propagator poles. The propagator $P = \kappa^{-1}$ has entries rational in c , with poles where $\det \kappa = 0$. For the standard families, $\kappa_{ii} = c/h_i$, so $\det \kappa$ vanishes at $c = 0$.

Source (ii): input shadow denominators. The quartic input Sh_4 involves quasi-primary exchange: $Q_{ijkl} = \sum_{\alpha} C_{ij,\alpha} N_{\alpha}^{-1} C_{kl,\alpha}$, where $N_{\alpha} = \langle \alpha | \alpha \rangle$ is the BPZ norm of the quasi-primary α . The norm N_{α} is a diagonal entry of the Gram matrix $M_h(c, 0)$ at weight $h = h_{\alpha}$, hence vanishes on the zero locus of $\det M_h(c, 0)$.

Source (iii): master-equation iteration. For $n \geq 5$, $\text{Sh}_n = -\nabla_H^{-1}(o^{(n)})$ where $o^{(n)} = \sum \{\text{Sh}_j, \text{Sh}_k\}_H$. By Lemma 22.15.10, ∇_H^{-1} introduces no new denominators (it divides by the integer $2n$). The H -Poisson bracket multiplies existing denominators and introduces the propagator entries P_{ij} . By induction, the denominators of Sh_n are products of those already present in $\text{Sh}_2, \text{Sh}_3, \text{Sh}_4$, and P .

The weight bound follows: the input quasi-primary norms N_{α} involve $\det M_m(c, 0)$ for $m \leq 2 \max_i(h_i)$ (since the exchange quasi-primaries have weight $\leq 2 \max(h_i)$). Each master-equation step preserves this bound. Hence Sh_n has denominator dividing a product of $\det M_m(c, 0)$ for $m \leq 2 \max_i(h_i)$, independent of n .

Conversely, at a Kac zero where a quasi-primary norm N_{α} vanishes, the exchange propagator N_{α}^{-1} diverges and creates a genuine pole of Sh_n whenever the corresponding contact coupling does not vanish on the chosen lane. $\square$

TABLE 22.1: Shadow denominators and their Kac-determinant origins. Every denominator factor is a Kac zero; the converse holds at weights $\leq 2 \max(h_i)$.

Shadow	Denominator	Kac origin	Weight
Q_{TTTT}^{Vir}	$c(5c+22)$	$\det M_4(c, 0)$	4
$Q_{TTWW}^{\mathcal{W}_3}$	$c(5c+22)^2$	$[\det M_4(c, 0)]^2$	4
$Q_{WWWW}^{\mathcal{W}_3}$	$c(5c+22)^3$	$[\det M_4(c, 0)]^3$	4
$Q_{T_4T_4}^{\mathcal{W}_4}$	c	$N_{\mathcal{W}_4} = c/4$	4
C_{333}^2	$5c(c+24)(5c+22)$	$\det M_4 \cdot \det M_6$	4, 6

Remark 22.15.14 (Two-propagator quartic in $\mathcal{W}_4$). In $\mathcal{W}_4 = \mathcal{W}(\mathfrak{sl}_4, f_{\text{prin}})$, the generator W_4 has conformal weight 4, coinciding with $h_\Lambda = 4$. The weight-4 quasi-primary space is therefore 2-dimensional, spanned by Λ and W_4 itself. The quartic exchange formula acquires two propagator channels:

$$Q_{ijkl} = \frac{C_{ij,\Lambda} C_{kl,\Lambda}}{N_\Lambda} + \frac{C_{ij,W_4} C_{kl,W_4}}{N_{W_4}}.$$

The Λ -channel has denominator containing $(5c + 22)$ (the level-4 Kac factor); the W_4 -channel has denominator $c/4$ only. In the (T, W_4) -mixed channel, $Q_{T_4 T_4} = C_{T W_4, W_4}^2 / N_{W_4} = 64/c$, which is *regular* at $c = -22/5$ (the Lee–Yang point where Λ decouples). This breaks the uniform denominator filtration of Proposition ?? and shows that the singularity structure of Sh_4 depends on the *number* of quasi-primary mediators, not just their Kac factors.

THEOREM 22.15.15 (*DS shadow depth increase;*). Drinfeld–Sokolov reduction increases shadow depth from class L to class M . Specifically:

- (i) *Principal*: $V_k(\mathfrak{sl}_3)$ is class L ($r_{\max} = 3$) but $\mathcal{W}_3 = \text{DS}_{\text{prin}}(V_k(\mathfrak{sl}_3))$ is class M ($r_{\max} = \infty$).
- (ii) *Non-principal*: the Bershadsky–Polyakov algebra $\mathcal{BP}_k = \text{DS}_{(2,1)}(V_k(\mathfrak{sl}_3))$ is class M ($r_{\max} = \infty$): $\text{Sh}_4 = 5(k+3)^2 / [8(12k^2+23k+9)(15k^2+26k+3)]$ is nonzero at generic k (Computation 22.15.19).

Proof. The universal affine vertex algebra $V_k(\mathfrak{sl}_3)$ has quadratic OPE (the current–current OPE $J^a(z)J^b(w) \sim k\delta^{ab}/(z-w)^2 + f_c^{ab}J^c(w)/(z-w)$ is purely linear in the currents). By the PBW universality criterion (Proposition 14.1.37), $V_k(\mathfrak{sl}_3)$ is chirally Koszul, and by the shadow-formality identification (Proposition ??), the shadow obstruction tower terminates at degree 3: the cubic shadow $\mathfrak{C}$ is the Lie bracket, and all higher obstructions vanish. Thus $V_k(\mathfrak{sl}_3)$ is class L .

Principal Drinfeld–Sokolov reduction introduces the composite field $\Lambda = (TT) - \frac{3}{10}\partial^2 T$ into the W - W OPE at pole order 2: the coefficient $\alpha = 16/(5c + 22)$ is nonzero for generic c . This makes the OPE non-quadratic and produces a nonvanishing quartic shadow $Q_{TTTT} = 10/[c(5c + 22)] \neq 0$ (Theorem ??). The quintic obstruction is $o^{(5)} = \{\text{Sh}_3, \text{Sh}_4\}_H$; on the T -line this reduces to the Virasoro quintic $o^{(5)}|_{x_W=0} = 480/[c^2(5c + 22)] \cdot x_T^5 \neq 0$ (Theorem 22.9.6). By shadow subalgebra autonomy (Theorem 22.15.20), the Virasoro sub-tower embeds into the $\mathcal{W}_3$ tower, so a nonvanishing Virasoro quintic implies a nonvanishing $\mathcal{W}_3$ quintic. Hence $r_{\max}(\mathcal{W}_3) = \infty$. $\square$

Remark 22.15.16. Theorem 22.15.15 shows that DS reduction does *not* preserve shadow depth class: the functor $\text{DS}: \text{class } L \rightarrow \text{class } M$ is not monotone. This is consistent with the general principle that DS reduction trades generators for relations; the output has fewer generators but more complicated OPE, and it is the OPE complexity that controls shadow depth (Definition ??).

Remark 22.15.17 (Geometric origin of shadow depth increase under DS). The depth increase $L \rightarrow M$ under DS reduction has a geometric explanation through the Slodowy-slice localization principle (Remark ??).

The affine Kac–Moody algebra $\widehat{\mathfrak{g}}_k$ lives on the *linear* space $J_\infty(\mathfrak{g}^*)$: its OPE is a Lie bracket (binary), so the shadow obstruction tower terminates at degree 3 (class L). DS reduction restricts to $J_\infty(S_f)$, the arc space of the Slodowy slice $S_f = f + \mathfrak{g}^e$. As a submanifold of $\mathfrak{g}^*$, the slice S_f is an affine subspace (a translate of the linear space $\mathfrak{g}^e$), so its *extrinsic geometry is trivially flat*. The nonlinearity arises instead in the *Poisson bracket*: the Kirillov–Kostant bracket on $\mathfrak{g}^*$ is linear, but its restriction to S_f via the Dirac bracket (Hamiltonian reduction along the coadjoint orbit) acquires higher-order terms, because the constraint algebra $\mathfrak{g}/\mathfrak{g}^e$ introduces denominators and cross terms when eliminated. At the arc-space

level, the Dirac bracket on $J_\infty(S_f)$ has a Taylor expansion in the $\mathcal{W}$ -algebra generators whose r -th order terms are precisely the degree- r shadow data:

- (i) The *cubic shadow* of $\mathcal{W}_N$ records the leading nonlinearity of the Dirac bracket on S_f : the binary Lie bracket on $\mathfrak{g}^*$ restricts to a bracket on S_f that has cubic corrections from the eliminated $\mathfrak{n}_+$ -directions.
- (ii) The *quartic contact coefficient* $Q_{\text{Vir}}^{\text{contact}} = 10/[c(5c + 22)]$ detects the degree-4 shadow of the Dirac bracket expansion: the iterated composition of the quadratic Virasoro OPE ($T \cdot T \sim T^2$) in the bar complex generates quartic terms at degree 4 that have no counterpart in the linear KM bracket on $\mathfrak{g}^*$. This is a bar-complex phenomenon: the quartic contact coefficient measures the obstruction to extending the degree-3 shadow to degree 4, not a direct correction to the binary bracket itself.
- (iii) Higher shadows Sh_r for $r \geq 5$ record the r -th order Dirac bracket structure on $J_\infty(S_f)$. The quintic obstruction $o_{\text{Vir}}^{(5)} \neq 0$ (Theorem 22.9.6) says the Poisson algebra on $J_\infty(S_{f_{\text{prin}}})$ for $\mathfrak{sl}_2$ has genuine fifth-order nonlinearity in its Dirac bracket, even though the slice itself is a one-dimensional affine subspace of $\mathfrak{sl}_2^*$.

Scope of the geometric explanation. The Slodowy-slice localization principle explains the depth increase $L \rightarrow M$ specifically for $\mathcal{W}$ -algebras obtained by DS reduction. It does *not* explain the shadow depth of the primitive archetypes in classes G , L , and C : Heisenberg (class G), Kac–Moody (class L), and $\beta\gamma$ (class C) are fundamental families that do not arise from DS reduction. Their shadow depths are controlled by algebraic properties (scalar OPE (class G), the Jacobi identity (class L), and rank-one abelian rigidity (class C , Corollary 22.5.16)), not by Slodowy-slice geometry.

What the geometric principle *does* explain is the passage from class L to class M : the DS functor performs Hamiltonian reduction from $J_\infty(\mathfrak{g}^*)$ to $J_\infty(S_f)$, replacing the linear Kirillov–Kostant bracket with the nonlinear Dirac bracket on the slice. The shadow obstruction tower of the $\mathcal{W}$ -algebra is the Taylor expansion of this Dirac bracket, and DS reduction is the localization functor that creates the infinite tower from the finite one.

Remark 22.15.18 (DS ghost system and shadow consistency). The central charge formula $c_{\mathcal{W}_N}(k) = (N-1)[1 - N(N+1)(t-1)^2/t]$ (with $t = k+N$) and the Sugawara formula $c_{\hat{\mathfrak{sl}}_N}(k) = (N^2-1)k/(k+N)$ give a ghost central charge $c_{\text{ghosts}}(k) = c_{\hat{\mathfrak{sl}}_N} - c_{\mathcal{W}_N}$ that is level-dependent in general. At the shadow level, the kappa relation $\kappa(\mathcal{W}_N)(c(k)) + \kappa_{\text{ghosts}}(k) = \kappa(\hat{\mathfrak{sl}}_N)(k)$ is satisfied identically for all N ; the ghost kappa is level-dependent in general (unlike the ghost central charge for a fixed algebra). At the quartic level, $Q_{\hat{\mathfrak{sl}}_N} = 0$ (Jacobi) while $Q_{\mathcal{W}_N} \neq 0$: the quartic is *created* by the ghost sector, not transported. These are *consistency checks* between two independently computed shadow obstruction towers, not a proof that DS reduction commutes with the shadow obstruction tower as a functor. The depth-increase obstruction (Theorem 22.15.15) shows that a naive functorial statement $\text{DS}(\Theta_{\hat{\mathfrak{g}}}) = \Theta_{\mathcal{W}(\hat{\mathfrak{g}})}$ cannot hold at the level of shadow obstruction towers; the correct formulation must involve the BRST cohomology of the full current-plus-ghost system.

The Feigin–Frenkel dual level for $\mathcal{W}_N$ is $k' = -k - 2N$ (i.e. $t \mapsto -t$ with $t = k+N$), satisfying $c(k) + c(k') = K_N$ where $K_N = 2(N-1)(2N^2+2N+1)$ is the Koszul conductor.

COMPUTATION 22.15.19 (Bershadsky–Polyakov shadow obstruction tower). The Bershadsky–Polyakov algebra $\mathcal{BP}_k = \mathcal{W}^k(\mathfrak{sl}_3, f_{(2,1)})$ has standard central charge $c_{\text{BP}}(k) = -(2k+3)(3k+1)/(k+$

3) with central-charge conductor $K_{\text{BP}}^c = 50$; the tower below is computed on the shifted conformal-vector scalar $c(k) = -2(12k^2 + 23k + 9)/(k + 3) = 2 - 24(k + 1)^2/(k + 3)$, whose reflection sum is $K^{\text{shift}} = 196$ (a separate convention from the standard conductor), and on the T -line:

r	$\text{Sh}_r^{T\text{-line}}(\mathcal{BP}_k)$
2	$-(12k^2 + 23k + 9)/[k + 3]$
3	2
4	$5(k + 3)^2/[8(12k^2 + 23k + 9)(15k^2 + 26k + 3)]$
5	$3(k + 3)^3/[2(12k^2 + 23k + 9)^2(15k^2 + 26k + 3)]$

The σ -invariant: $\Delta^{(2)} = 98 = K^{\text{shift}}/2$, $\Delta^{(3)} = 4$ (universal), $\Delta^{(4)}$ level-dependent with poles at $c = 0$, $c = 196$, $c = -22/5$, $c = 1002/5$. The J -line (residual $U(1)$) has class G (depth 2): the current is abelian.

THEOREM 22.15.20 (*Shadow subalgebra autonomy*;). Let $B \subset \mathcal{A}$ be a conformal sub-VOA satisfying:

- (i) the kappa matrix is block-diagonal between the B -generators and the complementary generators: $\kappa_{ij} = 0$ whenever ϕ_i is a B -generator and ϕ_j is not (or vice versa);
- (ii) B is *OPE-closed*: for every $n \geq 0$ and every pair of B -generators ϕ_i, ϕ_j , the quasi-primary projection of $\phi_i(n)\phi_j$ lies in the vacuum module of B . Equivalently, $H_{\text{cyc}}^2(B)$ is a sub-dg-Lie-algebra of the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.

Then

$$\text{Sh}_n(\mathcal{A})|_{x_{\mathcal{A} \setminus B} = 0} = \text{Sh}_n(B) \quad \text{for all } n \geq 2.$$

Proof. Condition (i) implies block-diagonality of the propagator $P = \kappa^{-1}$: the B -variables and complementary variables decouple in the H -Poisson bracket (22.12). Concretely,

$$\{f, g\}_H|_{x_{\mathcal{A} \setminus B} = 0} = \{f|_{x_{\mathcal{A} \setminus B} = 0}, g|_{x_{\mathcal{A} \setminus B} = 0}\}_{H_B},$$

where $\{-, -\}_{H_B}$ is the H -Poisson bracket of B (with propagator $P_B = \kappa_B^{-1}$). The input data also restricts: $\text{Sh}_2(\mathcal{A})|_{x_{\mathcal{A} \setminus B} = 0} = \text{Sh}_2(B)$ (by block-diagonality of κ), and $\text{Sh}_3(\mathcal{A})|_{x_{\mathcal{A} \setminus B} = 0} = \text{Sh}_3(B)$ (the gravitational cubic tensor from Theorem ?? restricts correctly, and condition (ii) ensures that any non-gravitational cubic coupling C_{ijk} with all B -indices does not receive contributions from quasi-primaries outside B).

For the quartic input Sh_4 : the quasi-primary exchange formula $Q_{ijkl} = \sum_{\alpha} C_{ij, \alpha} N_{\alpha}^{-1} C_{kl, \alpha}$ sums over *all* weight-4 quasi-primaries α of $\mathcal{A}$. Condition (ii) ensures that any $\alpha \notin B$ has $C_{ij, \alpha} = 0$ for all B -indices i, j , since the OPE $\phi_i \phi_j$ cannot produce quasi-primaries outside the B module. Hence Sh_4 restricts correctly.

Since the displayed multivariable master equation determines Sh_n uniquely from lower-order data (by Lemma 22.15.10), and both the bracket and the input restrict compatibly, the claim follows by induction on n . $\square$

Remark 22.15.21 (*OPE-closedness is necessary*). Condition (ii) cannot be dropped. In $\mathcal{W}_4 = \mathcal{W}(\mathfrak{sl}_4, f_{\text{prin}})$, the sub-VOA $B = \langle T, W_3 \rangle$ satisfies (i) but not (ii): the OPE $W_{3(1)}W_3$ produces $c_{334}W_4$ (the coupling through the weight-4 generator outside B). The W_4 -exchange contributes $4c_{334}^2/c$ to $\text{Sh}_4(\mathcal{W}_4)|_{x_4=0}$ in the pure x_3^+ channel, so the restriction exceeds $\text{Sh}_4(\mathcal{W}_3)$ by this amount. Only the Virasoro subalgebra $\langle T \rangle$ is both block-diagonal and OPE-closed in $\mathcal{W}_N$ for all N .

COROLLARY 22.15.22 (*W-line alternating vanishing;*). For $\mathcal{W}_3$, $\text{Sh}_n|_{x_T=0} = 0$ for all odd n . The pure W -sector shadow is nonzero only at even degrees.

Proof. The $\mathbb{Z}/2$ automorphism $W \mapsto -W$ of $\mathcal{W}_3$ acts on the deformation space as $x_W \mapsto -x_W$, $x_T \mapsto x_T$. Equivariance of the master equation forces every Sh_n to be $\mathbb{Z}/2$ -invariant: each monomial $x_T^a x_W^b$ in Sh_n has b even. Since $a + b = n$, the exponent a has the same parity as n . Restricting to $x_T = 0$ retains only the $a = 0$ term, which requires n to be even. For odd n , no $a = 0$ monomial exists, so $\text{Sh}_n|_{x_T=0} = 0$.

The even-degree restrictions are generically nonzero: $\text{Sh}_4|_{x_T=0} = Q_{WWWW} x_W^4 \neq 0$ (the displayed $\mathcal{W}_3$ quartic-channel computation), and similarly $\text{Sh}_6|_{x_T=0} \neq 0$ (verified computationally). $\square$

THEOREM 22.15.23 (*Shadow obstruction tower as cyclic L_∞ MC potential;*). Let $(\ell_k^{\text{tr}})_{k \geq 1}$ denote the transferred L_∞ operations on $H_{\text{cyc}}^2(\mathcal{A})$ (via the homotopy transfer theorem applied to the modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$). The shadow coefficients are the cyclic invariants of the transferred operations:

$$\text{Sh}_r = \langle \eta, \ell_{r-1}^{\text{tr}}(\eta, \dots, \eta) \rangle_{\text{cyc}},$$

and the shadow potential $S_{\mathcal{A}}(x) = \sum_{r \geq 2} \text{Sh}_r x^r / r!$ is the cyclic L_∞ Maurer–Cartan potential restricted to the primary line $\Theta = x \cdot \eta$:

$$S_{\mathcal{A}}(x) = W(x \cdot \eta), \quad W(\Theta) = \sum_{k \geq 1} \frac{1}{(k+1)!} \langle \Theta, \ell_k^{\text{tr}}(\Theta, \dots, \Theta) \rangle.$$

The critical equation $dS_{\mathcal{A}}/dx = 0$ is the Maurer–Cartan equation of the transferred L_∞ structure, and its critical locus models the full MC moduli by the Kontsevich–Soibelman homotopy transfer equivalence $\text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}}) \simeq \text{MC}(H^*(\mathfrak{g}_{\mathcal{A}}^{\text{mod}}))$.

This potential coincides with the complementarity action of Definition ?? restricted to the primary line and genus 0. At genus 0, the MC equation on H_{cyc}^2 implies associativity of the shadow quantum product, recovering the WDVV equation of the shadow CohFT.

Proof. Expand $W(x\eta) = \sum_{k \geq 1} \frac{x^{k+1}}{(k+1)!} \langle \eta, \ell_k^{\text{tr}}(\eta, \dots, \eta) \rangle = \sum_{r \geq 2} \frac{x^r}{r!} \text{Sh}_r$, identifying $\text{Sh}_r = \langle \eta, \ell_{r-1}^{\text{tr}}(\eta, \dots, \eta) \rangle$. The curvature $\text{Sh}_2 = \langle \eta, \ell_1^{\text{tr}}(\eta) \rangle = \langle \eta, d^{\text{tr}}\eta \rangle = \kappa$ recovers the Hessian; the cubic $\text{Sh}_3 = \langle \eta, \ell_2^{\text{tr}}(\eta, \eta) \rangle$ recovers the Lie bracket contribution; the quartic $\text{Sh}_4 = \langle \eta, \ell_3^{\text{tr}}(\eta, \eta, \eta) \rangle$ recovers the Λ -exchange (the homotopy-transferred ternary operation). The identification with the complementarity action follows from the genus-0 specialization: the complementarity action $\mathfrak{S}_{\mathcal{A}}$ (Definition ??) evaluates the modular MC element $\Theta_{\mathcal{A}}$ on the cyclic deformation complex; at genus 0 and on the primary line, this reduces to $W(x \cdot \eta)$ by the bar-intrinsic construction (Theorem ??). $\square$

PROPOSITION 22.15.24 (*Shadow potential convergence;*). For the Virasoro algebra at central charge $c \notin \{0, -22/5\}$:

- (i) The shadow obstruction tower $\sum_{r \geq 2} \text{Sh}_r t^r$ has finite convergence radius. By the closed form $H(t) = t^2 \sqrt{Q_L(t)}$ (Theorem ??), the radius equals the distance from the origin to the nearest zero of $Q_L(t)$.
- (ii) The shadow potential $S_{\text{vir}}(x) = \sum_{r \geq 2} \text{Sh}_r x^r / r!$ is an entire function of x : since $H(t) = t^2 \sqrt{Q_L(t)}$ is algebraic with convergence radius $R > 0$, the Cauchy estimate gives $|\text{Sh}_r| \leq M/R^r$ for constants $M, R > 0$ depending on c . Then $|\text{Sh}_r/r!| \leq M/(R^r \cdot r!)$ decays super-exponentially, giving infinite convergence radius by the ratio test.

- (iii) At the Kac zeros $c = 0$ and $c = -22/5$, the convergence radii collapse: $P = \kappa^{-1}$ diverges at $c = 0$, and Sh_4 has a pole at $c = -22/5$.

Proof. Part (i): by Theorem ??, the shadow generating function satisfies the algebraic relation $H(t)^2 = t^4 Q_L(t)$, so $H(t) = t^2 \sqrt{Q_L(t)}$ is an algebraic function of t . Its singularities are precisely the zeros of $Q_L(t)$ (branch points of the square root). The convergence radius of the Taylor series of H equals the distance to the nearest singularity. Each shadow coefficient is a rational function of c with denominator $c^{a_r} (5c + 22)^{b_r}$ (Proposition 22.15.13); for fixed $c \notin \{0, -22/5\}$ the zeros of Q_L are at finite nonzero distance from the origin, giving $R > 0$.

Part (ii): by the Cauchy integral formula for Taylor coefficients of a function analytic on a disk of radius R , $|\text{Sh}_r| \leq \sup_{|t|=R'} |H(t)| / (R')^r$ for any $R' < R$. This is a geometric bound $|\text{Sh}_r| \leq M \cdot (1/R')^r$. The factorial in the potential kills this geometric growth: $|\text{Sh}_r/r!| \leq M / (R'^r \cdot r!) \rightarrow 0$ super-exponentially.

Part (iii): at $c = 0$, $\kappa = 0$ and Q_L degenerates (its leading coefficient vanishes); at $c = -22/5$, the Kac determinant vanishes at level 4 and Sh_4 has a pole. $\square$

Remark 22.15.25 (Shadow discriminant instability). The discriminant of the truncated critical equation (the locus in c where critical points of $S_{\mathcal{A}}^{\leq N}$ collide) changes at every truncation order N . At degree 4 the discriminant numerator is $(15c + 56)$; at degree 5 it becomes $(30c + 133)(90c + 271)$; at degrees 6 and 7 it is an irreducible polynomial of degree 4 and 7 respectively. The zeros of the truncated discriminant cluster toward the Kac zeros $c = 0$ and $c = -22/5$ as $N \rightarrow \infty$, consistent with the shadow potential being entire: the full discriminant of an entire function is an infinite product whose Taylor approximants have migrating roots.

The *denominators* of the shadow discriminant (the pole locus) are stable: always $c^{N(N-1)/2} (5c + 22)^{f(N)}$, in agreement with Proposition 22.15.13: the shadow pole structure is a genuine invariant controlled by the Kac determinant.

22.15.4 The MC moduli curve

The shadow potential $S_{\mathcal{A}}(x; c)$ (Theorem 22.15.23) is entire in x for generic c (Proposition 22.15.24). Its critical locus is the *MC moduli curve*.

Definition 22.15.26 (MC moduli curve;). For a chiral algebra $\mathcal{A}$ of shadow class $\mathcal{M}$ with $\dim H_{\text{cyc}}^2 = 1$, the *MC moduli curve* is the analytic subset

$$\mathcal{M}_{\mathcal{A}} := \{(x, c) \in \mathbb{C} \times \mathbb{C}^* : (\partial S_{\mathcal{A}} / \partial x)(x; c) = 0, x \neq 0\},$$

equipped with the projection $\pi: \mathcal{M}_{\mathcal{A}} \rightarrow \mathbb{C}_c^*$ to the central-charge line (punctured at the Kac locus $K = \{c \in \mathbb{C} : \det \kappa(c) = 0\}$). The fiber $\pi^{-1}(c)$ is the set of nontrivial Maurer–Cartan solutions at central charge c .

THEOREM 22.15.27 (MC moduli curve structure;). Let $\mathcal{A}$ be a chiral algebra of shadow class $\mathcal{M}$ with $\dim H_{\text{cyc}}^2 = 1$. The MC moduli curve satisfies:

- (a) *Discrete fibers.* For each $c \notin K$, the fiber $\pi^{-1}(c)$ is a discrete (countable) subset of $\mathbb{C}_x^*$.
- (b) *Branch point accumulation.* The branch locus $B \subset \mathbb{C}_c^*$ of π accumulates at each point of the Kac locus K . In the degree- N truncation, the number of branch points grows linearly with N .

- (c) *Kac locus = essential singularity.* At each Kac zero $c_o \in K$, the MC moduli curve has an essential singularity: the shadow coefficients $\text{Sh}_n(c)$ have poles at c_o of order growing with n , and the monodromy of π around c_o involves infinitely many Picard–Lefschetz transpositions (one per accumulating branch point).
- (d) *Stable pole structure.* The shadow coefficients $\text{Sh}_n(c)$ are rational functions of c with poles only at the Kac locus K . The pole orders at each $c_o \in K$ grow linearly in n (Proposition 22.15.13).
- (e) *Unstable discriminant.* The discriminant $\Delta_N(c) = c^{a(N)}(5c + 22)^{b(N)}P_N(c)$ of the degree- N critical equation has stable factors $\{c, 5c + 22\}$ (Kac determinant factors) and an unstable factor P_N whose roots cluster toward the Kac zeros as $N \rightarrow \infty$.

Proof. Part (a) follows from the entirety of $S_{\mathcal{A}}$ in x : the derivative $\partial S/\partial x$ is a nonconstant entire function, hence has discrete zero set.

Part (b): the degree- N truncation replaces $\partial S/\partial x$ by a polynomial of degree $N - 1$ in x . The discriminant of this polynomial, computed explicitly for $N = 4, 5, 6, 7$, has the stated factorization with $\deg P_N$ growing linearly. The roots of P_N cluster toward $c = -22/5$ (the weight-4 Kac zero), as verified numerically.

Part (c): at a Kac zero c_o , the shadow coefficient $\text{Sh}_n(c_o)$ has a pole of order linear in n (from the iterated propagator $P = \kappa^{-1}$). The shadow potential $S(x; c_o)$ is therefore a formal (not convergent) power series, and the MC moduli curve has no well-defined fiber over c_o . The infinitely many branch points accumulating at c_o (from part (b)) generate infinitely many Picard–Lefschetz transpositions in the monodromy group.

Part (d) is Proposition 22.15.13.

Part (e): direct computation at $N = 4, 5, 6, 7$. □

THEOREM 22.15.28 (*Hadamard factorization of the MC potential;*). For a class $\mathcal{M}$ algebra $\mathcal{A}$ with $\dim H_{\text{cyc}}^2 = 1$ and central charge $c \notin K$, the derivative of the shadow potential has the Hadamard product representation

$$\frac{\partial S_{\mathcal{A}}}{\partial x}(x; c) = e^{ax+b} \cdot x \cdot \prod_{k=1}^{\infty} \left(1 - \frac{x}{x_k(c)}\right) e^{x/x_k(c)},$$

where $\{x_k(c)\}_{k \geq 1}$ are the nontrivial MC solutions, $b = \log(\kappa/2)$, and $a = -\sum_k 1/x_k(c)$. The product converges absolutely and uniformly on compact subsets of $\mathbb{C}_x$. The shadow potential has order $\rho = 1$ (the shadow coefficients grow geometrically as $|\text{Sh}_r| \sim (6/|c|)^r/r$, and the factorial in $r!$ reduces this to order 1). The Hadamard genus is therefore at most 1, and Weierstrass primary factors $E_1(u) = (1 - u)e^u$ ensure convergence.

Proof. The shadow potential $S_{\mathcal{A}}(x; c)$ is entire of order 1. The raw shadow coefficients satisfy $|\text{Sh}_r| \sim (2/r)(6/|c|)^{r-2}$ (Proposition 22.15.24), so $|\text{Sh}_r/r!| \sim (6e/|c|r)^r/r^{3/2}$ by Stirling, giving $\rho = \limsup_{r \rightarrow \infty} r \log r / (-\log |\text{Sh}_r/r!|) = 1$. By the Hadamard factorization theorem for entire functions of order 1, $\partial S/\partial x = e^{ax+b} x \prod_k E_1(x/x_k)$ where $E_1(u) = (1 - u)e^u$ is the Weierstrass primary factor of genus 1 and a, b are constants. The leading coefficient $e^b = \kappa/2$ is determined by $\partial^2 S/\partial x^2|_{x=0} = \kappa$ (Lemma 22.15.10), and $a = -\sum_k 1/x_k(c)$ by the standard Hadamard normalization. □

COROLLARY 22.15.29 (*MC solution counting*). The number $N(R; c)$ of nontrivial MC solutions with $|x_k(c)| \leq R$ satisfies the Jensen estimate

$$N(R; c) \leq \frac{1}{\log 2} \log \frac{\max_{|x|=2R} |\partial S / \partial x|}{|\kappa/2| \cdot R}.$$

Since $\partial S / \partial x$ has order 1, $N(R; c) = O(R)$ for fixed $c \notin K$: the MC solutions have at most linear density. They accumulate only at $x = \infty$, not at any finite point.

Proof. Apply Jensen's formula to the entire function $\partial S / \partial x$ on the disk of radius $2R$. The zero at the origin is removed by the factor $(\kappa/2)x$, and the order-one Hadamard factorisation of Theorem 22.15.28 gives linear growth of the Jensen integral. Thus the zero-counting function is $O(R)$. $\square$

REMARK 22.15.30 (*Trivial isomonodromy at rank 1*). The logarithmic derivative $(\partial^2 S / \partial x^2) / (\partial S / \partial x) = 1/x + \sum_k 1/(x - x_k(c))$ defines a meromorphic connection on $\mathbb{C}_x$ with simple poles at $x = 0$ and $x = x_k(c)$, all with residue 1. Since the residues are *scalar* (rank 1: the deformation space is one-dimensional), the commutators $[A_i, A_j] = 0$ vanish, and the Schlesinger system reduces to $dA_k/dc = 0$ (trivially satisfied). The connection is therefore *trivially isomonodromic* as c varies: the monodromy is the identity at each pole, independent of the positions $x_k(c)$.

At rank ≥ 2 (e.g., $\mathcal{W}_3$ with $\dim H_{\text{cyc}}^2 = 2$), the residues are matrices and the Schlesinger equations give nontrivial constraints on the variation of MC solutions with c . The isomonodromic structure at rank 2 is the subject of Conjecture 22.15.31.

CONJECTURE 22.15.31 (*Rank-2 isomonodromic structure*). For $\mathcal{W}_3$ with $\dim H_{\text{cyc}}^2 = 2$, the MC moduli (the critical locus of $S_{\mathcal{W}_3}$ on the two-dimensional deformation space (x_T, x_W) , viewed as a family of point configurations in $\mathbb{C}^2$ parameterized by c) satisfies the Schlesinger system for the KZ connection with 2×2 Casimir $\Omega = \text{diag}(\kappa_T, \kappa_W) = \text{diag}(c/2, c/3)$ (whose trace is $\kappa(\mathcal{W}_3) = 5c/6$).

BRANCH-LINE REDUCTIONS, PRIMITIVE MODULAR CHARACTERISTICS, AND THE INTRINSIC INVARIANT LADDER

The full modular Maurer–Cartan element $\Theta_{\mathcal{A}}$ lives in an infinite-dimensional convolution algebra. A *branch-line reduction* restricts $\Theta_{\mathcal{A}}$ to a configuration of minimal complexity (two-point branch lines, rank-one spectral sectors, genus-2 transparency windows) and proves structural theorems inside the resulting finite-dimensional quotient.

The *primitive modular characteristics* are the irreducible components of $\Theta_{\mathcal{A}}$ under the clutching maps of $\overline{\mathcal{M}}_{g,n}$: they are to the shadow obstruction tower what primitive elements are to a Hopf algebra. The intrinsic invariant ladder

$$\kappa(\mathcal{A}) \rightsquigarrow \Delta_{\mathcal{A}}(x) \rightsquigarrow \Theta_{\mathcal{A}}.$$

The load-bearing theorems are the scalar modular characteristic (Theorem ??), the spectral characteristic (Theorem ??), and the universal modular Maurer–Cartan theorem (Theorems ?? and ??). The purpose of the appendix is not to replace the full MC2 package by a smaller surrogate. It is to extract exact finite-dimensional quotients of that package and prove structural theorems inside those quotients. Those quotient theorems clarify which parts of the higher-genus story are already forced by the scalar and spectral shadows, and which parts still belong to the genuinely infinite cyclic L_{∞} geometry.

Two corrections organize the whole discussion. First, the natural intrinsic ladder is κ, Δ, Θ , not a comparison theorem such as Drinfeld–Kohno. The spectral discriminant is the first non-scalar invariant built purely from the modular Koszul package, whereas DK-type comparison theorems sit later in the theorem graph. Second, the universal class $\Theta_{\mathcal{A}}$ is available by Theorems ?? and ??. For one-channel families, the minimal class lies on a single line $\eta \otimes \Gamma_{\mathcal{A}}$; on the proved uniform-weight lane (Definition ??) this further specializes to $\kappa(\mathcal{A})\eta \otimes \Lambda$. The non-scalar content is organized by the shadow obstruction tower (Definition ??), with finite-order shadows proved through degree 4. The new constructions below therefore have a precise role: they are shadow and quotient theorems *inside* the proved finite-order modular package.

What is new here. The appendix proves five families of results.

- (i) It constructs the scalar Maurer–Cartan skeleton and the spectral cumulant hierarchy as canonical logarithmic shadows of $\Theta_{\mathcal{A}}$.
- (ii) It proves an abstract filtered obstruction theorem showing that the first nontrivial correction to a scalar shadow is necessarily traceless and quadratic.
- (iii) It proves that the positive-weight Virasoro sector is contractible in the effective L_0 -model, so the first non-scalar content is forced into finite reduced spectral sectors.
- (iv) It proves a genus-2 transparency theorem for every rank-two branch-line quotient with scalar square.

- (v) It computes the first primitive traceless coefficients in the pure branch and top-Hodge primitive quotients, including the universal genus-3 constant 7 on the shared $\widehat{\mathfrak{sl}}_2/\text{Virasoro}/\beta\gamma$ spectral sheet.

Construction 23.0.1 (Branch lines as shadow depth loci). Branch-line reductions are the geometric loci where the shadow depth $r_{\max}(\mathcal{A})$ transitions between archetype classes. The weight-changing line in the $\beta\gamma$ system (class C, $r_{\max} = 4$) degenerates to the Heisenberg line (class G, $r_{\max} = 2$) when the quartic contact invariant $\mu_{\beta\gamma}$ vanishes (Corollary 22.5.16). The general mechanism has three layers.

- (i) The shadow depth $r_{\max}(\mathcal{A})$ is the smallest integer r such that the obstruction class $o_{r+1}(\mathcal{A}) \in H^2(F^{r+1}\mathfrak{g}/F^{r+2}\mathfrak{g}, d_2)$ vanishes identically, or ∞ if no such r exists (Definition ??). It classifies chiral algebras into four archetype classes: G ($r_{\max} = 2$, Gaussian), L ($r_{\max} = 3$, Lie/tree), C ($r_{\max} = 4$, contact/quartic), M ($r_{\max} = \infty$, mixed).
- (ii) A branch line is a one-parameter family in which the shadow depth drops: there exists a critical value of the spectral parameter at which $o_{r_{\max}}(\mathcal{A})$ becomes cohomologous to zero, reducing the effective shadow depth by at least one. The primitive modular characteristics are the irreducible components of $\Theta_{\mathcal{A}}$ that survive on the branch line; those that vanish are precisely the obstructions that the branch-line reduction removes.
- (iii) For the $\beta\gamma$ system, the weight-changing branch line is the locus where the quartic contact invariant $\mu_{\beta\gamma} = \langle \eta, m_3(\eta, \eta, \eta) \rangle$ vanishes. At this locus the shadow obstruction tower truncates from degree 4 to degree 2, and the residual modular characteristic is the scalar $\kappa(\beta\gamma) = 1$, matching the Heisenberg value at rank 1. This is the content of the rank-one abelian rigidity argument of Corollary 22.5.16.

23.1 THE INVARIANT LADDER FROM FIRST PRINCIPLES

The modular characteristic hierarchy has three logarithmic levels and three different kinds of geometry.

- (i) The scalar level is governed by the single number $\kappa(\mathcal{A})$ and the tautological line $\kappa(\mathcal{A})\lambda_g$ on $\overline{\mathcal{M}}_g$ (Theorem ??).
- (ii) The spectral level is governed by the spectral discriminant $\Delta_{\mathcal{A}}(x)$, equivalently by the branch transport operator in the finite-rank spectral model (Theorem ??).
- (iii) The full level is governed by the cyclic deformation complex $\text{Def}_{\text{cyc}}(\mathcal{A})$ and the universal Maurer–Cartan class $\Theta_{\mathcal{A}}$ (Theorems ?? and ??).

The point of view of this appendix is that the scalar and spectral levels are not auxiliary notational devices. They are exact quotient faces of $\Theta_{\mathcal{A}}$, and they can therefore be studied as mathematical objects in their own right.

Definition 23.1.1 (Scalar Maurer–Cartan skeleton). Let $\mathcal{A}$ be a modular Koszul chiral algebra. Define the abelian dg Lie algebra

$$\mathfrak{s}_{\mathcal{A}} := \prod_{g \geq 1} \mathbf{Q} u_g, \quad |u_g| = 1 - 2g, \quad d = 0, \quad [-, -] = 0.$$

The *scalar Maurer–Cartan skeleton* of $\mathcal{A}$ is the element

$$\Theta_{\mathcal{A}}^{\text{sc}} := \sum_{g \geq 1} \kappa(\mathcal{A}) u_g \otimes \lambda_g \in \mathfrak{s}_{\mathcal{A}} \widehat{\otimes} \prod_{g \geq 1} H^{2g}(\overline{\mathcal{M}}_g, \mathbf{Q}). \quad (23.1)$$

PROPOSITION 23.1.2 (*The scalar shadow is an abelian MC element;*). For every modular Koszul chiral algebra $\mathcal{A}$, the class $\Theta_{\mathcal{A}}^{\text{sc}}$ of (23.1) is a Maurer–Cartan element of the abelian dg Lie algebra $\mathfrak{s}_{\mathcal{A}}$. It is exactly the image of $\Theta_{\mathcal{A}}$ under the scalar trace map of Theorem ??.

Proof. Each summand $u_g \otimes \lambda_g$ has total degree $(1 - 2g) + 2g = 1$, so $\Theta_{\mathcal{A}}^{\text{sc}}$ has Maurer–Cartan degree 1. Since $\mathfrak{s}_{\mathcal{A}}$ is abelian and has zero differential, the MC equation reduces to closedness, which is immediate because the classes λ_g are closed. The trace identity is precisely clause (i) of Theorem ??. $\square$

Remark 23.1.3 (*The scalar ladder is a quotient, not a replacement*). The existence of $\Theta_{\mathcal{A}}^{\text{sc}}$ does not compete with the full theorem. It identifies the maximal abelian quotient of the full modular deformation problem. Every finite or filtered approximation to $\Theta_{\mathcal{A}}$ that respects the scalar trace must reduce to $\Theta_{\mathcal{A}}^{\text{sc}}$ after projecting away all brackets and all non-scalar channels.

23.2 SPECTRAL CUMULANTS AND THE CONNECTED POTENTIAL

Theorem ?? isolates the first intrinsic non-scalar invariant: the spectral discriminant. The next step is to extract from it a canonical infinite hierarchy of characteristic numbers.

Definition 23.2.1 (*Spectral cumulants and connected potential*). Let $\mathcal{A}$ be a modular Koszul chiral algebra for which the spectral characteristic is realized by a finite-rank branch transport operator T_{br} with

$$\Delta_{\mathcal{A}}(x) = \det(1 - xT_{\text{br}}).$$

Define the *spectral cumulants*

$$\mathfrak{c}_m(\mathcal{A}) := \text{Tr}(T_{\text{br}}^m), \quad m \geq 1,$$

and the *connected spectral potential*

$$\Psi_{\mathcal{A}}(x) := -\log \Delta_{\mathcal{A}}(x).$$

THEOREM 23.2.2 (*Spectral cumulant hierarchy;*). The connected potential satisfies

$$\Psi_{\mathcal{A}}(x) = \sum_{m \geq 1} \frac{\mathfrak{c}_m(\mathcal{A})}{m} x^m. \quad (23.2)$$

Consequently:

- (i) each $\mathfrak{c}_m(\mathcal{A})$ is a canonical spectral invariant;
- (ii) the discriminant $\Delta_{\mathcal{A}}(x)$ is determined by finitely many cumulants once its degree is fixed;
- (iii) in the shared rank-two spectral sheet $\Delta(x) = (1 - 3x)(1 + x)$ of Theorem ??, one has

$$\mathfrak{c}_m = 3^m + (-1)^m. \quad (23.3)$$

Proof. Using $\Delta_{\mathcal{A}}(x) = \det(1 - xT_{\text{br}})$, one computes

$$-\log \Delta_{\mathcal{A}}(x) = -\log \det(1 - xT_{\text{br}}) = -\text{Tr} \log(1 - xT_{\text{br}}) = \sum_{m \geq 1} \frac{\text{Tr}(T_{\text{br}}^m)}{m} x^m,$$

which is (23.2). This proves (i). For (ii), write $\Delta_{\mathcal{A}}(x) = 1 - e_1x + e_2x^2 - \dots + (-1)^d e_dx^d$. The Newton identities recover the elementary symmetric polynomials e_i from the power sums $\mathfrak{c}_1, \dots, \mathfrak{c}_d$, so those first d cumulants determine $\Delta_{\mathcal{A}}$. Finally, in the shared sheet, T_{br} has eigenvalues 3 and -1 , hence (23.3). $\square$

Remark 23.2.3 (Connected cycle interpretation). Formula (23.2) is the connected-cycle expansion of the spectral transport. The coefficient $\mathfrak{c}_m(\mathcal{A})/m$ is the cyclic trace of length- m branch transport, divided by the number of cyclic choices of basepoint. In particular, $\Psi_{\mathcal{A}}(x)$ is the connected one-loop spectral shadow of the full modular Maurer–Cartan class.

23.3 AN ABSTRACT FILTERED OBSTRUCTION THEOREM

The full MC2 theorem resolves the existence of $\Theta_{\mathcal{A}}$. The next theorem clarifies a different question: where can a first nontrivial correction appear in a trace-compatible quotient or truncation of a Maurer–Cartan problem?

Definition 23.3.1 (Trace-compatible filtered dg Lie algebra). A trace-compatible filtered dg Lie algebra consists of:

- (i) a complete descending filtration $L = F^1 L \supseteq F^2 L \supseteq \cdots$ by dg Lie ideals;
- (ii) an abelian dg Lie algebra S ;
- (iii) a morphism of filtered dg Lie algebras $\text{tr}: L \rightarrow S$ such that $\text{tr}[x, y] = 0$ for all $x, y \in L$.

Write $L^\circ := \ker(\text{tr})$ for the traceless sector.

THEOREM 23.3.2 (*First obstruction is traceless and quadratic*;). Let $(L, F^\bullet, \text{tr})$ be a trace-compatible filtered dg Lie algebra, and let $\theta_{\text{sc}} \in S^1$ be a closed degree-1 element. Suppose that $\mathfrak{g}^{(1)} \in F^1 L / F^2 L$ is a first-order lift of θ_{sc} . For any representative $\tilde{\mathfrak{g}}_1 \in F^1 L$, define the curvature modulo $F^3 L$ by

$$\Omega_2(\tilde{\mathfrak{g}}_1) := d\tilde{\mathfrak{g}}_1 + \frac{1}{2}[\tilde{\mathfrak{g}}_1, \tilde{\mathfrak{g}}_1] \pmod{F^3 L}.$$

Then:

- (i) $\Omega_2(\tilde{\mathfrak{g}}_1)$ defines a class

$$o_2 \in H^2(F^2 L / F^3 L)$$

independent of the representative;

- (ii) $o_2 = 0$ if and only if $\mathfrak{g}^{(1)}$ lifts to a Maurer–Cartan solution modulo $F^3 L$;
- (iii) the class o_2 lies in the traceless sector $H^2(F^2 L^\circ / F^3 L^\circ)$.

Proof. Because $\mathfrak{g}^{(1)}$ is closed modulo $F^2 L$, the curvature of $\tilde{\mathfrak{g}}_1$ lies in $F^2 L$. A standard graded Jacobi identity computation gives

$$d\Omega_2(\tilde{\mathfrak{g}}_1) \equiv 0 \pmod{F^3 L},$$

so Ω_2 is a cocycle modulo $F^3 L$. If one changes the representative by an element $\alpha \in F^2 L$, then

$$\Omega_2(\tilde{\mathfrak{g}}_1 + \alpha) - \Omega_2(\tilde{\mathfrak{g}}_1) \equiv d\alpha \pmod{F^3 L},$$

because every bracket involving α lands in $F^3 L$. This proves (i).

For (ii), a correction $\mathfrak{g}_2 \in F^2 L / F^3 L$ produces a Maurer–Cartan solution modulo $F^3 L$ exactly when

$$d\mathfrak{g}_2 = -\Omega_2(\tilde{\mathfrak{g}}_1) \pmod{F^3 L}.$$

So the obstruction vanishes precisely when the class o_2 vanishes.

Finally,

$$\text{tr}(\Omega_2(\tilde{\mathfrak{g}}_1)) = d \text{tr}(\tilde{\mathfrak{g}}_1) + \frac{1}{2} \text{tr}[\tilde{\mathfrak{g}}_1, \tilde{\mathfrak{g}}_1] = d\theta_{\text{sc}} + 0 = 0.$$

Hence the obstruction class lies in the kernel of the trace map. This is (iii). $\square$

COROLLARY 23.3.3 (*Vanishing criterion for filtered lifts*;). In the situation of Theorem 23.3.2, assume in addition that

$$H^2(F^n L^\circ / F^{n+1} L^\circ) = 0 \quad \text{for all } n \geq 2.$$

Then every scalar Maurer–Cartan skeleton admits a lift to an honest Maurer–Cartan element of L . If in addition

$$H^1(F^n L^\circ / F^{n+1} L^\circ) = 0 \quad \text{for all } n \geq 2,$$

then the lift is unique up to gauge equivalence among all lifts with the same scalar trace.

Proof. The proof is the standard inductive extension argument. At stage n , the failure of a lift modulo $F^{n+2} L$ defines a class in $H^2(F^{n+1} L / F^{n+2} L)$. Repeating the trace computation from the proof of Theorem 23.3.2, one sees that this class lies in the traceless sector. The vanishing of H^2 kills the obstruction and produces a lift at the next stage. Completeness of the filtration yields a limit Maurer–Cartan element. The vanishing of H^1 gives uniqueness by the usual gauge-induction argument. $\square$

Remark 23.3.4 (Use after MC2). In the present repository the full lift already exists, so Corollary 23.3.3 is not needed to prove $\Theta_{\mathcal{A}}$. Its role is diagnostic: any finite or spectral approximation to $\Theta_{\mathcal{A}}$ begins to fail, if it fails at all, in the traceless quadratic sector.

23.4 VIRASORO POSITIVE-WEIGHT ACYCLICITY AND REDUCED SPECTRAL LOCALIZATION

This section isolates the first genuinely finite obstruction sector in the Virasoro family. The mechanism is the same one that already drives the PBW calculations: positive conformal weight is invertible under the L_0 -action.

Definition 23.4.1 (Effective positive-weight functor). Let $\tilde{V}_{\text{Vir}_c} = \bigoplus_{h \geq 2} M_h$ be the augmentation ideal of the Virasoro vacuum algebra, graded by conformal weight. An *effective positive-weight functor* on $\tilde{V}_{\text{Vir}_c}$ is a finite polynomial Schur functor built from tensors, symmetric powers, exterior powers, and finite-dimensional auxiliary spaces, with the condition that every homogeneous monomial has strictly positive total conformal weight.

If $\mathcal{F}(\tilde{V}_{\text{Vir}_c})$ is such a functor, define the *effective differential*

$$d_{\text{eff}} := \mathcal{F}(L_0),$$

where L_0 acts diagonally by conformal weight.

LEMMA 23.4.2 (*Positive-weight contraction*;). Let $W = \bigoplus_{m > 0} W_m$ be a positively graded vector space, and let D act on W_m by $m \text{ id}$. Then the complex (W, D) is contractible.

Proof. Define $h : W \rightarrow W$ by $h|_{W_m} = m^{-1} \text{id}$. Then on W_m one has

$$Dh + hD = \text{id}_{W_m}.$$

Hence id_W is null-homotopic. $\square$

THEOREM 23.4.3 (*Positive-weight Virasoro sectors are acyclic*;). For every effective positive-weight functor $\mathcal{F}(\tilde{V}_{\text{Vir}_c})$, the complex $(\mathcal{F}(\tilde{V}_{\text{Vir}_c}), d_{\text{eff}})$ is contractible. In particular,

$$H^\bullet(\mathcal{F}(\tilde{V}_{\text{Vir}_c}), d_{\text{eff}}) = 0.$$

Proof. Every homogeneous monomial of $\mathcal{F}(\tilde{V}_{\text{Vir}_c})$ has total conformal weight $m > 0$. On the weight- m subspace, d_{eff} acts by m id. Apply Lemma 23.4.2 weight by weight. $\square$

COROLLARY 23.4.4 (*Localization to reduced spectral sectors;*). In every quotient of the Virasoro modular deformation problem whose associated graded is built from effective positive-weight functors and a finite-dimensional reduced spectral sector, the positive-weight part is acyclic. Consequently the first non-scalar quotient data are forced into finite reduced spectral sectors.

Proof. The associated graded of the positive-weight part is acyclic by Theorem 23.4.3. Hence every spectral sequence argument collapses there, leaving only the reduced finite-rank sector. $\square$

Remark 23.4.5 (*The reduced line on the shared sheet*). On the shared sheet $\Delta(x) = (1 - 3x)(1 + x)$ of Theorem ??, the reduced spectral algebra is two-dimensional. Its traceless part is therefore one-dimensional. Any reduced traceless coefficient in a one-channel quotient must lie on a single line. The genus-2 coefficient in the branch-line quotient is therefore forced, a priori, to have the form $\mu_2(c) \tau \otimes \lambda_2$.

PROPOSITION 23.4.6 (*Odd-sheet rigidity for one-line reductions;*). Let $t = k + 2$ and write

$$c = 1 - \frac{6(k+1)^2}{k+2} = 13 - 6(t + t^{-1}).$$

Suppose that a reduced traceless Virasoro coefficient is represented on the shared spectral line by $m(t)\tau$, where:

- (i) $m(t) = m(t^{-1})$ (*sheet descent*);
- (ii) the same-family involution $k \mapsto -k - 4$, equivalently $t \mapsto -t$, acts by $\tau \mapsto -\tau$ (*odd spectral normalization*).

Then

$$m(t) = (t + t^{-1})Q((t + t^{-1})^2) \tag{23.4}$$

for a unique function Q . Equivalently, the descended coefficient is of the form

$$\mu(c) = (c - 13)P((c - 13)^2) \tag{23.5}$$

for a unique function P .

Proof. Set $u = t + t^{-1}$, so $c = 13 - 6u$. The sheet-descent assumption says that m depends only on u . Under the same-family involution, $t \mapsto -t$, hence $u \mapsto -u$. Because the spectral line is odd, the transformed coefficient must satisfy $m(-t) = -m(t)$, so the descended function of u is odd. Every odd function of u has the form $uQ(u^2)$, proving (23.4). Substituting $u = (13 - c)/6$ yields (23.5). $\square$

COROLLARY 23.4.7 (*The genus-2 one-line coefficient is centered at 13;*). Every genus-2 reduced traceless coefficient on the shared spectral line that obeys the hypotheses of Proposition 23.4.6 satisfies

$$\mu_2(26 - c) = -\mu_2(c), \quad \mu_2(13) = 0.$$

23.5 RANK-TWO BRANCH-LINE REDUCTIONS

The previous sections motivate a general finite-dimensional quotient. The right level of generality is a rank-two spectral sheet.

Construction 23.5.1 (Rank-two branch algebra). Fix distinct scalars $\lambda_+, \lambda_- \in \mathbf{C}$, and define

$$R_{\lambda_+, \lambda_-} := \mathbf{C}[K] / ((K - \lambda_+)(K - \lambda_-)).$$

Set

$$c := \frac{\lambda_+ + \lambda_-}{2}, \quad \delta := \frac{\lambda_+ - \lambda_-}{2}, \quad \tau := K - c.$$

Then

$$R_{\lambda_+, \lambda_-} = \mathbf{C} \cdot 1 \oplus \mathbf{C} \cdot \tau, \quad \tau^2 = \delta^2.$$

The line $\mathbf{C}\tau$ is the *branch line*.

Proof. Expanding the quadratic relation for K gives $K^2 - (\lambda_+ + \lambda_-)K + \lambda_+\lambda_- = 0$. Hence

$$(K - c)^2 = K^2 - 2cK + c^2 = ((\lambda_+ + \lambda_-)K - \lambda_+\lambda_-) - 2cK + c^2 = c^2 - \lambda_+\lambda_- = \delta^2.$$

So every polynomial in K reduces uniquely to a scalar plus a multiple of τ . $\square$

LEMMA 23.5.2 (*Universal branch moments*;). In the rank-two branch algebra one has

$$K^m = a_m + b_m \tau, \quad b_m = \frac{\lambda_+^m - \lambda_-^m}{\lambda_+ - \lambda_-}, \quad (23.6)$$

for every $m \geq 1$. Equivalently,

$$\text{pr}_\tau(K^m) = \frac{\lambda_+^m - \lambda_-^m}{\lambda_+ - \lambda_-} \tau.$$

Proof. Write $K^m = a_m + b_m \tau$. Evaluating on the two eigenspaces of K yields

$$\lambda_+^m = a_m + b_m \delta, \quad \lambda_-^m = a_m - b_m \delta.$$

Subtracting gives

$$2\delta b_m = \lambda_+^m - \lambda_-^m.$$

Since $2\delta = \lambda_+ - \lambda_-$, one obtains (23.6). $\square$

Definition 23.5.3 (Branch-line and primitive quotients). Let $\mathcal{A}$ be a modular Koszul chiral algebra whose spectral characteristic factors through a rank-two sheet.

- (i) The *branch-line quotient* keeps only the scalar vertex data $\kappa(\mathcal{A})\lambda_h$, the branch transport along edges, and the projection to the branch line $\mathbf{C}\tau$.
- (ii) The *pure-branch primitive quotient* further discards every positive-genus vertex decoration and every separating edge.
- (iii) The *top-Hodge primitive quotient* keeps the top Hodge line $\mathbf{Q}\lambda_{g(v)}$ on each vertex, retains only connected nonseparating graphs, and projects the spectral factor to the branch line.

Definition 23.5.4 (Hodge depth). For a connected stable graph Γ , define its *Hodge depth* by

$$\delta(\Gamma) := |E(\Gamma)| + \sum_{v \in V(\Gamma)} g(v).$$

THEOREM 23.5.5 (Depth formula;). For every connected stable graph Γ of total genus g ,

$$\delta(\Gamma) = g + |V(\Gamma)| - 1. \quad (23.7)$$

Consequently:

- (i) $\delta(\Gamma) \geq g$;
- (ii) equality holds if and only if $|V(\Gamma)| = 1$.

Thus the first primitive depth in genus g is exactly the one-vertex sector.

Proof. The genus formula for a connected stable graph is

$$g = b_1(\Gamma) + \sum_v g(v) = |E(\Gamma)| - |V(\Gamma)| + 1 + \sum_v g(v).$$

Rearranging gives (23.7). The corollaries are immediate. $\square$

23.6 GENUS-2 TRANSPARENCY

The one-dimensional branch line forces a strong vanishing statement in genus 2. The proof is entirely geometric: separating clutching sees λ_2 , and nonseparating clutching kills it.

LEMMA 23.6.1 (Separating Hodge splitting;). For the separating clutching map

$$\xi_{\text{sep}}: \overline{\mathcal{M}}_{1,1} \times \overline{\mathcal{M}}_{1,1} \longrightarrow \overline{\mathcal{M}}_2,$$

one has a canonical isomorphism of Hodge bundles

$$\xi_{\text{sep}}^* \mathbb{E}_2 \cong \text{pr}_1^* \mathbb{E}_1 \oplus \text{pr}_2^* \mathbb{E}_1.$$

Hence

$$\xi_{\text{sep}}^* \lambda_2 = \lambda_1 \boxtimes \lambda_1. \quad (23.8)$$

Proof. Let $C = C_1 \cup_q C_2$ be a separating nodal genus-2 curve with elliptic components C_1 and C_2 . The normalization description of the dualizing sheaf identifies sections of ω_C with pairs of sections of $\omega_{C_1}(q)$ and $\omega_{C_2}(q)$ whose residues at q add to zero. On an elliptic curve every section of $\omega_{C_i}(q)$ is already holomorphic, so the residue condition is automatic. Therefore

$$H^0(C, \omega_C) \cong H^0(C_1, \omega_{C_1}) \oplus H^0(C_2, \omega_{C_2}),$$

and this identification globalizes over the separating boundary family. Taking top Chern classes gives (23.8). $\square$

LEMMA 23.6.2 (Nonseparating Hodge extension;). For the nonseparating clutching map

$$\xi_{\text{ns}}: \overline{\mathcal{M}}_{1,2} \longrightarrow \overline{\mathcal{M}}_2,$$

one has an exact sequence

$$0 \longrightarrow \mathbb{E}_1 \longrightarrow \xi_{\text{ns}}^* \mathbb{E}_2 \longrightarrow \mathcal{O} \longrightarrow 0.$$

Consequently,

$$\xi_{\text{ns}}^* \lambda_2 = 0.$$

Proof. A point of the nonseparating boundary is an elliptic curve E with two marked points p, q identified. Sections of the dualizing sheaf of the nodal curve correspond to meromorphic differentials on E with at most simple poles at p and q and opposite residues. Such a space is generated by the holomorphic differential on E together with a normalized differential of the third kind having residues $+1$ and -1 at p and q . The quotient line is therefore trivial, which gives the exact sequence above. Since the quotient has vanishing first Chern class, one gets

$$\xi_{\text{ns}}^* \lambda_2 = c_2(\xi_{\text{ns}}^* \mathbb{E}_2) = 0.$$

□

THEOREM 23.6.3 (*Genus-2 transparency on a one-line branch quotient;*). Let $R = S \oplus T$ be a commutative algebra such that T is one-dimensional and $T^2 \subseteq S$. Let $\Xi_g \in H^\bullet(\overline{\mathcal{M}}_g, \mathbf{Q}) \otimes R$ be a clutching-compatible tower,

$$\xi_{g_1, g_2}^* \Xi_{g_1 + g_2} = \Xi_{g_1} \boxtimes \Xi_{g_2}.$$

Assume that:

- (i) the genus-1 traceless part vanishes;
- (ii) the genus-2 traceless part lies on the top Hodge line:

$$\text{pr}_T(\Xi_2) = \nu_2 \tau \otimes \lambda_2 \tag{23.9}$$

for some nonzero generator τ of T .

Then $\nu_2 = 0$.

Proof. Restrict to the separating boundary. By clutching,

$$\xi_{\text{sep}}^* \Xi_2 = \Xi_1 \boxtimes \Xi_1.$$

Because the genus-1 traceless part vanishes, the traceless part of $\Xi_1 \boxtimes \Xi_1$ vanishes as well. On the other hand, (23.9) and Lemma 23.6.1 give

$$\text{pr}_T(\xi_{\text{sep}}^* \Xi_2) = \nu_2 \tau \otimes \lambda_1 \boxtimes \lambda_1.$$

Now $\tau \neq 0$, and $\lambda_1 \boxtimes \lambda_1 \neq 0$ on $\overline{\mathcal{M}}_{1,1} \times \overline{\mathcal{M}}_{1,1}$, so $\nu_2 = 0$. Lemma 23.6.2 shows that there is no nonseparating contribution on the top Hodge line, because $\xi_{\text{ns}}^* \lambda_2 = 0$. □

COROLLARY 23.6.4 (*Virasoro genus-2 coefficient vanishes in the one-line quotient;*). In every Virasoro branch-line quotient whose genus-2 traceless part lies on λ_2 , the coefficient $\mu_2(c)$ vanishes identically.

Proof. Apply Theorem 23.6.3 to the one-dimensional branch line of the shared rank-two sheet. □

COROLLARY 23.6.5 (*The first primitive traceless coefficient begins in genus 3;*). In the top-Hodge branch-line quotient, the first possible nonzero primitive traceless contribution occurs in genus 3.

Proof. Genus 1 is scalar by hypothesis, and genus 2 is annihilated by Theorem 23.6.3. □

23.7 THE PURE-BRANCH PRIMITIVE GENUS-3 COEFFICIENT

The pure-branch quotient keeps only genus-zero vertices and nonseparating edges. In genus 3 there is only one primitive graph: the three-loop rose.

LEMMA 23.7.1 (*Uniqueness of the primitive rose in genus 3;*). In the pure-branch primitive quotient, the connected genus-3 sector is one-dimensional, generated by the one-vertex three-loop rose. If

$$\xi_{\text{rose}}^{(3)}: \overline{\mathcal{M}}_{0,6} \longrightarrow \overline{\mathcal{M}}_3$$

glues the ordered pairs (1, 2), (3, 4), and (5, 6), then the corresponding class is

$$\rho_3 := (\xi_{\text{rose}}^{(3)})_*(1).$$

Proof. In the pure-branch primitive quotient every vertex has genus 0, so the total genus is the first Betti number:

$$3 = b_1(\Gamma) = |E(\Gamma)| - |V(\Gamma)| + 1.$$

The primitive sector at minimal depth has $|V(\Gamma)| = 1$ by Theorem 23.5.5, hence $|E(\Gamma)| = 3$. The unique connected one-vertex graph with three edges is the rose. $\square$

THEOREM 23.7.2 (*Pure-branch primitive coefficient on a rank-two sheet;*). Let $\mathcal{A}$ be a modular Koszul chiral algebra whose spectral characteristic factors through the rank-two sheet R_{λ_+, λ_-} . In the pure-branch primitive quotient, the first primitive traceless coefficient is

$$\Theta_{3, \text{prim}}^{\text{pb}}(\mathcal{A}) = \frac{\lambda_+^3 - \lambda_-^3}{\lambda_+ - \lambda_-} \tau \otimes \rho_3. \quad (23.10)$$

For the shared sheet $\Delta(x) = (1 - 3x)(1 + x)$, this becomes

$$\Theta_{3, \text{prim}}^{\text{pb}} = 7 \tau \otimes \rho_3.$$

Proof. By Lemma 23.7.1, the primitive quotient is one-dimensional on the graph side, so the only possible coefficient is a scalar multiple of $\tau \otimes \rho_3$. Each loop contributes one copy of the branch transport operator K , so the total transport is K^3 . Projecting to the branch line and applying Lemma 23.5.2 gives (23.10). On the shared sheet, $(\lambda_+, \lambda_-) = (3, -1)$, hence the coefficient is $(27 - (-1))/4 = 7$. $\square$

REMARK 23.7.3 (*Rose coefficients in all genera*). The same proof gives the entire pure rose tower. If ρ_g^{rose} denotes the class of the g -loop rose, then

$$\Theta_{g, \text{rose}}^{\text{pb}}(\mathcal{A}) = \frac{\lambda_+^g - \lambda_-^g}{\lambda_+ - \lambda_-} \tau \otimes \rho_g^{\text{rose}}.$$

For the shared sheet this coefficient is $d_g = (3^g - (-1)^g)/4$.

23.8 THE TOP-HODGE PRIMITIVE QUOTIENT

The pure-branch quotient isolates the universal constant 7, but it forgets the scalar vertex data. The next exact quotient restores the top Hodge line on each vertex.

Definition 23.8.1 (Graph-normalized primitive classes). For $0 \leq h \leq g$, let

$$\xi_h^{(g-h)}: \overline{\mathcal{M}}_{h,2(g-h)} \longrightarrow \overline{\mathcal{M}}_g$$

be the map that glues the ordered pairs $(1, 2), \dots, (2(g-h)-1, 2(g-h))$. Define

$$\tilde{\eta}_{g,h} := \frac{1}{2^{g-h}(g-h)!} (\xi_h^{(g-h)})_*(\lambda_h), \quad \lambda_0 := 1.$$

The prefactor is the standard reciprocal automorphism factor for the one-vertex $(g-h)$ -loop graph.

Remark 23.8.2 (The genus-3 basis). For genus 3, the classes of Definition 23.8.1 are

$$\bar{\rho}_3 := \tilde{\eta}_{3,0}, \quad \bar{e}_3 := \tilde{\eta}_{3,1}, \quad \bar{\gamma}_3 := \tilde{\eta}_{3,2}.$$

These are respectively the three-loop rational rose, the elliptic bi-rose with a λ_1 -insertion, and the genus-2 monorose with a λ_2 -insertion.

THEOREM 23.8.3 (First primitive top-Hodge layer;). Let $\mathcal{A}$ be a modular Koszul chiral algebra whose spectral characteristic factors through the rank-two sheet R_{λ_+, λ_-} . In the top-Hodge primitive quotient, the first primitive layer in genus $g \geq 2$ is

$$\Sigma_g(\mathcal{A}) = \tau \otimes \left(\frac{\lambda_+^g - \lambda_-^g}{\lambda_+ - \lambda_-} \tilde{\eta}_{g,0} + \kappa(\mathcal{A}) \sum_{h=1}^{g-1} \frac{\lambda_+^{g-h} - \lambda_-^{g-h}}{\lambda_+ - \lambda_-} \tilde{\eta}_{g,h} \right). \quad (23.11)$$

Proof. By Theorem 23.5.5, the first primitive depth in genus g is the one-vertex sector. A one-vertex primitive graph is therefore determined by its vertex genus h and its loop number $g-h$. On the graph side this contributes the class $\tilde{\eta}_{g,h}$. On the scalar side, a genus- h vertex contributes $\kappa(\mathcal{A})\lambda_h$ for $h \geq 1$, whereas the genus-zero vertex is the undeformed tree-level base and contributes only the unit. On the spectral side, each loop contributes one factor of K , so the total branch transport is K^{g-h} . Projecting to the branch line and using Lemma 23.5.2 gives exactly (23.11). $\square$

COROLLARY 23.8.4 (The genus-3 primitive coefficient;). For genus 3 one has

$$\Sigma_3(\mathcal{A}) = \tau \otimes \left(\frac{\lambda_+^3 - \lambda_-^3}{\lambda_+ - \lambda_-} \bar{\rho}_3 + \kappa(\mathcal{A}) \frac{\lambda_+^2 - \lambda_-^2}{\lambda_+ - \lambda_-} \bar{e}_3 + \kappa(\mathcal{A}) \bar{\gamma}_3 \right).$$

On the shared sheet $(\lambda_+, \lambda_-) = (3, -1)$, this becomes

$$\Sigma_3(\mathcal{A}) = \tau \otimes (7\bar{\rho}_3 + 2\kappa(\mathcal{A})\bar{e}_3 + \kappa(\mathcal{A})\bar{\gamma}_3). \quad (23.12)$$

For Virasoro, where $\kappa(\text{Vir}_c) = c/2$ by Theorem ??, one gets

$$\Sigma_3(\text{Vir}_c) = \tau \otimes \left(7\bar{\rho}_3 + c\bar{e}_3 + \frac{c}{2}\bar{\gamma}_3 \right).$$

Proof. Substitute $g = 3$ into Theorem 23.8.3. For the shared sheet,

$$\frac{3^3 - (-1)^3}{3 - (-1)} = 7, \quad \frac{3^2 - (-1)^2}{3 - (-1)} = 2, \quad \frac{3 - (-1)}{3 - (-1)} = 1.$$

The Virasoro specialization follows from the scalar identity $\kappa(\text{Vir}_c) = c/2$. $\square$

Remark 23.8.5 (What genus 3 remembers). Equation (23.12) separates the first primitive traceless coefficient into three distinct sources:

- (i) the universal pure-branch constant 7, already visible on the three-loop rational rose;
- (ii) the genus-1 scalar shadow transported through two loops;
- (iii) the genus-2 scalar shadow transported through one loop.

The quotient therefore exhibits a clean operator-level decomposition of what the first primitive non-scalar correction can see.

23.9 SHARED-SHEET SPECIALIZATIONS AND CONTROL CASES

COROLLARY 23.9.1 (*Universal coefficients on the shared sheet;*). On the shared sheet of Theorem ??, the branch-line moments are

$$d_m := \frac{3^m - (-1)^m}{4},$$

so that

$$d_1 = 1, \quad d_2 = 2, \quad d_3 = 7, \quad d_{m+2} = 2d_{m+1} + 3d_m.$$

Accordingly,

$$\Sigma_g(\mathcal{A}) = \tau \otimes \left(d_g \bar{\eta}_{g,0} + \kappa(\mathcal{A}) \sum_{h=1}^{g-1} d_{g-h} \bar{\eta}_{g,h} \right)$$

for every algebra on the shared sheet.

Proof. This is the specialization of Lemma 23.5.2 and Theorem 23.8.3 to $(\lambda_+, \lambda_-) = (3, -1)$. The recurrence follows from the minimal polynomial $K^2 - 2K - 3 = 0$. $\square$

Example 23.9.2 (The scalar-only Heisenberg frame). The Heisenberg frame example in Part II shows the opposite extreme from the shared interacting sheet. Its higher-genus package is already controlled by the scalar invariant κ , so there is no nontrivial rank-two branch-line quotient to extract. In that sense the Heisenberg example is the scalar atom, whereas the shared $\widehat{\mathfrak{sl}}_2/\text{Virasoro}/\beta\gamma$ sheet is the first genuine spectral atom.

23.10 WHAT REMAINS OPEN ABOVE THE QUOTIENT

The quotients constructed here are exact, but they are not the whole story. They record only what is forced by the scalar shadow, the rank-two spectral sheet, and the stable-graph clutching algebra. The full modular deformation complex contains strictly more information.

Problem 23.10.1 (Branch realization of the full cyclic complex). Construct a natural morphism from the full cyclic deformation complex

$$\mathcal{R}_{\text{br}} : \text{Def}_{\text{cyc}}(\mathcal{A}) \longrightarrow \text{End}(V_{\text{br}}) \widehat{\otimes} C^*(\text{stable graphs})$$

whose logarithmic connected trace recovers the spectral potential $\Psi_{\mathcal{A}}(x)$.

Conjecture 23.10.2 (Spectral shadow principle;). For every modular Koszul chiral algebra $\mathcal{A}$, the full universal class $\Theta_{\mathcal{A}}$ admits a natural branch realization

$$\mathcal{R}_{\text{br}}: L_{\mathcal{A}}^{\circ} \longrightarrow \text{End}(V_{\text{br}, \mathcal{A}}) \llbracket x \rrbracket$$

whose connected one-loop image is exactly

$$-\log \Delta_{\mathcal{A}}(x) = \Psi_{\mathcal{A}}(x).$$

The proved spectral potential is the one-loop connected shadow of the full graph-valued Maurer–Cartan element.

Remark 23.10.3 (Why the logarithm is canonical). The conjecture is structurally forced: a Maurer–Cartan element in a completed dg Lie algebra decomposes into connected graph contributions by the standard exponential/logarithm correspondence. The determinant $\Delta_{\mathcal{A}}$ is the partition function (disconnected sum), and $\Psi_{\mathcal{A}} = -\log \Delta_{\mathcal{A}}$ is the connected potential. The identification would say that the spectral connected potential is exact at the one-loop level, with all higher-loop connected contributions lying in the traceless sector.

Problem 23.10.4 (Renormalization of primitive quotient coefficients). Determine whether the coefficients in the primitive quotients are exact images of the full Maurer–Cartan class or receive corrections from non-top-Hodge vertex decorations and genuinely higher cyclic L_{∞} -operations. In particular, decide whether the quotient formula

$$\Sigma_3(\text{Vir}_c) = \tau \otimes \left(7\bar{\rho}_3 + c\bar{e}_3 + \frac{c}{2}\bar{\gamma}_3 \right)$$

is already the exact genus-3 traceless image of Θ_{Vir_c} under a canonical branch realization.

Problem 23.10.5 (Beyond top Hodge). Describe the first quotient above the top-Hodge primitive layer. A natural candidate is the quotient that keeps one additional tautological vertex decoration, for example a ψ -class or a boundary divisor class, together with the same branch-line projection. Theorem 23.5.5 leaves two possible positions for the first new terms: the same depth with richer vertex decorations, or one depth higher with multi-vertex primitive graphs.

Remark 23.10.6 (The structural picture). The quotient theory established here has a clean shape.

- (i) The scalar Maurer–Cartan skeleton is the abelian shadow of the full universal class.
- (ii) The spectral discriminant produces a connected cumulant tower.
- (iii) The first nontrivial correction to a scalar shadow is forced into a traceless quadratic sector.
- (iv) In the Virasoro family, the positive-weight sector is contractible, so the first finite obstruction is spectral.
- (v) On every one-line branch quotient with scalar square, genus 2 is transparent.
- (vi) The first primitive top-Hodge coefficient therefore occurs in genus 3, and on the shared sheet its universal pure-branch part is the constant 7.

This is the exact content of the branch-line and primitive quotient calculation.

COMPUTATIONAL METHODS

The shadow obstruction tower of a chirally Koszul algebra is a square root.

The Maurer–Cartan element $\Theta_{\mathcal{A}}$ of a chirally Koszul algebra $\mathcal{A}$, restricted to a primary line L of the cyclic deformation complex, is the Taylor expansion of one algebraic function of degree 2. The function is $\sqrt{Q_L(t)}$, where Q_L is a quadratic polynomial determined by three invariants: the modular characteristic κ , the cubic shadow α , and the critical discriminant $\Delta = 8\kappa S_4$. The Taylor coefficients are the shadow tower. The branch points of $\sqrt{Q_L}$ are the singularities. The monodromy is -1 : the Koszul sign.

The structure is not three independent methods that happen to agree, but four languages for a single object:

Algebra	Taylor coefficients of $\sqrt{Q_L}$
Deformation theory	MC recursion as fixed-point equation
Analysis	Darboux asymptotics, Borel summability
Geometry	flat section of a logarithmic connection

These are not alternatives. They are the same object described in four ways. The cross-consistencies are tautologies, once one sees that the object is one.

24.1 THE SQUARE ROOT

Fix a chirally Koszul algebra $\mathcal{A}$ with $\kappa = \kappa(\mathcal{A}) \neq 0$. Let L be a one-dimensional primary slice of $\text{Def}_{\text{cyc}}^{\text{mod}}(\mathcal{A})$. The shadow tower on L is the sequence $\{S_r\}_{r \geq 2}$ of exact rational numbers defined by the degree- r projection of $\Theta_{\mathcal{A}}$ along L .

Definition 24.1.1 (Shadow metric). The shadow metric on L is the quadratic polynomial

$$Q_L(t) = 4\kappa^2 + 12\kappa\alpha t + (9\alpha^2 + 2\Delta)t^2, \quad \Delta = 8\kappa S_4.$$

The shadow generating function is $H(t) = t^2 \sqrt{Q_L(t)}$.

Three coefficients. A quadratic. An algebraic function of degree 2. The Taylor coefficients of $\sqrt{Q_L}$ are determined by (κ, α, S_4) through the convolution recursion.

LEMMA 24.1.2 (Taylor recursion for the formal square root;). Write $\sqrt{Q_L(t)} = \sum_{n \geq 0} a_n t^n$. Then

$$a_0 = 2\kappa, \quad a_1 = 3\alpha, \quad a_2 = 4S_4, \quad (24.1)$$

and for $n \geq 3$,

$$a_n = -\frac{1}{2a_0} \sum_{j=1}^{n-1} a_j a_{n-j}. \quad (24.2)$$

No square roots are extracted. Every a_n is a rational function of (κ, α, S_4) with rational coefficients.

Proof. Let $A(t) = \sum_{n \geq 0} a_n t^n$. The defining identity $A(t)^2 = Q_L(t)$ gives, by comparing coefficients of t^0, t^1, t^2 , the three initial values in (24.1). For $n \geq 3$ the coefficient of t^n in $Q_L(t)$ vanishes, hence $2a_0 a_n + \sum_{j=1}^{n-1} a_j a_{n-j} = 0$. Solving for a_n gives (24.2). $\square$

THEOREM 24.1.3 (*Riccati algebraicity*). The shadow coefficients satisfy

$$S_r = \frac{a_{r-2}}{r}, \quad r \geq 2.$$

Proof. The weighted generating function $H(t) = \sum_{r \geq 2} r S_r t^r$ satisfies the algebraic identity

$$H(t)^2 = t^4 Q_L(t),$$

which is the content of Theorem ?? . Both sides equal the bilinear form $\langle \Theta_L, \Theta_L \rangle$ evaluated on the cyclic pairing: the left side uses the generating function squared, the right uses the Gaussian decomposition $Q_L = (2\kappa + 3\alpha t)^2 + 2\Delta t^2$. Choosing the branch with $H(t) \sim 2\kappa t^2$ as $t \rightarrow 0$ gives $H = t^2 \sqrt{Q_L}$. The coefficient of t^r in H is $r S_r$. $\square$

Example 24.1.4 (*The first ten Virasoro shadows*). For the Virasoro algebra at central charge c : $\kappa = c/2$, $\alpha = 2$, $S_4 = 10/[c(5c + 22)]$. The convolution recursion gives the weighted Riccati-metric coefficients

$$\begin{aligned} R_2 &= \frac{c}{2}, \\ R_3 &= 2, \\ R_4 &= \frac{10}{c(5c + 22)}, \\ R_5 &= \frac{-48}{c^2(5c + 22)}, \\ R_6 &= \frac{80(45c + 193)}{3c^3(5c + 22)^2}, \\ R_7 &= \frac{-2880(15c + 61)}{7c^4(5c + 22)^2}, \\ R_8 &= \frac{80(2025c^2 + 16470c + 33314)}{c^5(5c + 22)^3}, \\ R_9 &= \frac{-1280(2025c^2 + 15570c + 29554)}{3c^6(5c + 22)^3}, \\ R_{10} &= \frac{256(91125c^3 + 1050975c^2 + 3989790c + 4969967)}{c^7(5c + 22)^4}. \end{aligned}$$

Every number is a rational function of c . The denominators encode a single Gram determinant. The numerators encode the shadow radius. The signs encode the argument of the nearest branch point. An ordered residue package $H_{\text{res}}(\text{Vir}_c; X)$ and its chain comparison determine the geometric equality $S_r(\text{Vir}_c; H_{\text{res}}) = R_r(\text{Vir}_c)$.

Example 24.1.5 (*Virasoro at $c = 1/2$*). At the Ising point $c = 1/2$: $\kappa = 1/4$, $\alpha = 2$, $S_4 = 10/[(1/2)(49/2)] = 40/49$. The shadow metric is $Q_L(t) = 1/4 + 6t + (36 + 640/49)t^2 = 1/4 + 6t + (2404/49)t^2$. The convolution recursion (24.2) produces $S_5, S_6, \dots$ as explicit fractions with denominators $c^{r-3}(5c + 22)^{\lfloor (r-2)/2 \rfloor} = (1/2)^{r-3}(49/2)^{\lfloor (r-2)/2 \rfloor}$, all exact. The growth rate $\rho \approx 12.5$; the tower diverges rapidly and requires Borel resummation.

Remark 24.1.6 (The cubic shadow $\alpha = 2$ is determined). The value $\alpha = 2$ for the Virasoro algebra is not assumed. It is *determined* by three independent routes: (i) the Sugawara self-coupling $C_{TT}^T = 2$ in the OPE $T(z)T(w) \sim \cdots + 2T(w)/(z-w)^2 + \cdots$; (ii) back-derivation from S_5 , via the identity $\alpha = -5\kappa S_5/(6S_4)$; (iii) the critical cubic (24.3): matching $45\alpha^2 = 180$ gives $\alpha^2 = 4$.

THEOREM 24.1.7 (Denominator theorem). For all $r \geq 4$:

$$\text{denom}(S_r) = (\text{const}) \cdot c^{r-3} (5c + 22)^{\lfloor (r-2)/2 \rfloor}.$$

No Kac determinant zeros beyond weight 4 appear.

Proof. Induction on n in the recursion (24.2). Base: $a_2 = 40/[c(5c+22)]$. Step: the product $a_j a_{n-j}$ contributes c^{n-2} and $(5c+22)^{\lfloor j/2 \rfloor + \lfloor (n-j)/2 \rfloor}$ in the denominator; the inequality $\lfloor j/2 \rfloor + \lfloor (n-j)/2 \rfloor \leq \lfloor n/2 \rfloor$ is saturated by $j = 2$ (for n even) or $j = 1$ (for n odd), making the bound exact. Division by $2c$ raises the c -power to $n-1$. $\square$

The shadow obstruction tower sees only the first Gram determinant. The quartic contact invariant $Q_{\text{Vir}}^{\text{ct}} = 10/[c(5c+22)]$ has poles at $c = 0$ and $c = -22/5$; the zeros of $\det G_4 = c^2(5c+22)/2$. The shadow obstruction tower's poles are the representation theory's zeros.

24.2 THE CONNECTION

The shadow metric Q_L is not merely an algebraic convenience. It defines a geometric structure.

Definition 24.2.1 (Shadow connection). The *shadow connection* is the logarithmic connection

$$\nabla^{\text{sh}} = d - \frac{Q'_L(t)}{2Q_L(t)} dt$$

on the double cover of the t -line branched at the zeros of Q_L .

PROPOSITION 24.2.2 (Properties of the shadow connection). (i) ∇^{sh} has logarithmic singularities at the zeros $t = t_{\pm}$ of Q_L , with residue $1/2$ at each.

(ii) The monodromy around each branch point is -1 .

(iii) The flat sections are $\sqrt{Q_L(t)}$ and $1/\sqrt{Q_L(t)}$.

Proof. The connection 1-form is $\omega = -Q'_L/(2Q_L) dt = -d \log Q_L/2$. At a simple zero t_+ of Q_L , ω has a simple pole with residue $-1/2$. The flat section $\Phi = \sqrt{Q_L}$ satisfies $d\Phi/\Phi = Q'_L/(2Q_L) dt$, so $\nabla^{\text{sh}}\Phi = 0$. Analytic continuation around t_+ sends $\sqrt{Q_L} \mapsto -\sqrt{Q_L}$: monodromy -1 . $\square$

The monodromy -1 is the Koszul sign. Circling a branch point of the shadow metric exchanges the two square root sheets, which corresponds to the involution $\mathcal{A} \leftrightarrow \mathcal{A}^1$ in the complementarity pairing. The shadow generating function $H(t) = t^2 \sqrt{Q_L(t)}$ is not a flat section: the t^2 prefactor is the degree offset, reflecting that the shadow obstruction tower begins at degree 2.

The Gaussian decomposition $Q_L = (2\kappa + 3\alpha t)^2 + 2\Delta t^2$ separates the free part (the perfect square, contributing a polynomial shadow obstruction tower) from the interacting part (the Δ correction, creating infinite shadow depth). This decomposition is visible in the connection:

- $\Delta = 0$: $\sqrt{Q_L} = |2\kappa + 3\alpha t|$ is polynomial, the connection has no branch points, the tower terminates.
- $\Delta \neq 0$: $\sqrt{Q_L}$ is genuinely algebraic, the connection has two branch points, the tower is infinite.

The depth classification (Definition ??) is the topology of the spectral curve of ∇^{sh} .

24.3 THE DISCRIMINANT

The discriminant of Q_L is

$$\text{disc}(Q_L) = (12\kappa\alpha)^2 - 4 \cdot 4\kappa^2 \cdot (9\alpha^2 + 2\Delta) = -32\kappa^2\Delta = -256\kappa^3 S_4.$$

The sign of disc determines the character of the branch points:

- $\text{disc} > 0$ (i.e. $\kappa S_4 < 0$): two real branch points, monotone asymptotics.
- $\text{disc} < 0$ (i.e. $\kappa S_4 > 0$): two complex-conjugate branch points, oscillating asymptotics.
- $\text{disc} = 0$ (i.e. $S_4 = 0$): double root, tower terminates.

For the Virasoro algebra: $\kappa S_4 = (c/2) \cdot 10/[c(5c + 22)] = 5/(5c + 22) > 0$ at all positive c . The branch points are complex conjugate, and the shadow coefficients oscillate.

Example 24.3.1 (Three discriminants). The discriminant $(1 - 3x)(1 + x)$ appears in three places.

For $\widehat{\mathfrak{sl}}_2$ bar cohomology: the generating function satisfies an algebraic equation with discriminant $(1 - 3x)(1 + x)$. The growth rate is 3, from the root $x = 1/3$. The Riordan numbers R_n count non-crossing partitions with a coloring constraint.

After Drinfeld–Sokolov reduction to the Virasoro algebra: the generating function rearranges into Motzkin differences $M(n+1) - M(n)$. Both come from the same discriminant. DS reduction preserves the branch cut.

For $\beta\gamma$ bar cohomology: the Fibonacci sequence 1, 1, 2, 3, 5, 8, . . . arises from a square-root ratio with the same discriminant type.

These are not coincidences. The discriminant is the Koszul invariant of the bar construction. The factor $(1 - 3x)$ encodes the growth rate 3, from triple residue extraction at each collision. The factor $(1 + x)$ encodes the Koszul sign: monodromy -1 of the shadow connection.

24.4 THE ASYMPTOTICS

The shadow growth rate is a continuous invariant.

Definition 24.4.1 (Shadow growth rate). Let $t_{\pm}$ be the zeros of Q_L , with $|t_-| \leq |t_+|$. The *shadow growth rate* is

$$\rho = \frac{1}{|t_-|} = \frac{\sqrt{9\alpha^2 + 2\Delta}}{2|\kappa|}$$

(Definition ??).

THEOREM 24.4.2 (Shadow asymptotics).

$$S_r \sim A \rho^r r^{-5/2} \cos(r\theta + \varphi) \quad (r \rightarrow \infty),$$

where $\theta = \arg(t_-)$ and A, φ are explicit constants from the Darboux expansion of $\sqrt{Q_L}$ at $t = t_-$.

Proof. The function $\sqrt{Q_L(t)}$ has algebraic singularities of order $1/2$ at $t = t_{\pm}$. The standard transfer theorem for algebraic singularities (Flajolet–Sedgewick, Chapter VI) gives $[t^n] \sqrt{Q_L(t)} \sim C t_-^{-n} n^{-3/2}$. Since $S_r = a_{r-2}/r$, the factor $1/r$ produces the $r^{-5/2}$ decay. When t_- is complex: $t_-^{-n} = |t_-|^{-n} e^{-in \arg(t_-)}$, and the real part gives the cosine. $\square$

Example 24.4.3 (Shadow growth rate classification).

Algebra	ρ	N^* at $t=1$	$ S_{20} $	Regime
Heis	0	∞	0	terminates
$\widehat{\mathfrak{sl}}_2$	0	∞	0	terminates
Vir, $c=13$	0.467	2	2.6×10^{-7}	convergent
Vir, $c=1$	6.24	0	1.3×10^{14}	divergent
Vir, $c=1/2$	12.5	0	8.2×10^{15}	rapidly divergent

The Koszul self-dual point $c = 13$ (where $\text{Vir}_c^1 = \text{Vir}_{26-c} = \text{Vir}_{13}$) is the unique minimum of $\rho(c)$ on the positive real axis, with $\rho(13) \approx 0.467 < 1$.

The critical cubic. Setting $\rho = 1$ gives

$$5c^3 + 22c^2 - 180c - 872 = 0, \quad (24.3)$$

with positive root $c^* \approx 6.125$. At $c < c^*$ the tower diverges; at $c > c^*$ it converges. The critical cubic arises from the discriminant of Q_L : the two branch points collide on the real axis at $c = c^*$, transitioning from complex-conjugate branch points (oscillating asymptotics) to real branch points (monotone asymptotics).

The phase slip. The branch points have argument $\theta(c) \in (\pi/2, \pi)$ for all $c > 0$, since $\text{disc}(Q_L) < 0$ forces complex roots. The Darboux transfer theorem gives approximate sign alternation in S_r , with beat period $\pi/(\pi - \theta)$. As $c \rightarrow \infty$, $\theta \rightarrow \pi$ and the alternation becomes permanent. At finite c , the pattern has a finite lifetime:

c	θ	first sign break
1	164°	$r = 17$
10	170°	$r \gg 30$
13	171°	$r \gg 30$
26	173°	$r = 35$

The sign breaks at $c = 1$ ($r = 17$) and $c = 26$ ($r = 35$) are verified by exact rational computation.

24.4.1 Borel summability

Definition 24.4.4 (Borel transform). The Borel transform of the shadow obstruction tower is

$$\mathcal{B}(s) = \sum_{r \geq 2} \frac{S_r}{\Gamma(r+1)} s^r.$$

Since $|S_r| \leq C \rho^r r^{-5/2}$ and $\Gamma(r+1) \sim \sqrt{2\pi r} (r/e)^r$, the Borel series converges on all of $\mathbb{C}$. The Borel transform is an entire function.

PROPOSITION 24.4.5 (Borel summability). Let $G(t) = \sum_{r \geq 2} S_r t^r$.

- (i) If $\rho < 1$, $G(t)$ converges absolutely at $t = 1$.
- (ii) If $\rho \geq 1$, $G(t)$ diverges at $t = 1$, but the Borel–Laplace integral

$$S[G](t) = \frac{1}{t} \int_0^\infty \mathcal{B}(s) e^{-s/t} ds$$

provides a resummation.

(iii) The optimal truncation order is $N^* = \lfloor 1/\rho \rfloor$.

Proof. Part (i): $\rho < 1$ means the radius of convergence exceeds 1. Part (ii): $\mathcal{B}$ is entire and of exponential type ρ ; the integration ray avoids singularities (the Borel transform has no singularities). Part (iii): saddle-point analysis. $\square$

Remark 24.4.6 (The Borel plane). For class G and class L algebras, $\rho = 0$ and the Borel transform is a polynomial. For class M algebras, $\rho > 0$ and the resurgent structure is nontrivial. The instanton actions $A_{\pm} = 1/t_{\pm}$ (the zeros of Q_L) are the singularities of the ordinary generating function. The Borel transform has cuts, not poles, because $\sqrt{Q_L}$ is algebraic. The Stokes constants at the branch points encode the non-perturbative content of the shadow obstruction tower.

24.5 THE MC RECURSION

The Maurer–Cartan equation $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$ in $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ projects to a recursion at each degree.

PROPOSITION 24.5.1 (MC recursion). For $r \geq 5$, given S_2, S_3, S_4 :

$$S_r = -\frac{1}{2r\kappa} \sum_{\substack{j+k=r+2 \\ 3 \leq j \leq k < r}} \epsilon(j, k) jk S_j S_k, \quad (24.4)$$

where $\epsilon(j, k) = 1$ if $j < k$ and $\epsilon(j, j) = \frac{1}{2}$.

Proof. The MC equation at degree r reads $r\kappa S_r + \frac{1}{2} \sum_{j+k=r+2, j, k \geq 2} jk S_j S_k = 0$. The term $(j, k) = (2, r)$ contributes $2r\kappa S_r$, absorbing the linear term. Solving for S_r over the remaining pairs with $j \geq 3$ gives the stated formula. $\square$

The MC recursion uses only the Lie bracket in the convolution algebra. It does not assume that Q_L is quadratic. The algebraicity theorem (Theorem ??) is the nontrivial content: on a primary line, the MC recursion is equivalent to the $\sqrt{Q_L}$ Taylor expansion.

THEOREM 24.5.2 (Algebraic–recursive equivalence). The shadow coefficients from the $\sqrt{Q_L}$ expansion and from the MC recursion coincide at every degree $r \geq 2$.

Proof. The $\sqrt{Q_L}$ recursion (24.2) states $2a_0 a_n + \sum_{j=1}^{n-1} a_j a_{n-j} = 0$ for $n \geq 3$. Setting $n = r - 2$ and $a_j = (j + 2)S_{j+2}$, $a_0 = 2\kappa$ reproduces the MC recursion (24.4) after reindexing. $\square$

This equivalence is not a verification. It is the theorem that the Maurer–Cartan equation on a primary line has a quadratic shadow metric, and therefore that the shadow obstruction tower is algebraic of degree 2.

24.6 THE DEPTH CREATION MECHANISM

Free bosons: $S_4 = 0$. Sugawara: $T = \sum (\partial\phi_a)^2$. Shadow obstruction tower of T : $S_4 \neq 0$.

The quadratic nonlinearity creates the quartic. Each free boson has $\rho = 0$ (class G , terminating at κ). The Sugawara composition produces $S_4 = 10/[c(5c + 22)] \neq 0$ (class M , infinite shadow depth). The mechanism: cross-correlators between independent bosons, mediated by the normal ordering in $:(\partial\phi)^2$.

24.6.1 Drinfeld–Sokolov reduction

The Drinfeld–Sokolov reduction $\widehat{\mathfrak{sl}}_N \rightarrow \mathcal{W}_N$ transforms a depth-3 tower (class L , $S_4 = 0$) into a depth- ∞ tower (class M , $S_4 \neq 0$). Three windows onto the mechanism:

HPL transfer. Ghost-number conservation in the BRST complex kills all coproduct corrections. Only the r -matrix structure survives. The transferred tower depends on the collision residues, not the higher A_∞ operations.

BRST spectral sequence. The ghost-number filtration induces a spectral sequence with E_1 page $H^q(\bar{B}^{\text{ch}}(\widehat{\mathfrak{sl}}_N))_h \otimes H^p(F_{\text{ghost}})_h$. The d_1 differential kills the affine generators, leaving T and higher-spin currents in E_2 . The Sugawara construction appears at the E_2 page.

Miura composition. The free-field realization $\mathcal{W}_N \hookrightarrow \mathcal{H}^{\otimes(N-1)}$ embeds the $\mathcal{W}$ -algebra into $N-1$ Gaussian towers. The quadratic Sugawara creates quartic cross-correlators from these Gaussian inputs.

THEOREM 24.6.1 (DS transfer consistency). For $N = 2, 3, 4, 5$ and levels $k = 1, 2, 3, 5, 10$, the DS-transferred shadow coefficients $S_r(\mathcal{W}_N)$ for $r = 2, \dots, 20$ agree exactly across all three methods.

Proof. The three methods are the direct Drinfeld–Sokolov transfer, the MC recursion on the transferred T -line data, and the shadow-metric reconstruction from the same transferred invariants. For each of the 4×5 pairs (N, k) , each method produces an exact rational value for every S_r , $2 \leq r \leq 20$. The finite comparison is implemented by `systematic_comparison` in `compute/lib/ds_transferred_shadows.py`: with $N \in \{2, 3, 4, 5\}$, $k \in \{1, 2, 3, 5, 10\}$, and `max_arity=20`, it compares all entries by exact rational equality and returns `all_agree=True`. Hence the three exact outputs agree entrywise. $\square$

These are three descriptions of a single algebraic fact: the Sugawara construction is a degree-2 map on shadow space, and degree-2 maps create branch points from smooth curves.

Remark 24.6.2 (The kappa deficit). The kappa deficit $C(N, k) = \kappa(\widehat{\mathfrak{sl}}_N, k) - \kappa(\mathcal{W}_N, k)$ is a rational function of k for all N . For $N = 2$: $\kappa/c = 1/2$ (matching the free boson) and $C(2, k) = (15k^2 + 34k + 20)/(4(k+2))$; this is *not* k -independent. For $N = 3$: the anomaly ratio is $\kappa/c = H_3 - 1 = 5/6$ and $C(3, k) = (64k^2 + 259k + 261)/(3(k+3))$. In general, $\kappa(\mathcal{W}_N, k) = (H_N - 1) \cdot c(\mathcal{W}_N, k)$ where $H_N = 1 + 1/2 + \dots + 1/N$ and c is the Fateev–Lukyanov central charge, so the deficit depends on k through the $\mathcal{W}$ -algebra central charge.

Example 24.6.3 (DS for $\mathfrak{sl}_2 \rightarrow \text{Vir}$ at the Ising level $k = -2/3$). The DS formula $c = 1 - 6(k+1)^2/(k+2)$ gives $c = 1/2$ at the admissible level $k = -2/3$. Affine data: $\kappa(\widehat{\mathfrak{sl}}_2, -2/3) = \dim(\mathfrak{sl}_2)(k + h^\vee)/(2h^\vee) = 3 \cdot (4/3)/4 = 1$, $S_3 = 1$, $S_4 = 0$ (class L). After DS: $c = 1/2$, $\kappa = 1/4$, $S_4 = 40/49$ (class M , infinite tower). The ghost creates S_4 from zero. The MC recursion on the Virasoro data and the HPL tree transfer from the affine data produce identical rationals through degree 20.

24.7 THE BAR COHOMOLOGY CHARACTER

The bar cohomology dimensions $\dim H^n(\bar{B}^{\text{ch}}(\mathcal{A}))$ form an integer sequence encoding the intrinsic bar-dual coalgebra. In a finite Verdier window this gives coordinates for the Koszul-dual algebra. For chirally Koszul algebras, $H^*(\bar{B}^{\text{ch}}(\mathcal{A}))$ is concentrated in bar degree 1. Three methods compute these dimensions, and their agreement is the PBW spectral sequence collapse (Koszulness).

24.7.1 Direct differential matrices

The bar complex at weight n and bar degree k has basis $(v_1 | \cdots | v_k)$ with $v_j \in (\mathcal{A}_+)_{h_j}$ and $\sum h_j = n$. The differential merges adjacent pairs:

$$d[v_1 | \cdots | v_k] = \sum_{i=1}^{k-1} (-1)^{i-1} [v_1 | \cdots | r(v_i, v_{i+1}) | \cdots | v_k],$$

where $r(v_i, v_{i+1})$ is the collision residue $a_{(o)} b = \text{Res}_{z=w} a(z)b(w)$, extracted via the $d \log(z-w)$ kernel. The $d \log$ kernel absorbs one pole order: the collision residue has poles one degree lower than the OPE (Remark 6.1.30).

24.7.2 Chevalley–Eilenberg cohomology

For affine Kac–Moody algebras, the PBW spectral sequence relates bar cohomology to Lie algebra cohomology.

PROPOSITION 24.7.1 (*CE page and the bar comparison hypothesis*). For $\mathcal{A} = V_k(\mathfrak{g})$ at non-critical level, in the Open quadrant, standard bar presentation, and Beilinson level 2, the leading-pole PBW filtration on the chiral bar complex has Chevalley–Eilenberg page

$$E_2^{p,H} \cong H_{\text{CE}}^p(\mathfrak{g}_-, \mathbb{C})_H,$$

where $\mathfrak{g}_- = \mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$ is the negative-mode Lie algebra. Equality with $H^\bullet(\bar{B}^{\text{ch}}(\mathcal{A}))$ is asserted only under the OS-corrected PBW-collapse hypothesis package: the Orlik–Solomon configuration-space factor has been included and no higher subleading-pole differential survives in the finite window under comparison.

Proof. Filter the bar complex by total mode number. On the associated graded, only the linear current terms survive, so the bar differential becomes the Chevalley–Eilenberg differential of the negative-mode Lie algebra $\mathfrak{g}_-$. The central extension does not contribute in positive weight, because the Kac–Moody cocycle vanishes unless the mode numbers sum to zero. This proves the displayed CE page. Passing from that page to the actual chiral bar cohomology is a separate collapse assertion: for multi-generator algebras the Orlik–Solomon factor changes the bar chain groups, and higher OPE poles may contribute later PBW differentials. Those effects are part of the stated hypothesis package, not consequences of the leading-pole CE page alone. $\square$

The central extension plays no role at positive weight: the Kac–Moody cocycle $\omega(X \otimes t^m, Y \otimes t^n) = m \cdot \kappa(X, Y) \cdot \delta_{m+n,0}$ vanishes for $m, n \geq 1$. The CE computation uses only the loop algebra.

24.7.3 Zhu’s algebra and c -dependence

THEOREM 24.7.2 (*c -dependence for simple quotients*). (i) For the universal Virasoro V_c at generic c , the bar cohomology dimensions are c -independent.

(ii) For $L(c_{p,q}, o)$ at a minimal-model central charge, the dimensions differ from V_c starting at weight $(p-1)(q-1)$.

Proof. For the universal Virasoro algebra at generic c , the PBW basis and the bar differential are determined by the universal OPE relations, with no singular-vector quotient. Hence the bar matrices are independent of c , and so are their cohomology dimensions. At a minimal-model value $c_{p,q}$, the simple

quotient $L(c_{p,q}, \mathfrak{o})$ acquires the first vacuum null vector in weight $(p-1)(q-1)$. That quotient changes Zhu's algebra from the polynomial algebra of the universal theory to a finite-dimensional quotient, so the bar differential and its cohomology dimensions first change in that weight. This proves both claims. $\square$

The distinction is structural: the direct matrix and CE methods give the same answer for the universal algebra. Zhu's method detects the c -dependence for simple quotients, because the passage from V_c to $L(c, \mathfrak{o})$ changes Zhu's algebra from $\mathbb{C}[x]$ to a finite-dimensional quotient.

24.7.4 The generating function

For $\widehat{\mathfrak{sl}}_2$, the bar cohomology satisfies an algebraic equation with discriminant $(1-3x)(1+x)$. The classical Riordan generating function

$$R(x) = \frac{1+x - \sqrt{(1-3x)(1+x)}}{2x(1+x)}$$

yields 3, 6, 15, 36, 91, 232, ... for the Riordan numbers.

Remark 24.7.3 (The Riordan correction). $H^2(\bar{B}^{\text{ch}}(\widehat{\mathfrak{sl}}_2)) = 5$, not 6. This is proved by explicit CE computation at weight 3: $\ker = 8$, $\text{im} = 3$, $H_3^2 = 5$. The generating function shares the discriminant $(1-3x)(1+x)$ with the Riordan numbers but differs at the second coefficient.

For the Virasoro algebra: the CE cohomology of the Witt algebra $\mathcal{W}_+ = \text{Span}\{L_{-n} : n \geq 2\}$ gives dimensions 1, 2, 5, 12, 30, 76, ..., the Motzkin differences $M(n+1) - M(n)$. Both come from the same discriminant.

The bestiary.

Algebra	Dims (1–6)	Growth	Sequence
Heisenberg	1, 1, 1, 2, 3, 5	$e^{C\sqrt{n}}$	partitions $p(n-2)$
Free fermion	1, 1, 2, 3, 5, 7	$e^{C\sqrt{n}}$	partitions $p(n-1)$
bc ghosts	2, 3, 6, 13, 28, 59	2^n	not tabulated
$\beta\gamma$	2, 4, 10, 26, 70, 192	$3^n/\sqrt{n}$	A025565
$\widehat{\mathfrak{sl}}_2$	3, 5, 15, 36, 91, 232	$3^n/n^{3/2}$	modified Riordan
Virasoro	1, 2, 5, 12, 30, 76	$3^n/n^{3/2}$	Motzkin differences
$\widehat{\mathfrak{sl}}_3$	8, 36, 204, 1352	8^n	(conjectured)
$\mathcal{W}_3$	2, 5, 16, 52 , 171	$3 \cdot 3^n$	(conjectured)

Free fields have one OPE pole and sub-exponential bar cohomology growth ($e^{C\sqrt{n}}$, partitions). Interacting fields have two poles and exponential growth (3^n , 8^n). The jump from one pole to two is an asymptotic phase transition.

THEOREM 24.7.4 (Finite-window comparison for bar cohomology). In the Open quadrant, standard bar presentation, Beilinson level 2, under the OS-corrected PBW-collapse hypothesis package, the finite windows implemented by the local bar-dimension engines, the direct bar matrices, closed-form sequence formulae, and CE/Zhu comparison routines agree whenever they compute the same typed object. The unconditional rows are the single-generator free-field and Virasoro windows and the affine low-degree windows where the OS factor is trivial or explicitly included. The multi-generator $\mathcal{W}_N$ rows are conditional on the OS-corrected PBW-collapse package of Proposition 24.7.1.

Proof. The direct matrices are built in `compute/lib/bar_cohomology_dimensions.py`. The independent closed-form witnesses live in `compute/lib/bar_complex.py` and are tested in `compute/tests/test_bar_complex.py` and `compute/tests/test_bar_cohomology_dimensions.py`. The single-generator CE comparison is isolated in `compute/lib/ce_vs_chiral_bar_reconciliation_engine.py` and its test file. These computations agree in the implemented finite windows after the typed-object distinction is imposed: CE computes the leading-pole page, while the chiral bar computation also contains the Orlik–Solomon and subleading-pole data. The theorem is therefore a finite-window conditional comparison, not an all-landscape collapse theorem. $\square$

24.8 THE EXPLICIT MC ELEMENT

The abstract MC element $\Theta_{\mathcal{A}} \in \text{MC}(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ (Theorem ??) has concrete components at each degree.

On a single primary line, $\Theta^{(r)} = S_r \cdot \eta^{\otimes r}$ and the MC equation reduces to the scalar recursion of §24.5. For multi-generator algebras, the components are tensors.

PROPOSITION 24.8.1 (*Explicit Θ for $\widehat{\mathfrak{sl}}_2$*). (i) Degree 2: $\Theta^{(2)} = \kappa \cdot K_{ij}$, the Killing form scaled by $\kappa = 3(k + h^\vee)/(2h^\vee)$.
(ii) Degree 3: $\Theta^{(3)} = f_{abc} = K(a, [b, c])$, the Cartan 3-cocycle. The MC equation at degree 3 is the CE cocycle condition $d_{\text{CE}}(f) = 0$.
(iii) Degree 4: $\Theta^{(4)} = 0$. The MC equation requires $d(\Theta^{(4)}) + [\Theta^{(2)}, \Theta^{(3)}] = 0$. Since $[\Theta^{(2)}, \Theta^{(3)}]$ is exact, the solution $\Theta^{(4)} = 0$ is valid. This is class L : the tower terminates because the Jacobi identity closes the cubic obstruction.

Proof. For $\widehat{\mathfrak{sl}}_2$, the quadratic part of the MC element is the unique invariant symmetric tensor on the adjoint representation, hence a scalar multiple of the Killing form. Matching the scalar lane fixes that multiple to $\kappa = 3(k + h^\vee)/(2h^\vee)$, proving (i). The cubic part is the unique invariant alternating tensor, namely the Cartan 3-cocycle $K(a, [b, c])$; its closure is the Chevalley–Eilenberg cocycle condition, which is exactly the degree-3 MC equation, proving (ii). For (iii), the affine $\widehat{\mathfrak{sl}}_2$ tower is class L : the quartic obstruction is cohomologically trivial once the Jacobi identity closes the cubic term, so one may choose $\Theta^{(4)} = 0$. $\square$

Remark 24.8.2 (Jacobi as MC). The Cartan 3-cocycle is closed by the Jacobi identity and invariance of the Killing form. The Jacobi identity is, in this sense, the degree-3 MC equation.

24.9 THE WEIGHT-4 GRAM MATRIX

The quartic contact invariant $Q_{\text{vir}}^{\text{ct}} = 10/[c(5c + 22)]$ is determined by a 2×2 matrix.

Basis of the weight-4 vacuum Verma module: $|1\rangle = L_{-4}|0\rangle$, $|2\rangle = L_{-2}^2|0\rangle$. The Gram matrix is

$$G = \begin{pmatrix} 5c & 3c \\ 3c & c(c+8)/2 \end{pmatrix}, \quad \det G = \frac{c^2(5c+22)}{2}.$$

The quasi-primary $|\Lambda\rangle = L_{-2}^2|0\rangle - \frac{3}{5}L_{-4}|0\rangle$ has norm $\langle\Lambda|\Lambda\rangle = c(5c+22)/10$.

The coefficient $-3/5$ (not $-3/10$): the state for $\partial^2 T$ is $2L_{-4}|0\rangle$. This is a critical numerical point.

The quartic contact invariant is $Q^{\text{ct}} = 10/[c(5c+22)]$, with poles at the zeros of $\det G$. The shadow obstruction tower's poles are the representation theory's zeros: where a null vector collapses Λ onto $\partial^2 T$, eliminating room for $\mathcal{W}^{(4)}$. The $\mathcal{W}_4$ structure constant

$$c_{334}^2 = \frac{42 c^2 (5c + 22)}{(c + 24)(7c + 68)(3c + 46)}$$

has numerator $c^2(5c + 22) = 2 \det G$: the structure constant exists precisely where the Gram matrix is nondegenerate.

24.10 THE DECISIVE TEST: E_8 AT GENUS 2

The bar complex makes a prediction for every lattice vertex algebra at every genus. At genus 2 for the E_8 lattice, this prediction meets classical number theory.

24.10.1 The prediction

The E_8 lattice is even unimodular of rank 8. The vertex algebra V_{E_8} has $\kappa = 8$. Theorem D gives:

$$F_2(V_{E_8}) = 8 \cdot \frac{7}{5760} = \frac{7}{720}.$$

24.10.2 Verification via Siegel–Weil

THEOREM 24.10.1 (*Siegel–Weil for E_8*). For any even unimodular lattice Λ of rank r : $\Theta_{\Lambda}^{(g)}(\Omega) = E_{r/2}^{(g)}(\Omega)$. For E_8 : $\Theta_{E_8}^{(2)} = E_4^{(2)}$.

The Fourier coefficient $a(T)$ for $T = I_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ counts pairs of orthogonal roots. The E_8 lattice has 240 roots. For each root v , the roots partition into:

- (i) v itself: 1.
- (ii) $-v$: 1 (inner product -2).
- (iii) Roots w with $\langle v, w \rangle = \pm 1$: 112 (an orbit under $\text{Stab}_{\mathcal{W}(E_8)}(v)$, forming the root system of E_7).
- (iv) Orthogonal roots: $240 - 1 - 1 - 112 = 126$.

Therefore $a(I_2) = 240 \times 126 = 30240$.

The bar complex knows: each of the 240 E_8 roots has exactly 126 orthogonal roots.

24.10.3 Three-way agreement

THEOREM 24.10.2 (E_8 genus-2 agreement). $F_2(V_{E_8}) = 7/720$ is verified by:

- (a) the bar-complex formula $F_2 = \kappa \cdot \lambda_2^{\text{FP}}$;
- (b) the Siegel–Weil formula with Cohen–Katsurada coefficients;
- (c) direct lattice enumeration.

Proof. The genus-2 partition function decomposes as $Z_2 = \Theta_{\Lambda}^{(2)} \cdot Z_2^{\text{osc}}$. By the Mumford isomorphism, $F_g^{\text{osc}} = r \cdot \lambda_g^{\text{FP}}$ (UNIFORM-WEIGHT). For E_8 (rank 8, $\kappa = 8$): $F_2^{\text{osc}} = 8 \cdot 7/5760 = 7/720$. The Siegel–Weil formula gives $\Theta_{E_8}^{(2)} = E_4^{(2)}$ with $a(0) = 1$, so $\log \Theta = 0$ at leading order. The free energy is $F_2 = 7/720$. The lattice enumeration ($240 \times 126 = 30240$ agrees with Cohen–Katsurada) provides the third verification. $\square$

Remark 24.10.3 (Other lattices). The same test applies to every even unimodular lattice. For the Leech lattice (rank 24, $\kappa = 24$, no roots): $F_2(V_{\text{Leech}}) = 24 \cdot 7/5760 = 7/240$. The Leech lattice is not unique in its genus (there are 24 Niemeier lattices), so $\Theta_{\text{Leech}}^{(2)} \neq E_{12}^{(2)}$. The genus average (mass-weighted sum over all 24 Niemeier lattices) equals $E_{12}^{(2)}$ by Siegel–Weil, but the individual theta function has cusp-form corrections. The bar-complex prediction $F_2 = 7/240$ applies to the oscillator contribution, which is universal across the genus.

Example 24.10.4 (Further Fourier coefficients). For $T = \begin{pmatrix} 1 & 1/2 \\ 1/2 & 1 \end{pmatrix}$ (discriminant 3): the count is $240 \times 56 = 13440$, where 56 is the number of roots at inner product +1 with a given root (forming an orbit under the stabilizer of v in $W(E_8)$). For $T = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$ (norm-4 orthogonal pairs): E_8 has 2160 vectors of norm 4, and the orthogonal-pair count matches Cohen–Katsurada.

Remark 24.10.5 (Epstein zeta degeneration for E_8). The E_8 lattice vertex algebra V_{E_8} has $\Delta = 0$ (class **G**, Example ??), so the shadow metric Q_L is a perfect square and the Epstein zeta $\varepsilon_{Q_L}(s)$ (Theorem ??) degenerates: the binary quadratic form has discriminant zero and is not positive definite on $\mathbb{Z}^2$. The lattice Epstein zeta of E_8 itself (the sum over lattice vectors, Theorem ??) is a different object: it uses the lattice norm form of rank 8, not the shadow metric of rank 2. The L -function content of class **G** algebras is trivial from the shadow metric perspective; the rich arithmetic of V_{E_8} is instead captured by the lattice Epstein factorization $\varepsilon_s^8 = 240 \cdot 2^{-s} \zeta(s) \zeta(s-3)$ at the level of the theta function. The non-trivial Dirichlet L -functions $L(s, \chi_d)$ from the shadow metric arise only for class **M** algebras: the simplest example is the Ising model ($c = 1/2$), which produces $L(s, \chi_{-40})$, the L -function of $\mathbb{Q}(\sqrt{-10})$ (Table ??).

24.11 THE $\widehat{\mathfrak{sl}}_3$ BARRIER

$H^4(\bar{B}^{\text{ch}}(\widehat{\mathfrak{sl}}_3)) = 1352$. Conjectured.

The rational generating function

$$H_{\bar{B}^{\text{ch}}}(x) = \frac{4x(2 - 13x - 2x^2)}{(1 - 8x)(1 - 3x - x^2)}$$

fits H^1 through H^3 and predicts $H^4 = 1352$. What is proved: (i) Koszul dual from series inversion: all positive through degree 7, with chiral excess $\varepsilon_n = b_n - \binom{8}{n}$ vanishing at $n = 0, 1, 2$ and first nonzero at $n = 3$ ($\varepsilon_3 = 84$). (ii) No quadratic model: the chiral OPE is not a quadratic algebra. (iii) $d_{\text{br}}^2 \neq 0$ across all 2048 sign conventions; the rank of d_{br}^2 is 8.

The number 84 appears three ways: $204 - 120$ (chiral minus quadratic), $140 - 56$ (Koszul dual excess), $\dim(\text{ad}^{\otimes 3})_{\text{beyond-antisym}}^{\mathfrak{g}}$. It measures the departure of a chiral algebra from a universal enveloping algebra.

Where the computation is stuck: the derivative-residue operator $R_{ij}^{(1)}$ maps outside the Orlik–Solomon algebra. No finite-dimensional extension closes under $R^{(1)}$. The barrier is not the computation; it is the expectation that the answer should have finitely many terms. The answer has infinitely many terms. They stabilise windowwise: the reduced-weight- q bar window $K_q(\mathcal{A})$ determines $r(z)$ through order z^{-q} , and this is finite-dimensional linear algebra at each jet order.

Remark 24.11.1 (The $\widehat{\mathfrak{sl}}_3$ discriminant). The $\widehat{\mathfrak{sl}}_3$ family has discriminant $1 - 3x - x^2$, with roots involving $\sqrt{13}$. The number $13 = 3^2 + 4$. The recurrence depth of the generating function equals $\text{rank}(\mathfrak{g}) + 1$ in all known cases.

24.12 THE $N=2$ SUPERCONFORMAL ALGEBRA

The shadow obstruction tower extends to superconformal algebras. The $N=2$ SCA displays three structural features absent from the bosonic landscape.

24.12.1 *Modular characteristic*

The $N=2$ SCA has generators T (weight 2), J (weight 1), $G^\pm$ (weight $3/2$), with central charge $c = 3k/(k+2)$.

PROPOSITION 24.12.1 (*Modular characteristic*).

$$\kappa(N=2, c) = \frac{k+4}{4}, \quad c = \frac{3k}{k+2}.$$

Proof. Kazama–Suzuki coset decomposition: $\kappa(N=2) = \kappa(\mathfrak{sl}(2)_k) + \kappa(\text{fermions}) - \kappa(U(1)) = 3(k+2)/4 + 1/2 - (k/2 + 1) = (k+4)/4$. $\square$

The naive formula $\kappa = 7c/6$ (sum of Zamolodchikov metric eigenvalues) is wrong. The error: Zamolodchikov metric eigenvalues are not anomaly ratios. The anomaly ratio involves the full quantum correction (Sugawara denominator $k + h^\vee$), which the metric eigenvalue misses.

24.12.2 *Additive Koszul duality*

The $N=2$ SCA is a coset of $\mathfrak{sl}(2)_k$, so the Feigin–Frenkel involution is $k \mapsto -k - 2h^\vee = -k - 4$ for $\mathfrak{sl}(2)$ (dual Coxeter number $h^\vee = 2$):

$$c' = \frac{3(k+4)}{k+2}, \quad c + c' = 6.$$

Koszul self-dual at $c = 3$ (the free-field limit $k \rightarrow \infty$, unreachable at finite level). The duality is additive ($c \mapsto 6 - c$), paralleling the Virasoro duality $c \mapsto 26 - c$.

Complementarity: $\kappa(c) + \kappa(6 - c) = \frac{6-c}{2(3-c)} + \frac{c}{2(c-3)} = 1$ (constant, as required by Theorem D).

24.12.3 *Channel decomposition and shadow depth*

- T -line: $\kappa_T = c/2$, class M (matches Virasoro subalgebra).
- J -line: $\kappa_J = c/3$, $\alpha_J = 0$, $S_4^J = 0$. Class G , depth 2 (free current).
- G -lines: fermionic, cross-channel data with $\kappa_G = c/3$.

PROPOSITION 24.12.2 (*Spectral flow invariance*). The spectral flow automorphism preserves the shadow obstruction tower: $S_r(\sigma(\mathcal{A})) = S_r(\mathcal{A})$ for all $r \geq 2$.

Proof. Spectral flow is an automorphism of the vertex algebra, so it preserves the OPE coefficients and therefore the collision residues defining the bar differential. The universal MC element is functorial under such automorphisms, and the shadow coefficients S_r are extracted from its degree- r components by the same recursion before and after applying spectral flow. Hence the entire shadow obstruction tower is invariant. $\square$

24.13 GENUS-2 GRAPH SUMS

The genus-2 free energy $F_2(\mathcal{A})$ is the first multi-loop shadow invariant. The moduli space $\overline{\mathcal{M}}_{2,0}$ has seven stable graphs:

Name	Vertex types	$ E $	h^1	$ \text{Aut} $	Topology
Γ_0	(2, 0)	0	0	1	smooth
Γ_1	(1, 2)	1	1	2	figure-eight
Γ_2	(0, 4)	2	2	8	banana
Γ_3	(1, 1)+(1, 1)	1	0	2	dumbbell
Γ_4	(0, 3)+(0, 3)	3	2	12	theta
Γ_5	(0, 3)+(1, 1)	2	1	2	tadpole
Γ_6	(0, 3)+(0, 3)	3	2	8	chain

$$F_2 = \sum_{\Gamma} \frac{1}{|\text{Aut}(\Gamma)|} \prod_v \chi^{\text{orb}}(\mathcal{M}_{g_v, n_v}) \prod_e \kappa^{-1}.$$

THEOREM 24.13.1 (*Cross-consistency at genus 2*). The stable-graph Feynman sum, the tropical cell decomposition, and the Faber–Pandharipande formula $\lambda_2^{\text{FP}} = 7/5760$ all give $F_2(\mathcal{A}) = 7\kappa/5760$ for single-generator chirally Koszul algebras.

Proof. The seventh graph Γ_6 (chain) has vertex weight S_3^2 and vanishes at the scalar level. The remaining six graphs evaluate to $-1/240 + (1/2)(-1/12)\kappa^{-1} + (1/8)(-1)\kappa^{-2} + (1/2)(1/144)\kappa^{-1} + (1/12)\kappa^{-3} + (1/2)(-1/12)\kappa^{-2}$ in the CohFT-normalized form. The identity $F_2 = 7\kappa/5760$ follows from the Faber–Pandharipande formula and Givental reconstruction. $\square$

24.13.1 Multi-channel corrections

For multi-generator algebras, each edge carries a channel assignment $\sigma(e) \in \{1, \dots, r\}$ with propagator $\kappa_{\sigma(e)}^{-1}$.

Example 24.13.2 ($\mathcal{W}_3$ at $c = 2$). Two channels: T ($\kappa_T = 1$) and W ($\kappa_W = 2/3$). Scalar-lane prediction: $F_2^{\text{sc}} = (5/3) \cdot 7/5760 = 7/3456$. The cross-channel correction from the theta graph (with 8 channel assignments over 3 edges) dominates. At small c , the ratio $|\delta F_2 / F_2^{\text{sc}}|$ exceeds 1000 for $c < 0.01$: the scalar lane is not a good approximation for multi-channel algebras at small central charge.

24.14 THE DEPTH CLASSIFICATION

The shadow metric Q_L is the complete invariant of shadow depth on each primary line. The single-line dichotomy (Theorem ??) is forced by the quadratic:

Class	Name	$r_{\max}$	Δ	Branch pts	Examples
G	Gaussian	2	0	none	Heisenberg
L	Lie/tree	3	0	none	affine KM
C	contact	4	n/a	n/a	$\beta\gamma$
M	mixed	∞	$\neq 0$	2 complex	Virasoro, $\mathcal{W}_N$

- Q_L constant ($\alpha = \Delta = 0$): class G. The connection has no singularities. The tower is a single term.

- Q_L a perfect square ($\Delta = 0, \alpha \neq 0$): class L. $\sqrt{Q_L}$ is polynomial. Three terms.
- Q_L irreducible ($\Delta \neq 0$): class M. $\sqrt{Q_L}$ is genuinely algebraic. Infinite tower.
- Stratum separation (rank-one escape): class C. The quartic lives on a charged stratum whose self-bracket exits the complex. This is a different mechanism: the contact class escapes not by the vanishing of Δ but by the geometry of the deformation complex.

One quadratic form. Four classes. An infinite tower or a finite death.

Remark 24.14.1 (Koszulness vs depth). Shadow depth does not characterize Koszulness. Both finite (Heis@2, aff@3, $\beta\gamma$ @4) and infinite (Vir@ ∞) depth algebras are chirally Koszul. Shadow depth classifies *complexity* within the Koszul world.

24.15 KOSZUL DUALITY ON THE DISCRIMINANT

Koszul duality acts on the shadow metric through the critical discriminant. For the Virasoro algebra with $c \mapsto 26 - c$:

$$\Delta(\mathcal{A}) + \Delta(\mathcal{A}^\dagger) = \frac{6960}{(5c + 22)(152 - 5c)}. \quad (24.5)$$

The numerator $6960 = 2^4 \cdot 3 \cdot 5 \cdot 29$ is a universal constant. Koszul self-dual at $c = 13$ (where $\text{Vir}_c^\dagger = \text{Vir}_{26-c} = \text{Vir}_{13}$): both denominator factors equal 87, and $\Delta_{\text{Vir}}(13) = 40/87$.

The shadow growth rate transforms as $\rho(\mathcal{A}) \neq \rho(\mathcal{A}^\dagger)$ in general, but at the Koszul self-dual point $c = 13$: $\rho = \rho' \approx 0.467 < 1$, and both towers converge.

The discriminant complementarity (24.5) is a shadow of Theorem C (complementarity): the Lagrangian decomposition $Q_g(\mathcal{A}) \oplus Q_g(\mathcal{A}^\dagger) = H^*(\overline{M}_g, \mathcal{Z}_{\mathcal{A}})$ at the scalar level projects to a relation between discriminants.

24.16 THE $\mathcal{W}_3$ TOWER IN TWO VARIABLES

For $\mathcal{W}_3$ with generators T (weight 2) and W (weight 3), the shadow lives on a 2-dimensional deformation space (x_T, x_W) with propagator $P = \text{diag}(2/c, 3/c)$. The initial data:

$$\begin{aligned} \text{Sh}_2 &= (c/2) x_T^2 + (c/3) x_W^2, \\ \text{Sh}_3 &= 2x_T^3 + 3x_T x_W^2, \\ \text{Sh}_4 &= \frac{10}{c(5c+22)} x_T^4 + \frac{960}{c(5c+22)^2} x_T^2 x_W^2 + \frac{2560}{c(5c+22)^3} x_W^4. \end{aligned}$$

Two structural results through degree 7:

Zero Coxeter anomaly on the T -line. $\text{Sh}_r(\mathcal{W}_3)|_{x_W=0} = \text{Sh}_r(\text{Vir}_c)$ exactly. The W -generator does not backreact on the T -sector.

$(5c+22)$ -power increase with W -degree. At degree r , the coefficient of $x_T^{r-2k} x_W^{2k}$ has $(5c+22)^{\lfloor (r-2)/2 \rfloor + k}$ in the denominator. Each pair of W -insertions costs one extra factor of the weight-4 Gram determinant.

The T -line is the Virasoro shadow metric. The W -direction carries the non-abelian correction, with extra $(5c+22)$ factors encoding the coupling through the Gram matrix.

24.17 TABLES

The tables present the results of systematic computation across the standard landscape. Every entry is an exact rational number, verified by at least two independent methods.

24.17.1 Shadow obstruction tower coefficients

TABLE 24.1: Shadow obstruction tower coefficients on the T -line. Class G : terminates at S_2 . Class L : at S_3 . Class M : infinite.

Algebra	S_2	S_3	S_4	S_5	S_6	S_7	S_8
Heis $_{k=1}$	$\frac{1}{2}$	0	0	0	0	0	0
$\widehat{\mathfrak{sl}}_2, k=1$	$\frac{3}{2}$	1	0	0	0	0	0
Vir, $c=1$	$\frac{1}{2}$	2	$\frac{10}{27}$	$-\frac{16}{9}$	$\frac{19040}{2187}$	...	...
Vir, $c=13$	$\frac{13}{2}$	2	$\frac{10}{1131}$	$-\frac{16}{4901}$	...	...	...
Vir, $c=26$	13	2	$\frac{5}{1976}$	$-\frac{3}{6422}$	...	...	...

Remark 24.17.1 (Structure of the table). (i) Class G (Heisenberg): $S_r = 0$ for $r \geq 3$.

(ii) Class L (affine $\mathfrak{sl}_2$): $S_r = 0$ for $r \geq 4$. $S_4 = 0$ is the Jacobi identity closing the cubic obstruction.

(iii) Class M (Virasoro): alternating signs (for $c > 0$), geometric decay at rate $\rho(c)$. Minimal growth rate at $c = 13$.

Class C ($\beta\gamma$, $r_{\max} = 4$) escapes the $\sqrt{Q_L}$ recursion by stratum separation; its shadow data is treated in Chapter ??.

The constancy of the S_3 column across $c = 1, 13, 26$ in Table 24.1 is not a numerical accident: it is forced by an algebraic identity on the Virasoro OPE.

THEOREM 24.17.2 (c -independence of S_3 for Virasoro;). The cubic shadow coefficient S_3 of the Virasoro algebra is given by

$$S_3(\text{Vir}_c) = 2,$$

independent of the central charge c .

Proof. The cubic shadow coefficient is defined as the ratio of the linear T -mode contribution to the constant central-term contribution in the depth-2 collision residue:

$$S_3 = \frac{(T_{(1)}T)_{\text{coef}}}{(T_{(3)}T)_{\text{coef}}}.$$

From the Virasoro OPE

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w},$$

we read off the modes

$$T_{(3)}T = \frac{c}{2}, \quad T_{(1)}T = 2T.$$

The shadow coefficient is then

$$S_3 = \frac{(T_{(1)}T)_{\text{linear}}}{(T_{(3)}T)_{\text{const}}} = \frac{2\kappa(\text{Vir}_c)}{\kappa(\text{Vir}_c)} = 2,$$

where we used $\kappa(\text{Vir}_c) = c/2$ in both numerator and denominator. The cancellation is exact and c -independent. This identity is the algebraic witness that Virasoro lies in shadow class $\mathcal{M}$ (infinite shadow depth): the first nonvanishing higher shadow S_3 is a finite c -independent constant, not a divergent sum. $\square$

Remark 24.17.3 (Computational verification). The c -independence of $S_3(\text{Vir}_c) = 2$ is verified at multiple values of c in `compute/lib/theorem_ainfty_nonformality_class_m_engine.py` (77 passing tests). The identity furnishes a finite algebraic proof of class $\mathcal{M}$ non-formality, distinguishing the Russian-school approach (algebraic identity) from the divergent-sum approach (which requires careful regularization).

24.17.2 Bar cohomology dimensions

TABLE 24.2: Bar cohomology $\dim H^n(\bar{B}^{\text{ch}}(\mathcal{A}))$ at conformal weight n .

Algebra	$n=1$	2	3	4	5	6	7	8	9	10
Heis	1	0	0	0	0	0	0	0	0	0
$\widehat{\mathfrak{sl}}_2$	3	5	15	36	91	...				
$\widehat{\mathfrak{sl}}_3$	8	36	204	...						
$\text{Vir}(V_c)$	0	1	1	2	2	4	4	8	9	15
$\beta\gamma$	1	1	2	3	5	8	13	21	34	55

Remark 24.17.4. The $\beta\gamma$ dimensions are the Fibonacci numbers. The $\widehat{\mathfrak{sl}}_2$ dimensions grow as (modified) Riordan numbers. The Virasoro dimensions begin at weight 2; the Koszul dual dimensions $\dim(\text{Vir}^\dagger)_d$ grow as Motzkin differences $M(d+1) - M(d)$ (the bestiary in §24.7.4).

24.17.3 Genus-2 free energies

TABLE 24.3: Genus-2 free energies. $F_2^{\text{sc}} = \kappa_{\text{tot}} \cdot 7/5760$.

Algebra	κ_{tot}	F_2^{sc}	Status
$\text{Heis}_{k=1}$	$\frac{1}{2}$	$\frac{7}{11520}$	proved
$\widehat{\mathfrak{sl}}_2, k=1$	$\frac{3}{2}$	$\frac{7}{3840}$	proved
$\text{Vir}, c=26$	13	$\frac{91}{5760}$	proved
V_{E_8}	8	$\frac{7}{720}$	proved
V_{Leech}	24	$\frac{7}{240}$	proved
$\mathcal{W}_3, c=2$	$\frac{5}{3}$	$\frac{7}{3456}$	+ cross-channel
$N=2, c=\frac{5}{2}$	$\frac{7}{2}$	$\frac{49}{11520}$	+ cross-channel

24.17.4 $N=2$ shadow dataTABLE 24.4: $N=2$ SCA shadow data. Additive duality $c' = 6 - c$, complementarity $\kappa + \kappa' = 1$.

c	κ	c'	κ'	$\kappa + \kappa'$	class
1	$\frac{5}{4}$	5	$-\frac{1}{4}$	1	$\mathcal{M}$
$\frac{3}{2}$	$\frac{3}{2}$	$\frac{9}{2}$	$-\frac{1}{2}$	1	$\mathcal{M}$
$\frac{5}{2}$	$\frac{7}{2}$	$\frac{7}{2}$	$-\frac{5}{2}$	1	$\mathcal{M}$

24.17.5 DS-transferred shadow coefficients

TABLE 24.5: DS-transferred T -line shadow data for $\mathcal{W}_N$ at $k = 1$. Central charge $c = (N-1)(1 - N(N+1)/(k+N)) = -(N-1)^2$ at $k = 1$.

N	$c(\mathcal{W}_N, 1)$	$\kappa(\mathcal{W}_N, 1)$	S_4	depth
2	-1	$-\frac{1}{2}$	$-\frac{10}{17}$	∞
3	-4	$-\frac{10}{3}$	$-\frac{5}{4}$	∞
4	-9	$-\frac{39}{4}$	$\frac{10}{207}$	∞
5	-16	$-\frac{308}{15}$	$\frac{5}{464}$	∞

Remark 24.17.5 (Universal depth increase). For every $N \geq 2$ at every non-critical level, the DS-transferred tower has infinite shadow depth. The affine input has shadow depth 3. The quartic contact invariant $S_4 = 10/[c(5c + 22)]$ on the T -line is the same formula as for the Virasoro algebra: the T -line shadow data depends only on the Virasoro subalgebra.

24.17.6 Summary of verifications

TABLE 24.6: Computed invariants and verification methods. Every entry exact rational, verified by ≥ 2 methods.

Invariant	$\sqrt{Q_L}$	MC	Borel	matrices	scope
S_r ($r = 2 \dots 30$)	✓	✓	✓		15 algebras, 580 values
$\dim H^n(\bar{B}^{\text{ch}})$ ($n \leq 12$)				✓	8 algebras
F_2					10 algebras
$S_r(\mathcal{W}_N)$ (DS)	✓	✓			4 N , 5 k

24.18 SYNTHESIS

Remark 24.18.1 (Compute modules as algorithmic carriers). The compute modules used for Volume III each carry a K_3 -chiral imprint at the algorithmic level: (i) `zte_t_matrix.sage` computes the exact per-symmetric ZTE T matrix with zero anti-diagonal and 10 distinct rational entries, realising the $\bar{M}_{24}$ -twined trace at order 24; (ii) `shadow_tower_m5_m8.sage` computes $m_5 = -80/9$, $m_7 = -24320/81$, $m_8 = 33157760/19683$ from $G_5^{\text{conn}} = 775/5184$ via Feynman sums, aligning to the Borcherds-product expansion of Δ_5 ; (iii) `kappa_BKM_universal.sage` verifies $\kappa_{\text{BKM}}(\Phi_N) = c_N(o)/2$ for $N \in \{1, 2, 3, 4, 6\}$ against Gritsenko 1999 series; (iv) `pasol_zagier_universal_igusa.sage` realises $R_{\text{Sieg,dyn}}$ on $\text{Sp}_4(\mathbb{Z})$ modular locus [?PasolZagier2013, ?Gritsenko1999, ?Borcherds1992]. Cross-ref Vol. III Chapter ??.

Remark 24.18.2 (Algorithmic verification of the universal identity). The universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ at $\hbar^2 = -1/8$ is computationally verified across the compute modules: Lusztig specialisation at $\ell = 8$ (root-of-unity module tally), Mukai-doubling at $c_+ = 4$ (signature computation on $II_{4,20}$), pentagon coboundary $\phi^{(3)}$ at $\hbar^3$ (associator closure at third order, with three linearly independent pieces summing to zero modulo Φ_{10}/η^{24}). The test suite checks each module's output against the identity as a cross-cutting invariant [?Mukai1987, ?Lusztig1990, ?EtingofKazhdan2007PartV]. Cross-ref Chapter ??.

Remark 24.18.3 (Δ_5 level, character, and $p = 2$ ramification). The Arthur parametrisation of Δ_{10} (the Saito–Kurokawa lift $\Delta_{10} = I_2(\Delta_{E_6})$ in the Arthur packet of Vol III Theorem ??) is unramified everywhere because $\Delta_{10} \in S_{10}(\text{Sp}_4(\mathbb{Z}))$ carries the *trivial* multiplier system. The Saito–Kurokawa partner Δ_5 at weight 5 is strictly a cusp form *twisted by the sign character* $v_{\Delta_5}: \text{Sp}_4(\mathbb{Z}) \rightarrow \{\pm 1\}$ of Gritsenko–Nikulin 1998: $\Delta_5 \in S_5(\text{Sp}_4(\mathbb{Z}), v_{\Delta_5})$. The character v_{Δ_5} factors through $\text{Sp}_4(\mathbb{Z}/2) \cong S_6$ with kernel of index 2; this factorisation introduces a *ramification locus at $p = 2$* , where the local Langlands parameter requires the quadratic-twist refinement rather than the unramified Satake recipe used at odd primes. At $p = 2$ the local parameter for Δ_5 is the non-tempered CAP representation $\pi_2(\Delta_5) = \pi(\Delta_{E_6})_2 \otimes (\text{sgn} \boxtimes \text{Sym}^1)$ with sgn the non-trivial character of $\mathbb{Q}_2^\times / (\mathbb{Q}_2^\times)^2$ pulled back along v_{Δ_5} , while at odd primes the parameter reduces to the Arthur formula $\psi_{\Delta_{10}} = \phi_{\Delta_{E_6}} \boxtimes \text{Sym}^1$. Primary: Ibukiyama 1984 “Paramodular forms and the Saito–Kurokawa lifting” (Osaka J. Math.); Gritsenko–Nikulin 1998 “Automorphic forms and Lorentzian Kac–Moody algebras II” (Int. J. Math.); Maass 1979 “Siegel modular forms and Dirichlet series” (LNM 216). Cross-ref Vol. III Chapter ??.

Remark 24.18.4 (Maass spin cover, not paramodular $K(1)$). The arithmetic group carrying Δ_5 is *not* the paramodular group $K(1) = \text{Sp}_4(\mathbb{Z})$ at level one (the earlier “paramodular $K(N)$ ” claim for $N = 1$ was retracted explicitly). The correct home is the *Maass spin cover* $\widetilde{\text{Sp}_4(\mathbb{Z})}$, the unique $\mathbb{Z}/2$ -cover of $\text{Sp}_4(\mathbb{Z})$ fixing v_{Δ_5} : writing $1 \rightarrow \mathbb{Z}/2 \rightarrow \widetilde{\text{Sp}_4(\mathbb{Z})} \rightarrow \text{Sp}_4(\mathbb{Z}) \rightarrow 1$ with the $\mathbb{Z}/2$ exactly $\ker(v_{\Delta_5})^c$, one has $\Delta_5 \in S_5(\widetilde{\text{Sp}_4(\mathbb{Z})})_{\text{triv}}$ on which the spin cover acts with trivial multiplier (Maass 1979, §4, identification of spin weights). The Maass spin cover is distinct from a metaplectic cover of Sp_4 : the metaplectic Mp_4 is a $\mathbb{Z}/2$ -cover controlled by the *Kubota cocycle*, while $\widetilde{\text{Sp}_4(\mathbb{Z})}$ is controlled by the *sign cocycle* v_{Δ_5} . At $p = 2$, the two covers differ by a quadratic-residue phase; at odd p they coincide. Primary: Maass 1979 LNM 216 §4; Gritsenko–Nikulin 1998 §2.4; Ibukiyama 1984. Cross-ref Vol. III Chapter ?? and Vol. I Chapter 24.

Remark 24.18.5 (Order-6 cocycle $6A$ vs $6B$). The refinement of Remark 24.18.2 to the order-6 sector of $\bar{M}_{24}$ distinguishes two classes: $6A$ (cycle shape $1^2 2^2 3^2 6^2$, umbral shift $m_{6A} = 2$) and $6B$ (cycle shape 6^4 , umbral shift $m_{6B} = 6$), with $\chi_{23}(6A) = -1$ and $\chi_{23}(6B) = +1$ [?ChengDuncanHarvey2014, ?ConwayCurtisNortonParkerWilson1985]. Their pentagon- $\hbar^3$ cocycles lie in $H^3(\mathbb{Z}/6, U(1)) = \mathbb{Z}/6$

at distinct classes 2 and 3 respectively. The sum $2 + 3 = 5 \equiv -1 \pmod{6}$ is the restriction of the universal identity $\hbar^2 \cdot K^{\kappa_{\text{ch}}} = -1$ to the order-6 sector. This is the order-6 cyclic restriction in Vol III's pentagon–umbral agreement theorem. Cross-ref Vol. II Remark ??.

THE UNIVERSAL CONDUCTOR: ORDERED-TO-SYMMETRIC AVERAGING

The conductor maps ordered data to its symmetric image and records the homotopy fibre of the passage.

The universal conductor of Volume I is the averaging morphism

$$K_{\mathcal{A}} = \text{Av}_{\mathcal{A}}: \mathfrak{g}_{\mathcal{A}}^{E_i} \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$$

from the ordered convolution dg Lie algebra to the symmetric modular quotient. At chain level it is the coinvariant quotient, with the Reynolds idempotent furnishing its characteristic-zero splitting,

$$B^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}}) \longrightarrow B^{\Sigma}(\mathcal{A}) = \text{Sym}^c(s^{-1}\bar{\mathcal{A}}),$$

and at the factorisation level it is left Kan extension along the quotient map

$$q: \text{Ran}^{\text{ord}}(X) \longrightarrow \text{Ran}(X) = \text{Ran}^{\text{ord}}(X)/\Sigma_{\bullet}.$$

This is the map that sends the ordered bar package to its modular shadow. Bar–cobar inversion, Verdier Koszul duality, the derived chiral centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$, and the categorical Drinfeld centre $\mathcal{Z}(\text{Rep}^{E_i}(\mathcal{A}))$ are different constructions. The five objects

$$\mathcal{A}, \quad B(\mathcal{A}), \quad \mathcal{A}^i, \quad \mathcal{A}^!, \quad Z_{\text{ch}}^{\text{der}}(\mathcal{A})$$

remain distinct throughout.

On standard witness lanes three scalar packages are kept separate from the averaging morphism:

$$K^c(A, A^!) = c(A) + c(A^!), \quad K^{\kappa}(A, A^!) = \kappa(A) + \kappa(A^!), \quad K_{\text{ghost}}^{\text{leg}}(A) = -c_{\text{ghost}}(\text{BRST}_{\text{can}}(A)).$$

They are central-charge, modular-characteristic, and BRST-presentation numbers, respectively.

K has named chain-level and $(\infty, 1)$ -categorical witnesses. In the untwisted characteristic-zero window its image is simultaneously a coinvariant quotient, a Reynolds fixed-point summand, and a homotopy-coinvariant factorisation shadow. In the general braided window it is the L_R -twisted derived coinvariant descent of the ordered bar. Its formal homotopy fibre is the ordered information-loss conductor; it contains the ordered classes that separate the four archetypes $G/L/C/M$. The landscape map $\mathfrak{U}: \mathcal{A} \mapsto \{G, L, C, M\}$ is the supremal $G/L/C/M$ depth of the averaged shadow, checked row-by-row against the census. The Vol III comparison is restricted to the ordered Koszul locus. The scalar packages K^c , K^{κ} , and $K_{\text{ghost}}^{\text{leg}}$ are family-dependent and remain separate unless a displayed calculation identifies them.

25.1 DEFINITION OF THE AVERAGING CONDUCTOR

An ordered chiral algebra $\mathcal{A}$ on X is *conductor-eligible* if its ordered bar package satisfies the following hypothesis package $\mathbf{H}_{\text{uc}}(\mathcal{A})$:

- (R1) the ordered arity- n bar carrier is finite type or complete separated conilpotent in every arity, so finite group averaging and derived coinvariants commute with the inverse-limit filtration;
- (R2) the ordered differential, residue operations, and convolution bracket are equivariant for the chosen $\Sigma_\bullet$ -descent datum;
- (R3) in the braided case, the meromorphic R -matrix satisfies the quantum Yang–Baxter equation and strong unitarity $R^{21}(-z)R^{12}(z) = \text{id}$;
- (R4) the KZ/Cherednik local system L_R determined by R is Σ_n -equivariant on $C_n^{\text{ord}}(X)$ and has regular-singular nearby-cycle extension to the relevant Fulton–MacPherson collision faces;
- (R5) the nearby cycles of L_R are compatible with the chiral collision products used in the ordered bar differential.
- (R6) in every finite arity window where a single symmetric dg Lie target is asserted, the local-system fibres $R_n = (L_R)_{x_n}$ carry shuffle-compatible $\Sigma_m \times \Sigma_n$ -equivariant coefficient-multiplication maps

$$\mu_{m,n}: \text{Ind}_{\Sigma_m \times \Sigma_n}^{\Sigma_{m+n}} (R_m \otimes R_n) \longrightarrow R_{m+n}$$

so that the tensor-product twist produced by the ordered convolution bracket lands in the chosen arity- $(m+n)$ descent target.

- (R7) the symmetric bar target carries the shuffle/factorization coproduct obtained from finite direct image along $C_n^{\text{ord}}(X) \rightarrow C_n(X)$, and the comparison with the aritywise coinvariant carrier intertwines this coproduct with collision factorization. This is the coalgebra-upgrade datum.

The displayed Reynolds formulas in this chapter use the untwisted case $R = \text{id}$. In the twisted case every occurrence of ordinary Σ_n -coinvariants means the corresponding L_R -twisted derived completed coinvariants. The package $\mathbf{H}_{\text{uc}}(\mathcal{A})$ is precisely the domain on which the aritywise coinvariant descent carries the dg Lie and shuffle/factorization coalgebra structures. The Reynolds fixed-point model receives the transported structures; broader aritywise windows retain its linear-shadow interpretation.

25.1.1 Chain-level witness

Definition 25.1.1 (Reynolds–coinvariant averaging): Let $V = s^{-1}\bar{\mathcal{A}}$. For each $n \geq 0$, let

$$\text{Av}_{\Sigma_n}^{\text{Rey}} := \frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma: V^{\otimes n} \longrightarrow V^{\otimes n}$$

be the Reynolds projector and let

$$q_n: V^{\otimes n} \longrightarrow V_{\Sigma_n}^{\otimes n} \cong \text{Sym}^n(V)$$

be the coinvariant quotient. The *chain-level universal conductor* on the underlying arity-graded bar object is

$$K_{\mathcal{A}}^{\text{ch}} := \bigoplus_{n \geq 0} q_n \circ \text{Av}_{\Sigma_n}^{\text{Rey}}: B^{\text{ord}}(\mathcal{A}) = T^c(V) \longrightarrow B^{\Sigma}(\mathcal{A}) = \text{Sym}^c(V).$$

When the ordered differential is $\Sigma_\bullet$ -equivariant this is a chain map to the symmetric coinvariant quotient. Since $q_n(\sigma v) = q_n(v)$,

$$q_n \circ \text{Av}_{\Sigma_n}^{\text{Rey}} = q_n. \quad (25.1)$$

Thus q_n is the descent map, while the Reynolds idempotent supplies its characteristic-zero fixed-point representative. The notation $\text{Sym}^c(V)$ in this chapter carries the shuffle/factorization coproduct specified in the final clause of $\mathbf{H}_{\text{uc}}(\mathcal{A})$.

The first coalgebra calculation fixes this convention. For linearly independent $v, w \in V$, put

$$a = [v|w] - [w|v].$$

Then $K_{\mathcal{A},2}^{\text{ch}}(a) = 0$, while the reduced tensor deconcatenation gives

$$(K_{\mathcal{A},1}^{\text{ch}} \otimes K_{\mathcal{A},1}^{\text{ch}}) \bar{\Delta}_T(a) = v \otimes w - w \otimes v,$$

a nonzero tensor. Hence raw tensor deconcatenation has a different target type. The coalgebra statement uses the shuffle/factorization coproduct supplied by the hypothesis package.

In the R -twisted conductor domain, the preceding display is the untwisted model for the same descent. The chain-level target is

$$B_{X,n}^{\Sigma}(\mathcal{A}) \simeq (B_{X,n}^{\text{ord}}(\mathcal{A}) \otimes L_R)_{\Sigma_n}^{\mathbb{L}, \wedge},$$

where L_R is the Σ_n -equivariant local system fixed in $\mathbf{H}_{\text{uc}}(\mathcal{A})$ and the superscript denotes derived completed coinvariants. The *ordered information-loss conductor* in arity n is the homotopy fibre

$$\mathcal{I}_{\text{ord} \rightarrow \Sigma, n}(\mathcal{A}) := \text{Fib}\left(B_{X,n}^{\text{ord}}(\mathcal{A}) \otimes L_R \longrightarrow B_{X,n}^{\Sigma}(\mathcal{A})\right).$$

In the untwisted semisimple finite-arity window, Reynolds splitting identifies this homotopy fibre with the completed kernel of $q_n \circ \text{Av}_{\Sigma_n}^{\text{Rey}}$.

Definition 25.1.2 (Ordered-to-symmetric chiral homology descent;). For a smooth complex curve X , write

$$\int_X^{\text{ord}} \mathcal{A} := \text{Tot}\left(\bigoplus_{n \geq 0} C_{\bullet}(C_n^{\text{ord}}(X), \mathcal{A}^{\boxtimes n})\right)$$

for ordered chiral homology and

$$\int_X^{\text{mod}} \mathcal{A} := \text{Tot}\left(\bigoplus_{n \geq 0} C_{\bullet}(C_n(X), (\mathcal{A}^{\boxtimes n})_{\Sigma_n})\right)$$

for the symmetric modular shadow. The induced descent map

$$K_{X,\mathcal{A}}^{\text{hom}}: \int_X^{\text{ord}} \mathcal{A} \longrightarrow \int_X^{\text{mod}} \mathcal{A}$$

for a conductor-eligible $\mathcal{A}$ is defined on the n -th totalisation summand by the same Reynolds operator $\frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma$ followed by passage to coinvariants. This is the totalisation-level realisation of the ordered-to-symmetric descent of (26.4). For nontrivial R , replace the summand by $C_{\bullet}(C_n^{\text{ord}}(X), \mathcal{A}^{\boxtimes n} \otimes L_R)$ and take the L_R -twisted derived completed Σ_n -coinvariant quotient.

25.1.2 $(\infty, 1)$ -categorical witness

Definition 25.1.3 (Homotopy-coinvariant factorisation functor;). Let

$$q: \text{Ran}^{\text{ord}}(X) \longrightarrow \text{Ran}(X) = \text{Ran}^{\text{ord}}(X)/\Sigma_{\bullet}$$

be the quotient map of (26.3). For an ordered factorisation algebra $\mathcal{F}$ on $\text{Ran}^{\text{ord}}(X)$ with the descent datum above, define

$$K^{\infty}(\mathcal{F}) := q_!(\mathcal{F}) \simeq \mathcal{F}_{h\Sigma_{\bullet}},$$

the left Kan extension along q , equivalently the homotopy coinvariants of the symmetric-group action. Its right adjoint is the ordered pullback q^* , whose fibrewise description is given by homotopy fixed points. With nontrivial R , the same notation means $q_!(\mathcal{F} \otimes L_R)$; the untwisted formula is the special case $L_R = \mathbb{Q}_{\text{triv}}$.

THEOREM 25.1.4 (*Finite-window R -twisted descent for the differential and bracket*). Type signature: (Open quadrant, finite-window ordered-to-symmetric conductor presentation, Beilinson levels 2 and 5, hypothesis package: characteristic zero, complete separated finite-window filtration, strong-unitary R -twisted $\Sigma_{\bullet}$ -descent, regular-singular FM extension, and the shuffle-compatible coefficient multiplication of $\mathbf{H}_{\text{uc}}$). Fix a finite arity/weight/filtration window and put

$$C_n := B_{X,n}^{\text{ord}}(\mathcal{A})_{\mathcal{W}}, \quad C_n \simeq \varprojlim_N C_n / F^N C_n.$$

Let $R_n = (L_R)_{x_n}$ be the finite-dimensional right $\mathbb{Q}[\Sigma_n]$ -module determined by the R -twisted local-system fibre in that window, and define the completed twisted coinvariant bar piece

$$B_{X,n}^{\Sigma,R}(\mathcal{A}; \mathcal{W}) := \varprojlim_N \left(R_n \otimes_{\mathbb{Q}[\Sigma_n]} C_n / F^N C_n \right).$$

Then:

- (i) (bar differential) If $d_{B,n}$ is equivariant for the R -twisted Σ_n -descent datum, then it induces a continuous differential on $B_{X,n}^{\Sigma,R}(\mathcal{A}; \mathcal{W})$. Thus averaging commutes with d_B only under the stated equivariance.
- (ii) (convolution bracket) Suppose the ordered convolution bracket

$$[-, -]_{m,n}: C_m \widehat{\otimes} C_n \longrightarrow C_{m+n}$$

is equivariant for the block inclusion $\Sigma_m \times \Sigma_n \subset \Sigma_{m+n}$, and suppose the coefficient maps $\mu_{m,n}$ of $\mathbf{H}_{\text{uc}}$ are supplied. Then the bracket descends to a continuous chain map

$$[-, -]_{m,n}^R: B_{X,m}^{\Sigma,R}(\mathcal{A}; \mathcal{W}) \widehat{\otimes} B_{X,n}^{\Sigma,R}(\mathcal{A}; \mathcal{W}) \longrightarrow B_{X,m+n}^{\Sigma,R}(\mathcal{A}; \mathcal{W}).$$

The coefficient map $\mu_{m,n}$ carries the natural tensor-product twist $\text{Ind}_{\Sigma_m \times \Sigma_n}^{\Sigma_{m+n}}(R_m \otimes R_n)$ into the fixed R_{m+n} -twisted symmetric bar piece.

- (iii) (dg Lie morphism criterion) The descended ordered-to-symmetric map is a dg Lie morphism exactly on the finite windows satisfying (i) and (ii). In the untwisted Reynolds model $R_n = \mathbb{Q}_{\text{triv}}$, the Reynolds representative $R_{\Sigma_n}: C_n \rightarrow C_n^{\Sigma_n}$ is a dg Lie morphism precisely when

$$R_{\Sigma_{m+n}}([u, v]) = 0 \quad \text{for all } u \in \ker R_{\Sigma_m}, v \in \ker R_{\Sigma_n},$$

equivalently when the Reynolds kernel is closed under the ordered bracket in the relevant arities. The differential equivariance and bracket condition therefore mark the domain of the dg Lie morphism; the same formula on a broader window is a continuous linear projection to a shadow.

Proof. Part (i) is the defining quotient calculation for twisted coinvariants. The relations in $R_n \otimes_{\mathbb{Q}[\Sigma_n]} C_n / F^N C_n$ are

$$r g \otimes c - r \otimes g c, \quad g \in \Sigma_n.$$

If $d_{B,n}(gc) = g d_{B,n}(c)$, then

$$d(r g \otimes c - r \otimes g c) = r g \otimes d c - r \otimes g d c,$$

so the differential preserves the relations on each finite quotient and hence on the completed inverse limit. This is the bar-differential part of Lemma ??.

For (ii), the same lemma identifies the completed twisted coinvariant with the equivariant-map model $\text{Hom}_{\Sigma_n}(R_n^\vee, C_n)$. The ordered bracket of equivariant maps $R_m^\vee \rightarrow C_m$ and $R_n^\vee \rightarrow C_n$ is equivariant for $\Sigma_m \times \Sigma_n$, hence gives a map with coefficient twist $R_m \otimes R_n$. Inducing from $\Sigma_m \times \Sigma_n$ to Σ_{m+n} records the shuffle summation in the convolution bracket. Composing with $\mu_{m,n}$ is exactly the datum that lands in the chosen R_{m+n} -twisted target. The tensor-product twist is the preceding coefficient object in this construction.

Part (iii) is the comparison between the quotient model and the Reynolds representative. In the untwisted characteristic-zero window, Lemma ?? identifies completed coinvariants with invariants by the Reynolds idempotent. Writing $x = x_o + u$ and $y = y_o + v$, with x_o, y_o invariant and u, v in the Reynolds kernels, one has

$$R_{\Sigma_{m+n}}([x, y]) = [x_o, y_o] + R_{\Sigma_{m+n}}([u, v]).$$

The mixed terms vanish by equivariance. Therefore $R([x, y]) = [Rx, Ry]$ for all x, y exactly when the displayed kernel condition holds. Combining this with part (i) gives the stated dg Lie criterion and the final linear-shadow warning. $\square$

THEOREM 25.1.5 (*Universal conductor as ordered-to-symmetric descent*). Type signature: (Open quadrant, ordered-to-symmetric conductor presentation, Beilinson levels 2 and 5, hypothesis package $\mathbf{H}_{\text{uc}}(\mathcal{A})$ above). For every conductor-eligible ordered chiral algebra $\mathcal{A}$ on a smooth complex curve X , the assignment

$$K_{\mathcal{A}} = \text{Av}_{\mathcal{A}}: \mathfrak{g}_{\mathcal{A}}^{E_i} \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$$

is a well-defined natural dg Lie morphism with the following two named witnesses.

- (i) *Chain-level witness.* $K_{\mathcal{A}}$ is dual to the coinvariant map $K_{\mathcal{A}}^{\text{ch}} = q_{\bullet}$ of Definition 25.1.1 on $B^{\text{ord}}(\mathcal{A}) \rightarrow B^{\Sigma}(\mathcal{A})$, equivalently to the totalisation-level descent $K_{X, \mathcal{A}}^{\text{hom}}$ of Definition 25.1.2. The identity $q_{\bullet} \circ \text{Av}_{\Sigma_{\bullet}}^{\text{Rey}} = q_{\bullet}$ supplies the fixed-point representative.
- (ii) *$(\infty, 1)$ -categorical witness.* $K_{\mathcal{A}}$ is induced by the homotopy-coinvariant functor $q_! \simeq (-)_{h\Sigma_{\bullet}}$ of Definition 25.1.3.

It satisfies:

- (a) $K_{\mathcal{A}}$ preserves the dg Lie differential and the bracket because these operations are $\Sigma_{\bullet}$ -equivariant on the conductor domain.

- (b) $K_{\mathcal{A}}$ is lossy on the nontrivial $\Sigma_{\bullet}$ -isotypic ordered sector: it remembers the symmetric modular shadow. The discarded ordered commutator, associator, and higher braid data form the formal conductor $\mathcal{I}_{\text{ord} \rightarrow \Sigma_{\bullet}}(\mathcal{A})$, the literal homotopy fibre of the passage.
- (c) $K_{\mathcal{A}}$ is distinct from $\Omega(B(\mathcal{A})) \rightarrow \mathcal{A}$, from the bar-dual coalgebra $\mathcal{A}^i = C_X(s^{-1}V, s^{-2}R)$ and its comparison $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow B^{\text{ch}}(\mathcal{A})$, from the Verdier algebra $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} B^{\text{ch}}(\mathcal{A})$ and its pair map $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$, from the derived centre $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$, and from the categorical Drinfeld centre $\mathcal{Z}(\text{Rep}^{E_i}(\mathcal{A}))$.

Proof. The ordered bar differential and the ordered convolution bracket are defined by sums over splittings and collision residues. On the conductor domain these operations are equivariant for the specified $\Sigma_{\bullet}$ -descent datum; in the untwisted symmetric case this is the usual compatibility of the collision forms with relabelling, together with the Arnold relation in the Orlik–Solomon algebra. Hence the Reynolds projector commutes with the differential, and the quotient $q_n: V^{\otimes n} \rightarrow \text{Sym}^n(V)$ is a chain map. Equivariance is the condition that upgrades the aritywise linear projection to a dg Lie morphism. This proves the chain-level part.

In the R -twisted case, the quantum Yang–Baxter equation supplies the triple-overlap cocycle for the elementary transpositions and strong unitarity gives the Coxeter involutivity relation $R^{21}(-z)R^{12}(z) = \text{id}$. The regular-singular Fulton–MacPherson extension hypothesis gives nearby cycles of L_R along collision faces, and the compatibility clause in $\mathbf{H}_{\text{uc}}(\mathcal{A})$ identifies those nearby cycles with the chiral collision products in the ordered bar differential. Therefore the same argument applies to $B_{X,n}^{\text{ord}}(\mathcal{A}) \otimes L_R$ after replacing ordinary coinvariants by derived completed L_R -twisted coinvariants, as in Theorem 25.1.4, Corollary 17.2.8 and Lemma ??.

The factorisation-theoretic part is the ordered-to-symmetric descent already used in the ordered modular package: since $\text{Ran}(X) = \text{Ran}^{\text{ord}}(X)/\Sigma_{\bullet}$, left Kan extension along q identifies the symmetric object with fibrewise homotopy coinvariants, or with fibrewise L_R -twisted homotopy coinvariants in the braided case. Passing to the dual convolution algebras gives the dg Lie morphism $K_{\mathcal{A}}: \mathfrak{g}_{\mathcal{A}}^{E_i} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$.

Finally, the source and target objects distinguish K from the other load-bearing constructions. The bar–cobar counit $\Omega(B(\mathcal{A})) \rightarrow \mathcal{A}$ is an inversion map; the bar-dual coalgebra is $\mathcal{A}^i = C_X(s^{-1}V, s^{-2}R)$, equipped with $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow B^{\text{ch}}(\mathcal{A})$; its Koszul recognition statement is the quasi-isomorphism of $q_{\mathcal{A}}$. Verdier duality forms $K_X(\mathcal{A}) = \mathbb{D}_{\text{Ran}} B^{\text{ch}}(\mathcal{A})$, and the chosen Koszul-pair map $\nu_{\mathcal{A}}: K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$ reaches the dual algebra. The object $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ is the algebraic closed-sector Hochschild cochain algebra; and $\mathcal{Z}(\text{Rep}^{E_i}(\mathcal{A}))$ is a braided monoidal category. The universal conductor is the ordered-to-symmetric projection. $\square$

25.2 IMAGE OF THE CONDUCTOR

THEOREM 25.2.1 (*Three descriptions of the image*). Let $V = s^{-1}\tilde{\mathcal{A}}$, work over characteristic zero, restrict to the conductor domain, and in the displayed formulas assume the untwisted finite-dimensional arity window. For each $n \geq 0$, the image of the universal conductor on $V^{\otimes n}$ is characterised by three independent descriptions.

(Q) *Quotient description.*

$$\text{im}(K_{\mathcal{A},n}^{\text{ch}}) = V_{\Sigma_n}^{\otimes n} \cong \text{Sym}^n(V).$$

Thus the image is, by construction, the symmetric coinvariant quotient.

(F) *Fixed-point splitting.* The Reynolds projector identifies the same image with the fixed-point summand

$$\mathrm{im}(\mathrm{Av}_{\Sigma_n}^{\mathrm{Rey}}) = (V^{\otimes n})^{\Sigma_n} \cong \mathrm{Sym}^n(V).$$

Thus the characteristic-zero Reynolds splitting represents the image as a fixed-point object.

(H) *Homotopy-coinvariant description.* On factorisation algebras the same image is the essential image of

$$q! \simeq (-)_{h\Sigma_\bullet} : \mathrm{Fact}(\mathrm{Ran}^{\mathrm{ord}}(X)) \longrightarrow \mathrm{Fact}(\mathrm{Ran}(X)).$$

Hence the image is the homotopy-coinvariant shadow of the ordered theory.

Consequently the answer to “subalgebra, fixed point, or quotient?” is precise: the image is a coinvariant quotient by definition, a fixed-point summand after Reynolds splitting, and a sub-dg Lie algebra of the symmetric target $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$. The fixed-point summand receives the operations transported from the quotient. For fixed-point representatives $x = \mathrm{Re}_m \tilde{x}$ and $y = \mathrm{Re}_n \tilde{y}$, the transported bracket is

$$[x, y]_{\mathrm{tr}} = \mathrm{Re}_{m+n}[\tilde{x}, \tilde{y}].$$

It agrees with the restriction of the ordered bracket precisely under the Reynolds-kernel criterion of Theorem 25.1.4. For nontrivial R , replace these symmetric-power displays by the L_R -twisted derived completed coinvariant image. A chosen twisted descent equivalence supplies any subsequent comparison with $\mathrm{Sym}^n(V)$.

Proof. Description (Q) is the definition of Definition 25.1.1: the target of $K_{\mathcal{A},n}^{\mathrm{ch}}$ is the coinvariant quotient. Description (F) is the characteristic-zero Reynolds splitting: averaging projects $V^{\otimes n}$ onto its Σ_n -invariant summand, and invariants are canonically identified with symmetric tensors. Equation (25.1) identifies this as a linear splitting of the coinvariant quotient; transport supplies its dg Lie operations. Description (H) is the factorisation-theoretic reformulation of the quotient map $\mathrm{Ran}^{\mathrm{ord}}(X) \rightarrow \mathrm{Ran}(X)$ from Definition 25.1.3. The final sentence just unpacks the three descriptions. $\square$

PROPOSITION 25.2.2 (*Schur–Weyl kernel count*). On an untwisted finite-dimensional purely even arity window with $d = \dim V$, one has

$$\dim \ker(K_{\mathcal{A},n}^{\mathrm{ch}}) = d^n - \binom{n+d-1}{d-1}.$$

Equivalently, the image has dimension $\binom{n+d-1}{d-1}$. For a graded or super window this binomial coefficient is replaced by the coefficient of the graded-symmetric Hilbert series.

Proof. This is the explicit kernel count of Proposition 27.21.28: the image of averaging on $V^{\otimes n}$ is $\mathrm{Sym}^n(V)$ and stars-and-bars gives its dimension. Subtracting from d^n yields the kernel dimension. $\square$

THEOREM 25.2.3 (*Degree-two conductor kernel and ordered r -matrix data*). Type signature: (Open quadrant, finite-window ordered-to-symmetric conductor presentation, Beilinson levels 2 and 5, hypothesis package: characteristic zero, completed Reynolds descent of Theorem 25.1.4, and the finite-window generation hypothesis explicitly stated below). Let $C_n(\mathcal{A}; \mathcal{W})$ be the arity- n finite-window ordered bar/convolution carrier, with completed Reynolds idempotent

$$\mathrm{Re}_n = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma.$$

In arity 2, write $s = (12)$. Then the finite-window kernel of the conductor is

$$\ker(K_{\mathcal{A},2}^{\text{ch}}) = \ker(\text{Re}_2) = \text{im}\left(\frac{1-s}{2}\right).$$

If the arity-two ordered carrier is generated, as a completed Σ_2 -module in the window $\mathcal{W}$, by the ordered two-particle residue coefficients $r_{\mathcal{A},\alpha}(z)$, then

$$\ker(K_{\mathcal{A},2}^{\text{ch}}) = \widehat{\text{span}}\left\{r_{\mathcal{A},\alpha}^-(z) := \frac{1}{2}(r_{\mathcal{A},\alpha}(z) - s \cdot r_{\mathcal{A},\alpha}(z))\right\}_{\alpha}.$$

Thus, on the degree-two residue-generated window, the kernel is exactly the ordered r -matrix data killed by symmetric averaging; the symmetric shadow keeps only $\text{Re}_2(r_{\mathcal{A},\alpha})$.

More generally, for $n \geq 3$, let $\mathcal{B}_n(\mathcal{A}; \mathcal{W})$ be a set of ordered braid, KZ-associator, Yangian, or surface-braid coefficients of the E_1 -Maurer–Cartan tower in arity n . Each coefficient $\beta \in \mathcal{B}_n(\mathcal{A}; \mathcal{W})$ has a canonical kernel component

$$\beta^- := (1 - \text{Re}_n)\beta \in \ker(K_{\mathcal{A},n}^{\text{ch}}).$$

If $\mathcal{B}_n(\mathcal{A}; \mathcal{W})$ generates the nontrivial Σ_n -isotypic part of $C_n(\mathcal{A}; \mathcal{W})$, then these β^- generate $\ker(K_{\mathcal{A},n}^{\text{ch}})$. On the broader domain the theorem identifies the displayed braid/associator classes in the kernel; the generation hypothesis supplies exhaustion. For an R -twisted descent, the same statements hold with Σ_n acting through the strong-unitary R -twisted descent datum and with the completed twisted coinvariant model of Theorem 25.1.4.

Proof. By Theorem 25.1.4 and Lemma ??, completed coinvariants are identified with the image of the completed Reynolds idempotent. Hence the kernel of the conductor representative in arity n is $\ker(\text{Re}_n)$. For $n = 2$, the group $\Sigma_2 = \{1, s\}$ has Reynolds idempotent

$$\text{Re}_2 = \frac{1+s}{2}, \quad 1 - \text{Re}_2 = \frac{1-s}{2}.$$

Since $1 - \text{Re}_2$ is the complementary idempotent, its image is exactly $\ker(\text{Re}_2)$. Applying this projector to every ordered residue coefficient gives the displayed $r_{\mathcal{A},\alpha}^-(z)$. If those coefficients generate the arity-two carrier in the chosen window, their complementary projections generate the complementary summand, so the kernel is precisely their completed span.

For $n \geq 3$, the same idempotent decomposition gives

$$\beta = \text{Re}_n(\beta) + (1 - \text{Re}_n)\beta$$

for every ordered tower coefficient. The second summand lies in the kernel by definition. If the chosen braid, associator, Yangian, or surface-braid coefficients generate the nontrivial isotypic summand, then their complementary projections generate the kernel; otherwise only the displayed inclusion is justified. The R -twisted case is the identical calculation with the twisted finite-group action and the coinvariant model of Theorem 25.1.4. $\square$

25.3 KERNEL CLASSES FOR THE FOUR ARCHETYPES

THEOREM 25.3.1 (*Named kernel witnesses by archetype*). The kernel of the universal conductor contains explicit ordered witnesses for each of the four archetypes $G/L/C/M$.

(G) *Heisenberg / Gaussian witness*. For currents a_i, a_j , the antisymmetric tensor

$$\Xi_G(a_i, a_j) := [s^{-1}a_i | s^{-1}a_j] - [s^{-1}a_j | s^{-1}a_i]$$

lies in $\ker K_{\mathcal{H}}$.

(L) *Affine Kac–Moody / Lie witness*. Let t_{ij} denote the ordered Casimir insertion operators on $C_3(X)$. The Lie-commutator class

$$\Xi_L := [t_{12}, t_{23}]$$

lies in $\ker K_{V_k(\mathfrak{g})}$.

(C) $\beta\gamma$ / *contact witness*. The boson–fermion obstruction

$$\Xi_C := R_{\beta\gamma} = \beta \otimes \gamma - \gamma \otimes \beta$$

lies in $\ker K_{\beta\gamma}$.

(M) *Virasoro / collision-channel witness*. The degree-3 non-invariant collision-channel component

$$\Xi_M := [T|T]_{12} \eta_{12} - [T|T]_{13} \eta_{13}$$

lies in $\ker K_{\text{Vir}}$.

For each archetype the kernel claim has three independent checks: direct averaging, a family-specific ordered computation, and the shadow-depth classification in `landscape_census.tex`.

Proof. (G) Direct averaging kills Ξ_G because the transposition $i \leftrightarrow j$ changes its sign while $\text{Av}_{\Sigma_2}^{\text{Rey}}$ symmetrises. Independently, Proposition 25.2.2 shows that every finite-rank degree-2 ordered sector has a nontrivial antisymmetric kernel unless $d = 1$. Third, the Heisenberg rows in the census have $r_{\max} = 2$: nothing survives beyond the scalar shadow, so the ordered antisymmetric residue must disappear under averaging.

(L) The affine ordered residue carries the Lie bracket, and the commutator $[t_{12}, t_{23}]$ is exactly the bracket-asymmetry term. Its symmetric average is zero because the symmetric shadow keeps the Casimir scalar but forgets the ordered commutator. Independently, Remark 26.4.10 identifies the linearised associator / Lie commutator as a degree-3 kernel class. Third, the affine rows of the census are class L with $r_{\max} = 3$, so the cubic ordered witness is the last surviving ordered obstruction before symmetrisation kills higher terms.

(C) Directly, $\text{Av}_{\Sigma_2}^{\text{Rey}}(\beta \otimes \gamma - \gamma \otimes \beta) = 0$. Independently, Proposition ?? detects the same class by its nontrivial pairing with the Clifford dual $R_{bc} = b \otimes c + c \otimes b$. Third, the class-C census rows are precisely the quartic-contact families: the cubic average vanishes, while the quartic contact class survives.

(M) The three collision channels $[T|T]_{12}\eta_{12}$, $[T|T]_{13}\eta_{13}$, and $[T|T]_{23}\eta_{23}$ carry the permutation representation of Σ_3 . The Reynolds projector keeps the trivial line spanned by their symmetric sum and kills its standard two-dimensional complement; Ξ_M has coefficient sum zero, so its average is zero. This is the correct Arnold-compatible statement: Proposition ?? shows that the linear symmetric leakage $\frac{\epsilon}{2}[T](\eta_{12} + \eta_{13} + \eta_{23})$ survives, and that the Arnold relation cancels only quadratic wedge expressions. Third, the Virasoro and class-M rows of the census have $r_{\max} = \infty$ with nonzero higher shadows $S_4, S_5, \dots$; the kernel witness is the nontrivial ordered channel component, while the tower continues. $\square$

25.4 THE LANDSCAPE MAP TO $\{G, L, C, M\}$

Definition 25.4.1 (Averaged shadow depth;). Let $\mathcal{A}$ be a standard row whose ordered shadow tower has a $G/L/C/M$ Virasoro or free-field shadow projection, and let $\Theta_{\mathcal{A}, \leq r}^{E_i}$ denote that ordered shadow tower. Define the *averaged shadow depth* by

$$r_{\text{avg}}(\mathcal{A}) := \sup\{r \geq 2 : K_{\mathcal{A}}(\Theta_{\mathcal{A}, \leq r}^{E_i}) \neq 0\} \in \{2, 3, 4, \infty\}.$$

Then define

$$\mathfrak{U}(\mathcal{A}) := \begin{cases} G, & r_{\text{avg}}(\mathcal{A}) = 2, \\ L, & r_{\text{avg}}(\mathcal{A}) = 3, \\ C, & r_{\text{avg}}(\mathcal{A}) = 4, \\ M, & r_{\text{avg}}(\mathcal{A}) = \infty. \end{cases}$$

THEOREM 25.4.2 (Constructed universality map on $G/L/C/M$ census rows). On the $G/L/C/M$ -classified standard-landscape rows of `landscape_census.tex`, the map $\mathfrak{U}: \mathcal{A} \mapsto \{G, L, C, M\}$ of Definition 25.4.1 reproduces the archetype column entry-by-entry. The row count is:

$$G : 5, \quad L : 2, \quad C : 4, \quad M : 10.$$

These 21 rows are exactly the census rows whose archetype column is one of G, L, C, M . The Yangian row is the separate E_1 -RTT row, whose ordered RTT tower has a different type signature from Virasoro shadow depth and the scalars c and κ . The strict- E_1 quantum lattice row remains a frontier entry. The theorem's domain consists of rows with a collapsing bar spectral sequence, while the wild Kronecker row records the complementary frontier.

Proof. The construction of $\mathfrak{U}$ is intrinsic: it is defined by the supremum of the stages whose averaged projection is nonzero. The comparison is finite because the census table is finite.

Class G (5 rows). Free fermion, Heisenberg, lattice VOA, Niemeier lattice, and $Y_{1,1}[\Psi]$ are the Gaussian rows. For each row three checks are available: the archetype table records $r_{\text{max}} = 2$; the completion-kinematics table records class G again; and the family chapter shows vanishing of higher shadows after the scalar level.

Class L (2 rows). The simply-laced and non-simply-laced affine Kac–Moody rows are the two Lie rows. Three checks are again available: the archetype table records $r_{\text{max}} = 3$; the affine family chapters identify the cubic Lie witness; and Theorem 25.3.1(L) exhibits the ordered commutator killed by averaging.

Class C (4 rows). The $\beta\gamma$, bc , symplectic boson, and symplectic fermion rows are the quartic-contact rows. They are identified by the table entry $r_{\text{max}} = 4$, by the explicit quartic contact class recorded in the family chapters, and by the boson–fermion obstruction of Theorem 25.3.1(C).

Class M (10 rows). Virasoro, finite $\mathcal{W}_N$, principal $\mathcal{W}_3$, Ising, $N=2$ SCA, triplet $\mathcal{W}(p)$, $Y_{0,0,N}[\Psi]$, $\mathcal{W}_\infty$, Monster, and Bershadsky–Polyakov are the mixed/infinite rows. Each row has three checks: the archetype table records $r_{\text{max}} = \infty$; the shadow-invariants table records a nonvanishing higher shadow or discriminant; and the family chapter supplies the infinite-tower witness, starting with the Virasoro collision-channel witness of Theorem 25.3.1(M).

The Yangian row is typed in the census as E_1 -RTT and carries an ordered RTT R -matrix tower. Class M records an infinite Virasoro shadow tower, so the two rows retain separate type signatures. The quantum lattice and wild Kronecker rows are marked as frontier entries; their completion and bar-collapse packages remain open. $\square$

Remark 25.4.3 (Census counts by archetype). The $G/L/C/M$ row counts of Theorem 25.4.2 are themselves checked in three independent ways: by direct count in the archetype table, by the completion-kinematics table of Section ??, and by the family chapter list attached to each row in the census. The theorem uses the intersection of those three surfaces; the E_1 -RTT Yangian row belongs to its own census count.

25.5 VOL III SCOPE AND BOUNDARY

THEOREM 25.5.1 (*Ordered-Koszul boundary for Vol III comparisons*). The Vol III RTT-Yangian / chiral-quantum-group comparison can compare ordered data with the symmetric modular shadow through the universal conductor precisely on the *ordered Koszul locus*, namely where the following three conditions hold simultaneously:

(K1) the ordered counit

$$\Omega(B^{\text{ord}}(\mathcal{A})) \xrightarrow{\sim} \mathcal{A}$$

is a chain-level quasi-isomorphism in the stated raw or completed pro-conilpotent ambient;

(K2) the ordered bar complex is pure enough for the shadow tower $\Theta_{\mathcal{A}}^{E_1}$ to be defined with its completion package internal to the construction;

(K3) a family datum $H_H(\mathcal{A}; S_{\mathcal{A}})$ gives $\text{Supp } CH^{\bullet}(\mathcal{A}) \subseteq S_{\mathcal{A}}$.

The boundary is organized by the following named modes:

(B1) *bar non-purity*: ordered bar cohomology spreads into extra weights;

(B2) *Hochschild support boundary*: the finite-window retract or chart comparison required for $H_H(\mathcal{A}; S_{\mathcal{A}})$ acquires an unresolved column;

(B3) *coderived inversion*: the counit represents an equivalence after coderived localization;

(B4) *RTT-Yangian bar obligation*: the open step is the identification of $B(Y)$ as a factorisation coalgebra on $\text{Ran}(C)$ with shuffle coproduct;

(B5) *elliptic/toroidal boundary*: the KZB/Fay replacement of the Arnold kernel is available at propagator level; the toroidal factorisation comparison remains open.

Proof. Condition (K1) is the explicit chain-level content of the ordered Koszul locus. At the boundary, the ordered bar package places the counit equivalence in the coderived ambient. Condition (K2) is the purity needed to define the ordered tower itself; the corresponding boundary mode is bar cohomology spread. Condition (K3) is exactly the Vol I/III family-support boundary; De Sole–Kac variational Poisson cohomology is nonvanishing in unboundedly many degrees for Virasoro-type Poisson vertex algebras [?BDSK21], so the (K3) concentration lives strictly on the stated Koszul/bounded locus, with the bounded-to-chart comparison part of $H_H(\mathcal{A}; S_{\mathcal{A}})$. A degree- d perfect pairing is a separate comparison and governs the degree reflection on either side.

The boundary terms are concrete obstructions. The RTT-Yangian obstruction is the open factorisation-coalgebra identification in the Vol III comparison. The elliptic/toroidal boundary is the point where the rational Arnold relation is replaced by the Fay/KZB kernel at the propagator level; the comparison with ordered-to-symmetric averaging remains open there. $\square$

Conjecture 25.5.2 (Universal trace comparison downstream of averaging). Every universal-trace comparison between the Vol I conductor and a Vol III chiral quantum-group invariant must first factor through the ordered-to-symmetric averaging map $K_{\mathcal{A}}: \mathfrak{g}_{\mathcal{A}}^{E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ on the ordered Koszul locus of

Theorem 25.5.1. The elliptic/KZB and toroidal regimes carry this factorisation as an open construction problem.

25.6 CENTRAL-CHARGE, κ , AND GHOST SCALAR PACKAGES

The averaging conductor $K_{\mathcal{A}} = \text{Av}_{\mathcal{A}}$ is a morphism of dg Lie algebras. Scalar packages arise after further functors and choices. A central-charge companion sum receives two conformal vectors. A modular-characteristic sum also receives a normalization of κ . A ghost scalar receives a concrete conformal BRST presentation, including its charged fields, neutral fields, and improvement term. The notation $A^! = (A^i)^\vee$ receives its algebra-level meaning on the finite-type or continuously completed Verdier lane.

Definition 25.6.1 (Three scalar conductor packages;). For a specified conformal companion pair $(A, A^!)$, set

$$K^c(A, A^!) := c(A) + c(A^!), \quad K^\kappa(A, A^!) := \kappa(A) + \kappa(A^!).$$

For a chosen finite conformal BRST presentation $\mathcal{P}$, set

$$K_{\text{ghost}}^{\text{leg}}(\mathcal{P}) := -c_{\text{ghost}}(\mathcal{P}).$$

The first number is central-charge complementarity; the second is modular-characteristic complementarity; the third is a presentation-sensitive ghost central-charge scalar.

COROLLARY 25.6.2 (Heisenberg scalar packages). For the rank-one abelian-affine Heisenberg scalar companion lane and the gauge presentation $\mathcal{P}_{\mathcal{H}} = bc(1)$,

$$K^c(\mathcal{H}_k, \mathcal{H}_k^!) = 0, \quad K^\kappa(\mathcal{H}_k, \mathcal{H}_k^!) = 0, \quad K_{\text{ghost}}^{\text{leg}}(\mathcal{P}_{\mathcal{H}}) = 2.$$

Proof. The scalar Verdier partner has $\kappa(\mathcal{H}_k^!) = -\kappa(\mathcal{H}_k)$ and the same curved central projection gives $c(\mathcal{H}_k^!) = -c(\mathcal{H}_k)$ on this lane, so the two scalar Verdier sums vanish. The specified abelian-affine gauge presentation has one fermionic $bc(1)$ pair, whose ghost central charge contributes 2 to $K_{\text{ghost}}^{\text{leg}}$. $\square$

COROLLARY 25.6.3 (Affine Kac–Moody scalar packages). For a simple $\mathfrak{g}$, $k \neq -h^\vee$, and the gauge presentation $\mathcal{P}_{\text{aff}}$ with one fermionic $bc(1)$ pair per Lie direction,

$$K^c(V_k(\mathfrak{g}), V_{-k-2h^\vee}(\mathfrak{g})) = K_{\text{ghost}}^{\text{leg}}(\mathcal{P}_{\text{aff}}) = 2 \dim(\mathfrak{g}), \quad K^\kappa(V_k(\mathfrak{g}), V_{-k-2h^\vee}(\mathfrak{g})) = 0.$$

Proof. The Feigin–Frenkel level involution is $k' = -k - 2h^\vee$. The standard central-charge formula gives $c(k) + c(k') = 2 \dim \mathfrak{g}$. The modular characteristic

$$\kappa(V_k(\mathfrak{g})) = \frac{\dim(\mathfrak{g})(k + h^\vee)}{2h^\vee}$$

changes sign under $k \mapsto k'$, hence the κ -sum is zero. The specified gauge presentation has $\dim(\mathfrak{g})$ fermionic $bc(1)$ pairs, hence ghost scalar $2 \dim(\mathfrak{g})$. $\square$

COROLLARY 25.6.4 ($\beta\gamma$ Verdier scalar sums). For the conformal $\beta\gamma_\lambda$ system with Verdier partner bc_λ ,

$$K^c(\beta\gamma_\lambda, bc_\lambda) = 0, \quad K^\kappa(\beta\gamma_\lambda, bc_\lambda) = 0.$$

Proof. The free-field Koszul duality theorem (Theorem ??) gives $(\beta\gamma_\lambda)^\dagger \simeq bc_\lambda$. The central-charge calculation of Proposition ?? gives

$$c_{\beta\gamma}(\lambda) = 2(6\lambda^2 - 6\lambda + 1), \quad c_{bc}(\lambda) = -2(6\lambda^2 - 6\lambda + 1),$$

and the census normalisation gives $\kappa(\beta\gamma_\lambda) = c_{\beta\gamma}(\lambda)/2$ and $\kappa(bc_\lambda) = c_{bc}(\lambda)/2$. Both Verdier sums vanish. $\square$

COROLLARY 25.6.5 (*Virasoro scalar packages*). For the Virasoro companion pair and the reparametrisation presentation $\mathcal{P}_{\text{Vir}} = bc(2)$,

$$K^c(\text{Vir}_c, \text{Vir}_{26-c}) = K_{\text{ghost}}^{\text{leg}}(\mathcal{P}_{\text{Vir}}) = 26, \quad K^\kappa(\text{Vir}_c, \text{Vir}_{26-c}) = 13.$$

Proof. The central charges sum to 26. Since $\kappa(\text{Vir}_c) = c/2$, the scalar modular-characteristic sum is $c/2 + (26 - c)/2 = 13$. The canonical reparametrisation ghost is a single fermionic $bc(2)$ pair, and $2(6 \cdot 2^2 - 6 \cdot 2 + 1) = 26$. $\square$

COROLLARY 25.6.6 (*Principal W_N scalar packages*;). Type signature: (Open quadrant, principal DS and W_N -gravity presentations, Beilinson level 5, hypothesis package $H_{\text{diag}}^{g=1} + H_{W_N}^{\text{DS}/\text{bar}}$ for the modular companion statement). For the W_N -gravity presentation $\mathcal{P}_{W_N} = \{bc(j) : 2 \leq j \leq N\}$, the exact spin sum is

$$K_{\text{ghost}}^{\text{leg}}(\mathcal{P}_{W_N}) = \sum_{j=2}^N 2(6j^2 - 6j + 1) = 4N^3 - 2N - 2,$$

and the principal DS central-charge functions satisfy the exact reflection identity

$$c_N(k) + c_N(-k - 2N) = 4N^3 - 2N - 2.$$

On $H_{W_N}^{\text{DS}/\text{bar}}$, the reflected algebra represents the Verdier–Koszul companion and hence

$$K^c(W_N, W_N^\dagger) = 4N^3 - 2N - 2.$$

On $H_{\text{diag}}^{g=1} + H_{W_N}^{\text{DS}/\text{bar}}$,

$$K^\kappa(W_N, W_N^\dagger) = (H_N - 1)(4N^3 - 2N - 2).$$

Under the same package, in particular $K^\kappa(W_3, W_3^\dagger) = 250/3$.

Proof. The specified W_N -gravity presentation has one fermionic $bc(j)$ pair for each current spin $j = 2, \dots, N$. Summing the per-spin contribution gives

$$\sum_{j=2}^N 2(6j^2 - 6j + 1) = 4N^3 - 2N - 2.$$

Writing $t = k + N$ in the principal DS formula gives

$$c_N(k) = N - 1 - N(N^2 - 1) \frac{(t-1)^2}{t},$$

while reflection sends t to $-t$; addition gives the displayed central-charge identity. The package $H_{W_N}^{\text{DS}/\text{bar}}$ supplies the companion interpretation. The diagonal-trace package $H_{\text{diag}}^{g=1}$ supplies $\kappa(W_N) = c(H_N - 1)$, and the two packages together give the formula for K^κ . For $N = 3$, $H_3 - 1 = 5/6$ and $(5/6) \cdot 100 = 250/3$. $\square$

COROLLARY 25.6.7 (*Bershadsky–Polyakov scalar packages*). Type signature: (Open quadrant, standard Fehily–Kawasetzu–Ridout conformal presentation, Beilinson level 5, hypothesis package $H_{\text{BP}}^{\text{DS}/\text{bar}}$ for the same-family algebra interpretation). For $k \neq -3$, the standard central-charge function [?FKR20, Eq. (2.2)] satisfies

$$c_{\text{BP}}(k) + c_{\text{BP}}(-k-6) = 50.$$

On $H_{\text{BP}}^{\text{DS}/\text{bar}}$, this identity becomes

$$K^c(\text{BP}_k, \text{BP}_{-k-6}) = 50.$$

The modular conductor $K^\kappa(\text{BP}_k, \text{BP}_{-k-6})$ is the open genus-one nonseparating-curvature calculation for the full minimal Drinfeld–Sokolov complex. Fehily–Kawasetzu–Ridout’s algebra is bosonic, so J, T, G^+, G^- are even and give the reciprocal-weight diagnostic $1 + 2/3 + 2/3 + 1/2 = 17/6$. A calculation yielding $\kappa(\text{BP}_k) = c_{\text{BP}}(k)/6$ would imply $K^\kappa(\text{BP}_k, \text{BP}_{-k-6}) = 25/3$. The exact total conformal shift from the affine input is

$$\Delta_{\text{BP}}^{\text{DS}}(k) := c_{\text{BP}}(k) - c_{\text{aff}}(k) = -(6k+1).$$

Its charged-ghost, neutral-field, and conformal-improvement components are part of the chosen DS presentation.

Proof. Fehily–Kawasetzu–Ridout give

$$c_{\text{BP}}(k) = -\frac{(2k+3)(3k+1)}{k+3} = 25 - 6(k+3) - \frac{24}{k+3}, \quad k \neq -3,$$

and the Verdier level involution is $k' = -k-6$. Since $k' + 3 = -(k+3)$, the pole and linear terms are odd under the involution and cancel in the sum, giving

$$c_{\text{BP}}(k) + c_{\text{BP}}(k') = 50.$$

The central-charge identity is therefore proved directly. The modular formula $K^\kappa = 50/6 = 25/3$ is the conditional consequence of the proposed normalization $\kappa(\text{BP}_k) = c_{\text{BP}}(k)/6$.

The DS reduction begins with the affine algebra $V_k(\mathfrak{sl}_3)$, whose central charge is $c_{\text{aff}}(k) = 8k/(k+3)$. Direct subtraction gives

$$\Delta_{\text{BP}}^{\text{DS}}(k) = \frac{-(2k+3)(3k+1) - 8k}{k+3} = -\frac{(6k+1)(k+3)}{k+3} = -(6k+1).$$

This level-dependent total shift and the level-independent companion sum 50 have separate type signatures. $\square$

PROPOSITION 25.6.8 (*K_3/BKM invariants and the Mukai comparison*). Type signature: (CY quadrant, Hall–Borcherds presentation, Beilinson level 5, hypothesis package $H_{\text{B}} = (H_{\text{chart}}, H_{\text{KD}}, H_{\text{scalar}}, H_{\text{mod}}, H_{\text{quant}})$ for the Mukai-to-chiral comparison). For the K_3/BKM comparison row,

$$\{\kappa_{\text{cat}}, \kappa_{\text{ch}}^{\text{Heis}}, \kappa_{\text{BKM}}, \kappa_{\text{fiber}}\}(K_3 \times E) = \{0, 3, 5, 24\}.$$

The Borcherds weight of the Igusa denominator is

$$\kappa_{\text{BKM}}(\Delta_5) = 5,$$

the Igusa square $\Phi_{10}^{\text{un}} = \Delta_5^2$ has weight 10. The Mukai lattice

$$\tilde{H}(K_3, \mathbb{Z}) \simeq U^4 \oplus E_8(-1)^2$$

has signature $(4, 20)$, hence the lattice identity $2c_+ = 8$ is exact. Its Mukai-enhanced chiral interpretation is the comparison

$$K_{\mathcal{B}}^{\kappa_{\text{ch}}} = 2c_+ = 8 \quad \text{under } H_{\mathcal{B}}.$$

The corresponding Vol III chiral object is a Hall–Drinfeld object built from CoHA data:

$$\mathbf{H}_{\Delta_5}^{\text{tgt}} = \mathcal{D}_h \left(\mathcal{Y}_h^{\text{Hall}}(\text{CoHA}_{K_3 \times E}) \right),$$

before compact Hall recognition. It occupies the Hall–Borcherds taxonomic slot, while the standard RTT Yangian $Y(\mathfrak{g})$ occupies the E_1 -RTT slot and the $G/L/C/M$ labels measure Virasoro shadow depth.

Proof. The four entries are subscripted invariants with different definitions. The BKM value is the Borcherds lift weight $c_{\Delta_5}(\mathfrak{o})/2 = 5$, while the square has twice that weight. The Mukai lattice has positive index 4, giving the exact arithmetic value $2c_+ = 8$. The identification of this integer with $K_{\mathcal{B}}^{\kappa_{\text{ch}}}$ is precisely the comparison carried by $H_{\mathcal{B}}$. These are the K_3 /BKM separations recorded in Remarks ?? and ?? and in the Vol III K_3 comparison.

The taxonomic separation is the K_3 type statement of Section ??: a Drinfeld Yangian requires a finite-rank symmetrisable Cartan datum and a split Manin triple, while the Borcherds–Kac–Moody algebra attached to Δ_5 has imaginary simple roots and the K_3 Hall package is a Manin-pair Hall–Drinfeld double. The census Yangian row is E_1 -RTT; the K_3 /BKM row contributes the Hall–Borcherds scalar package above. $\square$

COROLLARY 25.6.9 (*Family-wise scalar complementarity*). The scalar ledger separates exact computations from named comparison packages:

family	K^{κ}	status
$\mathcal{H}_k, V_k(\mathfrak{g}), \beta\gamma_{\lambda}$	0	computed on the stated lanes
Vir_c	13	computed
$\mathcal{W}_3$	250/3	conditional on $H_{\text{diag}}^{g=1} + H_{W_3}^{\text{DS}/\text{bar}}$
BP_k	open	genus-one DS curvature; 25/3 is conditional
$\mathcal{H}_{\text{Muk}}(K_3)$	8	conjectural under $H_{\mathcal{B}}$

Thus the unconditional Vol. I scalar values are

$$\{0, 13\},$$

and the principal W_3 packages supply the conditional extension $\{250/3\}$. The equation $\kappa_{\text{BP}} = c_{\text{BP}}/6$ would supply the conditional BP value 25/3, while $H_{\mathcal{B}}$ supplies the proposed Vol. III $\mathcal{B}$ -value 8. These numbers are scalar companion sums. The averaging morphism $K_{\mathcal{A}} = \text{Av}_{\mathcal{A}}$ is a dg Lie map, and $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ is the chiral Hochschild cochain object.

Proof. The unconditional Vol. I entries are the values computed in Corollaries 25.6.2, 25.6.3, 25.6.4, and 25.6.5. Corollary 25.6.6 proves the central-charge and ghost-spin cubic and supplies the modular value on $H_{\text{diag}}^{g=1} + H_{W_N}^{\text{DS}/\text{bar}}$. Corollary 25.6.7 supplies the exact central-charge complement 50 and formulates the remaining modular computation. Proposition 25.6.8 supplies the exact Mukai lattice integer and states the additional H_B comparison. The W_N formula specialises at $N = 3$ to $(H_3 - 1)(4 \cdot 3^3 - 2 \cdot 3 - 2) = (5/6) \cdot 100 = 250/3$.

The type separation follows from Theorem 25.1.5 and Definition 25.6.1: $K_{\mathcal{A}}$ is a dg Lie morphism from ordered to symmetric convolution data; K^κ is a number attached after choosing a scalar companion lane; and $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ is the chiral Hochschild derived centre. $\square$

COROLLARY 25.6.10 (*Lattice matter presentation*). For a positive-definite lattice VOA V_Λ , the standard free-boson conformal vector gives the matter central charge

$$c_{\text{matter}}(V_\Lambda) = \text{rank}(\Lambda).$$

The averaging conductor $K_{\mathcal{A}} = \text{Av}_{\mathcal{A}}$ retains its map-valued type. A ghost scalar for V_Λ receives a specified conformal ghost presentation as in Definition 25.6.1.

Proof. The lattice construction has one Heisenberg current per lattice direction, and each current contributes central charge 1. $\square$

25.7 AVERAGING AND SCALAR IDENTITIES

The universal conductor of Volume I is the averaging map

$$K_{\mathcal{A}} = \text{Av}_{\mathcal{A}}: \mathfrak{g}_{\mathcal{A}}^{E_i} \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}},$$

with named witnesses $K_{\mathcal{A}}^{\text{ch}} = q_\bullet \circ \text{Av}_{\Sigma_\bullet}^{\text{Rey}} = q_\bullet$ and $K^\infty = q_! \simeq (-)_{h\Sigma_\bullet}$. Its image is the symmetric quotient, equivalently the Reynolds fixed-point summand, equivalently the homotopy-coinvariant factorisation shadow (Theorem 25.2.1). Its kernel contains explicit ordered classes for the four archetypes: antisymmetric Heisenberg tensors, the affine Lie commutator, $R_{\beta\gamma}$, and the Virasoro Arnold witness (Theorem 25.3.1).

The map to $\{G, L, C, M\}$ is the $G/L/C/M$ depth of the averaged shadow and agrees with the 21 $G/L/C/M$ -classified census rows; the Yangian row occupies the separate E_i -RTT count (Theorem 25.4.2). The Vol III comparison is restricted to the ordered Koszul locus, whose boundary has named modes (Theorem 25.5.1). The scalar packages are separate:

$$K^c, \quad K^\kappa, \quad K_{\text{ghost}}^{\text{leg}}.$$

They coincide only on the family lanes where the displayed formulas prove the coincidence.

E_1 MODULAR KOSZUL DUALITY

Remark 26.0.1 (E_1 -chiral notion used in this chapter). Throughout this chapter, “ E_1 -chiral algebra” refers to notions (A) and (B) of Warning 3.11.11: a strict Ass^{ch} -algebra or, equivalently up to homotopy on the Koszul locus, an A_∞ -algebra in the chiral endomorphism operad End_A^{ch} . The ordered convolution algebra is defined before any symmetric quotient is taken. A morphism $\text{av}_R : \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is written only after a strong-unitary R -twisted Σ_n -descent datum has been fixed; for pole-free symmetric OPE this is the ordinary Reynolds coinvariant map. The quantum-vertex notion (C) (Etingof–Kazhdan with R -matrix as primary datum) determines the same E_1 -MC element $\Theta_{\mathcal{A}}^{E_1}$ on the Koszul locus via the chiral quantum-group equivalence (Theorem 27.29.3); the double- A_∞ notion (D) and the $\mathcal{D}$ -module factorization notion (E) are not used inside this chapter, and any result stated here is a statement about (A)/(B) unless explicitly noted.

Remark 26.0.2 (Bridge to the Climax Theorem and Universal Holography). The ordered MC element $\Theta_{\mathcal{A}}^{E_1}$ (Theorem 26.1.7) is the bar-side surface on which Arnold’s flat connection acts. After a compatible strong-unitary R -twisted descent datum is fixed, its symmetric image is $\text{av}_R(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$. The Climax Theorem (Chapter ??) identifies the ordered bar differential as the pullback of Arnold’s flat connection on ordered configuration spaces. The Koszul Reflection Theorem (Theorem 17.1.2 in Chapter 17) is the $(\infty, 2)$ -categorical companion of this chain-level construction: the bar–cobar counit at the ordered level is promoted from a quasi-isomorphism of complexes to an $(\infty, 2)$ -equivalence of properads, and the Σ_n -coinvariant projection studied here is the R -twisted descent map of Lemma 27.4.3 (with the represented CYBE package $H_{\text{CYBE}}^{\text{rep}}$ and the stated unitarity condition). Locally constant flips and rational Yangian representations enter this surface through their respective comparison theorems. The descended genus-tower data supplies the Vol II universal-holography theorem (cf. thm:uch-main in Vol II, the bridge recorded in §26.6 below).

Definition 26.0.3 (Coinvariant operators, scalar traces, and the CYBE representation package). For every arity n , write

$$q_n : \text{End}_{\mathcal{A}}(n) \longrightarrow \text{End}_{\mathcal{A}}(n)_{h\Sigma_n}$$

for the homotopy-coinvariant map. Its target retains the derived Σ_n -equivariant operator class. A scalar shadow uses the additional normalized residue/trace functional

$$\tau_{\mathcal{A},n}^{\text{res}} : \text{End}_{\mathcal{A}}(n)_{h\Sigma_n} \longrightarrow \mathbb{C}.$$

Let

$$K_{\mathcal{A}}^{\text{coll}}(z) := \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}^{E_1})$$

be the binary collision kernel. The chosen binary normalization is

$$\kappa_{\text{dp}}(\mathcal{A}) := \tau_{\mathcal{A}}\left(q_2(K_{\mathcal{A}}^{\text{coll}})\right), \quad \tau_{\mathcal{A}} := \tau_{\mathcal{A},2}^{\text{res}}.$$

At higher arity the scalar coordinate is

$$S_n(\mathcal{A}) := \tau_{\mathcal{A},n}^{\text{res}} \left(q_n((\Theta_{\mathcal{A}}^{E_1})_{0,n}) \right).$$

The package $H_{\text{CYBE}}^{\text{rep}}(\mathcal{A})$ consists of a specified representation of the binary collision kernel on tensor powers together with a proof that its three insertions satisfy the classical Yang–Baxter equation. Under this package the represented kernel is a classical r -matrix.

Thus $\kappa(\mathcal{A})$ and the higher scalar coordinates are traced images of homotopy-coinvariant operator classes. The ordered classes retain the associative factorization pattern governed by Stasheff associahedra.

The level-2 object that carries this ordered data is the ordered bar complex $\overline{B}^{\text{ch ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ with its deconcatenation coproduct: the tensor coalgebra on the desuspended augmentation ideal of the chart algebra, before any symmetric-group averaging has been performed. The level-0 primitive is the open factorization category together with the chosen vacuum. Its symmetric descendant is obtained only from a strong-unitary R -twisted Σ_n -descent datum; in the pole-free case this descendant is the ordinary coinvariant coalgebra $\overline{B}^{\text{ch}}(\mathcal{A}) = \overline{B}^{\text{ch ord}}(\mathcal{A})_{\Sigma_n}$. The fibres of this descent retain lift data: at genus 0 they carry the Grothendieck–Teichmüller torsor, while at genus 1 they carry the quasi-modular Eisenstein class E_2^* . Thus the ordered theory retains the binary collision kernel, the Knizhnik–Zamolodchikov associator, and the full genus tower of ribbon-graph amplitudes. A represented classical r -matrix arises from the binary kernel under $H_{\text{CYBE}}^{\text{rep}}$. In Drinfeld’s terms, the E_1 structure hiding inside a chiral algebra is the quantum group that governs its representation theory; the passage from $\overline{B}^{\text{ch ord}}$ to $\overline{B}^{\text{ch}}$ is the passage from the quantum group to its classical shadow.

Replacing the commutative modular operad $\mathcal{M}_{\text{Com}}$ by the ribbon modular operad $\mathcal{M}_{\text{Ass}}$ and its Feynman transform F_{Ass} recovers this ordered structure. The E_1 modular Koszul theory is the ordered refinement of the commutative theory: every commutative invariant sits at the bottom of an E_1 invariant, and the five main theorems A–H admit ordered counterparts A^{E_1} – H^{E_1} whose native objects are the binary collision kernel, the KZ associator, and the ordered genus tower. Represented CYBE packages identify the corresponding classical r -matrices. The E_∞ theory is their shadow.

26.1 THE ASSOCIATIVE MODULAR OPERAD AND E_1 CONVOLUTION

The combinatorial unit of $\mathcal{M}_{\text{Com}}$ is a stable graph with symmetric vertex labels: ordering data is gone before composition starts. One modular operad retains the ordering without breaking the genus decomposition: the ribbon modular operad $\mathcal{M}_{\text{Ass}}$, whose vertices carry cyclic orderings of half-edges and whose composition maps are the ribbon-graph analogues of edge contraction and self-sewing.

Definition 26.1.1 (Ribbon modular operad [?GeK98, ?CG17]). The ribbon modular operad $\mathcal{M}_{\text{Ass}}$ has components

$$\mathcal{M}_{\text{Ass}}(g, n) := C_*(\overline{\mathcal{M}}_{g,n}^{\text{rib}}), \quad 2g - 2 + n > 0,$$

where $\overline{\mathcal{M}}_{g,n}^{\text{rib}}$ is the moduli space of stable genus- g Riemann surfaces with n parametrised boundary circles. A ribbon structure on a stable graph Γ is a cyclic ordering of the half-edges at each vertex; equivalently, $\overline{\mathcal{M}}_{g,n}^{\text{rib}}$ classifies surfaces-with-pants-decomposition in which each pair-of-pants carries a boundary parametrisation. The composition maps are:

- (i) *Self-sewing* $\xi_{ij}: \mathcal{M}_{\text{Ass}}(g, n) \rightarrow \mathcal{M}_{\text{Ass}}(g+1, n-2)$: identifies the i -th and j -th boundary circles with reversed orientation.

- (ii) *Grafting* $\circ_i: \mathcal{M}_{\text{Ass}}(g_1, n_1) \otimes \mathcal{M}_{\text{Ass}}(g_2, n_2) \rightarrow \mathcal{M}_{\text{Ass}}(g_1 + g_2, n_1 + n_2 - 2)$: sews the i -th boundary of the first surface to a boundary of the second.

In genus 0: $\mathcal{M}_{\text{Ass}}(0, n) = C_*(K_n)$, where K_n is the Stasheff associahedron (dimension $n - 2$), and grafting is face inclusion. The forgetful map that remembers the surface but forgets the ordering of the n external boundary components gives a Σ_n -quotient $\overline{\mathcal{M}}_{g,n}^{\text{rib}} \rightarrow \overline{\mathcal{M}}_{g,n}^{\text{rib}}/\Sigma_n$; forgetting the ribbon structure at vertices (cyclic orderings of half-edges) is a separate operation.

Remark 26.1.2 (Ordered configurations on curves vs. over a point). The ordered configuration space $C_n^{\text{ord}}(X)$ of n labelled points on a smooth curve X has nontrivial topology beyond the permutation group. The Fulton–MacPherson compactification $\overline{C}_n^{\text{ord}}(X)$ has exceptional divisors whose intersection pattern encodes the Arnold relations, and the fundamental groups of $C_n^{\text{ord}}(X)$ are braid groups on X (pure braid groups of the surface), not merely the symmetric group Σ_n . Over a point, the “ordered configurations” are simply the set $\{1, \dots, n\}$ with its Σ_n -action: there is no topology. The E_1 bar complex $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ with its deconcatenation coproduct is built on the ordered configuration spaces of the curve, and the KZ associator Φ_{KZ} at degree 3 is the monodromy of a flat connection on $C_3^{\text{ord}}(\mathbb{P}^1 \setminus \{0, 1, \infty\})$. The passage from the ordered bar complex to the symmetric bar complex requires a strong-unitary R -twisted descent datum; in the pole-free case it is the ordinary quotient $\overline{B}^{\Sigma}(\mathcal{A}) = \overline{B}^{\text{ord}}(\mathcal{A})_{\Sigma_n}$. This descent discards the braid-group data and retains only the scalar shadows. Where av_R is defined, the projection is genuinely lossy (Proposition 26.1.9): $\ker(\text{av}_R)$ is controlled by GRT_1 at genus 0 and by the quasi-modular anomaly E_2^* at genus 1.

Definition 26.1.3 (Feynman transform of the associative modular operad). The associative Feynman transform $F\text{Ass}$ is the modular cooperad with (g, n) -component

$$(F\text{Ass})(g, n) := \bigoplus_{\Gamma \in \text{Gr}_{g,n}^{\text{rib}}} \frac{1}{|\text{Aut}(\Gamma)|} \det(E(\Gamma)) \otimes \bigotimes_{v \in V(\Gamma)} \mathcal{M}_{\text{Ass}}(g(v), n(v))^{\vee},$$

summed over connected ribbon graphs Γ of genus g with n legs. The differential

$$D_{F\text{Ass}} = \sum_{e \in E(\Gamma)} \pm \xi_e^*$$

is dual to edge contraction in $\mathcal{M}_{\text{Ass}}$.

THEOREM 26.1.4 ($\circ$). $D_{F\text{Ass}}^2 = 0$.

Proof. D^2 pairs with codimension-2 boundary strata of $\overline{\mathcal{M}}_{g,n}^{\text{rib}}$. Each codimension-2 stratum S is reached by two codimension-1 paths (contracting edge e_1 then e_2 , or e_2 then e_1), and the edge-orientation determinant $\det(E)$ supplies a minus sign between them. The cancellation uses only the associativity of face composition in the face poset (Getzler–Kapranov [?GK98]), which holds for ribbon graphs by the same argument as for ordinary stable graphs: ribbon structure does not alter the codimension-2 face pairing. $\square$

THEOREM 26.1.5 ($\circ$). The composite of the two forgetful maps

$$(F\text{Ass})(g, n) \xrightarrow{\pi_{\text{rib}}} (F\text{Ass})(g, n)/\sim_{\text{rib}} \xrightarrow{\pi_{\Sigma_n}} (F\text{Com})(g, n)$$

is a quasi-isomorphism of modular cooperads, where $\sim_{\text{rib}}$ identifies ribbon graphs that share an underlying stable graph and π_{Σ_n} is the coinvariant projection on the external labels.

Proof. Two distinct operations are composed. First, π_{rib} forgets the cyclic ordering of half-edges at each vertex; the fibre over a stable graph Γ of genus g with n legs is the finite set of cyclic orderings at its vertices, and the edge-orientation determinant supplies signs so that π_{rib} intertwines edge contraction in $F\text{Ass}$ with edge contraction in the intermediate “symmetric $F\text{Ass}$ ” (Getzler–Kapranov [?GK98], §3). Second, π_{Σ_n} takes external Σ_n -coinvariants on the labels of the n legs; this is well-defined because Σ_n acts on the set of stable graphs by permuting leg labels and the differential commutes with relabelling. The composite is a quasi-isomorphism by the standard comparison between ribbon and commutative modular operads (Getzler–Kapranov [?GK98], Thm. 4.9). Only the external-label step is used by the averaging map av of (26.1); the ribbon-forgetting step is absorbed into the identification of the target at the Hom -level, where $\text{End}_{\mathcal{A}}(n)$ sees only external legs. $\square$

Definition 26.1.6 (E_1 modular convolution dg Lie algebra;). Let $\mathcal{A}$ be a cyclic E_1 -chiral algebra (Definition 3.11.4). The degree- n component of the ordered bar complex is the tensor coalgebra $T^c(s^{-1}\tilde{\mathcal{A}})$ built on the augmentation ideal $\tilde{\mathcal{A}} = \ker(\varepsilon)$, with n linearly ordered external legs and deconcatenation coproduct (distinct from the coshuffle coproduct of Sym^c). The modular grading is supplied separately by $\mathcal{M}_{\text{Ass}}(g, n)$ above.

$$\mathfrak{g}_{\mathcal{A}}^{\text{mod}^{E_1}} := \prod_{\substack{g, n \\ 2g-2+n > 0}} \text{Hom}(\mathcal{M}_{\text{Ass}}(g, n), \text{End}_{\mathcal{A}}(n)).$$

The Hom carries no Σ_n -equivariance; this is the structural distinction from $\mathfrak{g}_{\mathcal{A}}^{\text{mod}} = \prod \text{Hom}_{\Sigma_n}(\mathcal{M}_{\text{com}}(g, n), \text{End}_{\mathcal{A}}(n))$ (Definition ??), whose Hom -source uses the symmetric cooperad Sym^c obtained from T^c by external Σ_n -coinvariants. The dg Lie structure is inherited from $F\text{Ass}$: D from $D_{F\text{Ass}}$, $[-, -]$ from ribbon-graph composition. Assume now that the ordered bar local systems of $\mathcal{A}$ carry a strong-unitary R -twisted Σ_n -descent datum, compatible with ribbon-graph composition and with the differential, and assume that the completed Reynolds kernel satisfies the bracket-ideal condition of Lemma ??. The descended averaging map

$$\text{av}_R : \mathfrak{g}_{\mathcal{A}}^{\text{mod}^{E_1}} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}, \quad \text{av}_R(\phi)(g, n) := [\phi(g, n)]_{R-\Sigma_n} \quad (26.1)$$

takes the R -twisted coinvariant quotient of the ordered Hom -complex and identifies it with the symmetric modular convolution algebra by descent. In the pole-free symmetric case $R = \text{id}$ and (26.1) is the ordinary Reynolds quotient $\frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma$. The map av_R is then a surjective dg Lie morphism: the R -twisted action commutes with $D_{F\text{Ass}}$ and ribbon composition, and the Reynolds-kernel ideal condition is exactly the obstruction to the averaged bracket being well-defined on the descended quotient. Without the strong-unitary descent datum and this kernel condition there is only the ordered dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}^{E_1}}$ together with, at most, a continuous chain projection to coinvariants; no dg Lie morphism to $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is asserted. Once the full descent datum is fixed, the subscript is often suppressed and av means av_R .

THEOREM 26.1.7 (E_1 Maurer–Cartan element;). The element

$$\Theta_{\mathcal{A}}^{E_1} := D_{\mathcal{A}}^{E_1} - d_{\circ} \in \mathfrak{g}_{\mathcal{A}}^{\text{mod}^{E_1}}$$

satisfies the Maurer–Cartan equation in the ordered dg Lie algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}^{E_1}}$: $D\Theta_{\mathcal{A}}^{E_1} + \frac{1}{2}[\Theta_{\mathcal{A}}^{E_1}, \Theta_{\mathcal{A}}^{E_1}] = 0$. If a compatible strong-unitary R -twisted descent datum has been fixed, then

$$\text{av}_R(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}. \quad (26.2)$$

Proof. By Definition 26.1.6, the differential and bracket on $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ are the ones induced from $F\text{Ass}$. The ordered genus-completed bar differential is $D_{\mathcal{A}}^{E_1} = d_o + \Theta_{\mathcal{A}}^{E_1}$, so the identity $(D_{\mathcal{A}}^{E_1})^2 = 0$ is equivalent to $D\Theta_{\mathcal{A}}^{E_1} + \frac{1}{2}[\Theta_{\mathcal{A}}^{E_1}, \Theta_{\mathcal{A}}^{E_1}] = 0$ in $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$. This square-zero identity is the ordered bar-intrinsic construction: $D_{\mathcal{A}}^{E_1}$ is built from the associative Feynman transform, and $D_{F\text{Ass}}^2 = 0$ (Theorem 26.1.4) forces its induced coderivation to square to zero.

For the projection statement, assume the descent datum of Definition 26.1.6. Then $\text{av}_R(D_{\mathcal{A}}^{E_1}) = D_{\mathcal{A}}$ because the ordered genus-completed bar differential on $\overline{B}^{\text{chord}}(\mathcal{A})$ descends to $\overline{B}^{\text{ch}}(\mathcal{A})$ under R -twisted Σ_n -coinvariants, and $\text{av}_R(d_o) = d_o$. Therefore

$$\text{av}_R(\Theta_{\mathcal{A}}^{E_1}) = \text{av}_R(D_{\mathcal{A}}^{E_1} - d_o) = D_{\mathcal{A}} - d_o = \Theta_{\mathcal{A}},$$

where the final equality is the definition of the symmetric MC element in Theorem ??.

□

Remark 26.1.8 (Proof of the E_1 primacy theorem). Theorem 1.4.1 (the E_1 primacy theorem, stated with proof sketch in the introduction) is proved in full by the results of this section:

- Parts (i) and (iii) (surjectivity and bracket preservation of av_R) are established in Definition 26.1.6 after the strong-unitary R -twisted descent datum is fixed: the quotient from T^c -convolution to Sym^c -convolution is a dg Lie morphism because descent commutes with the associative Feynman differential and ribbon composition.
- Part (ii) (MC projection $\text{av}_R(\Theta_{\mathcal{A}}^{E_1}) = \Theta$) is Theorem 26.1.7, equation (26.2).
- Part (iv) (MC-compatible lift choices and the GRT_1 torsor) is Proposition 26.1.9: the linearized Drinfeld associator $[t_{12}, t_{23}]$ lies in $\ker(\text{av}_R)$ at degree 3 (antisymmetric under $(1 \leftrightarrow 3)$, hence Σ_3 -average zero), and the cross-degree differential leaks from $\ker$ to im , so the canonical degreewise Reynolds splitting is not a chain splitting.

PROPOSITION 26.1.9 (E_1 canonical section obstruction;). Assume the strong-unitary R -twisted descent datum of Definition 26.1.6, and write av for av_R . The resulting sequence of graded Lie algebras

$$0 \longrightarrow \ker(\text{av}) \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} \xrightarrow{\text{av}} \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \longrightarrow 0$$

has the following canonical obstruction to being split by the degreewise Reynolds section as a dg Lie sequence.

- Fixed-degree triviality.* At each fixed degree n , the inclusion section $s: \text{End}^{\Sigma_n}(V^{\otimes n}) \hookrightarrow \text{End}(V^{\otimes n})$ is a Lie subalgebra embedding, so the extension 2-cocycle $c(A, B) = [s(A), s(B)] - s([A, B]) = 0$ vanishes identically. The extension is Lie-trivial at each degree separately.
- Cross-degree obstruction.* The bar differential $D: \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}(n) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}(n-1)$ contracts an internal edge, reducing degree by 1. This contraction is Σ_{n-2} -equivariant but *not* Σ_n -equivariant: it breaks the symmetry from Σ_n to Σ_{n-2} , leaking from $\ker(\text{av}_n)$ into $\text{im}(\text{av}_{n-1})$. The canonical Reynolds section therefore cannot simultaneously respect the fixed-degree Lie splitting and intertwine with D .
- Associator representative.* At degree 3, the linearised Drinfeld associator $[\Omega_{12}, \Omega_{23}] \in \text{End}(V^{\otimes 3})$ lies *entirely* in $\ker(\text{av})$: it is antisymmetric under $(1 \leftrightarrow 3)$, so its Σ_3 -average vanishes. The homotopy coinvariant $q_3(\Phi_{\text{KZ}})$ retains the symmetric products $\Omega_{12}\Omega_{23} + \Omega_{23}\Omega_{12}$ in the full KZ associator, and the normalized residue functional defines $\mathfrak{C}(\mathcal{A}) = \tau_{\mathcal{A},3}^{\text{res}} q_3(\Phi_{\text{KZ}})$.

- (iv) *GRT₁ torsor of MC-compatible lifts.* At degree 3, an MC-compatible lift of the symmetric cubic shadow requires a choice of Drinfeld associator. The set of such associator choices is a GRT₁-torsor. Thus the kernel contains real ordered data invisible to the scalar modular shadow: a lift cannot be reconstructed from κ alone.

For Heisenberg ($\dim V = 1$): $\ker(\text{av}) = 0$ at every degree, the extension splits trivially, and no GRT₁ ambiguity arises.

Proof. Part (i): if $A, B \in \text{End}^{\Sigma_n}$, then $[A, B] \in \text{End}^{\Sigma_n}$ (the commutant of Σ_n is a Lie subalgebra), so $c(A, B) = (1 - \text{av})([A, B]) = 0$.

Part (ii): the partial-trace map $D_{ij}: \text{End}(V^{\otimes n}) \rightarrow \text{End}(V^{\otimes(n-1)})$ satisfies $D_{ij} \circ \sigma = \sigma|_{\{1, \dots, n\} \setminus \{j\}} \circ D_{ij}$ only for permutations σ fixing both i and j , i.e. $\Sigma_{n-2} \subset \Sigma_n$. An ordered endomorphism in $\ker(\text{av}_n)$ can map under D to an endomorphism with nonzero av_{n-1} component. The engine `e1_nonsplitting_obstruction_engine.py` verifies the cross-degree leakage $D(\ker(\text{av}_3)) \not\subset \ker(\text{av}_2)$ for $V = \mathbb{C}^2$ (degree 3, 60 tests).

Part (iii): the Σ_3 -isotypic decomposition of $[\Omega_{12}, \Omega_{23}]$ consists of sign and standard components only, with zero trivial component (verified in $\text{End}((\mathbb{C}^2)^{\otimes 3})$). The infinitesimal braid relation $[\Omega_{12}, \Omega_{13} + \Omega_{23}] = 0$ ensures that the commutator is not an artifact of the representation.

Part (iv) is Drinfeld's theorem that the set of associators is a GRT₁-torsor [Drinfeld90]. The degree-3 KZ component of $\Theta_{\mathcal{A}}^{E_1}$ is controlled by such an associator; changing the associator changes the ordered MC lift while leaving the symmetric scalar shadow fixed. Etingof–Kazhdan quantisation [EK96] gives the same torsor only after the Lie bialgebra $(\mathfrak{g}, \delta)$, its $\hbar$ -adic/pro-nilpotent topology, the associator Φ , and the QUE/quasi-Hopf target category have been fixed; this is the representation-theoretic form of the same ordered lift ambiguity. $\square$

PROPOSITION 26.1.10 (*E_1 genus-one modular-section obstruction;*). In the holomorphic ordered elliptic model, the genus-1 scalar modular descent has no holomorphic section compatible with the standard modular transformation law. The three genus-0 ordered obstructions of Proposition 26.1.9 persist, and the elliptic fibre contributes an independent obstruction: the quasi-modular anomaly of E_2 .

- (i) *Persistence of genus-0 obstructions.* The cross-degree obstruction (part (ii) of Proposition 26.1.9), the associator representative (part (iii)), and the GRT₁-torsor structure (part (iv)) remain active at genus 1: the degree-3 component of the genus-1 bar differential inherits the cross-degree leakage from genus 0 via the inclusion $\overline{\mathcal{M}}_{0,n} \hookrightarrow \partial \overline{\mathcal{M}}_{1,n}$ of boundary strata.
- (ii) *Quasi-modular obstruction.* At genus 1 and degree 2, the E_1 propagator on the elliptic curve E_τ is $\eta_{12}^{(1)} = (\mathcal{G}'_1 / \mathcal{G}_1)(z_1 - z_2 \mid \tau) (dz_1 - dz_2)$ (Definition ??). The self-energy regularisation produces the Eisenstein series $E_2(\tau)$ (Theorem ??). Modular descent of the scalar genus-1 amplitude replaces the holomorphic quasi-modular form by its almost-holomorphic completion

$$E_2(\tau) \mapsto \widehat{E}_2(\tau) := E_2(\tau) - \frac{3}{\pi \text{Im}(\tau)},$$

the unique almost-holomorphic modular form of weight 2 and depth 1 on $\text{SL}_2(\mathbb{Z})$. Since Σ_1 is trivial, ordinary degree-one averaging is the identity; the completion is imposed by modularity in τ , not by the coinvariant quotient. A holomorphic section of the modular scalar theory would lift $\widehat{E}_2$ back to a holomorphic object on the ordered side, but the term $-3/(\pi \text{Im}(\tau))$ has no preimage in the holomorphic E_1 convolution algebra.

- (iii) *Independence from the genus-0 obstructions.* The quasi-modular obstruction is visible already at degree 1 (genus 1, one marked point), where the genus-0 obstructions are trivial: at degree 1 the Σ_1 -averaging is the identity, $\ker(\text{av}_1) = 0$, and the cross-degree and associator obstructions vanish. The non-holomorphic correction $-3/(\pi \text{Im}(\tau))$ lives in the genus-1 fibre direction and is independent of the purely combinatorial genus-0 obstructions.

Proof. Part (i): the boundary stratum $\overline{\mathcal{M}}_{0,n+2} \subset \partial \overline{\mathcal{M}}_{1,n}$ (obtained by pinching a non-separating cycle on a genus-1 surface to produce a rational curve with two identified points) embeds the genus-0 bar complex into the genus-1 bar complex. The cross-degree leakage $D(\ker(\text{av}_3)) \not\subset \ker(\text{av}_2)$ of Proposition 26.1.9(ii) propagates through this embedding: a genus-1 section would restrict to a genus-0 section on the boundary, contradicting Proposition 26.1.9.

Part (ii): the genus-1 propagator $K_{\text{reg}}^{(1)}(\tau) = -(\pi^2/3) E_2(\tau)$ is quasi-modular of weight 2 and depth 1 (Theorem ??). On the E_1 side, $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}(1, n)$ is built from holomorphic data on E_τ : the ordered bar complex uses the meromorphic propagator $\mathfrak{P}'_1/\mathfrak{P}_1$ and holomorphic modular forms $E_4, E_6, \dots$. The non-holomorphic correction $-3/(\pi \text{Im}(\tau))$ that converts E_2 to $\widehat{E}_2$ arises from the τ -periodicity defect of $\mathfrak{P}'_1/\mathfrak{P}_1$ (the shift $(\mathfrak{P}'_1/\mathfrak{P}_1)(z + \tau) = (\mathfrak{P}'_1/\mathfrak{P}_1)(z) - 2\pi i$, cf. Theorem ??): imposing $\text{SL}_2(\mathbb{Z})$ covariance on the scalar genus-1 amplitude absorbs this defect into the $\text{Im}(\tau)$ -dependent correction. Since $1/\text{Im}(\tau)$ is not holomorphic in τ , it cannot lie in the image of any holomorphic section.

Part (iii): at degree 1, the averaging map $\text{av}: \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}(1, 1) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}(1, 1)$ is the identity on symmetric invariants (since Σ_1 is trivial), and $\ker(\text{av}_1) = 0$. The three genus-0 obstructions (cross-degree, associator, GRT_1) vanish at degree 1. The quasi-modular obstruction is nonetheless present: it concerns the genus-1 fibre (dependence on τ), not the degree (dependence on n). The two obstructing mechanisms are therefore linearly independent in the relevant Ext group. $\square$

Remark 26.1.11 (Genus-1 non-splitting, the holomorphic anomaly, and the information lost by the modular shadow). The quasi-modular obstruction of Proposition 26.1.10 merits a closer examination from three angles: the physical origin of the obstruction, the mechanism that produces it, and the information it destroys.

(a) *Physical origin: the BCOV holomorphic anomaly.* The genus-1 free energy of any chiral algebra $\mathcal{A}$ with $\kappa = \kappa(\mathcal{A}) \neq 0$ is $F_1 = -\log \eta(\tau)^{2\kappa}$ (Theorem D at genus 1). The logarithmic derivative $\eta'(\tau)/\eta(\tau) = (\pi i/12) E_2(\tau)$ (standard q -expansion identity) gives

$$\partial_\tau F_1 = -2\kappa \frac{\eta'(\tau)}{\eta(\tau)} = -\frac{\pi i \kappa}{6} E_2(\tau).$$

The genus-1 amplitude is therefore controlled by the holomorphic quasi-modular Eisenstein series E_2 . There is no non-zero holomorphic modular form of weight 2 on $\text{SL}_2(\mathbb{Z})$. The modular completion of the genus-1 amplitude is almost holomorphic, and its $\bar{\tau}$ -derivative is proportional to $\kappa/(\text{Im } \tau)^2$. This is the genus-1 instance of the Bershadsky–Cecotti–Ooguri–Vafa holomorphic anomaly equation [BCOV93]. The BCOV equation at higher genus (Proposition ??) is the MC projection of $D\Theta + \frac{1}{2}[\Theta, \Theta] = 0$; at genus 1 the bracket term vanishes (there is no partition $1 = h + (1-h)$ with $h \geq 1$), and the sewing term reduces to the single statement that E_2 acquires a non-holomorphic correction under $\text{SL}_2(\mathbb{Z})$.

(b) *Mechanism:* $E_2 \mapsto \widehat{E}_2$. The ordered E_1 bar complex on the elliptic curve E_τ is built from the meromorphic propagator $\mathfrak{P}'_1/\mathfrak{P}_1$ and the holomorphic modular forms $E_4, E_6, \dots$; the series $E_2(\tau)$ enters through the self-energy regularisation of the genus-1 propagator. Scalar modular descent replaces E_2 by

$$\widehat{E}_2(\tau) = E_2(\tau) - \frac{3}{\pi \text{Im}(\tau)},$$

the unique almost-holomorphic modular form of weight 2 and depth 1. The correction $-3/(\pi \operatorname{Im} \tau)$ arises from the quasi-periodicity defect $(\mathcal{G}'_1/\mathcal{G}_1)(z + \tau) = (\mathcal{G}'_1/\mathcal{G}_1)(z) - 2\pi i$: integrating over the fundamental domain converts this shift into the $\operatorname{Im}(\tau)$ -dependent term. Since $1/\operatorname{Im}(\tau)$ is not holomorphic in τ , $\widehat{E}_2$ has no preimage in the holomorphic E_1 convolution algebra. Hence the scalar genus-1 modular theory has no holomorphic section. This is independent of the degreewise Σ_n -coinvariant map, which is the identity at $n = 1$.

(c) *Information loss and degree-1 independence.* The passage $E_2 \mapsto \widehat{E}_2$ destroys information. The holomorphic E_2 and the almost-holomorphic $\widehat{E}_2$ differ by $3/(\pi \operatorname{Im} \tau)$, a function that depends on $\bar{\tau}$ and therefore lies outside the holomorphic category in which the E_1 bar complex is defined. In physical terms, the modular shadow retains the almost-holomorphic completion $\widehat{E}_2$ but loses the holomorphic anomaly that distinguishes E_2 from a true modular form. The lost datum is precisely the obstruction to holomorphic modular section: the non-holomorphic correction imposed by modular descent has no preimage on the E_1 side, so the modular shadow cannot detect the mechanism that prevents such a section.

This information loss is visible already at degree 1. At $(g, n) = (1, 1)$, the symmetric group Σ_1 is trivial: av_1 is the identity, $\ker(\operatorname{av}_1) = 0$, and the three genus-0 obstructions (cross-degree leakage, associator, GRT_1 -torsor) vanish identically. The quasi-modular obstruction persists, because it lives in the genus-1 fibre direction (dependence on τ), not in the degree direction (dependence on n). Degree 1 is therefore the cleanest possible witness to the independence of the genus-1 obstruction from the genus-0 obstructions: every genus-0 mechanism is invisible, yet the modular-section obstruction survives. The physical content is that the conformal anomaly (controlled by κ) is a genuinely genus-1 phenomenon, not a shadow of any combinatorial structure at genus 0.

The strength of the quasi-modular obstruction is proportional to κ : at $\kappa = 0$ (the uncurved case), $F_1 = 0$ and the quasi-modular channel closes, while the genus-0 associator and cross-degree obstructions may still survive through the GRT_1 torsor. For Heisenberg $\mathcal{H}_\kappa$ at $\kappa \neq 0$ ($\kappa(\mathcal{H}_\kappa) = \kappa$, landscape census (Chapter ??)), the genus-1 quasi-modular obstruction is active, while the genus-0 associator obstruction is absent because the Heisenberg binary residue is the rank-one tensor $k\Omega_{\mathcal{H}}/z$ with $\Omega_{\mathcal{H}} = J \otimes J$ and carries no noncommutative Casimir channel.

Conjecture 26.1.12 (E_1 genus-two modular-section obstruction: seven stable-graph obstruction classes;). In the holomorphic ordered genus-2 model, a scalar Siegel-modular descent section is conjectured to be obstructed by seven stable-graph classes. The genus-0 and genus-1 obstruction mechanisms of Proposition 26.1.10 persist, and the seven stable graphs $\Gamma_A, \dots, \Gamma_G$ of $\overline{\mathcal{M}}_{2,0}$ (Figure ??; Computation ??) are conjectured to produce seven new obstruction classes $[\omega_\Gamma] \in \operatorname{Ext}_{\operatorname{dg Lie}}^1$, one per graph, organized as follows.

- (i) *Smooth graph A.* The genus-2 propagator on a smooth curve Σ_2 involves the 2×2 period matrix $\Omega \in \mathfrak{H}_2$. The Siegel quasi-modular sector (generated by $E_4^{(2)}, E_6^{(2)}, \chi_{10}, \chi_{12}$) replaces the elliptic quasi-modular sector of genus 1: the non-holomorphic completion of $(\operatorname{Im} \Omega)^{-1}$ (a 2×2 matrix, not a scalar) provides a Siegel analogue of the $E_2 \mapsto \widehat{E}_2$ obstruction.
- (ii) *Mumford shell (graphs B, C; codimension 1).* Graph B (figure-eight: genus-1 vertex with self-loop) carries the genus-1 quasi-modular obstruction on the vertex plus a propagator edge whose self-energy regularization introduces a new E_2 -type anomaly. Graph C (separating node: two genus-1 vertices joined by a bridge) carries a product of two independent genus-1 obstructions, one per vertex; the product is nonzero because the genus-1 obstruction of Proposition 26.1.10 is nonzero.

- (iii) *Planted-forest shell* (graphs D–G; codimension ≥ 2). Graph D (sunset: genus-0 vertex, two self-loops) carries a mixed-channel obstruction from the two propagator edges sharing a common genus-0 vertex; the cross-degree leakage of Proposition 26.1.9(ii) acts independently on each edge. Graph E (bridge-loop: genus-0 and genus-1 vertices, one bridge and one self-loop) couples the genus-0 cross-degree obstruction to the genus-1 quasi-modular obstruction through the bridge. Graph F (theta: two genus-0 vertices, three bridges) is the deepest stratum; its three edges produce the maximal mixed-channel obstruction, with 6 of 8 channel assignments mixed. Graph G (dumbbell: two genus-0 vertices with self-loops, one bridge) carries a product of two genus-1-type obstructions (each self-loop forms a genus-1 component) coupled through the bridge.
- (iv) *Independence*. The seven classes $[\omega_{\Gamma_A}], \dots, [\omega_{\Gamma_G}]$ are conjecturally linearly independent in Ext^1 : graphs A–C involve the Siegel and elliptic quasi-modular sectors, while D–G involve the combinatorial cross-degree mechanism. The two sectors interact only through clutching, and the automorphism orders $|\text{Aut}(\Gamma)| \in \{1, 2, 8, 12\}$ prevent cancellation.

PROPOSITION 26.1.13 (*Ordered MC components, coinvariant operators, and traced shadows*;). The degree- r component of $\Theta_{\mathcal{A}}^{E_1}$ at genus 0 is an element $r_r \in \text{End}(V^{\otimes r}) \otimes H^{r-2}(K_r) \otimes \mathcal{O}(*\Delta)$. Its homotopy coinvariant $q_r(r_r)$ remains operator-valued, and the normalized functional $\tau_{\mathcal{A},r}^{\text{res}}$ produces the scalar $S_r(\mathcal{A})$. In low degrees the three stages are:

Degree	Ordered component	Coinvariant operator	Scalar trace
$r = 2$	$K_{\mathcal{A}}^{\text{coll}}(z)$	$q_2(K_{\mathcal{A}}^{\text{coll}})$	$\kappa_{\text{dp}}(\mathcal{A}) = \tau_{\mathcal{A}} q_2(K_{\mathcal{A}}^{\text{coll}})$
$r = 3$	$(\Theta_{\mathcal{A}}^{E_1})_{0,3}$	$q_3((\Theta_{\mathcal{A}}^{E_1})_{0,3})$	$S_3(\mathcal{A}) = \tau_{\mathcal{A},3}^{\text{res}} q_3((\Theta_{\mathcal{A}}^{E_1})_{0,3})$
$r = 4$	$(\Theta_{\mathcal{A}}^{E_1})_{0,4}$	$q_4((\Theta_{\mathcal{A}}^{E_1})_{0,4})$	$S_4(\mathcal{A}) = \tau_{\mathcal{A},4}^{\text{res}} q_4((\Theta_{\mathcal{A}}^{E_1})_{0,4})$

The degree- r MC equation is the operadic boundary relation on ∂K_{r+1} . Under $H_{\text{CYBE}}^{\text{rep}}(\mathcal{A})$, the represented binary relation is the classical Yang–Baxter equation, and the represented kernel is a classical r -matrix. Associator and quartic R -matrix terminology likewise belongs to the corresponding represented comparison packages.

Proof. At genus 0, $\mathcal{M}_{\text{Ass}}(0, r) = C_*(K_r)$. The MC equation projected to degree r is the equation on ∂K_{r+1} : each codimension-1 face of K_{r+1} contributes one operadic composition. Stasheff [Sta63] identifies the relevant face complexes. Applying q_r gives the corresponding relation in $\text{End}_{\mathcal{A}}(r)_{h\Sigma_r}$; applying $\tau_{\mathcal{A},r}^{\text{res}}$ gives its scalar coordinate. The package $H_{\text{CYBE}}^{\text{rep}}$ identifies the represented binary operadic relation with the three-term CYBE in $\text{End}(V^{\otimes 3})$. $\square$

26.2 ORDERED CHIRAL HOMOLOGY

The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(\mathcal{J}^{-1}\bar{\mathcal{A}})$ is an algebraic object: a graded coalgebra with deconcatenation coproduct. The geometric object it represents is a $\mathcal{D}$ -module on the *ordered Ran space*.

Definition 26.2.1 (Ordered Ran space). Let X be a smooth algebraic curve over $\mathbb{C}$. The *ordered Ran space* is the disjoint union

$$\text{Ran}^{\text{ord}}(X) := \coprod_{n \geq 0} U_n(X), \quad U_n(X) = \{(z_1, \dots, z_n) \in X^n : z_i \neq z_j \text{ for } i \neq j\},$$

where $U_n(X) = X^n \setminus \bigcup_{i < j} \Delta_{ij}$ is the ordered configuration space of n distinct points on X . The Beilinson–Drinfeld Ran space is the $\Sigma_\bullet$ -coinvariant quotient

$$\mathrm{Ran}(X) = \mathrm{Ran}^{\mathrm{ord}}(X) / \Sigma_\bullet, \quad (26.3)$$

where Σ_n acts on $U_n(X)$ by permuting coordinates.

Definition 26.2.2 (Ordered factorisation $\mathcal{D}$ -module). Let $\mathcal{A}$ be a chiral algebra on X and let $j: U_n \hookrightarrow X^n$ denote the inclusion of the ordered configuration space. The *ordered factorisation $\mathcal{D}$ -module* of $\mathcal{A}$ on $\mathrm{Ran}^{\mathrm{ord}}(X)$ is the collection

$$\mathcal{F}_n^{\mathrm{ord}}(\mathcal{A}) := j_* j^*(\mathcal{A}^{\boxtimes n}) \in \mathcal{D}\text{-mod}(X^n), \quad n \geq 0,$$

where the OPE of $\mathcal{A}$, meromorphically extended across the diagonals, provides the $\mathcal{D}$ -module structure. No Σ_n -equivariance is imposed: the factorisation product, the KZ connection, and the chiral differential are encoded in the single object $\mathcal{F}^{\mathrm{ord}}(\mathcal{A})$ on $\mathrm{Ran}^{\mathrm{ord}}(X)$. The Beilinson–Drinfeld factorisation $\mathcal{D}$ -module on $\mathrm{Ran}(X)$ is obtained from $\mathcal{F}^{\mathrm{ord}}(\mathcal{A})$ only after a strong-unitary R -twisted Σ_n -equivariant structure has been constructed. In the pole-free symmetric case this is the ordinary Σ_n -equivariant descent $\mathcal{F}^\Sigma(\mathcal{A}) = (\mathcal{F}^{\mathrm{ord}}(\mathcal{A}))^{\Sigma_\bullet}$.

Definition 26.2.3 (Ordered chiral homology). The *ordered chiral homology* of $\mathcal{A}$ over X is the derived pushforward

$$\int_X^{\mathrm{ord}} \mathcal{A} := R\Gamma_{\mathrm{dR}}(\mathrm{Ran}^{\mathrm{ord}}(X), \mathcal{F}^{\mathrm{ord}}(\mathcal{A})) = \bigoplus_{n \geq 0} R\Gamma_{\mathrm{dR}}(X^n, \mathcal{F}_n^{\mathrm{ord}}(\mathcal{A})).$$

When such descent data exist, the coinvariant quotient (26.3) induces the *averaging map*

$$\mathrm{av}_R: \int_X^{\mathrm{ord}} \mathcal{A} \longrightarrow \int_X \mathcal{A}, \quad (26.4)$$

from ordered chiral homology to the Beilinson–Drinfeld chiral homology. This is the $\mathcal{D}$ -module incarnation of the algebraic averaging map $\mathrm{av}_R: \overline{B}^{\mathrm{ord}}(\mathcal{A}) \rightarrow \overline{B}^\Sigma(\mathcal{A})$ that sends the tensor coalgebra to its R -twisted Σ_n -coinvariant quotient. In the pole-free symmetric case $R = \mathrm{id}$.

PROPOSITION 26.2.4 (Symmetric descent). Let $\mathcal{A}$ be a chiral algebra on a smooth proper curve X .

- (i) If $\mathcal{A}$ is E_∞ -chiral with pole-free symmetric OPE, the ordinary coinvariant complex $(\int_X^{\mathrm{ord}} \mathcal{A})_{\Sigma_\bullet}$ computes $\int_X \mathcal{A}$. The quotient map from the raw ordered complex is not a quasi-isomorphism unless the $\Sigma_\bullet$ -action is homologically trivial.
- (ii) If $\mathcal{A}$ is genuinely E_1 -chiral and carries a strong-unitary R -twisted descent datum, then $(\int_X^{\mathrm{ord}} \mathcal{A})_{R, \Sigma_\bullet}$ computes $\int_X \mathcal{A}$. The kernel of av_R is the ordered braid-monodromic part discarded by descent; in the affine KZ case it contains the Drinfeld–associator class controlled by GRT_1 at degree 3 and the non-scalar R -matrix part at degree 2.

Proof. For the principal finite covering $\pi_n: C_n^{\mathrm{ord}}(X) \rightarrow C_n(X)$, descent of local systems gives

$$R\Gamma_{\mathrm{dR}}(C_n(X), \mathcal{F}_n) \simeq R\Gamma_{\mathrm{dR}}(C_n^{\mathrm{ord}}(X), \pi_n^* \mathcal{F}_n)^{\Sigma_n}.$$

In characteristic 0 the group algebra $k[\Sigma_n]$ is semisimple, so invariants and coinvariants are canonically quasi-isomorphic. This proves (i) in the pole-free case, where the equivariant structure is the ordinary tensor permutation with Koszul signs.

For (ii), replace the ordinary action by the action $\rho_R(\sigma_i) = \tau_{i,i+1} R_{i,i+1}(z_i - z_{i+1})$. The Yang–Baxter relation gives the braid relation and strong unitarity $R_{12}(z) R_{21}(-z) = \text{id}$ factors the braid action through Σ_n , so the same finite-cover descent applies with R -twisted invariants or coinvariants. Components not fixed by this descent action remain in the kernel. For the KZ connection at degree 3, the antisymmetric component of the linearized associator $[t_{12}, t_{23}]$ has zero Σ_3 -average; at degree 2 the kernel is the non-scalar part of the exchange kernel modulo its coinvariant residue. $\square$

THEOREM 26.2.5 (*Functoriality of the averaging map under chiral algebra morphisms*). Let $\text{ChirAlg}_X^{E_1, \text{cyc}, R}$ denote the category whose objects are cyclic E_1 -chiral algebras on the smooth proper curve X in the sense of Definition 3.11.4, equipped with a strong-unitary R -twisted Σ_n -descent datum compatible with the ordered bar differential and with ribbon composition. Morphisms $f: \mathcal{A} \rightarrow \mathcal{B}$ preserve the unit, augmentation, cyclic pairing τ , chiral product μ^{ch} at chain level, and intertwine the descent operators $\rho_{R, \mathcal{A}}$ and $\rho_{R, \mathcal{B}}$. Let $\mathfrak{g}_{E_1}^{(-)}, \mathfrak{g}_{\text{mod}}^{(-)}: (\text{ChirAlg}_X^{E_1, \text{cyc}, R})^{\text{op}} \rightarrow \text{dgLie}_k$ denote the contravariant assignments $\mathcal{A} \mapsto \mathfrak{g}_{\mathcal{A}}^{E_1}$ and $\mathcal{A} \mapsto \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ of Definition 26.1.6. Then:

- (i) $\mathfrak{g}_{E_1}^{(-)}$ and $\mathfrak{g}_{\text{mod}}^{(-)}$ are contravariant 2-functors on $\text{ChirAlg}_X^{E_1, \text{cyc}, R}$. For each $f: \mathcal{A} \rightarrow \mathcal{B}$ the induced pullback $f^*: \text{End}_{\mathcal{B}}(n) \rightarrow \text{End}_{\mathcal{A}}(n)$ on Hom-spaces (precomposition with $f^{\otimes n}$ post-composed with the cyclic-pairing-induced contraction) intertwines the F Ass-differential and bracket, yielding well-defined dg Lie morphisms $f_{E_1}^*: \mathfrak{g}_{\mathcal{B}}^{E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{E_1}$ and $f_{\text{mod}}^*: \mathfrak{g}_{\mathcal{B}}^{\text{mod}} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, functorial in f .
- (ii) av_R is a 2-natural transformation $\mathfrak{g}_{E_1}^{(-)} \Rightarrow \mathfrak{g}_{\text{mod}}^{(-)}$. The square

$$\begin{array}{ccc} \mathfrak{g}_{\mathcal{B}}^{E_1} & \xrightarrow{\text{av}_{R, \mathcal{B}}} & \mathfrak{g}_{\mathcal{B}}^{\text{mod}} \\ f_{E_1}^* \downarrow & & \downarrow f_{\text{mod}}^* \\ \mathfrak{g}_{\mathcal{A}}^{E_1} & \xrightarrow{\text{av}_{R, \mathcal{A}}} & \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \end{array}$$

commutes on the nose at chain level for every $f: \mathcal{A} \rightarrow \mathcal{B}$ in $\text{ChirAlg}_X^{E_1, \text{cyc}, R}$.

- (iii) *Compatibility with Maurer–Cartan*. The MC element $\Theta_{(-)}^{E_1}$ of Theorem 26.1.7 is natural in f : $f_{E_1}^*(\Theta_{\mathcal{B}}^{E_1}) = \Theta_{\mathcal{A}}^{E_1}$, and likewise $f_{\text{mod}}^*(\Theta_{\mathcal{B}}) = \Theta_{\mathcal{A}}$, so the diagram of part (ii) sends $\Theta_{\mathcal{B}}^{E_1} \mapsto \Theta_{\mathcal{A}}$ by either route.
- (iv) *Scope*. The averaging map is *not* a functor between categories of chiral algebras: there is no functor $\text{Av}: \text{ChirAlg}_X^{E_1, \text{cyc}, R} \rightarrow \text{ChirAlg}_X^{E_{\infty}, \text{cyc}}$ whose action on the convolution algebras realises $\text{av}_{R, \mathcal{A}}$ as $\mathfrak{g}_{\mathcal{A}}^{E_1} \rightarrow \mathfrak{g}_{\text{Av}(\mathcal{A})}^{\text{mod}}$. The codomain of $\text{av}_{R, \mathcal{A}}$ is $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, not $\mathfrak{g}_{\text{Av}(\mathcal{A})}^{\text{mod}}$, and no symmetrisation of the chiral product on $\mathcal{A}$ exists in $\text{ChirAlg}_X^{E_{\infty}, \text{cyc}}$ unless $\mathcal{A}$ is already E_{∞} -chiral (vertex algebra with symmetric OPE, $S(z) = \tau$, Proposition 26.2.4 (i)).

Proof. (i). For $f: \mathcal{A} \rightarrow \mathcal{B}$ a chiral algebra morphism, the pullback on multilinear endomorphisms is $(f^* \phi)(a_1, \dots, a_n) := \phi(f(a_1), \dots, f(a_n))$ for $\phi \in \text{End}_{\mathcal{B}}(n)$ and $a_i \in \mathcal{A}$. The ordered source imposes no Σ_n -equivariance; the F Ass differential and bracket act on the $\mathcal{M}_{\text{Ass}}(g, n)$ -coordinate and commute with this pullback. On the descended side, the hypothesis $f^{\otimes n} \rho_{R, \mathcal{A}}(\sigma) = \rho_{R, \mathcal{B}}(\sigma) f^{\otimes n}$ makes f^* well defined on R -twisted coinvariants. Functoriality is contravariance of pullback.

(ii). At each (g, n) , $\text{av}_{R,C}$ is the quotient map to R_C -twisted coinvariants. Since every morphism in $\text{ChirAlg}_X^{E_1, \text{cyc}, R}$ intertwines the descent actions, $f_{E_1}^*$ is R -equivariant. The universal property of coinvariants therefore gives

$$f_{\text{mod}}^* \circ \text{av}_{R,B} = \text{av}_{R,A} \circ f_{E_1}^*$$

on the chain complex before passing to cohomology. (iii). The MC element $\Theta_C^{E_1} = D_C^{E_1} - d_o$ is constructed from the bar differential on $\overline{B}^{\text{ord}}(C)$, which is f -natural: a chiral morphism $f: \mathcal{A} \rightarrow \mathcal{B}$ induces $f_*: \overline{B}^{\text{ord}}(\mathcal{A}) \rightarrow \overline{B}^{\text{ord}}(\mathcal{B})$ intertwining bar differentials, and the dual contravariant action on convolution algebras sends $D_B^{E_1} \mapsto D_A^{E_1}$ (the differential is defined by precomposition with the bar coproduct, which is algebra-independent). Subtracting the f -invariant combinatorial differential d_o gives $f_{E_1}^*(\Theta_B^{E_1}) = \Theta_A^{E_1}$. The analogous argument for $f_{\text{mod}}^*(\Theta_B) = \Theta_A$ uses the symmetric bar complex $\overline{B}^{\text{Sym}}$ in place of the ordered one. Combining with (ii): $\text{av}_{R,A}(\Theta_A^{E_1}) = \text{av}_{R,A}(f_{E_1}^*(\Theta_B^{E_1})) = f_{\text{mod}}^*(\text{av}_{R,B}(\Theta_B^{E_1})) = f_{\text{mod}}^*(\Theta_B) = \Theta_A$, recovering Theorem 26.1.7 naturally in f . (iv). Suppose a functor $\text{Av}: \text{ChirAlg}_X^{E_1, \text{cyc}, R} \rightarrow \text{ChirAlg}_X^{E_\infty, \text{cyc}}$ realises $\text{av}_{R,A}$ on convolution algebras as $\mathfrak{g}_A^{E_1} \rightarrow \mathfrak{g}_{\text{Av}(\mathcal{A})}^{\text{mod}}$. Then $\mathfrak{g}_{\text{Av}(\mathcal{A})}^{\text{mod}} = \mathfrak{g}_A^{\text{mod}}$ as dg Lie algebras, hence $\text{End}_{\text{Av}(\mathcal{A})}(n) = \text{End}_A(n)$ as Σ_n -equivariant endomorphism objects. But the chiral μ_A^{ch} on $\mathcal{A}$ does not in general descend to a symmetric chiral product on the underlying complex: the symmetric chiral product condition $\mu_A^{\text{ch}}(a, b) = \mu_A^{\text{ch}}(b, a)$ at chain level is precisely the E_∞ -chiral hypothesis $S(z) = \tau$. For genuinely E_1 -chiral $\mathcal{A}$ ($S(z) \neq \tau$, e.g. Yangian $Y_h(\mathfrak{g})$) no such symmetrisation exists at chain level: the antisymmetric/braiding component of μ_A^{ch} is a chain-level obstruction in $\ker(\text{av}_R)$ at degree 2 that prevents the existence of $\text{Av}(\mathcal{A})$ as a symmetric chiral algebra. Therefore av_R remains a coinvariant projection per algebra, never a functor between algebra categories. $\square$

COROLLARY 26.2.6 (*Ordered/symmetric chain-level kernel split, class-by-class, at degree 3;*). For each shadow class $\mathbf{X} \in \{\mathbf{G}, \mathbf{L}, \mathbf{C}, \mathbf{M}\}$ with archetype $\mathcal{A}_{\mathbf{X}} \in \{\mathcal{H}_k, \widehat{\mathfrak{g}}_k, \beta\gamma, \text{Vir}_c\}$ and a chiral morphism $f: \mathcal{A}_{\mathbf{X}} \rightarrow \mathcal{B}$ in $\text{ChirAlg}_X^{E_1, \text{cyc}, R}$:

- (a) *Ordered conclusion.* The induced map $f_{E_1}^*: \mathfrak{g}_B^{E_1} \rightarrow \mathfrak{g}_{\mathcal{A}_{\mathbf{X}}}^{E_1}$ preserves the degree-3 kernel filtration: $f_{E_1}^*(\ker(\text{av}_{R,B})|_{(0,3)}) \subseteq \ker(\text{av}_{R,\mathcal{A}_{\mathbf{X}}})|_{(0,3)}$. For $\mathcal{A}_{\mathbf{X}} = \widehat{\mathfrak{g}}_k$ the linearised KZ associator class $[t_{12}, t_{23}] \in \mathfrak{g}_{\mathcal{A}_{\mathbf{X}}}^{E_1}|_{(0,3)}$ lies in $\ker(\text{av}_{R,\mathcal{A}_{\mathbf{X}}})$ (Proposition 26.1.9(iii)), and is detected by the cubic shadow $\mathfrak{C}(\mathcal{A}_{\mathbf{X}}) = \tau_{\mathcal{A}_{\mathbf{X},3}}^{\text{res}} q_3(\Phi_{\text{KZ}})$ of the Drinfeld associator through the symmetric products $t_{12}t_{23} + t_{23}t_{12}$. The intermediate class $q_3(\Phi_{\text{KZ}})$ remains operator-valued.
- (b) *Symmetric conclusion.* The induced map $f_{\text{mod}}^*: \mathfrak{g}_B^{\text{mod}} \rightarrow \mathfrak{g}_{\mathcal{A}_{\mathbf{X}}}^{\text{mod}}$ is well-defined *only* on the Σ_3 -coinvariant component $\text{im}(\text{av}_{R,B})|_{(0,3)}$, and the class $[t_{12}, t_{23}]$ has no preimage in $\mathfrak{g}_B^{\text{mod}}$ unless $\mathcal{B}$ is itself E_∞ -chiral. The symmetric statement is therefore strictly weaker than the ordered statement of part (a).

The ordered and symmetric conclusions are different assertions at degree 3. The gap between them is exactly the GRT_1 -torsor data of Proposition 26.1.9(iv).

Proof. (a). By Theorem 26.2.5 (ii), $\text{av}_{R,\mathcal{A}_{\mathbf{X}}} \circ f_{E_1}^* = f_{\text{mod}}^* \circ \text{av}_{R,B}$ on $\mathfrak{g}_B^{E_1}$. If $\xi \in \ker(\text{av}_{R,B})|_{(0,3)}$, then $f_{\text{mod}}^*(\text{av}_{R,B}(\xi)) = 0$, and the commutation gives $\text{av}_{R,\mathcal{A}_{\mathbf{X}}}(f_{E_1}^*(\xi)) = 0$, so $f_{E_1}^*(\xi) \in \ker(\text{av}_{R,\mathcal{A}_{\mathbf{X}}})|_{(0,3)}$. For $\widehat{\mathfrak{g}}_k$ the explicit class $[t_{12}, t_{23}]$ realises a nonzero element of this kernel by Proposition 26.1.9 (iii): its Σ_3 -average vanishes by $(1 \leftrightarrow 3)$ -antisymmetry, and the symmetric-products contribution to $q_3(\Phi_{\text{KZ}})$

is the operator class $q_3(t_{12}t_{23} + t_{23}t_{12})$; its normalized trace is the cubic shadow $\mathfrak{C}(\widehat{\mathfrak{g}}_k) = \tau_{\widehat{\mathfrak{g}}_k,3}^{\text{res}} q_3(t_{12}t_{23} + t_{23}t_{12})$. (b). The symmetric statement on $\mathfrak{g}_{\mathcal{B}}^{\text{mod}}$ requires Σ_3 -coinvariance on the source, hence is well-defined only on $\text{im}(\text{av}_{R,\mathcal{B}})|_{(0,3)} \subseteq \mathfrak{g}_{\mathcal{B}}^{\text{mod}}$ (with the convention that $\text{av}_{R,\mathcal{B}}$ is surjective so the image equals $\mathfrak{g}_{\mathcal{B}}^{\text{mod}}$ at chain level, Definition 26.1.6). A preimage of $[t_{12}, t_{23}]$ in $\mathfrak{g}_{\mathcal{B}}^{\text{mod}}$ under $\text{av}_{R,\mathcal{B}}$ would require a Σ_3 -invariant lift, but the antisymmetric component is exactly what averaging annihilates. Such a lift exists precisely when $\mathcal{B}$ is E_∞ -chiral (where the entire E_1 ordered structure descends to the symmetric one by Proposition 26.2.4 (i)) and not otherwise. The ordered conclusion of part (a) is strictly stronger than the symmetric conclusion of part (b); conflating the two would import a GRT_1 -torsor splitting that Proposition 26.1.9(iv) forbids. $\square$

Remark 26.2.7 (Cross-volume reading: bulk-to-boundary and CY functoriality). The chain-level square of Theorem 26.2.5 (ii) is the Vol I form of two cross-volume compatibilities. (a) *Vol II bulk-to-boundary commutation* (*Vol II Remark ?? of sc_chtop_heptagon.tex*): the boundary restriction $\iota^*: \text{HT-QFT}_{X \times \mathbb{R}_{\geq 0}} \rightarrow \text{ChirAlg}_X$ commutes with av_R on the four-class fingerprint $\{\mathbf{G}, \mathbf{L}, \mathbf{C}, \mathbf{M}\}$. Theorem 26.2.5 (ii) provides the Vol I-internal naturality witness that allows the Vol II compatibility to be stated as a chain-level identity rather than a class-level coincidence: for every chiral morphism $f: \iota^* \mathcal{F}_{\mathcal{B}} \rightarrow \iota^* \mathcal{F}_{\mathcal{A}}$ induced by a bulk morphism on factorisation algebras, the squares of parts (ii) on $\mathcal{A}$ and $\mathcal{B}$ glue into a cube whose commutation realises the boundary-to-bulk averaging compatibility. (b) *Vol III CY-to-chiral factorisation* $\Phi_d^{(\Sigma_{d-1}, C)} = \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}} \circ \Phi_d^{\text{FA}}$ (*Vol III chapters/theory/cy_to_chiral.tex Theorem phi-two-stage-factorisation; compute/lib/kodaira_spencer_e1_engine.py*): stage 1 $\Phi_d^{\text{FA}}: \text{CY}_d\text{-Cat} \rightarrow E_d\text{-HolFA}(\text{CY}_d)$ is a canonical holomorphic factorisation algebra on the CY_d variety, pinned up to contractible choice by Kontsevich–Tamarkin E_d -formality and Costello–Gwilliam–Li locality; stage 2 $\text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}}: E_d\text{-HolFA}(\text{CY}_d) \rightarrow \text{ChirAlg}_C^{E_1}$ is factorisation homology over a closed $(d-1)$ -cycle Σ_{d-1} followed by restriction to a reference curve $C \subset \text{CY}_d$, producing an E_1 -chiral algebra on the curve at $d \geq 3$. For each named pair (Σ_{d-1}, C) , the composite $\Phi_d^{(\Sigma_{d-1}, C)}$ is an object-level construction, not yet functorial in CY morphisms beyond the named defect-bimodule cases. Under the Vol III hypothesis that these composites extend to a functor on a sub-2-category of shifted-Lagrangian correspondences, Theorem 26.2.5 guarantees that the CY-internal averaging $\text{av}_{R, \Phi_d^{(\Sigma_{d-1}, C)}(X)}$ is natural in those correspondences. The Vol III claim therefore reduces to the established Vol I 2-naturality plus the Vol III object-level two-stage data $(\Phi_d^{\text{FA}}, \text{Sp}_{\Sigma_{d-1}, C}^{\text{ch}})$, with no further functoriality input required. A single CY_d category produces a family of chiral shadows indexed by (Σ_{d-1}, C) ; the 2-naturality discipline applies separately on each member of the family. (c) *Cross-volume scope*. The non-existence of a global functor $\text{Av}: \text{ChirAlg}_X^{E_1, \text{cyc}, R} \rightarrow \text{ChirAlg}_X^{E_\infty, \text{cyc}}$ (part (iv) of Theorem 26.2.5) forbids any cross-volume reading of av_R as a symmetrisation of chiral algebras. The correct cross-volume reading is the 2-natural transformation between two convolution-algebra 2-functors fixed at each algebra, plus the bulk-to-boundary restriction for the Vol II side and the CY-functoriality envelope for the Vol III side.

THEOREM 26.2.8 (*Averaging kernel under completed Reynolds descent;*). Type signature: (Open quadrant, completed ordered-to-symmetric convolution presentation, Beilinson levels 2 and 5, hypothesis package: characteristic-zero finite arity groups, the completed Reynolds descent of Lemma ??, the strong-unitary R -twisted descent datum of Definition 26.1.6, the Reynolds-kernel bracket-ideal condition when a Lie kernel is asserted, and Conjecture 35.13.1 only for the Willwacher/ grt_1 clauses). Let $\mathcal{A}$ be a chirally

Koszul E_1 -chiral algebra of shadow class $\mathbf{X} \in \{\mathbf{G}, \mathbf{L}, \mathbf{C}, \mathbf{M}\}$ on the formal disc D . At genus 0 and bar degree n , write

$$\mathrm{Re}_n : \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1}(\mathbf{o}, n) \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1}(\mathbf{o}, n)^{\Sigma_n}$$

for the completed Reynolds projector of Lemma ??, and set

$$K_n^{\mathrm{Re}} := \ker(\mathrm{Re}_n), \quad K_{\bullet}^{\mathrm{Re}} := \bigoplus_{n \geq 2} K_n^{\mathrm{Re}}.$$

When the full R -twisted descent and bracket-ideal hypotheses hold, the quotient map

$$\mathrm{av}_R : \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1} \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$$

is a dg Lie morphism; only on that surface do we also write $\ker(\mathrm{av}_R)$ for the genuine dg Lie kernel. Before that surface is supplied, $K_{\bullet}^{\mathrm{Re}}$ is only the completed degreewise Reynolds complement. Write $\Omega_{ij} \in \mathrm{End}(\mathcal{A}^{\otimes n})$ for the symmetric Casimir acting on strands i and j via the trace form of $\mathcal{A}$, and $\mathbf{t}_n \subset \mathrm{End}(\mathcal{A}^{\otimes n})$ for the Drinfeld–Kohno Lie algebra generated by $\{\Omega_{ij}\}_{1 \leq i < j \leq n}$ modulo the infinitesimal braid relations $[\Omega_{ij}, \Omega_{ik} + \Omega_{jk}] = \mathbf{o}$ (for distinct i, j, k) and $[\Omega_{ij}, \Omega_{kl}] = \mathbf{o}$ (for disjoint indices). Then the following hold.

- (i) *Isotypic description of K_n^{Re} at each bar-degree $n \geq 2$.* The Σ_n -equivariant decomposition of $\mathrm{End}(\mathcal{A}^{\otimes n})$ into isotypic components

$$\mathrm{End}(\mathcal{A}^{\otimes n}) = \bigoplus_{\lambda \vdash n} \mathrm{End}(\mathcal{A}^{\otimes n})_{[\lambda]}$$

induces a direct-sum decomposition

$$K_n^{\mathrm{Re}} = \widehat{\bigoplus_{\lambda \vdash n, \lambda \neq (n)} \mathrm{End}(\mathcal{A}^{\otimes n})_{[\lambda]}}, \quad (26.5)$$

i.e. K_n^{Re} is the completed direct sum of all Σ_n -isotypic components indexed by partitions $\lambda \vdash n$ distinct from the trivial one-row partition (n) . The surjection $\mathrm{Re}_n : \mathrm{End}(\mathcal{A}^{\otimes n}) \twoheadrightarrow \mathrm{End}(\mathcal{A}^{\otimes n})^{\Sigma_n}$ is the projection onto the trivial isotypic component $[(n)]$, and its kernel is the complementary sum.

- (ii) *Graded Lie kernel versus degreewise Reynolds complement.* Under the Reynolds-kernel bracket-ideal condition of Lemma ??, the direct sum $K_{\bullet}^{\mathrm{Re}}$ is a graded Lie subalgebra of $(\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1}, [-, -])$ with respect to the Gerstenhaber-type bracket:

$$[K_m^{\mathrm{Re}}, K_n^{\mathrm{Re}}] \subseteq K_{m+n-1}^{\mathrm{Re}} \quad (m, n \geq 2).$$

Without that bracket-ideal condition, the theorem asserts only the completed vector-space splitting of part (i). The degreewise Reynolds complement is not automatically stable under the bar differential D : the cross-degree leakage

$$D(K_n^{\mathrm{Re}}) \not\subseteq K_{n-1}^{\mathrm{Re}}$$

of Proposition 26.1.9 (ii) exhibits the raw degreewise projection as a map

$$K_n^{\mathrm{Re}} \rightarrow \mathrm{im}(\mathrm{Re}_{n-1}) \quad \text{with non-zero image,}$$

unless the stronger equivariance making av_R a chain map has been imposed. On the full dg descent surface, $\ker(\mathrm{av}_R)$ is instead a dg Lie ideal.

- (iii) *Degree-2 collapse.* At bar-degree $n = 2$, the only non-trivial partition is $\lambda = (1, 1)$ (the sign representation of Σ_2). The sign-isotypic component of $\text{End}(\mathcal{A}^{\otimes 2})$ consists of the antisymmetric part $\wedge^2(\tilde{\mathcal{A}})^{\otimes 2} \subset \mathcal{A}^{\otimes 2}$ -valued endomorphisms. For all four archetypes $\mathcal{A}_{\mathbf{X}} \in \{\mathcal{H}_k, \widehat{\mathfrak{g}}_k, \beta\gamma, \text{Vir}_c\}$, the spectral residue $r_{\mathcal{A}_{\mathbf{X}}}(z)$ is Σ_2 -symmetric (Corollary 26.2.9 below, via the unitarity-plus-CYBE normalisation of Proposition 26.1.9 (iii)), hence

$$K_2^{\text{Re}}|_{\mathcal{A}_{\mathbf{X}}, r_{\mathcal{A}_{\mathbf{X}}}(z)\text{-slot}} = 0, \quad \mathbf{X} \in \{\mathbf{G}, \mathbf{L}, \mathbf{C}, \mathbf{M}\}, \quad (26.6)$$

on the slot carrying the binary spectral datum. Off that slot the sign-isotypic slice consists of genuine antisymmetric endomorphisms, which enter K_2^{Re} but do not contribute to the bar-cohomology of the chiral product because they are annihilated by the second differential.

- (iv) *Degree-3 generator and Ihara bracket on class L.* At bar-degree 3, the Σ_3 -isotypic decomposition is $[(3)] \oplus [(2, 1)] \oplus [(1^3)]$ (trivial, standard, sign), and

$$K_3^{\text{Re}} = \text{End}(\mathcal{A}^{\otimes 3})_{[(2, 1)]} \oplus \text{End}(\mathcal{A}^{\otimes 3})_{[(1^3)]}.$$

Inside $\mathfrak{t}_3 \subset \text{End}(\mathcal{A}^{\otimes 3})$, the element

$$\xi_3 := [\Omega_{12}, \Omega_{23}]$$

lies in K_3^{Re} by Proposition 26.1.9 (iii) (antisymmetry under $(1 \leftrightarrow 3)$ forces Σ_3 -average zero); the dual generator $\xi'_3 := [\Omega_{13}, \Omega_{23}]$ is the second independent generator obtained by the Σ_3 -action, and the infinitesimal braid relation enforces $[\Omega_{12} + \Omega_{13} + \Omega_{23}, \Omega_{ij}] = 0$ for each $\{i, j\} \subset \{1, 2, 3\}$. On class $\mathbf{L}$ ($\mathcal{A} = V_k(\mathfrak{g})$, $r^{KM}(z) = k \Omega_{\text{tr}}/z$) the ambient Gerstenhaber-type bracket $[-, -]_{\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}}$ on the convolution dGLA couples the degree-3 generators to degree-4 generators through the operadic slot-composition law: composing ξ_3 with ξ'_3 at the i -th operadic slot produces a bar-degree- $(3 + 3 - 2) = 4$ endomorphism of $\mathcal{A}^{\otimes 4}$, and taking the commutator (summing over slot choices i with the operadic sign convention of Definition 26.1.6) yields the *Ihara generator*

$$\Xi_4 := [\xi_3, \xi'_3]_{\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}} = \sum_{i \in \{1, 2, 3\}} (-1)^{\epsilon(i)} \xi_3 \circ_i \xi'_3 - \xi'_3 \circ_i \xi_3 \in K_4^{\text{Re}}, \quad (26.7)$$

where $\epsilon(i) \in \{0, 1\}$ is the operadic sign. The element Ξ_4 is antisymmetric under the Klein four-group $V_4 = \langle (1 \leftrightarrow 3), (2 \leftrightarrow 4) \rangle \subset \Sigma_4$, hence lies in the sign-plus-standard-plus-hook components $\text{End}(\mathcal{A}^{\otimes 4})_{[(2, 1, 1)]} \oplus \text{End}(\mathcal{A}^{\otimes 4})_{[(1^4)]}$ of the isotypic decomposition (26.5) at $n = 4$, in particular *not* in the trivial- Σ_4 -component. On classes $\mathbf{G}, \mathbf{C}, \mathbf{M}$, the generators ξ_3, ξ'_3 vanish on the binary slice of $r_{\mathcal{A}}(z)$ in the sense of Theorem ?? (iv); however, their ambient $\mathfrak{t}_3$ -image is non-zero at chain level on every class for which the algebra has a non-abelian Lie bracket, so the class-refinement is a statement about which generators have *non-zero effect on the spectral residue*, not about the vanishing of ξ_3 as an element of K_3^{Re} .

- (v) *Class-stratified lower bound on graded dimension.* Define $K_n^{\text{ess}}(\text{Re})$ to be the quotient of K_n^{Re} by elements whose image in the bar cohomology $H^\bullet(\overline{B}^{\text{ord}}(\mathcal{A}))$ under the bar differential is zero, modulo the ambient Σ_n -action. Then for a class- $\mathbf{X}$ archetype $\mathcal{A}_{\mathbf{X}}$ at generic parameter,

$$\dim K_n^{\text{ess}}(\text{Re})|_{\mathcal{A}_{\mathbf{X}}} \geq \begin{cases} 0, & \mathbf{X} = \mathbf{G}, \\ \dim \mathfrak{t}_n^{\text{Lie-free}} - \dim \mathfrak{t}_n^{\Sigma_n}, & \mathbf{X} \in \{\mathbf{L}, \mathbf{C}\}, n \geq 3, \\ \dim_{\text{rat}} \text{grt}_1^{(n)} \oplus (\text{depth tail}), & \mathbf{X} = \mathbf{M}, n \geq 3, \end{cases}$$

where $\mathfrak{t}_n^{\text{Lie-free}}$ is the degree- n component of the free Lie algebra on $\{\Omega_{ij}\}$ modulo the infinitesimal braid relations, and $\mathfrak{grt}_1^{(n)}$ is the weight- n component of the Grothendieck–Teichmüller Lie algebra (Willwacher [?Willwacher15]; dimension table in Conjecture 35.13.1 (ii)). For class $\mathbf{G}$ the kernel vanishes uniformly in n because $\mathcal{A} = \mathcal{H}_k$ is abelian, so $\Omega_{ij} = k \cdot \mathbf{1} \otimes \mathbf{1}$ is a scalar and $[\Omega_{ij}, \Omega_{kl}] = 0$ identically.

- (vi) *Cobomological map to $\mathfrak{grt}_1$ (conditional on Conjecture 35.13.1 and on the residual-square-zero condition).* Let $\overline{\text{Tot}}: K_{\bullet}^{\text{Re}} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_i}$ be the inclusion, and let $H^{\bullet}(\text{id} - \text{Re})$ denote the Σ -equivariant cohomology of the antisymmetrising projector $\text{id} - \text{Re}$ acting on $(\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_i}, D)$. Then the composite

$$\Psi: H^{\bullet}(K_{\bullet}^{\text{Re}}, D^{\text{res}}) \xrightarrow{\text{Willwacher}} H^{\bullet}(\text{GC}_2) \cong \mathfrak{grt}_1$$

is a graded Lie algebra map, where D^{res} is the *residual differential* obtained from the cross-degree leakage by projecting the output of D back onto K_{n-1}^{Re} via $\text{id} - \text{Re}$ (i.e. the Σ_{n-1} -antisymmetrising component of D). The condition

$$(D^{\text{res}})^2 = 0$$

is part of this clause; it is not formal from $D^2 = 0$ unless the projection commutes with the relevant filtered differential or the resulting curvature term is separately killed. The Willwacher arrow is the composite of the formality map Φ of Conjecture 35.13.1 (i) with the Willwacher isomorphism of part (ii) of the same conjecture. On the image the map Ψ recovers the Deligne–Drinfeld generator σ_{2k+1} as the Willwacher image of the Ihara bracket tower $[\xi_3, [\xi_3, \dots, [\xi_3, \xi'_3] \dots]]$ with k inner brackets, for each $k \geq 1$.

- (vii) *Class-resolution of Ψ (conditional on Conjecture 35.13.1).* The image of Ψ stratifies by shadow class as follows (compatible with Conjecture 35.13.1 (iii)):

$$\text{im}(\Psi|_{\mathcal{A}_{\mathbf{X}}}) = \begin{cases} 0, & \mathbf{X} = \mathbf{G}, \\ \langle \sigma_3 \rangle \subset \mathfrak{grt}_1, & \mathbf{X} = \mathbf{L}, \\ \langle \sigma_3 \rangle \subset \mathfrak{grt}_1, & \mathbf{X} = \mathbf{C}, \\ \oplus_{k \geq 1} \langle \sigma_{2k+1} \rangle \subset \mathfrak{grt}_1, & \mathbf{X} = \mathbf{M}. \end{cases}$$

- (viii) *$(\infty, 1)$ -categorical upgrade.* On the full dg descent surface, the chain-level dg Lie kernel $\ker(\text{av}_R)$ lifts to the $(\infty, 1)$ -categorical fibre of the averaging map viewed as a morphism of pro-nilpotent L_{∞} -algebras; the fibre $\text{hofib}(\text{av}_R) \in \text{dgLie}^{\infty}$ has underlying chain complex quasi-isomorphic to $(\ker(\text{av}_R), D)$ by the long-exact-sequence argument of Theorem 26.2.5 (ii) applied to the canonical short exact sequence $0 \rightarrow \ker(\text{av}_R) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_i} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \rightarrow 0$; the non-splitting of Proposition 26.1.9 (iv) is the obstruction to trivialising this fibre, and identifies $\pi_0(\text{hofib}(\text{av}_R))$ with the GRT_1 -torsor of MC-section gauge classes.

Proof. (i). The degree- n averaging projector Re_n is the Reynolds operator $\frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma \cdot (-)$ on the space $\text{End}(\mathcal{A}^{\otimes n})$ (after section choice along $\iota_{0,n}^{\text{rib}}$, per Definition 26.1.6). The division by $n!$ uses characteristic zero. On each finite quotient of the completed arity piece, under the isotypic decomposition $\text{End}(\mathcal{A}^{\otimes n}) = \oplus_{\lambda \vdash n} \text{End}(\mathcal{A}^{\otimes n})_{[\lambda]}$, the Reynolds operator projects onto the trivial isotypic component $\text{End}(\mathcal{A}^{\otimes n})_{[(n)]}$ and annihilates every other component by orthogonality of characters (Frobenius–Schur): for each $\lambda \neq (n)$, $\sum_{\sigma} \chi_{\lambda}(\sigma) = n! \langle \chi_{\lambda}, \chi_{(n)} \rangle = 0$ because $\chi_{\lambda} \perp \chi_{(n)}$ as characters of distinct irreducible representations. Therefore Re_n is the trivial-isotypic

projector, its kernel is the complementary sum (26.5) on each finite quotient, and the completed statement follows by inverse limit from Lemma ?? . Its image is $\text{End}(\mathcal{A}^{\otimes n})^{\Sigma_n}$. The numerical identity $\dim K_n^{\text{Re}}|_{V=\mathbb{C}^2} = 2^n - (n+1) = \dim V^{\otimes n} - \dim \text{Sym}^n V$ is verified through arity 10 in the compute engine `compute/lib/averaging_kernel_dim_engine.py` (functions `hecke_kernel_dim_sl2_fund`, `hecke_kernel_decomposition_sl2_fund`, and `schur_weyl_decomposition_sl2`).

(ii). For the bracket stability, work under the full descent package of Definition 26.1.6, including the Reynolds-kernel ideal condition of Lemma ?? . The Reynolds operator is Σ -linear and intertwines the operadic slot composition because ribbon-graph composition commutes with the external Σ -action up to the section-choice ambiguity absorbed into the boundary equivalence class (Theorem 26.1.5). The kernel-ideal condition is exactly what prevents a bracket of two killed ordered components from reappearing in the symmetric quotient. Consequently, for $f \in K_m^{\text{Re}}$ and $g \in K_n^{\text{Re}}$,

$$\text{Re}_{m+n-1}([f, g]) = [\text{Re}_m(f), \text{Re}_n(g)] = [0, 0] = 0,$$

so $[f, g] \in K_{m+n-1}^{\text{Re}}$. This gives the graded Lie inclusion $[K_m^{\text{Re}}, K_n^{\text{Re}}] \subseteq K_{m+n-1}^{\text{Re}}$ without requiring a Littlewood–Richardson analysis of the bracket.

Non-stability under D follows from Proposition 26.1.9(ii): the partial trace D_{ij} is Σ_{n-2} -equivariant but not Σ_n -equivariant; projected onto the trivial Σ_{n-1} -isotypic component, the result need not vanish, so $D(K_n^{\text{Re}}) \not\subseteq K_{n-1}^{\text{Re}}$ on the raw degreewise Reynolds surface. The numerical witness is the 60-test chain-level verification at $n = 3$, $V = \mathbb{C}^2$, in the engine `e1_nonsplitting_obstruction_engine.py`. If the stronger descent hypotheses make av_R a chain map, this leakage is killed in the quotient and $\ker(\text{av}_R)$ is stable under D .

(iii). At $n = 2$ the non-trivial partition is $\lambda = (1, 1)$, with character $\chi_{(1,1)}(\sigma) = \text{sgn}(\sigma)$. The spectral residue slot of $\text{End}(\mathcal{A}^{\otimes 2})$ is the subspace spanned by $r_{\mathcal{A}}(z) \in \mathcal{A}^1 \otimes \mathcal{A}^1[[z^{-1}]]$, which by the unitarity hypothesis $r_{\mathcal{A}}(z) + \tau r_{\mathcal{A}}(-z) = 0$ of Definition 3.11.4 (classical Yang–Baxter + unitarity, Drinfeld [?Drinfeld90]) satisfies $\tau \cdot r_{\mathcal{A}}(z) = r_{\mathcal{A}}(z)$ on the symmetric component (where τ is the flip). This is stated in Corollary 26.2.9 below for each of the four archetypes by direct computation: $\mathcal{H}_k$: $r_{\mathcal{H}}(z) = k\Omega_{\mathcal{H}}/z$ with $\Omega_{\mathcal{H}} = J \otimes J$, rank-one and symmetric; $V_k(\mathfrak{g})$: $r^{KM}(z) = k\Omega_{\text{tr}}/z$ with symmetric trace-form Casimir Ω_{tr} , hence τ -invariant; $\beta\gamma$: $r(z) = 0$, trivially symmetric; Vir_c : $r(z) = (c/2)/z^3 + 2T/z$, both terms symmetric in the two slots ($c/2$ central, T acting on both slots through the symmetric Gerstenhaber bracket). Therefore on the $r_{\mathcal{A}}(z)$ -slot, the sign-isotypic component of $\text{End}(\mathcal{A}^{\otimes 2})$ vanishes, giving (26.6). Off that slot, the sign-isotypic slice contains genuine antisymmetric endomorphisms (e.g., the image of the antisymmetrisation $\wedge^2(\bar{\mathcal{A}}) \hookrightarrow \mathcal{A}^{\otimes 2}$), but such endomorphisms are annihilated by the second bar differential on the Koszul locus (Theorem ??) and do not contribute to the bar cohomology of the chiral product.

(iv). At $n = 3$ the Σ_3 -isotypic decomposition $[(3)] \oplus [(2, 1)] \oplus [(1^3)]$ is standard, with $[(3)]$ one-dimensional (trivial), $[(2, 1)]$ two-dimensional (standard), $[(1^3)]$ one-dimensional (sign). The element $\xi_3 = [\Omega_{12}, \Omega_{23}] \in \mathfrak{t}_3$ is antisymmetric under the transposition $(1 \leftrightarrow 3)$ because $\Omega_{12} \mapsto \Omega_{23}$ and $\Omega_{23} \mapsto \Omega_{12}$ under $(1 \leftrightarrow 3)$, reversing the commutator sign; hence ξ_3 has trivial-component coefficient zero, placing it in $[(2, 1)] \oplus [(1^3)] = K_3^{\text{Re}}$ (Proposition 26.1.9(iii)). The companion $\xi'_3 = [\Omega_{13}, \Omega_{23}]$ is obtained from ξ_3 by the transposition $(1 \leftrightarrow 2)$ acting on strand labels, and the infinitesimal braid relation $[\Omega_{12} + \Omega_{13} + \Omega_{23}, \Omega_{ij}] = 0$ supplies the single relation among $\{\xi_3, \xi'_3, [\Omega_{13}, \Omega_{12}]\}$ that cuts the free Lie algebra on $\{\Omega_{ij}\}_{1 \leq i < j \leq 3}$ down to the Drinfeld–Kohno Lie algebra $\mathfrak{t}_3$.

The operadic Gerstenhaber-type bracket on the convolution dGLA $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ (Definition 26.1.6, inherited from $F\text{Ass}$) couples $\xi_3, \xi'_3 \in \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}(0, 3)$ into an element of $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}(0, 4)$ by the operadic slot-composition formula

$$[\xi_3, \xi'_3]_{\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}} = \sum_{i=1}^3 (\xi_3 \circ_i \xi'_3 - (-1)^{|\xi_3||\xi'_3|} \xi'_3 \circ_i \xi_3),$$

where $\xi_3 \circ_i \xi'_3$ is the operation on $\mathcal{A}^{\otimes 4}$ obtained by applying ξ'_3 to strands $\{i, i+1, i+2\}$ first and then applying ξ_3 by substituting its output into the i -th input of the remaining operation (ribbon-graph composition in $\mathcal{M}_{\text{Ass}}(0, 4)$; the sign convention is the Koszul–Gerstenhaber one from $F\text{Ass}$). The result Ξ_4 lies in $\text{End}(\mathcal{A}^{\otimes 4})$ and its Σ_4 -isotypic type is determined by symmetry: the substitution pattern with strands $\{1, 2, 3\}$ glued at one slot gives a result that is negated by the Klein four-group element $(1 \leftrightarrow 3)(2 \leftrightarrow 4) \in V_4 \subset \Sigma_4$ (direct computation: the transposition $(1 \leftrightarrow 3)$ swaps $\xi_3 \leftrightarrow \xi'_3$ with a sign from the bracket’s antisymmetry, and the transposition $(2 \leftrightarrow 4)$ acts on the inner gluing strand, contributing an additional sign through the operadic relabelling of the innermost Casimir index). The combined sign is -1 , so Ξ_4 lies in the odd V_4 -isotypic subspace, which decomposes into the Σ_4 -components $\text{End}(\mathcal{A}^{\otimes 4})_{[(2,1,1)]} \oplus \text{End}(\mathcal{A}^{\otimes 4})_{[(1^4)]}$ (since the Klein-four odd subspace of the regular Σ_4 -representation is the sum of these two isotypic pieces, Fulton–Harris [?FH91] §2.3). Therefore $\Xi_4 \in K_4^{\text{Re}}$, giving (26.7).

The class dependence: on class **L**, the Casimir Ω_{tr} has non-zero quadratic action (the Lie bracket of $\mathfrak{g}$ acts as the structure tensor on $\mathfrak{g} \otimes \mathfrak{g}$), hence $\xi_3, \xi'_3 \neq 0$ in $\text{End}(V^{\otimes 3})$ for generic representations V . On class **G** ($\mathfrak{g}$ abelian), $[\Omega_{ij}, \Omega_{kl}] = 0$ because Ω_{ij} is a scalar $\mathbf{1} \otimes \cdots \otimes \mathbf{1}$; so $\xi_3 = 0$. On class **C** ($\beta\gamma, \mathfrak{g}$ absent), the residue $r_{\mathcal{A}}(z) = 0$ makes the whole Ω -tower vacuous on the spectral slot but not on the module-theoretic slot: the $\beta\gamma$ -module structure provides a non-zero Casimir action on non-vacuum modules, so ξ_3 can be non-zero on such modules. On class **M** (Virasoro), the Casimir L_0 satisfies $[L_0, L_0] = 0$ but the quadratic shadow $T \otimes T$ produces a non-trivial commutator through the conformal weight-2 OPE $T(z)T(w) \sim (c/2)/(z-w)^4 + \cdots$; the Jacobi identity then yields a non-zero ξ_3^{Vir} at bar-degree 3.

(v). The lower bound follows from dimension counting in $\mathfrak{t}_n$ against the Σ_n -invariant subalgebra $\mathfrak{t}_n^{\Sigma_n}$: the difference $\dim \mathfrak{t}_n - \dim \mathfrak{t}_n^{\Sigma_n}$ is the dimension of the isotypic complement, which injects into K_n^{Re} via the inclusion $\mathfrak{t}_n \hookrightarrow \text{End}(\mathcal{A}^{\otimes n})$ (injective because the Drinfeld–Kohno Lie algebra is realised faithfully on $V^{\otimes n}$ for any faithful representation V of $\mathfrak{g}$, e.g., the adjoint, Drinfeld [?Drinfeld90]). For class **L** and class **C**, the depth-3 truncation of Conjecture 35.13.1(iii) caps $\text{im}(\Psi)$ at the one-dimensional $\langle \sigma_3 \rangle$, matching the $r_{\max} = 3$ (class **L**) and $r_{\max} = 4$ (class **C**) shadow truncation. For class **M** the depth tower is infinite, so the Ihara/Willwacher generators $\{\sigma_{2k+1}\}_{k \geq 1}$ all appear at rational weights tracked by the Deligne–Ihara conjecture (classical for $n \leq 13$; verified computationally through weight 19 by Brown [?Brown12]), giving the $\text{grt}_1^{(n)}$ -dimension as the rational weight- n component; adding the depth-tail correction for the even-weight cusp contributions at $n = 12$ and higher yields the total lower bound. Class **G** has $[\Omega_{ij}, \Omega_{kl}] = 0$ identically, so the Reynolds kernel vanishes.

(vi). On $K_{\bullet}^{\text{Re}}$ define

$$D^{\text{res}} := (\text{id} - \text{Re}) \circ D.$$

The assumption $(D^{\text{res}})^2 = 0$ is exactly the residual square-zero condition stated in the theorem. Without it this paragraph would define only a projected endomorphism, not a cochain complex. Under this condition, the Willwacher map $\Phi: \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \rightarrow \text{GC}_2$ of Conjecture 35.13.1(i) restricts along $\text{Re} \circ \overline{\text{Tot}} = 0$ to a map

$$H^{\bullet}(K_{\bullet}^{\text{Re}}, D^{\text{res}}) \rightarrow H^{\bullet}(\text{GC}_2).$$

By part (ii) of the same conjecture, the ordered associator classes land in the degree-zero summand

$$H^0(\mathrm{GC}_2) \cong \mathfrak{grt}_1$$

through the Willwacher isomorphism. On the Ihara bracket tower $[\xi_3, [\xi_3, \dots, [\xi_3, \xi'_3] \dots]]$ with k inner brackets, the image is the nested wheel cocycle $\mathcal{W}_{2k+1}$ of GC_2 (because each Ihara bracket in $\mathfrak{t}_n$ corresponds to gluing a chord at the innermost vertex of the wheel), which represents $\sigma_{2k+1} \in \mathfrak{grt}_1$ by Willwacher [?Willwacher15].

(vii). The class stratification of $\mathrm{im}(\mathcal{Y})$ follows from part (vi) combined with Conjecture 35.13.1(iii): the wheel cocycles activated by class $\mathbf{X}$ are precisely those at depth $\leq r_{\max}(\mathbf{X})$, i.e., σ_3 for class $\mathbf{L/C}$ and all σ_{2k+1} for class $\mathbf{M}$; class $\mathbf{G}$ vanishes because the Reynolds kernel vanishes.

(viii). The homotopy fibre $\mathrm{hofib}(\mathrm{av}_R)$ in the model category of pro-nilpotent L_∞ -algebras is computed on the full dg descent surface, where av_R is a dg Lie morphism. The short exact sequence

$$0 \rightarrow \ker(\mathrm{av}_R) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}} \rightarrow 0$$

of dg Lie algebras gives a fibre sequence $\mathrm{hofib}(\mathrm{av}_R) \rightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$ in dgLie^∞ where $\mathrm{hofib}(\mathrm{av}_R)$ is modelled at chain level by the mapping cone

$$\mathrm{Cone}(\mathrm{av}_R : \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod} E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}})[-1],$$

which is quasi-isomorphic to $(\ker(\mathrm{av}_R), D)$. Non-splitting (Proposition 26.1.9(iv)) identifies $\pi_0(\mathrm{hofib}(\mathrm{av}_R))$ as the MC-section space modulo gauge, which is the GRT_1 -torsor by Drinfeld [?Drinfeld90]/Etingof–Kazhdan [?EK96]. $\square$

COROLLARY 26.2.9 (*Binary collision-kernel Σ_2 -symmetry on the four displayed windows*;). For each archetype $\mathcal{A}_{\mathbf{X}} \in \{\mathcal{H}_k, \widehat{\mathfrak{g}}_k, \beta\gamma, \mathrm{Vir}_c\}$ with corresponding binary collision kernel $K_{\mathcal{A}_{\mathbf{X}}}^{\mathrm{coll}}(z)$ in the canonical chain model (Table in `landscape_census.tex`), the flip action of $\tau \in \Sigma_2$ fixes its displayed tensor coefficient modulo the unitarity/classical–Yang–Baxter normalisation $K_{\mathcal{A}}^{\mathrm{coll}}(z) + \tau K_{\mathcal{A}}^{\mathrm{coll}}(-z) = 0$ specialised at $z \rightarrow z$ on the symmetric slot. Under $H_{\mathrm{CYBE}}^{\mathrm{rep}}(\mathcal{A}_{\mathbf{X}})$ the represented kernel is a classical r -matrix.

Proof. $\mathcal{H}_k$: $K_{\mathcal{H}}^{\mathrm{coll}}(z) = k\Omega_{\mathcal{H}}/z$ with $\Omega_{\mathcal{H}} = J \otimes J$, hence flip-invariant in the rank-one tensor window. $\widehat{\mathfrak{g}}_k$: $K_{\mathrm{coll}, KM}^{\mathrm{coll}}(z) = k\Omega_{\mathrm{tr}}/z$ with $\Omega_{\mathrm{tr}} \in \mathrm{Sym}^2(\mathfrak{g})$ the symmetric trace-form Casimir, flip-invariant by definition of Sym^2 . $\beta\gamma$: the beta–gamma modular Koszul triple has collision entry $K_{\beta\gamma}^{\mathrm{coll}}(z) = 0$ (class $\mathbf{C}$ vanishing of the binary residue, from d log-absorption of the simple-pole $\beta\gamma$ OPE), so the tensor coefficient is flip-invariant. Vir_c : $K^{\mathrm{coll}}(z) = (c/2)/z^3 + 2T/z$; the leading central term $c/2$ is scalar, flip-invariant; the subleading $2T/z$ -term has T acting on both slots symmetrically under $\mathrm{Sym}^2(\mathrm{Vir})$ by the conformal field identity $T(z)T(w) = T(w)T(z)$ modulo poles, which are flip-symmetric in z, w . Hence the displayed tensor coefficients are τ -invariant on the binary slot, completing the four-class check. $\square$

Remark 26.2.10 (*Cross-volume bridge: kernel structure and Vol II $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ heptagon*). Theorem 26.2.8 is the Vol I *completed Reynolds* statement of the ordered kernel structure underlying Vol II’s $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ -heptagon (Vol II, Chapter on `sc_chtop_heptagon.tex`). The seven heptagon corners of that structure correspond to the seven faces $F_1, \dots, F_7$ of Theorem ??, and the completed Reynolds complement K_n^{Re} at bar-degree $n \geq 3$ carries the ordered infinitesimal gauge data connecting the seven corners under the

grt₁-action: the Ihara-bracket tower $[\xi_3, [\xi_3, \dots, [\xi_3, \xi'_3]]]$ of part (vi) is the Vol I graded-Lie incarnation of the Φ_{17} -cocycle record, with $\Phi_{13} \leftrightarrow \xi_3$ at bar-degree 3 and $\Phi_{17} \leftrightarrow [\xi_3, \xi'_3]$ at bar-degree 4 (class **L** entries from the affine Kac–Moody face). The cross-volume consistency is the identity

$$\mathrm{Lie}(\mathrm{Stab}_{\mathrm{GRT}^{\mathrm{fin}}}(F_1)) = \ker(\Psi|_{\mathcal{A}}) \subseteq K_{\bullet}^{\mathrm{Re}},$$

stating that the Lie algebra of the $\mathrm{GRT}^{\mathrm{fin}}$ -stabiliser of the bar-hub face F_1 is the kernel of the cohomological map Ψ of part (vi) (i.e., the elements of $K_{\bullet}^{\mathrm{Re}}$ that do not survive to non-trivial **grt₁**-cocycles).

Remark 26.2.11 (Ordered chiral homology and the bar complex). The algebraic bar complex $\overline{B}^{\mathrm{ord}}(\mathcal{A})$ computes the ordered chiral homology on the formal disk D : the degree- n component $\overline{B}_n^{\mathrm{ord}}(\mathcal{A})$ is the de Rham cohomology of $\mathcal{F}_n^{\mathrm{ord}}(\mathcal{A})$ restricted to the formal neighbourhood of the n -fold diagonal in D^n . On a global curve X of genus $g \geq 1$, the ordered chiral homology acquires additional structure from the Hodge bundle: the fiberwise differential satisfies $d_{\mathrm{fib}}^2 = r(z) \cdot \omega_g$ (matrix-valued in $\mathrm{End}(V^{\otimes 2}) \otimes H^2(\overline{M}_g)$ at degree 2), which upon Σ_2 -averaging reduces to the scalar curvature $d_{\mathrm{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ of the symmetric theory.

Example 26.2.12 (Bounded and chart chiral Hochschild of the Heisenberg). The Heisenberg $\mathcal{H}_k$ is the rank-one even superboson. Bakalov–De Sole–Kac compute its bounded chiral cohomology as

$$\dim H_{\mathrm{ch},b}^n(\mathcal{H}_k, \mathcal{H}_k) = (2, 1, 0, \dots),$$

and hence its bounded Poincaré polynomial is

$$P_{\mathcal{H}_k}(t) = 2 + t.$$

This is [BDSK21, Theorem 7.4]. A bounded-to-chart quasi-isomorphism $\chi_{\mathcal{H}_k}^{\mathrm{bd}}$ transports the same dimensions to $C_{\mathrm{ch}}^{\bullet}(\mathcal{H}_k, \mathcal{H}_k)$ and realizes the family datum $H_H(\mathcal{H}_k; \{0, 1\})$. An ordered-to-symmetric quasi-isomorphism supplies the corresponding ordered calculation. The curvature scalar $\kappa = k$ and the collision kernel $r_{\mathcal{H}}(z) = k\Omega_{\mathcal{H}}/z$ belong to the modular and ordered projections, respectively.

Example 26.2.13 (Ordered chiral homology of $Y_h(\mathfrak{sl}_2)$ on an elliptic curve). The passage from genus 0 to genus 1 replaces $\mathbb{C}^{\times}$ by an elliptic curve $E_{\tau} = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ and introduces two decisive changes: the bar propagator acquires the elliptic function $\wp_1(z, \tau) = \theta'_1(z|\tau)/\theta_1(z|\tau)$ in place of $1/z$, and the KZ connection is replaced by the KZB connection carrying a local $d\tau$ component whose descended curvature has Hodge shadow $\omega_1 = c_1(\lambda)$ on $\overline{M}_{1,n}$.

Bar propagator. On E_{τ} :

$$\eta_{ij}^{(1)} = d \log E(z_i, z_j) = \wp_1(z_i - z_j, \tau) d(z_i - z_j),$$

weight 1.

Definition 26.2.14 (Elliptic KZB connection;). At degree n , on the ordered configuration space of $E_{\tau} = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$, the Bernard–Felder elliptic KZB connection in the KZ normalisation is

$$\nabla_{\mathrm{KZB}} = d - \hbar \sum_{i < j} \Omega_{ij} \wp_1(z_{ij}, \tau) dz_{ij} - \frac{\hbar}{2\pi i} \sum_i D_i d\tau, \quad (26.8)$$

where $\hbar = 1/(k + h^{\vee})$, hence $\hbar = 1/(k + 2)$ for $\mathfrak{sl}_2$, and D_i is the Bernard modular Hamiltonian whose leading collision term is $\sum_{j \neq i} \wp(z_{ij}, \tau) \Omega_{ij}$. The $d\tau$ term is absent at genus 0; its descended Hodge shadow is the genus-one scalar curvature $\kappa(\mathcal{A}) \cdot \omega_1$.

PROPOSITION 26.2.15 (*Elliptic KZB flatness and scope*;). For a vertex-algebraic current system whose OPE coefficients satisfy the Jacobi identity and whose invariant tensor Ω_{ij} is the quadratic Casimir, the connection (26.8) is flat on the elliptic configuration space in the Bernard–Felder/CEE normalisation (Bernard [Bernard88, §§3–4]; Calaque–Enriquez–Etingof [CEE09, Prop. 6.6]). The proof uses exactly two inputs: the OPE Jacobi identity for the algebraic residues and the theta heat equation for the $d\tau$ component. It is a flatness statement for the KZB local system; Yangian or RTT duality enters only after an additional representation-theoretic comparison map is supplied.

Degree 0: the center. At degree 0 there is no configuration space: the ordered chiral homology reduces to the center $Z(Y_h(\mathfrak{sl}_2)) = \mathbb{C}[\text{qdet } T(u)]$, the polynomial algebra on the quantum determinant (Molev). The averaging kernel is trivial: $\ker(\text{av}_0) = 0$.

Degree 1: Künneth. At degree 1 the KZB connection is trivial (no pairs $i < j$). The Künneth theorem gives $H^*(C_1^{\text{ord}}) = H^*(E_\tau) \otimes H^*(s^{-1}\bar{Y}_h, d_{\text{bar}})$. Since the Yangian is Koszul dual to the affine algebra $V_k(\mathfrak{sl}_2)$ (class L , Koszul), the bar cohomology at degree 1 is $s^{-1}\mathfrak{sl}_2$ in degree 1. With $\dim H^*(E_\tau) = 4$:

$$H^*(C_1^{\text{ord}}(E_\tau, Y_h(\mathfrak{sl}_2))) \cong (s^{-1}\mathfrak{sl}_2)^{\oplus 4}, \quad \dim = 12.$$

At genus 0, $H^*(D^\times)$ contributes only in degree 0, giving dimension 3; the passage to genus 1 multiplies by 4.

Degree 2: KZB flat sections and the represented Belavin kernel. The degree-2 collision kernel has the Belavin elliptic representation

$$r^{\text{ell}}(z, \tau) = k \left(\frac{\wp_1(z, \tau)}{2} H \otimes H + \phi_+(z, \tau) E \otimes F + \phi_-(z, \tau) F \otimes E \right),$$

where $\phi_\pm$ are Belavin’s ϕ -functions. The KZB flatness argument supplies $H_{\text{CYBE}}^{\text{rep}}$, so this represented kernel is a classical elliptic r -matrix. At $k = 0$, $r^{\text{ell}} = 0$. The KZB monodromy at degree 2 has three generators:

- (i) *Puncture*: $M_\gamma = \exp(2\pi i \hbar \Omega)$, the R -matrix.
- (ii) *A-cycle*: $\Phi(w + 1) = R \cdot \Phi(w)$.
- (iii) *B-cycle*: $\Phi(w + \tau) = q^\Omega \cdot \Phi(w)$ where $q = e^{2\pi i \hbar}$.

For generic $\hbar$, the monodromy has no invariant vectors ($H^0 = 0$), and the Euler characteristic of the rank-4 KZB local system on $E_\tau \setminus \{0\}$ gives $\dim H^1 = 4$. The homotopy coinvariant is the operator $q_2(K_{k, \mathfrak{sl}_2}^{\text{coll}})$, and the trace-form normalization gives

$$\tau_{k, \mathfrak{sl}_2} q_2(K_{k, \mathfrak{sl}_2}^{\text{coll}}) = \frac{3k}{4}, \quad \kappa(V_k(\mathfrak{sl}_2)) = \frac{3k}{4} + \frac{3}{2} = \frac{3(k+2)}{4}.$$

Genus-1 enhancement of the averaging kernel. The kernel $\ker(\text{av}_2)$ at genus 1 is strictly larger than at genus 0: the B -cycle monodromy q^Ω introduces new antisymmetric classes in the $\wedge^2 V$ channel (eigenvalue $e^{3\pi i/(k+2)}$ of M_B) that have no genus-0 analogue. This is the structural content of the genus-1 E_1 enhancement: the ordered theory at genus 1 sees the quantum group parameter $q = e^{2\pi i \hbar}$ through the B -cycle, while the symmetric shadow retains only the scalar traces (WZW conformal blocks).

Degeneration. In the limit $\tau \rightarrow i\infty$, $\wp_1(z, \tau) \rightarrow 1/z$, the B -cycle collapses, and:

$$\lim_{\tau \rightarrow i\infty} \int_{E_\tau}^{\text{ord}} Y_h(\mathfrak{sl}_2) = \int_{D^\times}^{\text{ord}} Y_h(\mathfrak{sl}_2),$$

recovering the genus-0 ordered chiral homology. The Belavin r -matrix degenerates to the rational $r(z) = k \Omega_{\mathfrak{g}}/z$, and the KZB connection degenerates to the KZ connection.

26.2.1 Formality: when ordered equals symmetric

Four formality conditions control the relationship between ordered chiral homology and its symmetric shadow. Condition (a) is unconditional; conditions (b)–(d) are logically ordered implications that, on the standard landscape, are all equivalent to class **G**.

Remark 26.2.16 (Topological Hochschild homology and the stratified comparison). The disk D is a stratified space with closed stratum $\partial D = S^1$ and open stratum $D^\times$. Two chain complexes compute invariants of a chiral algebra $\mathcal{A}$ from these strata.

The *topological Hochschild homology* is the factorisation homology of a locally constant interval model extracted from $\mathcal{A}$ after a chosen real-ray/topological comparison. If A_∂ denotes that boundary E_1 -algebra and $\mathcal{F}_{A_\partial}$ its locally constant factorization algebra on the circle, then

$$\mathrm{HH}_*^{\mathrm{top}}(\mathcal{A}; A_\partial) := \int_{S^1} \mathcal{F}_{A_\partial} \simeq \mathrm{HH}_{\bullet, \mathrm{alg}}(A_\partial).$$

This is not the $\mathcal{D}$ -module restriction of $\mathcal{A}$ to ∂D . It is computed by the cyclic bar complex $B_n^{\mathrm{cyc}}(A_\partial) = A_\partial^{\otimes n}/\text{cyclic}$ with the Hochschild differential; it uses the E_1 product (and higher A_∞ operations only after a chosen chain model/transfer) but no meromorphic data, no Arnold relations, and no spectral parameter.

The *ordered chiral homology of $D^\times$* is the factorisation homology of the ordered factorisation $\mathcal{D}$ -module $\mathcal{F}^{\mathrm{ord}}(\mathcal{A})$ over $\mathrm{Ran}^{\mathrm{ord}}(D^\times)$ (Definition 26.2.3); it depends on the full OPE, the Arnold forms, and the FM compactification.

The comparison map $\int_{D^\times}^{\mathrm{ord}} \mathcal{A} \rightarrow \mathrm{HH}_*^{\mathrm{top}}(\mathcal{A}; A_\partial)$ is induced by the boundary retraction $D^\times \rightarrow S^1$ together with the chosen interval-model comparison, which forgets the complex structure. Operad formality (Theorem 26.2.18 below) makes this a quasi-isomorphism for E_∞ -chiral algebras; Theorem 26.2.19 shows it fails for genuinely E_1 -chiral algebras, where the ordered complex carries holomorphic data (the r -matrix, the spectral parameter, the Arnold relations) invisible to the topological theory on S^1 .

Definition 26.2.17 (Formality hierarchy). (a) *Operad formality.* The chain operad $C_*(\overline{\mathrm{FM}}_n(\mathbb{C}))$ is formal: quasi-isomorphic to its cohomology (the Arnold algebra) via a quasi-isomorphism depending on a Drinfeld associator $\Phi \in \exp(\hat{\mathfrak{t}}_3)$ (Kontsevich, Tamarkin). Unconditional: depends only on the operad, not on any algebra.

(b) *Algebra formality.* The transferred A_∞ -structure on $H^*(\mathcal{A})$ has $m_k^{\mathrm{tr}} = 0$ for $k \geq 3$. Holds for class **G** (Heisenberg); fails for classes **L**, **C**, **M**.

(c) *Convolution algebra formality.* The L_∞ brackets $\ell_k = 0$ for $k \geq 3$ in $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}}$. Equivalent to class **G** (Proposition 14.1.70).

(d) *SC-formality.* The Swiss-cheese type operations $m_k^{\mathrm{SC}} = 0$ for $k \geq 3$. Equivalent to class **G**.

Level (a) guarantees that ordered and symmetric give the same answer *as chain complexes* for E_∞ -chiral algebras; levels (b)–(d) control whether the answer is *simple* (no higher operations).

THEOREM 26.2.18 (Formality bridge). Let $\mathcal{A}$ be an E_∞ -chiral algebra. The Kontsevich–Tamarkin operad formality quasi-isomorphism induces a quasi-isomorphism of ordered chiral chains on the punctured disk to topological Hochschild chains:

$$C_n^{\mathrm{ord}}(D^\times, \mathcal{A}) \xrightarrow[\Phi]{\sim} B_n^{\mathrm{cyc}}(\mathcal{A}). \quad (26.9)$$

The transferred $\mathcal{A}_\infty$ -structure on $H^*(\mathcal{A})$ may carry non-trivial higher operations m_k^{tr} for $k \geq 3$: what operad formality guarantees is that the ordered and symmetric complexes compute the same cohomology, not that the cohomology is formal.

Proof. The Kontsevich–Tamarkin quasi-isomorphism $\varphi_\Phi: C_*(\overline{\text{FM}}_n(\mathbb{C})) \xrightarrow{\sim} H^*(\overline{\text{FM}}_n(\mathbb{C}))$ is Σ_n -equivariant and respects the operad composition. For E_∞ -chiral $\mathcal{A}$, the ordered factorisation $\mathcal{D}$ -module $\mathcal{F}_n^{\text{ord}}(\mathcal{A})$ is Σ_n -equivariant (the OPE is symmetric by hypothesis), so the tensor product $\varphi_\Phi \otimes \text{id}$ transfers the ordered chiral complex (de Rham model on FM compactifications) to the cyclic bar complex (Arnold model). The Σ_n -equivariance of both factors ensures the quasi-isomorphism descends to the coinvariant quotient. $\square$

THEOREM 26.2.19 (*Formality failure for genuinely E_1 -chiral algebras*). Let $\mathcal{A}$ be genuinely E_1 -chiral (tier (c): R -matrix not derived from any E_∞ -chiral OPE). The chain-level formality bridge (26.9) does not exist: the $\mathcal{D}$ -module $\mathcal{F}_n^{\text{ord}}$ is not Σ_n -equivariant ($S(z) \neq \tau$ breaks the symmetry), and the ordered chiral complex is strictly richer than the cyclic bar complex. By Arnold’s theorem $\dim H^*(C_n(\mathbb{C})) = n!$, the ordered complex at degree n has

$$\dim C_n^{\text{ord}} = (\dim \mathcal{A})^n \cdot n!, \quad \dim B_n^{\text{cyc}} = (\dim \mathcal{A})^n.$$

The ratio $n!$ measures the holomorphic data in the ordered theory that the symmetric quotient discards.

Proof. Arnold’s Poincaré polynomial for $H^*(C_n(\mathbb{C}))$ is $P_n(t) = \prod_{j=0}^{n-1} (1 + jt)$; setting $t = 1$ gives $P_n(1) = n!$. The ordered chiral complex is $\Omega_{\log}^*(\overline{\text{FM}}_n^{\text{ord}}) \otimes (s^{-1}\bar{\mathcal{A}})^{\otimes n}$; at the cohomological level the $\Omega_{\log}^*$ factor contributes the Arnold algebra of total dimension $n!$. The Σ_n -non-equivariance of the bar differential (from $S(z) \neq \tau$) obstructs the descent to the symmetric quotient that the formality bridge requires. $\square$

Remark 26.2.20 (*Comparison with Ben-Zvi–Brochier–Jordan and Latyntsev*). Two existing constructions integrate braided structures over surfaces. Ben-Zvi, Brochier, and Jordan integrate braided monoidal categories over surfaces: for a ribbon category $\mathcal{C}$ and a surface Σ , $\int_\Sigma \mathcal{C}$ is a categorical invariant. Ordered chiral homology integrates chiral algebras over curves at the chain level. For affine Kac–Moody at level k , the expected comparison is

$$\text{HH}_*\left(\int_\Sigma \text{Rep}_q(\mathfrak{g})\right) \simeq \int_X^{\text{ord}} V_k(\mathfrak{g}),$$

where $q = e^{2\pi i/(k+h^\vee)}$: the categorical Hochschild homology of the categorical invariant recovers the ordered chiral homology of the algebraic one. For class **M** (Virasoro at generic c), the BBJ framework requires a finite ribbon category, which is unavailable; ordered chiral homology applies without restriction. Latyntsev constructs chiral homology for factorisation coalgebras on curves, providing an algebraic counterpart to the analytic construction here; the chain-level comparison for irregular singularities (class **M**) remains open.

26.3 THE E_1 SHADOW OBSTRUCTION TOWER

The E_∞ shadow obstruction tower extracts scalar invariants $\kappa, \mathfrak{C}, \mathfrak{Q}, \dots$ from the MC element $\Theta_{\mathcal{A}}$ through normalized residue and trace functionals. The homotopy Σ_r -coinvariant is first an operator class. Before this coinvariant projection, the genus-0 degree- r component of $\Theta_{\mathcal{A}}^{E_1}$ is a meromorphic function of $r - 1$ collision coordinates valued in $\text{End}(V^{\otimes r})$: the E_1 shadow at degree r .

Definition 26.3.1 (E_1 shadow at degree r). The E_1 shadow at degree r of a cyclic E_1 -chiral algebra $\mathcal{A}$ is the component

$$r_r(z_1, \dots, z_{r-1}) := (\Theta_{\mathcal{A}}^{E_1})_{0,r} \in \text{End}(V^{\otimes r}) \otimes \Omega^{r-2}(\overline{\text{FM}}_r^{\text{ord}}(\mathbb{C})),$$

where $(\Theta_{\mathcal{A}}^{E_1})_{0,r}$ is the genus-0, degree- r component of the E_1 MC element (Theorem 26.1.7). The variables $z_1, \dots, z_{r-1}$ are the consecutive difference coordinates $z_i = w_{i+1} - w_i$ on the ordered configuration space; the form degree $r - 2 = \dim K_r$ reflects the quotient by translation and dilation.

THEOREM 26.3.2 (E_1 MC equation at finite degree and represented comparison equations;). The Maurer–Cartan equation for $\Theta_{\mathcal{A}}^{E_1}$, projected to genus 0 and degree r , gives the following identities:

- (i) *Degree 2* ($r = 2$). The binary collision kernel satisfies the two-face operadic boundary relation obtained from the MC equation. Under $H_{\text{CYBE}}^{\text{rep}}(\mathcal{A})$ its represented insertions satisfy the classical Yang–Baxter equation:

$$[r_{12}(z_1), r_{13}(z_1 + z_2)] + [r_{12}(z_1), r_{23}(z_2)] + [r_{13}(z_1 + z_2), r_{23}(z_2)] = 0. \quad (26.10)$$

The representation package supplies the insertion maps entering this three-term tensor equation.

- (ii) *Degree 3* ($r = 3$). The ternary MC component satisfies its five-face operadic relation. Under the KZ associator comparison this becomes the pentagon/quasi-associativity relation for $r_3(z_1, z_2) \in \text{End}(V^{\otimes 3})$:

$$d_{\text{bar}} r_3 + [r_{12}, r_3]_{1,23} + [r_{23}, r_3]_{12,3} = 0, \quad (26.11)$$

where the notation $[-, -]_{I,J}$ denotes the Lie bracket in which tensor factors in I are on the left and those in J on the right. The boundary faces of the associahedron K_4 give the five pentagon terms.

- (iii) *Degree 4* ($r = 4$). The obstruction to extending the triple (r, r_3) to degree 4 is $o_5 \in H^2(F^5 \mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1} / F^6)$, and

$$d_{\text{bar}} r_4 + \{r_3 \circ_2 r_3 \text{ boundary terms}\} + [r, r_4] = 0.$$

Under the quartic represented comparison package this is the quartic R -matrix identity.

Proof. The MC equation $D\Theta^{E_1} + \frac{1}{2}[\Theta^{E_1}, \Theta^{E_1}] = 0$ on $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$ (Definition 26.1.6) projected to genus 0 and degree r uses the face structure of the Stasheff associahedra K_{r+1} : ∂K_3 has 2 faces, ∂K_4 has 5 faces, and ∂K_5 has 9 faces.

Part (i) is the binary operadic relation from the two endpoints of K_3 . The package $H_{\text{CYBE}}^{\text{rep}}$ sends its operadic compositions to the three insertions in equation (26.10). Part (ii): the genus-0, degree-3 MC component on $\overline{\text{FM}}_4^{\text{ord}}(\mathbb{C})$ identifies with the boundary analysis of K_4 (the pentagon), whose five edges give the five terms of the quasi-associativity relation. Part (iii) follows by the same mechanism at degree 4, using the nine codimension-1 faces of K_5 . $\square$

THEOREM 26.3.3 (*Coinvariant operators and normalized scalar shadows;*). The homotopy Σ_r -coinvariant of the ordered degree- r component is the operator class $q_r((\Theta_{\mathcal{A}}^{E_1})_{0,r})$. In degrees 2, 3, 4:

$$\begin{aligned} \text{av}_{r=2}(K_{\mathcal{A}}^{\text{coll}}(z)) &= q_2(K_{\mathcal{A}}^{\text{coll}}) \in \text{End}_{\mathcal{A}}(2)_{h\Sigma_2}, \\ \text{av}_{r=3}((\Theta_{\mathcal{A}}^{E_1})_{0,3}) &= q_3((\Theta_{\mathcal{A}}^{E_1})_{0,3}) \in \text{End}_{\mathcal{A}}(3)_{h\Sigma_3}, \\ \text{av}_{r=4}((\Theta_{\mathcal{A}}^{E_1})_{0,4}) &= q_4((\Theta_{\mathcal{A}}^{E_1})_{0,4}) \in \text{End}_{\mathcal{A}}(4)_{h\Sigma_4}. \end{aligned}$$

The normalized functionals of Definition 26.0.3 give

$$\kappa_{\text{dp}}(\mathcal{A}) = \tau_{\mathcal{A}} q_2(K_{\mathcal{A}}^{\text{coll}}), \quad S_r(\mathcal{A}) = \tau_{\mathcal{A},r}^{\text{res}} q_r((\Theta_{\mathcal{A}}^{E_1})_{0,r}).$$

For scalar and abelian families $\kappa = \kappa_{\text{dp}}$; for affine Kac–Moody the Sugawara channel adds $\dim(\mathfrak{g})/2$.

Proof. The averaging map $\text{av}(\phi)(g, n) = (1/n!) \sum_{\sigma \in \Sigma_n} \sigma \cdot \phi(g, n)$ sends $\text{Hom}(\mathcal{M}_{\text{Ass}}(g, n), \text{End}_{\mathcal{A}}(n))$ to $\text{Hom}_{\Sigma_n}(\mathcal{M}_{\text{Com}}(g, n), \text{End}_{\mathcal{A}}(n))$. Since the MC element $\Theta_{\mathcal{A}}^{E_1}$ maps to $\Theta_{\mathcal{A}}$ under averaging (eq. (26.2)), the component projections also correspond: the degree- r component of $\text{av}(\Theta_{\mathcal{A}}^{E_1})$ is $q_r((\Theta_{\mathcal{A}}^{E_1})_{0,r})$ by construction. Composition with the chosen normalized functional $\tau_{\mathcal{A},r}^{\text{res}}$ gives the scalar coordinate. The affine shift is the separate Sugawara self-contraction recorded in Appendix ??.

Remark 26.3.4 (Finite-degree verification of the FG shadow theorem). Theorem 26.3.3 supplies the degree-2, 3, 4 verification of Theorem 27.30.1: at finite degree, the Francis–Gaitsgory shadow is the homotopy Σ_n -coinvariant operator of the associative theory. Its scalar coordinates use the functionals $\tau_{\mathcal{A},n}^{\text{res}}$.

Remark 26.3.5 (Ribbon structure count). The number of ribbon structures on a connected stable graph Γ is

$$\#\text{Rib}(\Gamma) = \prod_{v \in V(\Gamma)} (\text{val}(v) - 1)!,$$

where the product runs over all vertices and each factor counts the cyclic orderings of the half-edges incident to v . The E_1/E_{∞} multiplicity ratio for graph Γ is $\#\text{Rib}(\Gamma)/|\text{Aut}(\Gamma)|$. By the orbit-stabiliser theorem applied to the $\text{Aut}(\Gamma)$ -action on the set of ribbon structures:

$$\sum_{\substack{\tilde{\Gamma} \text{ ribbon} \\ \tilde{\Gamma} \mapsto \Gamma}} \frac{1}{|\text{Aut}_{\text{rib}}(\tilde{\Gamma})|} = \frac{\#\text{Rib}(\Gamma)}{|\text{Aut}(\Gamma)|}.$$

Computational verification: `theorem_higher_dim_modular_operad_engine.py` (55 tests); $\chi^{\text{orb}}(\overline{\mathcal{M}}_2) = -1/240$ verified by three independent paths.

Remark 26.3.6 (FCom = FAss at the scalar level). At the scalar level, the Feynman transforms of the commutative and associative modular operads produce identical amplitudes: the modular characteristic $\kappa(\mathcal{A})$, all shadow obstruction tower coefficients $S_r(\mathcal{A})$, and the scalar genus- g free energies $F_g^{\text{sc}}(\mathcal{A})$ are E_n -independent. Concretely, for every connected stable graph Γ :

$$\sum_{\substack{\tilde{\Gamma} \text{ ribbon} \\ \tilde{\Gamma} \mapsto \Gamma}} \frac{\phi^{\text{sc}}(\tilde{\Gamma})}{|\text{Aut}_{\text{rib}}(\tilde{\Gamma})|} = \frac{\phi^{\text{sc}}(\Gamma)}{|\text{Aut}(\Gamma)|} \cdot \prod_{v \in V(\Gamma)} (\text{val}(v) - 1)!,$$

where $\phi^{\text{sc}}(\Gamma) = \kappa^{|\mathcal{E}(\Gamma)|}$ is the scalar insertion and the ribbon multiplicity $\prod (\text{val}(v) - 1)!$ from Remark 26.3.5 cancels exactly against the Σ_n -coinvariance normalization in the passage from the $F\text{Ass}$ graph sum to the $F\text{Com}$ graph sum.

This is the quantitative content of E_1 primacy at the scalar level: every scalar modular invariant of the bar complex is insensitive to the choice of modular operad ($F\text{Com}$ vs $F\text{Ass}$ vs FE_n for any $n \geq 1$). The modular shadow obstruction tower $(\kappa, \mathfrak{C}, \mathfrak{Q}, \dots)$ sees only Σ_n -coinvariant data by construction (Theorem 26.3.3). The E_1 side carries strictly more information: the R -matrix $r(z)$, the full S_n -Frobenius character decomposition of each bar degree, and the KZ associator are all killed by the averaging map av . Computational verification: `theorem_higher_dim_modular_operad_engine.py` (55 tests) verifies $F\text{Com} = F\text{Ass}$ for all standard families at genus 1 and 2 by direct ribbon-weighted graph summation.

Remark 26.3.7 (Eulerian weight of κ : parity-dependent). At degree 2, the first Eulerian idempotent $e_1 = \frac{1}{2}(\text{id} - \sigma_{12})$ projects onto the sign representation of Σ_2 . The desuspended generator $s^{-1}\phi$ has degree $h - 1$ where h is the conformal weight.

- *Even desuspended degree* (h odd: Heisenberg $h=1$, $\beta\gamma$ $h=1$): Σ_2 acts trivially on $[s^{-1}\phi|s^{-1}\phi]$. The antisymmetriser kills it; κ lives *entirely in Eulerian weight 2* (symmetric), invisible to Harrison.
- *Odd desuspended degree* (h even: Virasoro $h=2$, W_3 generator T at $h=2$): Σ_2 acts by the sign; e_1 preserves it. Here κ lives *entirely in Eulerian weight 1* (Harrison).

For multi-generator algebras the decomposition is mixed: $\kappa(\mathcal{W}_3) = \frac{5c}{6} = c/2 + c/3$ splits as $\kappa_{TT} = c/2$ at weight 1 (odd desuspended T) and $\kappa_{WW} = c/3$ at weight 2 (even desuspended W), with cross-channel $\kappa_{TW} = 0$ by weight parity on $\overline{\mathcal{M}}_{1,1}$. Computational verification: `eulerian_weight_mc_engine.py` (67 tests).

Remark 26.3.8 (The MC equation is not Eulerian-weight-graded). Neither the Lie bracket on $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ nor the differential D preserves Eulerian weight. The Lie bracket is determined by the weight-1 (Harrison/Lie^c) restriction via the PBW universal property, but individual MC elements (including κ for even-degree generators) live in higher weights. At genus ≥ 1 , the BV operator Δ_{cyc} further mixes weights. Consequence: the shadow obstruction tower $(\kappa, \mathfrak{C}, \mathfrak{Q}, \dots)$ cannot be recovered from the Harrison part alone. Instead, the *derivative tower* $\{\partial^k \phi\}_{k \geq 0}$, with desuspended degree $h+k-1$ alternating in parity, supplies all Eulerian weight classes at every degree, explaining how the Virasoro algebra (single generator, odd desuspended degree) achieves infinite shadow depth.

Example 26.3.9 (The E_1 shadow archetypes).

	$r^{\text{coll}}(z)$	$r_3(z_1, z_2)$	$r_4(z_1, z_2, z_3)$
Heisenberg $\mathcal{H}_k$	k/z	0	0
Affine $\hat{\mathfrak{g}}_k$	$k\Omega_{\text{tr}}/z$	KZ associator $\Phi_{\text{KZ}}(\hat{\mathfrak{g}}_k)$	0
$\beta\gamma$	$\Theta_{\beta\gamma}$ (nilpotent, no pole)	0	$\mathfrak{Q}^{\text{ct}} \neq 0$
Virasoro	$(c/2)/z^3 + 2T/z$	non-trivial	non-trivial
$Y_h(\mathfrak{g})$	$r_{\text{YB}}(z)$	Drinfeld associator $\Phi_h(\mathfrak{g})$	non-trivial

Remark 26.3.10 (Three binary kernels: Laplace, collision, and pre-dualisation;). Three meromorphic kernels occur in the binary calculation. Their symbols record their distinct pole orders, target spaces, and normalizations.

- (a) *Laplace kernel* $K_{\mathcal{A}}^{\text{L}}(z) = \int_0^\infty e^{-\lambda z} \{\cdot_\lambda \cdot\} d\lambda \in \mathcal{A} \widehat{\otimes} \mathcal{A}[[z^{-1}]]$: the full OPE generating function, encoding every singular term of the operator product expansion as a Laurent series in z^{-1} . Pole orders match the OPE directly.

$$\begin{aligned}
 \text{Heisenberg } \mathcal{H}_k: & \quad K^{\text{L}}(z) = k/z^2 \\
 \text{Affine } \hat{\mathfrak{g}}_k: & \quad K^{\text{L}}(z) = k \kappa^{ab}/z^2 + f^{ab}{}_c J^c/z \\
 \text{Virasoro:} & \quad K^{\text{L}}(z) = (c/2)/z^4 + 2T/z^2 + \partial T/z
 \end{aligned}$$

- (b) *Collision residue* $K_{\mathcal{A}}^{\text{coll}}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}^{E_1}) \in \text{End}_{\mathcal{A}}(z) \otimes \mathcal{O}(*\Delta)$: the binary collision kernel, extracted by residue along the collision divisor using the $d \log(z_1 - z_2)$ measure. Because $d \log$ absorbs one power of $(z_1 - z_2)$, every pole order drops by one relative to the Laplace kernel. For bosonic algebras, only odd-order poles survive (even-order OPE poles descend to odd-order residues). A

chosen quadratic presentation supplies $q_{\mathcal{A}}: \mathcal{A}^i \rightarrow \overline{B}_X(\mathcal{A})$, and the Koszul-locus comparison is $H^\bullet(q_{\mathcal{A}})$. Verdier duality supplies the separate passage to $\mathcal{A}^! := D_{\text{Ran}}(\mathcal{A}^i)$ under its finite-type hypotheses.

$$\begin{array}{ll} \text{Heisenberg } \mathcal{H}_k: & K_{\mathcal{H}}^{\text{coll}}(z) = k\Omega_{\mathcal{H}}/z \quad (\text{simple pole; OPE had double}) \\ \text{Affine } \hat{\mathfrak{g}}_k: & K^{\text{coll}}(z) = k\Omega_{\mathfrak{g}}/z \quad (\text{level-prefixed; vanishes at } k = 0) \\ \text{Virasoro:} & K^{\text{coll}}(z) = (c/2)/z^3 + 2T/z \quad (\text{cubic + simple; no even poles}) \end{array}$$

This is the master object from which the others descend: the genus-0, degree-2 shadow $K_{\mathcal{A}}^{\text{coll}}(z) = \text{Res}_{0,2}^{\text{coll}}(\Theta_{\mathcal{A}}^{E_1})(z)$. Under $H_{\text{CYBE}}^{\text{rep}}(\mathcal{A})$ its represented image is a classical r -matrix.

- (c) *Pre-dualisation form* $K_{\mathcal{A}}^{\text{pre}}(z) \in \mathcal{A} \otimes \mathcal{A}$: the collision residue computed in $\mathcal{A} \otimes \mathcal{A}$, before applying the bar pairing to pass one or both factors to $\mathcal{A}^!$. Pole orders are identical to (b); the target space and normalisation differ (the Koszul pairing absorbs a scalar factor).

$$\begin{array}{ll} \text{Heisenberg } \mathcal{H}_k: & K^{\text{pre}}(z) = k/z \\ \text{Affine } \hat{\mathfrak{g}}_k: & K^{\text{pre}}(z) = k\Omega_{\mathfrak{g}}/z \\ \text{Virasoro:} & K^{\text{pre}}(z) = (c/2)/z^3 + 2T/z \end{array}$$

Relations. The three are connected by two operations.

- $d \log$ extraction: $K^{\text{L}}(z) \xrightarrow{\text{Res}_{d \log}} K^{\text{pre}}(z)$. Every pole order drops by one. Mnemonic: $z^{-n} dz = z^{-(n-1)} d \log z$, so the residue along $d \log(z_1 - z_2)$ of a pole of order n in the OPE is a pole of order $n - 1$ in the collision residue.
- Koszul dualisation: $K^{\text{pre}}(z) \xrightarrow{\text{id} \otimes \kappa} K^{\text{coll}}(z)$. Same pole structure, different target space ($\mathcal{A} \otimes \mathcal{A} \rightarrow \mathcal{A}^i \otimes \mathcal{A}^i$); Verdier duality sends $\mathcal{A}^i$ to $\mathcal{A}^!$ only after the Ran finite-type hypotheses hold.

The archetype table (Example 26.3.9) lists the collision kernel $K^{\text{coll}}(z)$. The E_1 scalar kernel $K^{\text{sc}}(z) \in \mathbb{C}(z)$ is its vacuum projection; the homotopy Σ_2 -coinvariant is an operator class, and

$$\kappa_{\text{dp}}(\mathcal{A}) = \tau_{\mathcal{A},2}^{\text{res}}(q_2(K^{\text{sc}}))$$

is its normalized scalar trace.

Normalisation note for affine Kac–Moody. The archetype table (Example 26.3.9) lists $K^{\text{coll}}(z) = k\Omega_{\text{tr}}/z$: the canonical affine collision kernel, with trace-form Casimir fixed by context. Some formal constructions (e.g. the KZ connection, eq. (26.12)) use the Sugawara-normalised coefficient $(k+h^\vee)^{-1}\Omega_{\text{KZ}} z^{-1}$ in the connection kernel. The canonical affine collision kernel carries the explicit level prefix k and specializes to zero at $k = 0$. For $k \neq 0$, the two expressions are related by the separate trace-form, KZ-Casimir, and Sugawara normalizations of Appendix ?? (The Koszul-dual level shift $k \mapsto -k - 2h^\vee$ is a *separate* operation on the underlying family of chiral algebras; it is not accomplished by this rescaling alone. See in the concordance.)

Convention. The notation K^{L} , K^{pre} , and K^{coll} records the three targets throughout. The coinvariant operator is $q_2(K^{\text{coll}})$ and its scalar coordinate is $\tau_{\mathcal{A},2}^{\text{res}} q_2(K^{\text{coll}})$. The symbol r is reserved for a represented collision kernel satisfying $H_{\text{CYBE}}^{\text{rep}}$.

Remark 26.3.11 (Arithmetic refinement of E_1 shadow depth). The E_1 shadow depth r_{max} admits a finer decomposition $d = 1 + d_{\text{arith}} + d_{\text{alg}}$ via Theorem ?? (Chapter ??), where d_{arith} counts critical lines

of L -functions governing the spectral curve and d_{alg} records the algebraic shadow obstruction tower contribution.

Construction 26.3.12 (KZ associator as degree-3 E_1 shadow of $\hat{\mathfrak{g}}_k$). For $\mathcal{A} = \hat{\mathfrak{g}}_k$ (affine Kac–Moody algebra), the ordered bar complex on $\overline{\text{FM}}_3^{\text{ord}}(\mathbb{C})$ carries the KZ connection

$$\nabla_{\text{KZ}} = d - \frac{1}{k+h^\vee} \left(\frac{\Omega_{12}}{z_1 - z_2} dz_{12} + \frac{\Omega_{23}}{z_2 - z_3} dz_{23} \right), \quad (26.12)$$

where $\Omega_{ij} = \sum_a t_i^a \otimes t_j^a$ is the Casimir acting on the i -th and j -th tensor factors. The monodromy of this connection as the ordered pair (z_1, z_2, z_3) traverses the boundary cycle of $\overline{\text{FM}}_3^{\text{ord}}(\mathbb{C})$ is the *KZ associator*

$$\Phi_{\text{KZ}} = \sum_{w \in \{t_{12}, t_{23}\}^*} \zeta(w) w \in \exp(\widehat{\text{Lie}}(t_{12}, t_{23})),$$

with $\zeta(w)$ the Drinfeld–Kontsevich multiple zeta values. This is the degree-3 E_1 shadow:

$$r_3(\hat{\mathfrak{g}}_k) = \Phi_{\text{KZ}}(\hat{\mathfrak{g}}_k) = \Phi_{\text{KZ}}\left(\frac{1}{k+h^\vee} \Omega_{12}, \frac{1}{k+h^\vee} \Omega_{23}\right).$$

Its homotopy coinvariant $q_3(\Phi_{\text{KZ}})$ is the cubic operator class. The specified functional $\tau_{\hat{\mathfrak{g}}_k, 3}^{\text{res}}$ defines the scalar cubic shadow

$$\mathfrak{C}(\hat{\mathfrak{g}}_k) = \tau_{\hat{\mathfrak{g}}_k, 3}^{\text{res}} q_3(\Phi_{\text{KZ}}),$$

whose trace-form specialization is proportional to $\kappa(\hat{\mathfrak{g}}_k)(x, [y, z])$.

Construction 26.3.13 (Formal ordered degree-2 shadow series). The genus-refined degree-2 projection of the ordered E_1 Maurer–Cartan element defines the formal series

$$R^{E_1, \text{bin}}(z; \hbar) = \sum_{g \geq 0} \hbar^{2g} r_g(z)$$

with genus-0 term $r_0(z) = R(z)$ equal to the ordered genus-0 exchange kernel. This series is the formal ordered degree-2 shadow package attached to $\Theta_{\mathcal{A}}^{E_1}$.

Its coefficientwise Maurer–Cartan relations come from the degree-2 projection of the ordered E_1 MC equation. On affine or free benchmark surfaces the conjectural refinement gives elliptic/genus-1 formulas for the first correction $r_1(z)$, but such line-side modular-kernel realizations are not part of the proved theorem surface of this chapter.

26.4 THE E_1 FIVE-THEOREM SURFACES ON THE STRICT ORDERED TOWER

The genus-0 theory promoted each E_∞ scalar shadow to an E_1 operator at the same degree: κ_{dp} is the normalized trace of the binary collision kernel, while $\mathfrak{C}$ is the normalized trace of the coinvariant Drinfeld associator. A represented CYBE package turns the binary kernel into a classical r -matrix. The genus tower so far still uses the commutative modular operad $\mathcal{M}_{\text{Com}}$; the promotion is incomplete until the same replacement happens at every genus. The genus- g ordered bar complex on $\mathcal{M}_{\text{Ass}}$ supplies the missing structure: the binary kernel acts on internal edges, the associator controls vertex reordering, and the genus- g partition function acquires a ribbon surface decomposition invisible to Σ_n -coinvariants. The five surfaces A^{E_1} – H^{E_1} below are the all-genus ordered analogues on the strict ordered Mittag–Leffler tower: the formal $F\text{Ass}$ graph differential is square-zero, the curved genus perturbation is filtration-continuous, and the line-side modular kernel is the degree-2 component of the ordered Maurer–Cartan element.

Definition 26.4.1 (Strict ordered Mittag–Leffler modular tower). A cyclic E_1 -chiral algebra $\mathcal{A}$ belongs to the *strict ordered Mittag–Leffler modular tower* if:

- (O₁) each finite ordered genus stage is a coaugmented conilpotent $F\text{Ass}$ -coalgebra, and the inverse system is complete for the coaugmentation/finite-window topology;
- (O₂) the $F\text{Ass}$ graph differential and the vertex bar differential assemble to a square-zero total differential on every finite ordered genus stage;
- (O₃) the genus- g curvature perturbation preserves the completed finite-window filtration and gives a Mittag–Leffler tower of cones;
- (O₄) the degree-2 ordered kernel $R^{E_1, \text{bin}}(z; \hbar)$ is the degree-2 projection of the ordered Maurer–Cartan element and therefore satisfies the projected ordered MC equation;
- (O₅) the finite-stage ordered Hochschild/coHochschild comparison is natural in the tower maps.

THEOREM 26.4.2 (*Theorem A ^{E_1} at all genera: ordered bar–cobar adjunction; .*). Let $\mathcal{A}$ be a cyclic E_1 -chiral algebra in the strict ordered Mittag–Leffler modular tower. The genus- g ordered bar complex $\overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A})(g, n)$ is an $F\text{Ass}$ -coalgebra (Definition 26.1.3) with continuous differential satisfying $D^2 = 0$. The completed bar and cobar functors at genus g form an adjunction

$$\Omega^{(g)} \dashv \overline{B}^{\text{ch}^{(g)}} : \text{Alg}_{F\text{Ass}} \rightleftarrows \text{Coalg}_{F\text{Ass}}.$$

Koszul exchange carries the formal ordered degree-2 shadow series $R^{E_1, \text{bin}}(z; \hbar)$ (Construction 26.3.13): its genus- g coefficient records the ordered degree-2 correction on this bar-level surface. Interpreting this series as a genuine higher-genus line-side modular R -matrix requires extra Yangian input not proved here. The symmetric Theorem A is recovered from Theorem A ^{E_1} only after a compatible strong-unitary R -twisted descent datum identifies the ordered coinvariant quotient with the symmetric bar coalgebra. Without that descent datum the theorem remains an ordered $F\text{Ass}$ adjunction and makes no assertion in the symmetric modular convolution algebra.

Proof. The $F\text{Ass}$ -coalgebra structure on the ordered bar complex follows from the universal property of the Feynman transform: $D_{F\text{Ass}}^2 = 0$ (Theorem 26.1.4) gives the differential on the graph complex, and the bar differential of $\mathcal{A}$ at each vertex is compatible with the operad composition maps of $\mathcal{M}_{\text{Ass}}$. The adjunction follows by the same argument as in the E_∞ case (Theorem 8.0.54), replacing the commutative modular operad by $\mathcal{M}_{\text{Ass}}$: the cobar construction $\Omega^{(g)}$ is defined as the completed tensor algebra over $F\text{Ass}$ with differential dual to the coalgebra structure. Conilpotence at finite stage and continuity in the inverse-limit topology are exactly the convergence hypotheses in Definition 26.4.1.

The formal ordered degree-2 shadow package: at each genus g , the opposite-duality identification $\overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A}^{\text{op}}) \cong \overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A})^{\text{cop}}$ is encoded at the degree-2 shadow level by $R^{E_1, \text{bin}}(z; \hbar)$ restricted to genus $\leq g$. This is opposite-coalgebra duality on the ordered surface, not Verdier duality on $\text{Ran}(X)$. $\square$

THEOREM 26.4.3 (*Theorem B ^{E_1} at all genera: ordered bar–cobar inversion; .*). On the strict ordered E_1 Koszul locus, the counit

$$\Omega^{(g)}(\overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A})(g, \bullet)) \xrightarrow{\sim} \mathcal{A}$$

is a quasi-isomorphism at every genus g in the completed inverse-limit topology. This is bar–cobar inversion: it recovers $\mathcal{A}$ from its own ordered bar coalgebra. The ordered line-side dual is obtained by the

completed linear/cobar dual of $\overline{B}^{\text{chord}}(\mathcal{A})$; it becomes the Verdier–Koszul dual $\mathcal{A}^!$ only after passage to the unordered Ran-space bar and Verdier duality.

Proof. At every finite stage the ordered bar coalgebra is conilpotent by Definition 26.4.1; hence the algebraic cobar sums terminate on each finite word. The genus perturbation is filtration-continuous and the cones form a Mittag–Leffler tower, so Proposition 9.1.37 gives a well-defined completed cobar differential. On the associated graded for the finite-window filtration the counit is the genus-0 PBW Koszul counit, hence a quasi-isomorphism by Theorem 9.10.17. The filtered quasi-isomorphism criterion lifts this to each finite stage, and the Mittag–Leffler condition passes the quasi-isomorphism to the inverse limit. Verdier duality is not used in this inversion. $\square$

THEOREM 26.4.4 (*Theorem C^{E_1} at all genera: ordered complementarity;*). For $\mathcal{A}$ in the strict ordered tower, at genus g and each degree n with $2g - 2 + n > 0$, the ordered complementarity takes the form

$$Q_{g,n}^{E_1}(\mathcal{A}) + Q_{g,n}^{E_1}(\mathcal{A}^{!E_1}) = H^*(\overline{\mathcal{M}}_{g,n}^{\text{rib}}, Z^{E_1}(\mathcal{A})),$$

where $Q_{g,n}^{E_1}(\mathcal{A}) := C_{\Delta}^{(g,n)} \square_{C^{e,(g,n)}}^{\mathbf{R}} C_{\Delta}^{(g,n)}$ is the genus- g , degree- n ordered partition function and $Z^{E_1}(\mathcal{A})$ is the E_1 center (the space of R -matrix-equivariant elements).

The scalar complementarity identity is the family-dependent Theorem C shadow obtained after symmetric descent and Verdier duality, not a universal vanishing statement: on the classical G/L/C/M rows the constants are 0, 13, $250/3$, $25/3$, with the Mukai-enhanced K3 row contributing the separate value 8. The ordered refinement keeps the R -matrix-equivariant cohomology class whose scalar image gives that number.

Proof. The genus- g ordered complementarity extends from genus 0 (the genus-0 ordered complementarity theorem) by the same modular extension principle used for the E_{∞} complementarity (Theorem ??): the E_1 MC element $\Theta_{\mathcal{A}}^{E_1}$ gives a genus- g deformation of the genus-0 diagonal bicomodule, and the ordered chiral Hochschild–coHochschild identification carries through at each genus. The E_1 center $Z^{E_1}(\mathcal{A})$ is the subspace of elements satisfying $R(z) \cdot a = a$ (braiding-invariant), replacing the naive center of the E_{∞} theory. $\square$

THEOREM 26.4.5 (*Theorem D^{E_1} at all genera: formal ordered degree-2 shadow series;*). The formal ordered degree-2 shadow series $R^{E_1, \text{bin}}(z; \hbar) = \sum_{g \geq 0} \hbar^{2g} r_g(z)$ obtained from the genus-refined degree-2 projection of $\Theta_{\mathcal{A}}^{E_1}$ is the E_1 degree-2 characteristic package of $\mathcal{A}$. It satisfies the degree-2 projection of the ordered Maurer–Cartan equation

$$D R^{E_1, \text{bin}} + \frac{1}{2} [R^{E_1, \text{bin}}, R^{E_1, \text{bin}}] = 0 \quad (26.13)$$

in $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$, and its properties mirror those of the scalar $\kappa(\mathcal{A})$:

- (i) *Universality:* $R^{E_1, \text{bin}}$ depends only on the E_1 -chiral algebra $\mathcal{A}$, not on auxiliary choices.
- (ii) *Additivity:* for $\mathcal{A} = \mathcal{A}_1 \otimes \mathcal{A}_2$ with vanishing mixed OPE, $R_{\mathcal{A}_1 \otimes \mathcal{A}_2}^{E_1, \text{bin}} = R_{\mathcal{A}_1}^{E_1, \text{bin}} \otimes 1 + 1 \otimes R_{\mathcal{A}_2}^{E_1, \text{bin}}$.
- (iii) *Anti-symmetry:* $R_{\mathcal{A}^{\text{op}}}^{E_1, \text{bin}}(z; \hbar) = R_{\mathcal{A}}^{E_1, \text{bin}}(z; \hbar)^{-1}$ on the ordered bar surface.
- (iv) *Coinvariant operator and scalar trace:* $q_2(R^{E_1, \text{bin}}(z; \hbar))$ belongs to $\text{End}_{\mathcal{A}}(2)_{\hbar \Sigma_2}[[\hbar]]$, and

$$\tau_{\mathcal{A}} q_2(R^{E_1, \text{bin}}(z; \hbar)) = \kappa_{\text{dp}}(\mathcal{A}) + O(\hbar^2).$$

For affine Kac–Moody, the full characteristic adds the Sugawara term $\dim(\mathfrak{g})/2$.

This theorem packages the genuine ordered line-side modular kernel at the level at which the theorem is stated: the kernel is the degree-2 component of the ordered Maurer–Cartan element. Specialising this formal kernel to a representation-theoretic Yangian or KZB operator is extra structure, not part of Theorem D^{E_1} .

Proof. The degree-2 ordered Maurer–Cartan relation (26.13) is the degree-2 MC equation in $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$: it follows from $D_{F\text{Ass}}^2 = 0$ by restriction to the two-point component.

(i) Universality: $R^{E_1, \text{bin}}$ is determined by the $F\text{Ass}$ -coalgebra structure on $\overline{B}^{\text{ch ord}}(\mathcal{A})$, which depends only on $\mathcal{A}$.

(ii) Additivity: for $\mathcal{A} = \mathcal{A}_1 \otimes \mathcal{A}_2$ with vanishing mixed OPE, the ordered bar complex decomposes as a product $\overline{B}^{\text{ch ord}}(\mathcal{A}_1 \otimes \mathcal{A}_2) \cong \overline{B}^{\text{ch ord}}(\mathcal{A}_1) \otimes \overline{B}^{\text{ch ord}}(\mathcal{A}_2)$ (ordered shuffle theorem), and the monodromy of a product connection is additive.

(iii) Anti-symmetry: opposite-duality gives $\overline{B}^{\text{ch ord}}(\mathcal{A}^{\text{op}}) \cong \overline{B}^{\text{ch ord}}(\mathcal{A})^{\text{cop}}$, and the monodromy of the co-opposite is the inverse.

(iv) Coinvariant operator and scalar trace: by Theorem 26.3.3 at degree 2. $\square$

THEOREM 26.4.6 (*Theorem H^{E_1} at all genera: ordered chiral Hochschild at genus g ;*). For every genus g , every $\mathcal{A}$ in the strict ordered tower, and every complete $\mathcal{A}$ -bimodule M , the genus- g ordered chiral Hochschild homology is computed coalgebraically:

$$\text{HH}_{\bullet}^{\text{ch}, (g)}(\mathcal{A}, M) \simeq \text{coHH}_{\bullet}^{\text{ch}, (g)}(C, \mathbb{K}_{\mathcal{A}}^{\text{bi}}(M)),$$

where $C = \overline{B}^{\text{ch ord}}(\mathcal{A})$ and the genus- g twisted differential is the continuous ordered genus perturbation supplied by the strict tower. If a compatible strong-unitary R -twisted descent datum is fixed, the R -twisted Σ_n -coinvariant of the ordered chiral Hochschild complex recovers the symmetric chiral Hochschild complex of Theorem H as an R -descent comparison of complexes; cohomology is taken after this chain-level descent.

Proof. The genus-0 ordered Hochschild/coHochschild comparison is Theorem 15.13.8. The strict ordered tower makes the genus- g differential a continuous finite-window perturbation of that comparison; the same associated-graded argument used in Theorem 26.4.3 preserves the bimodule/bicomodule equivalence at every finite stage and then passes to the Mittag–Leffler inverse limit. Under strong-unitary R -descent, Proposition 27.4.3 identifies the symmetric complex with the R -twisted descent of the ordered complex in each finite window; characteristic-zero exactness of the finite group action is used after this descent datum has been constructed. A family datum $H_H(\mathcal{A}; S)$ on the descended symmetric chart then gives $\text{Supp } CH^{\bullet}(\mathcal{A}) \subseteq S$. Its construction combines the ordered support transport of Theorem 35.4.34 -- whose finite-window-retract hypothesis is, in the family-generic case, the open Conjecture 35.4.27 -- with the filtered ordered-to-symmetric comparison of Corollary 35.4.38 and the compatible finite-window retract. De Sole–Kac variational Poisson cohomology is nonvanishing in unboundedly many degrees for Virasoro-type Poisson vertex algebras [BDSK21], so the support conclusion lives strictly on the stated Koszul/bounded locus, with the bounded-to-chart comparison part of $H_H(\mathcal{A}; S)$. A perfect degree- d pairing supplies any degree-reflection statement separately. $\square$

Remark 26.4.7 (Associative modular Maurer–Cartan surface). Theorems 26.4.2–26.4.6 establish the associative modular MC theory asked for by Theorem 27.30.5: the E_1 deformation complex is $\mathfrak{g}_{\mathcal{A}}^{\text{mod } E_1}$

(Definition 26.1.6), and the canonical MC element is $\Theta_{\mathcal{A}}^{E_1} := D_{\mathcal{A}}^{E_1} - d_o$. The ordered cyclic compactification is the Feynman transform $F\text{Ass}$ of the ribbon modular operad (Definition 26.1.3).

Remark 26.4.8 (Symmetric-ordered comparison table). The five symmetric theorems and their ordered counterparts have the following surfaces. A symmetric theorem is the R -twisted Σ_n -coinvariant of the corresponding ordered theorem only after the required descent datum has been fixed.

	Symmetric (E_∞)	Ordered (E_1)	Refinement
A (existence)	$\overline{B}^{\text{ch}}(\mathcal{A}): F\text{Com-coalgebra}$	$\overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A}): F\text{Ass-coalgebra}$	associahedra replace permutohedra
B (inversion)	$\Omega(\overline{B}^{\text{ch}}(\mathcal{A})) \simeq \mathcal{A}$	$\Omega^{\text{ord}}(\overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A})) \simeq \mathcal{A}$	retains R -matrix and associator
C (complementarity)	$Q_g + Q_g^! = H^*(\overline{M}_{g,n}, Z)$	$Q_g^{E_1} + Q_g^{!,E_1} = H^*(\overline{M}_{g,n}^{\text{rib}}, Z^{E_1})$	R -equivariant center replaces center
D (leading coeff.)	$\tau_{\mathcal{A}} q_2(K_{\mathcal{A}}^{\text{coll}}) = \kappa_{\text{dp}}(\mathcal{A})$	$K_{\mathcal{A}}^{\text{coll}}(z)$ (operator kernel)	coinvariant operator $\rightarrow$ normalized trace
H (chiral Hochschild)	$\text{HH}^{\text{ch}}(\mathcal{A}, \mathcal{A}) \simeq Z^{\text{der}}(\mathcal{A})$	$\text{HH}^{E_1}(\mathcal{A}, M) \simeq \text{ordered center}$	ordered Hochschild $\rightarrow$ line algebra

Physically, the symmetric column governs the *bulk* (closed-string/holomorphic) sector: the partition function, the deformation ring, the genus tower. The ordered column governs the *line-operator* (open-string/topological) sector: the R -operator, the Drinfeld associator, and the spectral genus tower. Its binary semiclassical term is the represented collision kernel; $H_{\text{CYBE}}^{\text{rep}}$ identifies it with a classical r -matrix. The coinvariant projection $\text{av}: \mathfrak{g}_{\mathcal{A}}^{\text{mod} E_1} \rightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is the functor that forgets the ordering and recovers the bulk from the boundary.

Remark 26.4.9 (E_1 primitive kernel). The cofree-coderivation principle for $F\text{Ass}$ yields an E_1 primitive kernel

$$K_{\mathcal{A}}^{E_1} := \log_{\star}(\Theta_{\mathcal{A}}^{E_1}) \in \prod_{\substack{g,n \\ 2g-2+n>0}} \text{End}(V^{\otimes n}) \otimes \Omega^{n-2}(\overline{\text{FM}}_n^{\text{ord}}(\mathbb{C})),$$

where $\log_{\star}$ is the operadic logarithm on the $F\text{Ass}$ -coalgebra $\overline{B}^{\text{ch}^{\text{ord}}}(\mathcal{A})$, decomposing the full MC element into primitive (one-vertex) contributions.

Coinvariant recovery. The averaging map of Definition 26.1.6 sends the E_1 primitive kernel to the E_∞ primitive kernel:

$$\text{av}(K_{\mathcal{A}}^{E_1}) = K_{\mathcal{A}}.$$

This is the primitive-level refinement of Theorem 26.3.3: the coinvariant projection is compatible with the operadic logarithm under the full descent package of Definition 26.1.6, because only then is av a dg Lie morphism rather than a continuous chain projection.

Low-degree identifications.

- (i) $(K_{\mathcal{A}}^{E_1})_{0,2} = K_{\mathcal{A}}^{\text{coll}}(z)$ is the binary collision kernel. Under $H_{\text{CYBE}}^{\text{rep}}$ its represented image is a classical r -matrix. The homotopy coinvariant is $q_2(K_{\mathcal{A}}^{\text{coll}})$, and $\kappa_{\text{dp}}(\mathcal{A}) = \tau_{\mathcal{A}} q_2(K_{\mathcal{A}}^{\text{coll}})$. For affine Kac-Moody in trace-form normalization,

$$\tau_{k,\mathfrak{g}} q_2(K_{k,\mathfrak{g}}^{\text{coll}}) = \frac{k \dim(\mathfrak{g})}{2h^\vee}, \quad \kappa(V_k(\mathfrak{g})) = \tau_{k,\mathfrak{g}} q_2(K_{k,\mathfrak{g}}^{\text{coll}}) + \frac{\dim(\mathfrak{g})}{2}.$$

- (ii) $(K_{\mathcal{A}}^{E_1})_{0,3} = \Phi_{\text{KZ}}(\mathcal{A})$, the KZ/Drinfeld associator (genus 0, degree 3, for affine algebras; Construction 26.3.12). Its homotopy coinvariant is $q_3(\Phi_{\text{KZ}})$, and the normalized scalar coordinate is $S_3(\mathcal{A}) = \tau_{\mathcal{A},3}^{\text{res}} q_3(\Phi_{\text{KZ}})$.
- (iii) $(K_{\mathcal{A}}^{E_1})_{1,1}$ is the genus-1 primitive, whose coinvariant carries the genus-1 operator and whose normalized modular trace gives $\kappa(\mathcal{A})\lambda_1$ (the scalar and all-weight lanes coincide at genus 1).

E_1 primitive master equation. The MC equation $D\Theta^{E_1} + \frac{1}{2}[\Theta^{E_1}, \Theta^{E_1}] = 0$ expressed in primitive generators takes the form

$$dK_{\mathcal{A}}^{E_1} + K_{\mathcal{A}}^{E_1} \star_{E_1} K_{\mathcal{A}}^{E_1} = 0,$$

where $\star_{E_1}$ is the convolution product on the $F\text{Ass}$ modular cooperad, whose degree- r component is governed by the face structure of the Stasheff associahedron K_{r+1} . In particular, the degree-2 component is the binary operadic boundary relation; $H_{\text{CYBE}}^{\text{rep}}$ identifies its represented image with the classical Yang–Baxter equation. The degree-3 component maps to the pentagon under the KZ associator comparison. Averaging recovers the E_∞ primitive master equation $dK_{\mathcal{A}} + K_{\mathcal{A}} \star K_{\mathcal{A}} + \hbar \Delta_{\text{ns}}(K_{\mathcal{A}}) = 0$.

Remark 26.4.10 (Lie/associative dichotomy in the averaging kernel;). The degreewise Reynolds projection from the ordered E_1 -convolution surface to the symmetric modular surface exhibits a Lie/associative dichotomy: at degree 3, the linearized Drinfeld associator $[t_{12}, t_{23}]$ (a Lie commutator) lies in K_3^{Re} , and hence in $\ker(\text{av}_R)$ once the full R -twisted dg descent surface is imposed. Its Σ_3 -average vanishes exactly because the commutator is antisymmetric under the transposition $(1 \leftrightarrow 3)$. The operator $q_3(\Phi_{\text{KZ}})$, when the descended map is available, receives contributions from the symmetric/associative products $t_{12} t_{23} + t_{23} t_{12}$ in the full KZ associator Φ_{KZ} . The scalar coordinate $S_3(\mathcal{A}) = \tau_{\mathcal{A},3}^{\text{res}} q_3(\Phi_{\text{KZ}})$ records the chosen traced residue of this operator. The averaged level-5 modular shadows obtained by open trace and clutching see the associative part of the KZ expansion. A Hilbert-space tensor-product interpretation requires a separate Hilbert completion and comparison map; the open-sector (E_1) invariants retain the braiding/ R -matrix structure.

PROPOSITION 26.4.11 (Σ_n -irreducible decomposition of the ordered bar complex;). Let $V = \bigoplus_i \mathbb{C} \cdot \phi_i$ be the generating space of a chiral algebra $\mathcal{A}$, with $\dim V = d$ and desuspended degree $|s^{-1}\phi_i| = h_i - 1$ where h_i is the conformal weight of ϕ_i . The Σ_n -action on the ordered bar component $B^{\text{ord},n}(\mathcal{A}) \supset V^{\otimes n}$ has:

- (i) *Schur–Weyl decomposition.* As a $\text{GL}(V) \times \Sigma_n$ -representation:

$$V^{\otimes n} = \bigoplus_{\substack{\lambda \vdash n \\ \ell(\lambda) \leq d}} \mathbb{S}^\lambda(V) \otimes V_\lambda,$$

where $\mathbb{S}^\lambda(V)$ is the Schur functor and V_λ is the irreducible Σ_n -representation indexed by λ . The multiplicity of V_λ equals $\dim \mathbb{S}^\lambda(V)$, computed by the Weyl dimension formula.

- (ii) *Frobenius characteristic.* The character of the Σ_n -representation on $V^{\otimes n}$ is

$$\text{ch}(V^{\otimes n}) = \sum_{\lambda \vdash n} \dim(\mathbb{S}^\lambda(V)) s_\lambda,$$

where s_λ is the Schur function. This encodes which Σ_n -irreps contribute at each bar degree.

- (iii) *Signed Reynolds complement.* The degreewise signed Reynolds projector Re_n^{sgn} projects onto a single isotypic component: for generators of even desuspended degree (h odd: Heisenberg, affine

KM), Re_n^{sgn} retains the *trivial* representation $V_{(n)}$; for generators of odd desuspended degree (h even: Virasoro), the Koszul sign makes Re_n^{sgn} retain the *sign* representation $V_{(1^n)}$. All other isotypic components lie in $\ker(\text{Re}_n^{\text{sgn}})$ and are annihilated.

(iv) *Information ratio*. The fraction of ordered bar data surviving Re_n^{sgn} is

$$\frac{\dim \text{im}(\text{Re}_n^{\text{sgn}}|_{V^{\otimes n}})}{\dim V^{\otimes n}} = \frac{\binom{d+n-1}{n}}{d^n} \quad (\text{even desuspended degree}), \quad \frac{\binom{d}{n}}{d^n} \quad (\text{odd desuspended degree}).$$

For sl_2 ($d = 3$) at $n = 4$: $\dim V^{\otimes 4} = 81$, $\dim \text{Sym}^4(V) = 15$, ratio $\approx 18.5\%$. For Virasoro single generator ($d = 1$), the ratio is $1/1 = 100\%$ at every n (consistent with the trivial Σ_n -action on a one-dimensional space).

Proof. Part (i) is the Schur–Weyl theorem for $\text{GL}_d \times \Sigma_n$ acting on $V^{\otimes n}$ (Fulton–Harris [FH91], Appendix A). Part (ii) is its translation into the symmetric-function basis. Part (iii): the Reynolds operator $(1/n!) \sum_{\sigma} \sigma$ projects onto the Σ_n -invariant subspace, which for degree-0 elements is $\text{Sym}^n(V)$ (the trivial isotypic) and for degree-1 elements acquires Koszul signs that convert the trivial projection into the sign projection. Part (iv): $\dim \text{Sym}^n(V) = \binom{d+n-1}{n}$ and $\dim \Lambda^n(V) = \binom{d}{n}$ are the standard multi-set and subset counts. Computational verification: `sn_bar_irrep_decomp_engine.py` (Schur–Weyl decomposition, character tables for Σ_1 – Σ_5 , hook-length formula, 120+ tests). $\square$

26.5 CYCLIC TRACE, RIBBON STRUCTURE, AND THE $1/N$ EXPANSION

The E_1 modular-Koszul theory organises amplitudes by genus through the ribbon modular operad, but a bare stable graph carries no canonical N -weight: the Euler characteristic $\chi(\Sigma_\Gamma)$ requires a ribbon surface, hence a cyclic ordering at each vertex. The missing datum is a cyclic trace on the open-color algebra.

LEMMA 26.5.1 (*Bare graphs do not determine a 't Hooft expansion*;). A bare modular stable-graph expansion does not canonically define a 't Hooft N -expansion.

Proof. The N -weight in a 't Hooft expansion is $N^{V-E+F} = N^{\chi(\Sigma_\Gamma)}$, determined by the number of faces F of the thickened surface Σ_Γ . A bare stable graph does not specify cyclic orderings of half-edges at vertices; hence it does not determine a ribbon surface, hence does not determine F , hence carries no canonical N -power. The same underlying graph admits inequivalent ribbon structures with different genera. $\square$

THEOREM 26.5.2 (*Cyclicity is the ribbon-enabling datum*;). Let $(O, m_\bullet, \tau)$ be a graded vector space with multilinear operations $m_n: O^{\otimes n} \rightarrow O$ and a degree-zero nondegenerate bilinear pairing $\tau: O \otimes O \rightarrow k$. Define the cyclic tensors

$$\tilde{m}_n(x_0, \dots, x_n) := \tau(m_n(x_1, \dots, x_n), x_0).$$

If $\tilde{m}_n$ satisfies cyclic invariance $\tilde{m}_n(x_0, \dots, x_n) = (-1)^\epsilon \tilde{m}_n(x_1, \dots, x_n, x_0)$ (with Koszul sign ϵ), then each operation m_n determines a cyclic $(n+1)$ -tensor, and every Feynman graph built from these tensors canonically thickens to a ribbon graph.

Proof. The pairing identifies $\text{Hom}(O^{\otimes n}, O) \cong \text{Hom}(O^{\otimes(n+1)}, k)$. Under this identification, m_n becomes the $(n+1)$ -linear form $\tilde{m}_n$. Cyclic invariance means $\tilde{m}_n$ descends to a function on cyclic words of length $n+1$: there is no distinguished output among the $n+1$ legs. Each vertex therefore carries a cyclic

order on its incident half-edges, which is exactly the data needed for canonical ribbon thickening: at each vertex, the cyclic order determines the local surface, and gluing via internal edges produces a global ribbon surface Σ_Γ with a well-defined face decomposition. $\square$

COROLLARY 26.5.3 (*Operads are too small for traces;*). Any open/closed theory closed under Swiss-cheese composition *and* trace-contraction cannot be encoded by a rooted operad. The minimal closure is a wheeled two-colored operadic object; for multi-interface gluing, a properad.

Proof. Operadic composition is indexed by rooted trees (acyclic, one output per vertex). Trace-contraction $\sum_i m_2(x, e_i) \otimes e^i$ creates a one-vertex graph with a loop, not an operadic graph. The closure under both composition and contraction generates graphs with arbitrary numbers of loops: wheeled graphs. Properadic structure allows multiple outputs per vertex, accommodating multi-boundary and multi-interface gluing. $\square$

THEOREM 26.5.4 (*Exact N^χ weighting from traced open color;*). Let $(O, m_\bullet, \tau)$ be a cyclic $\mathcal{A}_\infty$ -algebra with matrix realization $O_N := \text{Mat}_N \otimes O_o$ and trace $\tau_N := \text{Tr}_N \otimes \tau_o$. For a connected ribbon graph Γ with V vertices, E edges, and F faces, the bare amplitude scales as N^F (one factor per closed index loop). Under 't Hooft rescaling $g^2 \mapsto \lambda/N$, the rescaled amplitude factors as

$$\text{Amp}_\Gamma^\lambda(O_N) = N^{V-E+F} \cdot \text{Amp}_\Gamma^{\text{red}}(O_o, \lambda) = N^{\chi(\Sigma_\Gamma)} \cdot \text{Amp}_\Gamma^{\text{red}}(O_o, \lambda).$$

The total genus expansion is then

$$\sum_{\Gamma \text{ ribbon}} \frac{N^{\chi(\Sigma_\Gamma)}}{|\text{Aut}_{\text{rib}}(\Gamma)|} W_\Gamma \Phi_\Gamma^T = \sum_{g=0}^{\infty} N^{2-2g} F_g(\lambda),$$

where $\lambda = g_{\text{YM}}^2 N$. In a multi-weight channel decomposition, the coefficient is $F_g = F_g^{\text{sc}} + \delta F_g^{\text{cross}}$ for $g \geq 2$. This is a literal 't Hooft expansion: the N -power is determined by the Euler characteristic of the thickened surface.

Proof. Cyclic structure (Theorem 26.5.2) gives canonical ribbon thickening, so faces are well-defined. We count N -powers in two steps.

Step 1: bare double-line counting. With the normalization $\tau_N = \text{Tr}_N$ (not $(1/N) \text{Tr}_N$), the propagator $\tau_N^{-1} = \sum_{i,j} E_{ij} \otimes E_{ji}$ carries no explicit N -factor: it merely routes double-line indices through each internal edge. Likewise, vertex traces route indices but produce no bare N -powers. The only source of N is the summation over each closed index loop: every face of the ribbon graph Γ corresponds to one such loop, contributing a factor of N . Hence the bare amplitude scales as N^F .

Step 2: 't Hooft rescaling. Writing the action with overall normalization $g^{-2} \tau_N(\dots)$, each propagator acquires g^2 and each vertex g^{-2} , giving total coupling $g^{2(E-V)}$. Setting $\lambda = g^2 N$ yields $g^{2(E-V)} = (\lambda/N)^{E-V}$, so the rescaled amplitude carries N -power $F - (E - V) = V - E + F = \chi(\Sigma_\Gamma)$ by Euler's formula. $\square$

Remark 26.5.5 (*The logical chain*).

$$\text{modular graph sum} + \text{cyclic trace} + \text{matrix realization} \implies \text{literal 't Hooft sum}.$$

Plain modular E_i gives genus-organized expansion. Cyclic traced modular E_i gives 't Hooft expansion. Ribbonized modular Swiss-cheese gives holographic open/closed 't Hooft language.

Definition 26.5.6 (Ribbonized modular Swiss-cheese theory). The *ribbonized modular Swiss-cheese theory* $\text{RSC}_{\text{tr}}^{\text{mod}}$ is the two-colored wheeled modular properad with:

- (i) *closed color*: the modular/chiral sector (Chapters ??–26);
- (ii) *open color*: the E_1 /chiral or A_∞ -chiral line sector;
- (iii) *mixed operations*: bulk-to-boundary and boundary-to-line interactions;
- (iv) *trace data*: a nondegenerate invariant pairing τ on the open color;
- (v) *wheel operations*: contractions of outputs with inputs via τ ;
- (vi) *ribbon data*: cyclic order at each open vertex, so every open graph thickens to a surface (Theorem 26.5.2).

The open input is a cyclic A_∞ -object $(O, m_\bullet, \tau)$; the closed input is the modular datum $\Theta_{\mathcal{A}}$. The tree part recovers the Boardman–Vogt resolution $W(\text{SC}^{\text{ch}, \text{top}})$ of the Swiss-cheese operad (Volume II, §??).

Remark 26.5.7 (The correct holographic language). The three levels of language are:

Language	Content
plain modular E_1	genus-organized expansion
cyclic traced modular E_1	't Hooft $1/N$ expansion
ribbonized modular Swiss-cheese	holographic open/closed 't Hooft language

26.6 CROSS-VOLUME BRIDGE: ORDERED MC TO UNIVERSAL HOLOGRAPHY

The ordered modular MC element $\Theta_{\mathcal{A}}^{E_1} \in \mathfrak{g}_{\mathcal{A}}^{\text{mod} E_1}$ of Theorem 26.1.7 is the bar-side input that the Vol II universal-holography theorem (Vol II thm: uch-main) consumes after R -twisted Σ_n -coinvariant projection. Its Vol II use factors through Theorem 26.1.7 and Proposition 26.1.9.

Remark 26.6.1 (Ordered-to-holographic bridge). Theorem 26.1.7 produces the ordered MC element $\Theta_{\mathcal{A}}^{E_1}$ on the modular E_1 convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod} E_1}$ built from the associative Feynman transform $F\text{Ass}$ (Definition 26.1.3). Proposition 26.1.9 pins down the precise content lost by the symmetric image $\text{av}_R(\Theta_{\mathcal{A}}^{E_1}) = \Theta_{\mathcal{A}}$: the GRT_1 -torsor structure at genus 0, the quasi-modular anomaly $E_2 \mapsto \widehat{E}_2$ at genus 1 (Proposition 26.1.10), and seven Siegel/clutching obstruction classes at genus 2 (Conjecture 26.1.12).

The ordered bar-cobar adjunction is upgraded to an $(\infty, 2)$ -equivalence at properad level by the Koszul Reflection Theorem (Theorem 17.1.2 in Chapter 17); the Climax Theorem (Chapter ??) identifies the genus-0 affine/tangent finite-window collision part of the bar differential with the Fulton–MacPherson residue realisation of the KZ–Arnold bar superconnection. The R -twisted descent of Lemma 27.4.3 (under classical Yang–Baxter and unitarity $R(z) R^{\text{op}}(-z) = \text{id}$ on R ; automatic for rational Yangians and generic- q trigonometric $U_q(\widehat{\mathfrak{g}})$, vacuous for $R(z) = \tau$) relates the ordered bar $\overline{B}^{\text{ord}}(\mathcal{A})$ to its symmetric image $\overline{B}^{\Sigma}(\mathcal{A})$ at properad level; on chains, this descent is the present chapter's averaging map av_R .

The universal-holography theorem (Vol II thm: uch-main) promotes the $\text{SC}^{\text{ch}, \text{top}}$ -pair structure on $(\mathcal{A}^{\text{cel}}, Z_{\text{ch}}^{\text{der}}(\mathcal{A}^{\text{cel}}))$ to a chain-level statement of celestial holography for the non-logarithmic standard landscape: the symmetric MC element $\Theta_{\mathcal{A}} = \text{av}_R(\Theta_{\mathcal{A}}^{E_1})$ supplies the genus tower of soft-factor coefficients (uniform-weight lane), with multi-weight cross-channel correction $\delta F_g^{\text{cross}}$ visible only in the multi-weight lane. The chain-level closed-sector statement at $g \geq 1$ for class $\mathbf{M}$ remains Conjectured (Vol II conj: uch-gravity-chain-level); the weight-completed statement is unconditional.

Remark 26.6.2 (Bridge conventions). The bridge uses three fixed conventions.

- (A) E_1 -chiral notion. The ordered MC element $\Theta_{\mathcal{A}}^{E_1}$ is constructed from notions (A)/(B) of Warning 3.11.11: strict Ass^{ch} -algebra or $\mathcal{A}_\infty$ in $\text{End}_{\mathcal{A}}^{\text{ch}}$. The Etingof–Kazhdan quantum-vertex notion (C) determines the same MC element on the Koszul locus via Theorem 27.29.3, and the universal-holography reading of Vol II is on this Koszul locus.
- (B) $\text{SC}^{\text{ch},\text{top}}$ is bicoloured. The Vol II universal-holography statement uses the chiral Swiss-cheese operad $\text{SC}^{\text{ch},\text{top}}$, not E_3 . The two are related by topologization (Sugawara at non-critical level for class $\mathbf{L}$, iterated Sugawara for class $\mathbf{M}$ in the weight-completed category) but not by Dunn additivity: the Swiss-cheese operad is two-coloured with directionality, Dunn does not apply.
- (C) *Topologization scope.* Topologization is Proved chain-level on the original complex for class $\mathbf{L}$ at non-critical level (Theorem ??); for class $\mathbf{M}$ original-complex chain-level topologization is open, the weight-completed statement is Proved via the iterated-Sugawara tower of Vol II thm:e-infinity-topologization-ladder. Cross-volume statements carry this scope qualifier.

Remark 26.6.3 (Vol III specialisation: chiral Yangians from CY data). The Vol III chiral Yangian construction (Vol III chapters on K_3 Yangian and CY_4 p_1 -twisted double current algebra) produces concrete E_1 -chiral algebras as the boundary chiral algebras of specific 6d holomorphic Chern–Simons or 4d/5d HT theories on Calabi–Yau geometries. Each such concrete chiral Yangian $Y(\mathfrak{g})^{\text{ch}}$ enters the E_1 -modular comparison through notions (A)/(B) (with an associator-rigidified witness from notion (C) on the Koszul locus); its ordered MC element is a specialisation of $\Theta_{\mathcal{A}}^{E_1}$. The non-splitting obstructions of Proposition 26.1.9 (genus 0, GRT_1) and Proposition 26.1.10 (genus 1, $E_2 \mapsto \widehat{E}_2$) survive on the Vol III locus and record the precise sense in which the symmetric shadow $\kappa_{\text{ch}}^{\text{Vol III}}$ loses associator and quasi-modular data carried by the ordered E_1 object.

26.7 E_1 MODULAR KOSZUL DUALITY ON $\mathbf{H}_{\Delta_5}$

THEOREM 26.7.1 (*Conditional Δ_5 bar-cobar inversion target;*). Let $\mathbf{H}_{\Delta_5}$ be a filtered E_1 -chiral Hall bialgebra at the Lusztig specialisation $\hbar^2 = -1/8$ on the bi-based Ran surface $(\text{Ran}(E_{24}^{\text{nod},\text{sm}}), \bar{\mathcal{A}}_2)$. Assume the following finite-window data.

- (D1) *Compact Hall source and finite Hall–Borcherds recognition.* In every height, charge, and conformal-weight window the Hall object is represented by a compact finite Hall source whose associated graded Hall algebra is identified with the corresponding finite Borcherds truncation of $\mathfrak{g}_{\Delta_5}$, with root multiplicities and Euler form fixed by the Borcherds product for Δ_5 .
- (D2) *Source datum.* The Hall object is built from a named K_3 source, with augmentation, coproduct, completion, and the $\hbar^2 = -1/8$ specialisation compatible with the finite truncations.
- (D3) *Parity and root fixtures.* The real-root set, imaginary simple-root multiplicities, Weyl vector, and super-parity signs are fixed once and transported unchanged through the Hall, BKM, and ordered bar constructions.
- (D4) *PBW and no-extra condition.* The ordered PBW spectral sequence degenerates in each finite window, and no additional root spaces, central summands, hidden extensions, or torsion classes appear beyond the Borcherds datum in (D1).
- (D5) *Completion and comparison maps.* The completion is the Mittag–Leffler inverse limit of these compact finite windows, and there are filtration-preserving maps from $B_{\text{ch}}^{E_1}(\mathbf{H}_{\Delta_5})$ and its cobar object

to the finite Hall–Borcherds truncations, compatible with the product, coproduct, differential, augmentation, inverse-system maps, and the ordered-to-symmetric averaging map.

Then the finite-window counits are quasi-isomorphisms and pass to the completed inverse limit, giving the conditional inversion equivalence

$$\Omega_X^{E_1}(B_{\text{ch}}^{E_1}(\mathbf{H}_{\Delta_5})) \xrightarrow{\sim} \mathbf{H}_{\Delta_5}$$

at $\hbar^2 = -1/8$. Without (D1)–(D5) the displayed arrow is a target: it is not an unconditional theorem about $\mathbf{H}_{\Delta_5}$.

Proof. Hypotheses (D1)–(D4) put each finite Hall–Borcherds window in the strict ordered E_1 Koszul locus of Theorem 26.4.3; the finite-window bar–cobar counit is therefore a quasi-isomorphism. Hypothesis (D5) identifies these counits with the Hall–Borcherds comparison system and makes the transition maps compatible with the completed inverse limit. The Mittag–Leffler passage in Theorem 26.4.3 gives the displayed equivalence. $\square$

Remark 26.7.2 (E_1 ordering at the Δ_5 point). Assume the D1–D5 recognition datum of Theorem 26.7.1, equivalently the finite-window projection of Convention ???. Under that datum the E_1 -ordered convention matters. The averaging map $\text{av} = \text{Torelli}_{K_3} \circ \text{KugaSatake} \circ j_{\text{Kod}}$ from $\mathfrak{g}_{\Delta_5}^{E_1}$ to $\mathfrak{g}_{\Delta_5}^{\text{mod}}$ is a chiral averaging map, not an inverse to the bar–cobar counit. It collapses the Hall-theoretic ordered commutators of $\mathbf{H}_{\Delta_5}$, after the compact Hall source and comparison maps have been supplied, onto the Mukai-doubled symmetric chiral homology. The class-M dichotomy position ($r_{\text{max}} = \infty$, Virasoro-type) reflects the infinite positive-root family of the BKM Lie algebra. Cross-ref Vol. III, Chapter ??, Theorems A and D.

Remark 26.7.3 (Siegel-modular E_1 target cocycle at the K_3 base point). Under the same D1–D5 recognition datum, the displayed candidate E_1 target cocycle for $\mathbf{H}_{\Delta_5}$ is the Siegel-modular upgrade of the Drinfeld 1990 rational associator $\Phi_{\text{rat}}^{\text{Drinfeld}}(z_1, z_2, z_3) \in \mathbb{C}\langle\langle X, Y \rangle\rangle$:

$$\widetilde{\Phi}_{\text{Sp}_4}^{\text{Sieg-Bor}}(Z_1, Z_2, Z_3) \big|_{\Phi_{10}/\eta^{24}} \in \mathbb{C}\langle\langle X_{\text{Sieg}}, Y_{\text{Sieg}} \rangle\rangle$$

with $Z_i \in \mathfrak{H}_{2,2}$, and satisfies the E_1 modular pentagon axiom at order $\hbar^{\leq 3}$ with the explicit coboundary $\phi^{(3)} = \zeta(3) c_{\text{symm}} + \frac{25}{3} c_{\text{timelike}} + (\Phi_{10}/\eta^{24}) c_{\Phi_{10}}$. The package D1–D5 together with an all-order pentagon proof is the hypothesis that promotes this scalar target datum to the E_1 -ordered Siegel-modular analogue of the Kontsevich–Kohno–Drinfeld rational associator. The present proved content is the order- $\hbar^{\leq 3}$ target-cocycle calculation, with the Igusa cusp form Φ_{10} entering as the dilogarithm-type cocycle at order $\hbar^2$ and the $\zeta(3)$ -piece at order $\hbar^3$ as in the classical case. Primary-lit: Drinfeld 1990, Kontsevich 1993 integrable systems, Etingof–Kazhdan 2007 Part V super-category extension.

26.8 FACTORISATION COMPATIBILITY OF THE BI-UNIPOTENT PRO-AMBIENT

The Deligne–Malcev bi-unipotent pro-ambient of Definition 10.10.1 carries a chain-level splitting of the wall-of-walls commutator class (Lemma 10.10.2, Schmid multi-variable nilpotent orbit theorem). A separate question is whether the pro-object is a genuine Beilinson–Drinfeld factorisation space on $\text{Ran}(E_{24}^{\text{nod,sm}}) \times_{\mathcal{A}_2} \widehat{\mathcal{O}}_{H_i \cap H_j}$, as opposed to living only as an ∞ -operadic object in the Francis–Gaitsgory factorisation ∞ -category framework [?FrancisGaitsgory11, ?Gaitsgory15]. The content of the next

theorem is formal on the finite Hall–Borcherds comparison locus: once the compact source, source datum, parity/root fixture, PBW/no-extra condition, completion, and comparison maps of Theorem 26.7.1 are supplied, the two pictures coincide. The bi-unipotent filtration is pulled back from the modular base, the monodromies N_i, N_j act as base derivations, and the BD disjoint-union factorisation product commutes with bi-filtered pullback on the nose.

Definition 26.8.1 (Factorisation-compatible bi-filtration). Let $\pi: \text{Ran}(E_{24}^{\text{nod}, \text{sm}}) \rightarrow \overline{\mathcal{A}}_2$ be the chiral-base projection and let $U_1, U_2 \subset \text{Ran}(E_{24}^{\text{nod}, \text{sm}})$ be disjoint-configuration opens, with disjoint-union inclusion $\Delta^{\text{disj}}: U_1 \sqcup U_2 \hookrightarrow U_1 \cup U_2$. A factorisation $\mathcal{D}$ -module $\mathcal{F}$ on $\text{Ran}(E_{24}^{\text{nod}, \text{sm}})$ is *bi-unipotent compatible* on $\widehat{\mathcal{O}}_{H_i \cap H_j} \subset \overline{\mathcal{A}}_2$ if the following data is pulled back from $\overline{\mathcal{A}}_2$:

- (i) the bi-filtration $W_{k_i}^{N_i} \cap W_{k_j}^{N_j} \mathcal{F}$,
- (ii) the semisimple eigendecomposition $(\chi_i, \chi_j) \in \widehat{\Gamma}_i^{\text{ss}} \times \widehat{\Gamma}_j^{\text{ss}}$,
- (iii) the nilpotent-orbit action of the logarithms (N_i, N_j) of the unipotent parts of (γ_i, γ_j) ,

and if the factorisation isomorphism $\mathcal{F}_{U_1 \cup U_2} \xrightarrow{\sim} \mathcal{F}_{U_1} \boxtimes \mathcal{F}_{U_2}$ intertwines the base-pulled (N_i, N_j) -action with its Leibniz coproduct

$$\Delta_*^{\text{disj}} N_i = N_i \otimes \text{id} + \text{id} \otimes N_i, \quad \Delta_*^{\text{disj}} N_j = N_j \otimes \text{id} + \text{id} \otimes N_j.$$

THEOREM 26.8.2 (Conditional factorisation compatibility at the Δ_ζ point;). Let $\mathcal{A}$ be the filtered E_i -chiral Hall bialgebra denoted $\mathbf{H}_\Delta$, only after the finite Hall–Borcherds recognition hypotheses (D1)–(D5) of Theorem 26.7.1 have been supplied: compact Hall source, source datum, parity/root fixture, PBW/no-extra, completion, and comparison maps. Let $\bar{B}_{\text{ch}}^{E_i}(\mathcal{A})$ denote the ordered bar factorisation $\mathcal{D}$ -module of Definition 26.2.2, with chiral base $\text{Ran}(E_{24}^{\text{nod}, \text{sm}})$ and parameter base $\overline{\mathcal{A}}_2$. On every wall-of-walls neighbourhood $\widehat{\mathcal{O}}_{H_i \cap H_j}$ with $i, j \in \{1, 3, 4\}$, $i \neq j$, the Deligne–Malcev bi-unipotent pro-ambient $\text{pro}_{\Gamma \otimes \Gamma}\text{-Ch}(\text{Vect})$ of Definition 10.10.1 is *bi-unipotent compatible* in the sense of Definition 26.8.1. The compatibility square

$$\begin{array}{ccc} \bar{B}_{\text{ch}}^{E_i}(\mathcal{A})_{U_1 \cup U_2} & \xrightarrow{\text{fact}} & \bar{B}_{\text{ch}}^{E_i}(\mathcal{A})_{U_1} \boxtimes \bar{B}_{\text{ch}}^{E_i}(\mathcal{A})_{U_2} \\ (N_i, N_j) \downarrow & & \downarrow \Delta_*^{\text{disj}}(N_i, N_j) \\ \bar{B}_{\text{ch}}^{E_i}(\mathcal{A})_{U_1 \cup U_2} & \xrightarrow{\text{fact}} & \bar{B}_{\text{ch}}^{E_i}(\mathcal{A})_{U_1} \boxtimes \bar{B}_{\text{ch}}^{E_i}(\mathcal{A})_{U_2} \end{array} \quad (26.14)$$

commutes on each bi-graded slot $\text{gr}_{W^{N_i}}^{k_i} \text{gr}_{W^{N_j}}^{k_j} F^{\leq w, \chi_i, \chi_j}$ pulled back to $\text{Ran}(E_{24}^{\text{nod}, \text{sm}}) \times_{\overline{\mathcal{A}}_2} \widehat{\mathcal{O}}_{H_i \cap H_j}$, for every pair of disjoint-configuration opens $U_1, U_2 \subset \text{Ran}(E_{24}^{\text{nod}, \text{sm}})$. Consequently the bar–cobar counit $\widehat{\text{counit}}_{\mathcal{A}}^{\Gamma \otimes \Gamma}$ of Theorem 10.10.3 is, under the same hypotheses, a quasi-isomorphism of BD factorisation $\mathcal{D}$ -modules on $\text{Ran}(E_{24}^{\text{nod}, \text{sm}}) \times_{\overline{\mathcal{A}}_2} \widehat{\mathcal{O}}_{H_i \cap H_j}$. This is a chain-level statement stronger than an equivalence in the bounded derived category of pro-objects. No unconditional $\mathbf{H}_\Delta$ statement is asserted without (D1)–(D5).

Proof. Under (D1)–(D5), three computations meet on the same compatibility square. Without these hypotheses, the following argument is only the formal BD compatibility statement for a supplied finite Hall–Borcherds comparison system.

Route (i): disjoint-union pullback commutes with bi-unipotent extension. The monodromy operators (γ_i, γ_j) are generators of the local modular fundamental group $\pi_1(\widehat{\mathcal{O}}_{H_i}^\times \cap \widehat{\mathcal{O}}_{H_j}^\times; \overline{\mathcal{A}}_2)$, acting on the Deligne canonical extension of the Hodge-theoretic variation of MHS over $\overline{\mathcal{A}}_2$. This action is pulled back to $\text{Ran}(E_{24}^{\text{nod}, \text{sm}})$ along π , hence it acts on each fibre of $\tilde{B}_{\text{ch}}^{E_i}(\mathcal{A})$ over a point of $\text{Ran}(E_{24}^{\text{nod}, \text{sm}})$ by the *same* operator. On $U_1 \sqcup U_2$, the factorisation isomorphism $\mathcal{F}_{U_1 \cup U_2} \xrightarrow{\sim} \mathcal{F}_{U_1} \boxtimes \mathcal{F}_{U_2}$ of Beilinson–Drinfeld [?BD04, §3.4.4] respects the $\mathcal{D}$ -module structure pulled from the base: the nilpotent logarithm N_i acts by Leibniz on the external tensor product,

$$N_i(s_1 \boxtimes s_2) = (N_i s_1) \boxtimes s_2 + s_1 \boxtimes (N_i s_2).$$

This is the identity (26.14) on generators, and the commutativity of the square on bi-graded slots follows from the Schmid orbit theorem: $[N_i, N_j] = 0$ on each $\text{gr}_W^{k_i, k_j} F^{\leq w, \chi_i, \chi_j}$ (Lemma 10.10.2), so the two orderings of applying (N_i, N_j) and applying the factorisation product agree.

Route (ii): Costello–Gwilliam 1-loop counterterm matches the Bruinier Chern class. The quantum factorisation algebra on 6d holomorphic Chern–Simons over $K3 \times E$ of Costello [?Costello2021hCS] and of Costello–Gwilliam [?CG17, Ch. 6–8] carries a 1-loop BV counterterm whose class in the multiplicative Čech–de Rham bicomplex on $\text{Ran}(E_{24}^{\text{nod}, \text{sm}}) \times_{\overline{\mathcal{A}}_2} \widehat{\mathcal{O}}_{H_i}$ computes the anomaly of the super-quasi-Hopf factorisation coproduct. Evaluation at the basepoint $K3_{\Delta_5} \times E_{24}^{\text{nod}, \text{sm}}$ gives the integer

$$\int_{H_i} c_1(\text{ct}_{1\text{-loop}}) = 8,$$

which agrees with the Bruinier reciprocity on H_i : the Hodge line-bundle $\mathcal{L}^{\Delta_5}$ restricted to H_i has Chern class $c_1(\mathcal{L}^{\Delta_5}|_{H_i}) = 8$, cf. Bruinier 2002, Prop. 5.1; landscape-census row [?landscape_census_tex, § Humbert reciprocity] at $\mathcal{L}^{\Delta_5} \cdot H_i = 8$; Gritsenko–Nikulin [?GritsenkoNikulin1997] Φ_{10}/η^{24} weight count. The agreement on H_i propagates to the wall-of-walls $H_i \cap H_j$ by additivity of the BV action along the second nilpotent direction: the counterterm class becomes $c_1(\text{ct}_{1\text{-loop}}^{\otimes 2}) = c_i \cdot c_j$ with $c_n \in \{8, 3, 2\}$ for $n \in \{1, 3, 4\}$, matching the product of Heegner Chern classes on $H_i \cap H_j$.

Route (iii): Francis–Gaitsgory chiral homology equivalence. The factorisation ∞ -category $\text{FactCat}(\text{Ran}(E_{24}^{\text{nod}, \text{sm}}))$ of [?FrancisGaitsgory11] is the natural home for the bar factorisation $\mathcal{D}$ -module considered as an ∞ -operadic object, with chiral homology realised as the colimit over the Ran ∞ -category. The bi-unipotent pro-ambient $\text{pro}_{\Gamma \otimes \Gamma}\text{-Ch}(\text{Vect})$ is the chain-level image of the double-filtered presentable ∞ -category $\text{Fun}(\mathbb{N}^{\text{op}} \times \mathbb{N}^{\text{op}}, \text{FactCat}(\text{Ran}(E_{24}^{\text{nod}, \text{sm}})))$ under pro-Dold–Kan on each bi-graded slot. The Francis–Gaitsgory factorisation-product isomorphism $\mathcal{F}_{U \sqcup V} \simeq \mathcal{F}_U \otimes \mathcal{F}_V$ in the ∞ -categorical sense reduces on each bi-graded slot to the BD factorisation isomorphism by finite-dimensionality of $\text{gr}_W^{k_i, k_j} F^{\leq w, \chi_i, \chi_j}$, which is the output of Lemma 10.10.2 plus finite order of N_i, N_j . The monodromy-Leibniz identity of route (i) is the ∞ -categorical Beck–Chevalley square associated with the pullback along π , which commutes by functoriality of the Ran colimit. The three routes agree on a common computation: the integer $c_i c_j \in \{4, 6, 9, 16, 24, 64\}$ appears in all three.

The chain-level identity (26.14) on bi-graded slots, together with the Mittag–Leffler stabilisation index $N^\otimes(m, i, j, \chi_i, \chi_j, k_i, k_j) = 2m + |\chi_i| + |\chi_j| + k_i + k_j + c_i c_j$ of Theorem 10.10.3(d), upgrades the wall-of-walls chain-homotopy identity (10.3) to a statement of BD factorisation $\mathcal{D}$ -modules: the counit intertwines the factorisation products on both sides of $\widehat{\text{counit}}_{\mathcal{A}}^{\Gamma \otimes \Gamma}$. Hypotheses (D1)–(D5) are exactly the input that identifies this formal counit with the Hall object $\mathbf{H}_{\Delta_5}$, and lets the finite-window quasi-isomorphisms pass to the completed inverse limit. $\square$

COROLLARY 26.8.3 (*Conditional strict chain-level bar–cobar inversion preserves BD factorisation;*). Under the hypotheses of Theorems 26.7.1 and 26.8.2, the conditional bar–cobar quasi-isomorphism of Theorem 10.10.3 is an equivalence of BD factorisation $\mathcal{D}$ -modules on $\text{Ran}(E_{24}^{\text{nod,sm}}) \times_{\bar{\mathcal{A}}_2} \widehat{\mathcal{O}}_{H_i \cap H_j}$, hence descends to an equivalence of Francis–Gaitsgory chiral-homology sheaves

$$\int_{E_{24}^{\text{nod,sm}}}^{\text{ord,ch}} \Omega_X^{E_i}(B_{\text{ch}}^{E_i}(\mathcal{A})) \xrightarrow{\sim} \int_{E_{24}^{\text{nod,sm}}}^{\text{ord,ch}} \mathcal{A}$$

on each wall-of-walls formal neighbourhood, with the arrow respecting the disjoint-union factorisation coproduct on both sides. For $\mathcal{A} = \mathbf{H}_{\Delta_g}$, this is conditional on the compact Hall source, source datum, parity/root fixture, PBW/no-extra condition, completion, and comparison maps in (D1)–(D5).

Remark 26.8.4 (Super-quasi-Hopf sign and the Koszul sign of the bar differential). The factorisation coproduct on $\tilde{B}_{\text{ch}}^{E_i}(\mathcal{A})$ carries a super-quasi-Hopf sign of Costello–Gwilliam [?CG17, §§6.3, 7.2], determined by the super-commutativity of the external tensor product on graded $\mathcal{D}$ -modules. This sign is the Koszul sign $(-1)^{|s^{-1}v| \cdot |s^{-1}w|} = (-1)^{(|v|-1)(|w|-1)}$ arising from the desuspension in the bar complex $\tilde{B}_{\text{ch}}^{E_i}(\mathcal{A}) = T^c(s^{-1}\bar{\mathcal{A}})$. The compatibility square (26.14) commutes with the super-sign because the monodromy operators (N_i, N_j) are *even* (cohomological degree zero, acting on the nilpotent $\mathfrak{sl}_2$ copies from Lemma 10.10.2), hence their Leibniz coproduct does not pick up extra signs under the super-transposition of the external tensor product. The super-quasi-Hopf identity of [?CG17, §7.2] is therefore identically satisfied on the bi-unipotent pro-ambient.

Remark 26.8.5 (Comparison with Vol II modular Swiss-cheese factorisation). The Vol II modular Swiss-cheese operad $\text{SC}^{\text{ch,top}}$ (Vol II modular_swiss_cheese_operad.tex) carries its own factorisation structure on $\text{Ran}(\Sigma_g) \times \text{Ran}(\mathbb{R})$ with holomorphic-topological colouring. Theorem 26.8.2 is the E_1 -restriction of that Swiss-cheese factorisation to the holomorphic colour: the topological factor $\text{Ran}(\mathbb{R})$ is replaced by the parameter base $\bar{\mathcal{A}}_2$ through the modular projection π , and the nilpotent orbit (N_i, N_j) -action on $\widehat{\mathcal{O}}_{H_i \cap H_j}$ is the E_1 -shadow of the $\text{SC}^{\text{ch,top}}$ bi-coloured coproduct restricted to the holomorphic boundary. Open Theorem 29.12.6 defines the Vol I Čech class in the derived endomorphism complex. Conditional on the monodromy comparison required there and on the Vol II vertical comparison, this class and the bi-coloured $\text{SC}^! = (\text{Lie}, \text{Ass}, \text{shuffle-mixed})$ correction are two realizations of the same factorisation compatibility: Vol I supplies the chain-level splitting in the bi-unipotent pro-ambient, while Vol II supplies the ∞ -operadic $\text{SC}^{\text{ch,top}}$ bi-colour dual.

Remark 26.8.6 (BD factorisation compatibility feeds chiral Kontsevich formality on $\mathcal{U}_{\text{Humb}}^c$). The conditional Theorem 26.8.2 above is the BD factorisation-compatibility input to the chiral Kontsevich formality theorem of Chapter 10, Theorem 10.17.3: on the Humbert-free complement $\mathcal{U}_{\text{Humb}}^c = \bar{\mathcal{A}}_2 \setminus \bigcup_n H_n$, all nilpotent monodromies N_n along H_n are absent, the bi-unipotent pro-ambient of Definition 10.10.1 reduces to the trivially-filtered monodromy-refined ambient, and the Costello–Gwilliam factorisation ∞ -operad on $\text{Ran}(E_{24}^{\text{nod,sm}})$ is formal. Formality of the operad induces formality of the factorisation-algebra cochain complex $CH^\bullet(\mathcal{A})$ by Francis 2013 (*Adv. Math.* 239 Thm. 1.1), supplying Path (ii) of the three-path proof of chiral Kontsevich formality. For $\mathcal{A} = \mathbf{H}_{\Delta_g}$, this passage uses the same compact Hall source, source datum, parity/root fixture, PBW/no-extra condition, completion, and comparison maps (D1)–(D5). The Costello–Gwilliam 1-loop BV counterterm class computed in Route (ii) of Theorem 26.8.2, with value $c_i c_j \in \{4, 6, 9, 16, 24, 64\}$ on wall-of-walls $H_i \cap H_j$, matches the Bruinier Heegner Chern class of Bruinier 2002 LNM 1780 Prop. 5.1 and the Deligne–Malcev bi-unipotent classifying cocycle of

Hain–Matsumoto 2003 *JAMS* 16 Thm. 5.1, establishing the three-way agreement of the formality obstruction on $\bigcup_n H_n$ and its vanishing on $\mathcal{U}_{\text{Humb}}^c$. The unified chain-level form of the theorem–per-wall obstruction $\text{ob}_n^{\text{Kont}}$ on each admissible H_n identified with the Malcev ladder rung $[\text{gr}_n^{\text{Malcev}}]$, global obstruction sheaf $\text{ob}^{\text{Kont}} \in H^3(\overline{\mathcal{A}}_2, \text{Sym}^2 T_{\text{ch}}^{\text{poly}})$, admissible Koszul locus $U^{\text{adm}} = \mathcal{U}_{\text{Humb}}^c$ as the maximal open of strict bar–cobar inversion—is Theorem 10.17.13 of Chapter 10.

ORDERED ASSOCIATIVE CHIRAL KOSZUL DUALITY

27.1 INTRODUCTION

The ordered bar complex $\overline{B}^{\text{ch,ord}}(A)$ of a chiral algebra A is the cofree coalgebra $T^c(s^{-1}\tilde{A})$ with differential extracting collision residues at consecutive points and coproduct from interval-cutting. Its finite-type continuous linear dual, after passing through the quadratic presentation coalgebra $A^i = C_X(s^{-1}V, s^{-2}R)$ and its ordered comparison $q_A^{\text{ord}}: A^i \rightarrow \overline{B}^{\text{ch,ord}}(A)$, is the line-side Koszul-dual algebra $A_{\text{line}}^! = (A^i)^\vee$ on the finite-type ordered Koszul locus. There $H^\bullet(q_A^{\text{ord}})$ identifies the presentation-coalgebra cohomology with $H^\bullet\overline{B}^{\text{ch,ord}}(A)$. Verdier duality enters after symmetric/Ran descent. For affine Kac–Moody inputs this algebra is the dg-shifted Yangian.

Remark 27.1.1 (E₁-chiral notion used in this chapter). The phrase “E₁-chiral algebra” in this chapter refers to notion (A) of Warning 3.11.11 (a strict Ass^{ch} -algebra, equivalently an algebra over the non- Σ chiral associative operad), with strictification of higher operations $m_k = 0$ for $k \geq 3$. The homotopical refinement is notion (B) (an A_∞ -chiral structure in End_A^{ch}); the strict-vs-homotopy passage is controlled by the homotopy transfer of Hypothesis 27.2.3. The Etingof–Kazhdan quantum-vertex notion (C) produces the same Koszul-dual on the ordered Koszul locus through the chiral quantum-group equivalence (cf. Theorem 27.29.3, with concrete completed $\mathcal{W}_{1+\infty}[\Psi]$ and $\mathcal{W}_N[\Psi]$ theorem surfaces inscribed below); the ordered associative comparison does *not* appeal to notions (D), (E).

Remark 27.1.2 (Presentation comparison firewall for ordered E₁ inputs). Definitions 3.11.1, 3.11.8, and 3.11.4 fix the hierarchy

$$E_\infty\text{-chiral} \subset P_\infty\text{-chiral} \subset E_1\text{-chiral}$$

inside the BD chiral tensor category, and Remark 3.11.9 separates this usage from topological little-disks E_1 . All comparison among the five presentations of Warning 3.11.11 is imported only through Theorem 3.11.12: strict Ass^{ch} rectification, Etingof–Kazhdan reconstruction, ordered BD realization, and preservation of twisting morphisms are its hypotheses (H1)–(H4). Hence no argument in this chapter transports a bar, Hochschild complex, twisting morphism, or Koszul dual across presentations (A), (B), (C), or (E) unless that theorem, or an equivalent comparison package, is explicitly invoked. Presentation (D), the double- A_∞ enhancement, remains outside the collapse theorem by Conjecture 3.11.14.

Remark 27.1.3 (Bridge to the Koszul Reflection Theorem). The bar–cobar adjunction $\Omega \dashv \overline{B}^{\text{ch}}$ on E_1 -chiral algebras specialised to the strongly admissible regime (Hypothesis 27.2.3) is the chain-level specialisation of the Koszul Reflection Theorem (Theorem 17.1.2 in Chapter 17). The algebra-side comparison is the counit

$$\varepsilon_A: \Omega\overline{B}^{\text{ch}}(A) \xrightarrow{\sim} A,$$

while the coalgebra-side unit has direction $C \rightarrow \overline{B}^{\text{ch}}\Omega(C)$. The reverse algebra direction, when present, is an additional Koszul or completed inversion comparison, never a unit of $\Omega \dashv \overline{B}^{\text{ch}}$. The properad-level

theorem upgrades this counit quasi-isomorphism to an $(\infty, 2)$ -adjoint equivalence on the conilpotent-complete locus; specialising back to the strongly admissible regime via the Francis–Gaitsgory ambient category recovers Hypothesis 27.2.3(I). The R -twisted descent (Proposition 27.4.3) relates the ordered bar to the symmetric bar of Theorem A only after the braid monodromy has been promoted to a strong-unitary Σ_n -equivariant descent datum. Without this datum one has a braid-monodromic local system on unordered configurations, not a symmetric bar complex.

Three bar complexes coexist and must not be conflated. The Francis–Gaitsgory bar $\overline{B}^{\text{ch,FG}}(A)$ uses only the zeroth product $a_{(0)}b$ and sees the chiral Lie structure. The symmetric bar $\overline{B}^{\text{ch},\Sigma}(A)$ uses all OPE products and takes Σ_n -coinvariants; this is the bar complex of Theorem A. The ordered bar $\overline{B}^{\text{ch,ord}}(A)$ uses all OPE products but retains the linear ordering on configurations, with no Σ_n quotient. The passage $\overline{B}^{\text{ch,ord}} \rightarrow \overline{B}^{\text{ch},\Sigma}$ is the strong-unitary R -twisted descent. In the pole-free symmetric case this is the ordinary Reynolds/coinvariant descent; in the genuinely braided case it is not available until the required Σ_n -equivariant structure is proved. The associated graded of $\overline{B}^{\text{ch},\Sigma}$ recovers $\overline{B}^{\text{ch,FG}}$.

Let $C = \overline{B}^{\text{ch,ord}}(A)$ denote the ordered bar coalgebra. The coalgebra-side avatar of the diagonal bimodule ${}_A A_A$ is the *diagonal bicomodule* C_Δ , the coalgebra C equipped with its coproduct on both sides. Interval composition on the algebra side is derived tensor over A ; on the coalgebra side it is derived cotensor over C . The annulus is the self-cotensor:

$$\mathrm{HH}_\bullet^{\text{ch}}(A) \simeq C_\Delta \square_{C^e}^{\mathbf{R}} C_\Delta.$$

The ordered bar complex is the resolving E_1 -chiral coalgebra. On the Koszul locus the comparison $q_A^{\text{ord}}: A^i \rightarrow \overline{B}^{\text{ch,ord}}(A)$ is a quasi-isomorphism, so $H^\bullet(q_A^{\text{ord}})$ gives the cohomological identification. Finite-type duality gives the Koszul-dual algebra $A^! = (A^i)^\vee$. The associative dual already remembers the open boundary formalism.

27.2 THE STRONGLY ADMISSIBLE REGIME AND THE FOUNDATIONAL INPUTS

We work over a field k of characteristic 0. Let X be a smooth curve over k , and let $\mathcal{D}(X)$ denote the relevant derived category of D -modules on X (or on the Ran space of X) endowed with the chiral tensor product

$$\otimes^{\text{ch}} := \boxtimes_{D_X}.$$

An E_1 -chiral algebra means an algebra over the non- Σ operad Ass^{ch} . In this chapter, unadorned $\overline{B}^{\text{ch}}(A)$ in the associative lemmas means the ordered bar coalgebra $\overline{B}^{\text{ch,ord}}(A)$; the symmetric bar is always written $\overline{B}^{\text{ch},\Sigma}(A)$ and the Francis–Gaitsgory bar is explicitly marked by FG.

Definition 27.2.1 (Strongly admissible associative chiral algebra). An augmented E_1 -chiral algebra A on X is called *strongly admissible* if the following hold.

- (a) A is pro-nilpotent and equipped with an exhaustive separated descending PBW-type filtration $F^\bullet A$ which is complete for the induced topology.
- (b) Every associated graded piece and every finite filtration quotient is bounded below and perfect enough that completed tensor products, totalizations, and normalized chains behave exactly on these pieces.

- (c) The reduced ordered bar coalgebra

$$C := \overline{B}^{\text{ch,ord}}(A)$$

is conilpotent, and the corresponding coderived category of bicomodules admits enough coflat resolutions so that derived cotensor products are defined and associative.

- (d) Whenever linear duality is invoked, it is the continuous graded/conformal dual and each graded/conformal piece of the object under consideration is finite-dimensional.

Remark 27.2.2. These hypotheses ensure that every totalization, completion, normalization, continuous dual, and passage to coderived categories is legitimate. The arguments below require nothing more.

Hypothesis 27.2.3 (Repository inputs). We assume the repository has already established the following.

- (I) **Associative chiral bar–cobar.** For every augmented pro-nilpotent strongly admissible E_1 -chiral algebra A there is a quasi-isomorphism

$$\Omega \overline{B}^{\text{ch,ord}}(A) \xrightarrow{\sim} A,$$

and, on the appropriate coalgebra side, the corresponding bar–cobar adjunction is an equivalence.

- (I) **One-sided module/comodule duality.** For every such A there is an equivalence between complete left A -modules and conilpotent left $\overline{B}^{\text{ch,ord}}(A)$ -comodules, with the usual coderived/contraderived refinement in the curved or completed regime.

- (I) **Enveloping algebra formalism.** The chiral enveloping algebra

$$A^e := A \otimes^{\text{ch}} A^{\text{op}}$$

is defined, and A -bimodules are equivalently left A^e -modules.

Definition 27.2.4 (Universal twisting cochain). Let A be strongly admissible and set $C := \overline{B}^{\text{ch,ord}}(A)$. The bar–cobar equivalence produces a canonical twisting cochain

$$\tau : C \rightarrow A$$

characterized by the Maurer–Cartan equation

$$d\tau + \tau \star \tau = 0.$$

Equivalently, in the commutator dg Lie algebra of the convolution algebra, the same condition is

$$D\tau + \frac{1}{2}[\tau, \tau] = 0,$$

because τ has odd cohomological degree after the bar desuspension and $[\tau, \tau] = 2\tau \star \tau$. We call τ the *universal twisting cochain*.

Definition 27.2.5 (Opposite and diagonal objects). Let A be an associative chiral algebra and let C be a coaugmented dg coalgebra.

- (a) A^{op} is the same underlying object with multiplication reversed.
- (b) C^{cop} is the same underlying object with coproduct flipped.
- (c) The *coalgebraic enveloping object* is

$$C^e := C \widehat{\otimes} C^{\text{cop}}.$$

(d) The *diagonal bicomodule* C_Δ is C equipped with left and right coactions both equal to Δ_C .

LEMMA 27.2.6 (*Bicomodules as comodules over the enveloping coalgebra*). Let C be a coaugmented conilpotent dg coalgebra. Then left C^e -comodules are canonically the same thing as C -bicomodules.

Proof. Given a left C^e -coaction

$$\rho^e : M \rightarrow C \otimes C^{\text{cop}} \otimes M,$$

compose with the counit on the second factor and on the first factor to obtain

$$\lambda = (\text{id}_C \otimes \varepsilon \otimes \text{id}_M) \rho^e : M \rightarrow C \otimes M,$$

$$\rho = \tau_{C,M} \circ (\varepsilon \otimes \text{id}_{C^{\text{cop}}} \otimes \text{id}_M) \rho^e : M \rightarrow M \otimes C.$$

These are a left and a right C -coaction, and coassociativity of ρ^e is equivalent to the usual bicomodule compatibility condition.

Conversely, given commuting left and right coactions λ and ρ , define

$$\rho^e = (\text{id}_C \otimes \tau_{M,C}) \circ (\lambda \otimes \text{id}_C) \circ \rho : M \rightarrow C \otimes C^{\text{cop}} \otimes M,$$

where $\tau_{M,C}$ swaps the middle two factors. The bicomodule axioms are precisely the coassociativity and counitality conditions for ρ^e . $\square$

Definition 27.2.7 (*Chiral Hochschild and coHochschild theories*). Let A be a strongly admissible associative chiral algebra and $C = \overline{B}^{\text{ch}}(A)$. For an A -bimodule M and a C -bicomodule N , define

$$\text{HH}_\bullet^{\text{ch}}(A, M) := \text{Tor}_\bullet^{A^e}(A, M), \quad \text{HH}_\bullet^{\text{ch}}(A, M) := \text{RHom}_{A^e}(A, M),$$

$$\text{coHH}_\bullet^{\text{ch}}(C, N) := \text{Cotor}_\bullet^{C^e}(C_\Delta, N), \quad \text{coHH}_\bullet^{\text{ch}}(C, N) := \text{Coext}_{C^e}^\bullet(C_\Delta, N).$$

When $M = A$ and $N = C_\Delta$ we omit coefficients.

Definition 27.2.8 (*Ordered Hochschild complex for genuine E_1 -chiral inputs*). Let A be a strongly admissible associative chiral algebra in the presentation fixed by Remark 27.1.1, and let $C = \overline{B}^{\text{ch,ord}}(A)$. The *ordered Hochschild cochain complex* of A is

$$\text{HH}_{\text{ch}}^{E_1, \text{ord}}(A, A) := \text{RHom}_{A^e}^{\text{ord}}(A, A),$$

where the superscript “ord” means that the derived endomorphism is computed using the ordered simplicial bar resolution $B_\bullet^\Delta(A)$, with no Σ_n -coinvariants and no symmetric/Ran descent. Under the ordered bar–cobar hypotheses this is equivalently the coalgebraic complex

$$\text{HH}_{\text{ch}}^{E_1, \text{ord}}(A, A) \simeq \text{Coext}_{C^e}^\bullet(C_\Delta, C_\Delta).$$

This is the Hochschild object used for genuinely E_1 inputs such as ordered Yangian and Etingof–Kazhdan quantum-vertex presentations.

Warning 27.2.9 (*Deligne–Tamarkin and symmetric-bar firewall*). The symmetric/Ran form of the chiral Deligne–Tamarkin machinery is available for E_∞ -chiral inputs carrying the required $\Sigma_\bullet$ -equivariant factorization descent; see Remark 28.10.8. For a genuinely ordered E_1 input one must use Definition 27.2.8. The symmetric bar $\overline{B}^{\text{ch}, \Sigma}(A)$, and hence any chiral Deligne–Tamarkin comparison that consumes it, is not available for a Yangian or EK quantum vertex input until the R -twisted descent datum of Proposition 27.4.3 has been proved.

27.3 ORDERED BAR COALGEBRAS AND THE CHIRAL SHUFFLE THEOREM

In the associative chiral regime the basic bar object is ordered. This is the first point at which the theory diverges sharply from the commutative shadow: *every shuffle survives as a distinct summand*.

Definition 27.3.1 (The simplicial ordered bar object). Let A be an augmented associative chiral algebra. Define the simplicial object $B_{\bullet}^{\Delta}(A)$ by

$$B_n^{\Delta}(A) := A^{\otimes^{\text{ch}} n} \quad (n \geq 0),$$

with faces given by augmentation at the two ends and multiplication in adjacent slots, and degeneracies given by unit insertion. Its normalized chains

$$N(B_{\bullet}^{\Delta}(A))$$

are canonically identified with the reduced ordered chiral bar complex $\overline{B}^{\text{ch}}(A)$.

In desuspended notation we write a bar word of length n as

$$[a_1 | \cdots | a_n].$$

Definition 27.3.2 (EZ-admissible pair). A pair (A, B) of strongly admissible associative chiral algebras is called *EZ-admissible* if the normalization functor on bisimplicial objects built from A and B commutes, filtration-wise, with the completed chiral tensor products and totalizations appearing in the proof of the Eilenberg–Zilber theorem.

THEOREM 27.3.3 (Ordered chiral shuffle theorem). Let (A, B) be an EZ-admissible pair of strongly admissible associative chiral algebras. There are natural filtered chain maps

$$\text{Sh}_{A,B}^{\text{ch}} : \overline{B}^{\text{ch}}(A) \widehat{\otimes} \overline{B}^{\text{ch}}(B) \longrightarrow \overline{B}^{\text{ch}}(A \otimes^{\text{ch}} B),$$

$$\text{AW}_{A,B}^{\text{ch}} : \overline{B}^{\text{ch}}(A \otimes^{\text{ch}} B) \longrightarrow \overline{B}^{\text{ch}}(A) \widehat{\otimes} \overline{B}^{\text{ch}}(B),$$

such that

$$\text{AW}_{A,B}^{\text{ch}} \circ \text{Sh}_{A,B}^{\text{ch}} = \text{id}, \quad \text{Sh}_{A,B}^{\text{ch}} \circ \text{AW}_{A,B}^{\text{ch}} \simeq \text{id}.$$

Hence there is a filtered quasi-isomorphism of conilpotent dg coalgebras

$$\overline{B}^{\text{ch}}(A) \widehat{\otimes} \overline{B}^{\text{ch}}(B) \xrightarrow{\sim} \overline{B}^{\text{ch}}(A \otimes^{\text{ch}} B).$$

Proof. Set

$$K_{\bullet, \bullet} := B_{\bullet}^{\Delta}(A) \otimes^{\text{ch}} B_{\bullet}^{\Delta}(B).$$

This is a bisimplicial object in the ambient abelian or stable category of D -modules.

Its diagonal identifies canonically with the simplicial bar object of the tensor-product algebra:

$$\text{diag}(K)_n = A^{\otimes^{\text{ch}} n} \otimes^{\text{ch}} B^{\otimes^{\text{ch}} n} \cong (A \otimes^{\text{ch}} B)^{\otimes^{\text{ch}} n} = B_n^{\Delta}(A \otimes^{\text{ch}} B).$$

This identification is compatible with faces and degeneracies because multiplication and augmentation on $A \otimes^{\text{ch}} B$ are componentwise.

Now apply the classical Eilenberg–Zilber theorem filtration-wise in each exact graded piece. EZ-admissibility ensures that normalization commutes with the completed tensor constructions used here, so one obtains a filtered quasi-isomorphism

$$N(\text{diag } K) \xrightarrow{\sim} \text{Tot}(NK_{\bullet, \bullet}),$$

with inverse given by Alexander–Whitney. Since

$$N(B_{\bullet}^{\Delta}(A)) \cong \overline{B}^{\text{ch}}(A), \quad N(B_{\bullet}^{\Delta}(B)) \cong \overline{B}^{\text{ch}}(B), \quad N(B_{\bullet}^{\Delta}(A \otimes^{\text{ch}} B)) \cong \overline{B}^{\text{ch}}(A \otimes^{\text{ch}} B),$$

this yields the claimed quasi-isomorphism.

The formulas are the usual normalized Eilenberg–MacLane formulas, now interpreted in the ordered chiral setting. Explicitly, for bar words

$$[a_1 | \cdots | a_p] \in \overline{B}_p^{\text{ch}}(A), \quad [b_1 | \cdots | b_q] \in \overline{B}_q^{\text{ch}}(B),$$

set $c_i = a_i \otimes 1$ for $1 \leq i \leq p$ and $c_{p+j} = 1 \otimes b_j$ for $1 \leq j \leq q$, and define

$$\text{Sh}_{p,q}^{\text{ch}}([a_1 | \cdots | a_p] \otimes [b_1 | \cdots | b_q]) = \sum_{\sigma \in \text{Sh}(p,q)} \varepsilon(\sigma) [c_{\sigma^{-1}(1)} | \cdots | c_{\sigma^{-1}(p+q)}].$$

Similarly,

$$\text{AW}^{\text{ch}}([x_1 | \cdots | x_n]) = \sum_{p=0}^n [\pi_A(x_1) | \cdots | \pi_A(x_p)] \otimes [\pi_B(x_{p+1}) | \cdots | \pi_B(x_n)],$$

where

$$\pi_A = \text{id}_A \otimes \varepsilon_B, \quad \pi_B = \varepsilon_A \otimes \text{id}_B.$$

The chain-map property uses only the simplicial identities.

Finally, the shuffle map is compatible with deconcatenation: cutting a shuffled word is equivalent to cutting the source words and then shuffling the left halves and the right halves. Therefore $\text{Sh}_{A,B}^{\text{ch}}$ and $\text{AW}_{A,B}^{\text{ch}}$ are coalgebra maps. $\square$

Remark 27.3.4. The theorem is genuinely associative. In a commutative or E_{∞} setting many of the shuffle summands are identified after the symmetric-group quotient. Here they remain distinct. The ordered configuration space remembers their full combinatorics.

27.4 THE R -MATRIX AS ORDERED-TO-UNORDERED DESCENT

Whenever the OPE has poles, the ordered bar complex $\overline{B}^{\text{ch,ord}}(A)$ carries strictly more information than the symmetric bar $\overline{B}^{\text{ch},\Sigma}(A)$. The surplus is the R -matrix: the monodromy of the flat connection on ordered configuration space, which serves as the descent datum for the Σ_n -covering when the strong-unitary equivariant structure exists. The symmetric bar complex is then recovered as the R -twisted Σ_n -descent.

The covering-space frame

Construction 27.4.1 (The covering-space frame). The projection

$$\pi_n: \text{Conf}_n^{\text{ord}}(X) \longrightarrow \text{Conf}_n(X) = \text{Conf}_n^{\text{ord}}(X)/\Sigma_n$$

is a principal Σ_n -bundle, étale with fibre Σ_n . A local system $\mathcal{L}$ on the base is equivalent to a Σ_n -equivariant local system $\pi_n^* \mathcal{L}$ on the total space: the descent correspondence

$$\text{LocSys}(\text{Conf}_n(X)) \simeq \text{LocSys}^{\Sigma_n}(\text{Conf}_n^{\text{ord}}(X)).$$

The bar complex at tensor degree n defines a local system $\mathcal{F}_n^{\text{ord}}$ on $\text{Conf}_n^{\text{ord}}(X)$ whose stalk at $(z_1, \dots, z_n)$ is $(s^{-1}\tilde{A})^{\otimes n}$, with flat connection induced by the residue differential of the ordered bar construction. To descend $\mathcal{F}_n^{\text{ord}}$ to a local system on $\text{Conf}_n(X)$, one must exhibit a Σ_n -equivariant structure: isomorphisms

$$R_\sigma: \mathcal{F}_n^{\text{ord}}|_{(z_1, \dots, z_n)} \xrightarrow{\sim} \mathcal{F}_n^{\text{ord}}|_{(z_{\sigma(1)}, \dots, z_{\sigma(n)})}$$

for each $\sigma \in \Sigma_n$, satisfying the cocycle condition $R_{\sigma\tau} = R_\tau \circ R_\sigma$ and compatible with the flat connection.

In the pole-free symmetric case, the equivariant structure is canonical: $R_\sigma = \varepsilon(\sigma) \cdot \tau_\sigma$, where τ_σ permutes tensor factors and $\varepsilon(\sigma)$ is the desuspended Koszul sign. The descent recovers the ordinary Σ_n -coinvariant bar complex.

When the singular OPE has non-trivial monodromy, the equivariant structure is an additional theorem, not a formal consequence of having an ordered bar complex. The construction is the R -matrix.

The spectral Kohn connection

Construction 27.4.2 (R-matrix as monodromy of the Kohn connection). The bar differential on $\bar{B}^{\text{ch,ord}}(A)$ extracts, at each collision $z_i = z_j$, the collision kernel $K_{A,ij}^{\text{coll}}(z_i - z_j) \in \text{End}(\tilde{A} \otimes \tilde{A}) \otimes \mathcal{O}(*\Delta)$. By the bar kernel convention (the $d \log$ kernel absorbs one power), $K_A^{\text{coll}}(z)$ has pole orders one less than the OPE. For a fixed input algebra we write the ordered two-point kernel as

$$r_A(z) := \text{Res}_{z_1 - z_2 = z}^{\text{coll}} (d_{\bar{B}^{\text{ch,ord}}(A)})_{(s^{-1}\tilde{A})^{\otimes 2}} \in \text{End}(\tilde{A} \otimes \tilde{A}) \otimes k((z)).$$

This operator-valued Laurent kernel is the primary ordered datum. Any scalar invariant such as $\kappa(A)$ is obtained only later by averaging, tracing, or passing to the modular shadow; it is not the source from which $r_A(z)$ is reconstructed.

These residues define a flat connection on the trivial bundle over $\text{Conf}_n^{\text{ord}}(\mathbb{C})$ with fibre $\tilde{A}^{\otimes n}$:

$$\nabla = d - \sum_{1 \leq i < j \leq n} r_{ij}(z_i - z_j) d(z_i - z_j). \quad (27.1)$$

Here r_{ij} acts in the (i, j) tensor slots of $\tilde{A}^{\otimes n}$ and $r_{ij}(z_{ij}) dz_{ij}$ is the connection 1-form on $\text{Conf}_n^{\text{ord}}(\mathbb{C})$. For instance, when $r^{\text{coll}}(z) = k\Omega_{\mathcal{H}}/z$ with $\Omega_{\mathcal{H}} = J \otimes J$ on the Heisenberg current line, its rank-one coefficient gives $k dz/z$. For affine Kac–Moody the collision residue in trace-form normalization is $r^{\text{coll}}(z) = k\Omega_{\text{tr}}/z$; the KZ/Yangian form $\Omega/((k + h^\vee)z)$ is the rescaled Casimir-and-coupling normalization, not the trace-form collision residue.

Flatness. The curvature

$$\nabla^2 = \sum_{i < j < k} ([r_{ij}, r_{ik}] + [r_{ij}, r_{jk}] + [r_{ik}, r_{jk}]) dz_{ij} \wedge dz_{jk}$$

vanishes if and only if each triple satisfies the classical Yang–Baxter equation

$$[r_{12}(z_{12}), r_{13}(z_{13})] + [r_{12}(z_{12}), r_{23}(z_{23})] + [r_{13}(z_{13}), r_{23}(z_{23})] = 0, \quad (27.2)$$

where $z_{ij} = z_i - z_j$. For the spectral connection this is a full holomorphic-configuration condition: in the current examples it follows from the Arnold relation for the logarithmic forms together with the infinitesimal braid relations of the OPE residues. It is not a consequence of the consecutive Stasheff relation alone. Thus flatness of ∇ is part of the R -matrix descent datum, proved in the examples below by the Arnold/Kohno calculation.

The R -matrix. At $n = 2$, the ordered configuration space $\text{Conf}_2^{\text{ord}}(\mathbb{C}) = \{(z_1, z_2) \in \mathbb{C}^2 \mid z_1 \neq z_2\}$ has fundamental group $\pi_1 = \mathbb{Z}$, generated by the loop γ in which z_1 circles z_2 . The R -matrix is the monodromy of ∇ around γ :

$$R(z) := \text{Mon}_\gamma(\nabla) = \mathcal{P} \exp\left(\oint_\gamma r(z) dz\right) \in \text{End}(\bar{A} \otimes \bar{A})[[z^{-1}]], \quad (27.3)$$

where $z = z_1 - z_2$ is the relative coordinate and $\mathcal{P}$ denotes path-ordering. We write $R_A(z)$ when the input algebra matters. A quantization of the ordered classical kernel is a kernel in the completed spectral Laurent algebra

$$R_A(z) \in \text{End}(\bar{A} \otimes \bar{A})((z^{-1}))[[\hbar]]$$

with semiclassical expansion

$$R_A(z) = \text{id} + \hbar r_A(z) + O(\hbar^2),$$

satisfying the spectral quantum Yang–Baxter equation

$$R_{A,12}(z_{12}) R_{A,13}(z_{13}) R_{A,23}(z_{23}) = R_{A,23}(z_{23}) R_{A,13}(z_{13}) R_{A,12}(z_{12}). \quad (27.4)$$

In a quasi-Hopf or EK presentation the corresponding modified Yang–Baxter equation is the associator-twisted braided hexagon; in the strict RTT normalization it is exactly (27.4). The passage $r_A \rightsquigarrow R_A$ is therefore a quantization datum (DK/EK, KZ monodromy, or an RTT/FRT kernel), not a formal consequence of the CYBE alone.

At general n , the pure braid group $P_n = \pi_1(\text{Conf}_n^{\text{ord}}(\mathbb{C}))$ has standard generators γ_{ij} ($i < j$, the loop in which z_i winds around z_j with all other points fixed). The flat connection ∇ induces a monodromy representation

$$\rho: P_n \rightarrow \text{GL}(\bar{A}^{\otimes n}), \quad \gamma_{ij} \mapsto R_{ij}(z_{ij}).$$

The half-braid transports used for adjacent deck transformations give a B_n -representation precisely when the corresponding braid relations hold. For KZ-type connections this is the Kohno–Drinfeld theorem; its infinitesimal shadow is the CYBE (27.2).

The descent theorem

PROPOSITION 27.4.3 (*R -matrix twisted descent*). Let A be a strongly admissible associative chiral algebra with ordered bar coalgebra $C = \bar{B}^{\text{ch,ord}}(A)$ and R -matrix $R(z)$ as in Construction 27.4.2. Assume that the monodromy operators satisfy the Yang–Baxter relations and the strong-unitarity relation $R_{12}(z)R_{21}(-z) = \text{id}$, compatibly for all adjacent transpositions. Then the unordered symmetric bar complex is the R -twisted Σ_n -descent:

$$\bar{B}^{\text{ch},\Sigma}(A)_n \simeq (\bar{B}^{\text{ch,ord}}(A)_n)^{R\text{-}\Sigma_n}, \quad (27.5)$$

where Σ_n acts on adjacent transpositions by $\sigma_i \cdot (a_1 \otimes \cdots \otimes a_n) = (\tau_{i,i+1} \circ R_{i,i+1}(z_i - z_{i+1})) (a_1 \otimes \cdots \otimes a_n)$. If the Yang–Baxter relation holds without strong unitarity, the same formula gives a B_n -monodromic local system on $\text{Conf}_n(\mathbb{C})$; it does not give a symmetric Σ_n -quotient and must not be identified with $\overline{B}^{\text{ch},\Sigma}(A)_n$.

Proof. The proof proceeds in three steps: we establish the Σ_n -action, verify its well-definedness, and identify the fixed locus.

Step 1: the twisted Σ_n -action. The covering $\pi_n: \text{Conf}_n^{\text{ord}}(\mathbb{C}) \rightarrow \text{Conf}_n(\mathbb{C})$ presents the base as the orbit space of the free Σ_n -action on ordered configurations. An element $\sigma_i = (i, i+1) \in \Sigma_n$ lifts to a path in $\text{Conf}_n^{\text{ord}}(\mathbb{C})$ that continuously exchanges z_i and z_{i+1} . The monodromy of the flat connection ∇ (eq. (27.1)) along this path decomposes into two factors:

- (i) the permutation $\tau_{i,i+1}$ of tensor slots in $\bar{A}^{\otimes n}$, from the coordinate transposition, and
- (ii) the parallel transport $R_{i,i+1}(z_i - z_{i+1})$ of the fibre, from the flat connection on ordered configuration space.

Define the R -twisted action on generators by

$$\rho_R(\sigma_i) := \tau_{i,i+1} \circ R_{i,i+1}(z_i - z_{i+1}).$$

Step 2: well-definedness via YBE and strong unitarity. The assignment $\sigma_i \mapsto \tau_{i,i+1} \circ R_{i,i+1}(z_i - z_{i+1})$ defines a representation $\rho_R: B_n \rightarrow \text{GL}(\bar{A}^{\otimes n})$ of the braid group, provided the braid relation holds, as proved below. To factor ρ_R through $\Sigma_n = B_n / \langle \sigma_i^2 \rangle$, we must also verify the Coxeter relations.

Involutivity ($\rho_R(\sigma_i)^2 = \text{id}$): this is exactly the strong-unitarity hypothesis $R_{12}(z) R_{21}(-z) = \text{id}$. It is automatic in the pole-free symmetric case and holds for the normalised rational R -matrices used below. It is not a consequence of the Yang–Baxter equation alone: without it the monodromy remains braid-group valued and no Σ_n -descent has been constructed.

Distant commutativity ($\rho_R(\sigma_i) \rho_R(\sigma_j) = \rho_R(\sigma_j) \rho_R(\sigma_i)$ for $|i - j| \geq 2$): immediate because $R_{i,i+1}$ and $R_{j,j+1}$ act in disjoint tensor slots.

The braid relation $\rho_R(\sigma_i) \rho_R(\sigma_{i+1}) \rho_R(\sigma_i) = \rho_R(\sigma_{i+1}) \rho_R(\sigma_i) \rho_R(\sigma_{i+1})$ is the critical constraint. Expanding:

$$\begin{aligned} & (\tau_{i,i+1} \circ R_{i,i+1})(\tau_{i+1,i+2} \circ R_{i+1,i+2})(\tau_{i,i+1} \circ R_{i,i+1}) \\ &= (\tau_{i+1,i+2} \circ R_{i+1,i+2})(\tau_{i,i+1} \circ R_{i,i+1})(\tau_{i+1,i+2} \circ R_{i+1,i+2}). \end{aligned}$$

Conjugating the tensor permutations to the left and using the standard identities $\tau_{i,i+1} R_{j,j+1} \tau_{i,i+1}^{-1} = R_{\sigma_i(j), \sigma_i(j+1)}$, this reduces to

$$R_{12}(z_{12}) R_{13}(z_{13}) R_{23}(z_{23}) = R_{23}(z_{23}) R_{13}(z_{13}) R_{12}(z_{12}),$$

the Yang–Baxter equation. This holds because the flatness $\nabla^2 = 0$ implies the CYBE (eq. (27.2)), and the path-ordered exponential converts the infinitesimal CYBE into the exponentiated YBE (this is the content of the Kohno–Drinfeld theorem: the monodromy representation of a flat Knizhnik–Zamolodchikov connection satisfies the Yang–Baxter equation).

Step 3: identification of the descent. The result is a genuine Σ_n -action ρ_R on $\overline{B}^{\text{ch,ord}}(A)_n$. By the descent equivalence for principal bundles, a Σ_n -equivariant local system on the total space $\text{Conf}_n^{\text{ord}}(\mathbb{C})$

descends to a local system on $\text{Conf}_n(\mathbb{C})$. The descended local system is the equaliser of the ρ_R -action, which at the level of global sections is the R -twisted Σ_n -invariant subspace:

$$(\overline{B}^{\text{ch,ord}}(A)_n)^{R \cdot \Sigma_n} := \{x \in \overline{B}^{\text{ch,ord}}(A)_n \mid \rho_R(\sigma) \cdot x = x \text{ for all } \sigma \in \Sigma_n\}.$$

We claim this equals $\overline{B}^{\text{ch},\Sigma}(A)_n$. By construction, the symmetric bar complex $\overline{B}^{\text{ch},\Sigma}(A)_n$ is the complex of sections of the descended local system $\mathcal{F}_n$ on $\text{Conf}_n(\mathbb{C})$ whose pullback to $\text{Conf}_n^{\text{ord}}(\mathbb{C})$ is $\mathcal{F}_n^{\text{ord}}$ with the ρ_R -equivariant structure. The descent-ascend adjunction for étale Σ_n -coverings gives

$$\Gamma(\text{Conf}_n(\mathbb{C}), \mathcal{F}_n) = \Gamma(\text{Conf}_n^{\text{ord}}(\mathbb{C}), \mathcal{F}_n^{\text{ord}})^{R \cdot \Sigma_n}.$$

The left side is $\overline{B}^{\text{ch},\Sigma}(A)_n$ and the right side is $(\overline{B}^{\text{ch,ord}}(A)_n)^{R \cdot \Sigma_n}$, completing the proof. $\square$

COROLLARY 27.4.4 (*Pole-free descent is naive*). For a pole-free E_∞ -chiral algebra (a commutative chiral algebra whose chiral product extends across the diagonal without singularities), the collision residue vanishes: $r(z) = 0$. Hence $\nabla = d$ is the trivial flat connection, $R(z) = \text{id}$, and (27.5) reduces to the ordinary Σ_n -coinvariant:

$$\overline{B}^{\text{ch},\Sigma}(A)_n \simeq (\overline{B}^{\text{ch,ord}}(A)_n)_{\Sigma_n}.$$

For chiral algebras with nontrivial singular OPE ($\widehat{\mathfrak{g}}_k$, Vir_c , $\mathcal{H}_k$, lattice algebras, W -algebras), the R -matrix $R(z) \neq \text{id}$ carries spectral dependence derived from the local OPE. The descent to a symmetric bar is then genuinely R -twisted and requires the strong-unitary equivariant datum of Proposition 27.4.3.

Proof. If the OPE has no poles, every collision residue vanishes identically, so the connection form in (27.1) is zero and the monodromy (27.3) is the identity. Since $\rho_R(\sigma_i) = \tau_{i,i+1} \circ R_{i,i+1}(z_i - z_{i+1})$, the R -twisted Σ_n -action reduces to the plain permutation $\tau_{i,i+1}$, and the R -twisted invariants identify with the ordinary Σ_n -coinvariants by the Reynolds idempotent, since $\text{char } k = 0$. $\square$

PROPOSITION 27.4.5 (*Symmetric descent and ordered surplus*). Let A be a strongly admissible associative chiral algebra.

- (i) If A is pole-free and E_∞ -chiral, then $R(z) = \text{id}$ and the Reynolds map identifies the ordered bar coinvariants with the Beilinson–Drinfeld symmetric bar:

$$\overline{B}^{\text{ch,ord}}(A)_\Sigma \xrightarrow{\sim} \overline{B}^{\text{ch},\Sigma}(A).$$

In characteristic zero the invariant and coinvariant descriptions are equivalent by the ordinary Reynolds idempotent.

- (ii) If A has a nontrivial collision residue but the strong-unitary R -twisted descent datum of Proposition 27.4.3 is fixed, then

$$\overline{B}^{\text{ch},\Sigma}(A)_n \simeq (\overline{B}^{\text{ch,ord}}(A)_n)^{R \cdot \Sigma_n}.$$

The map $\text{av}_R: \overline{B}^{\text{ch,ord}}(A) \rightarrow \overline{B}^{\text{ch},\Sigma}(A)$ is the R -twisted Reynolds projection. Its kernel is the non-invariant ordered sector; it is not a quasi-isomorphism of the raw ordered bar complex unless that kernel is acyclic.

- (iii) If A is genuinely E_1 -chiral and no strong-unitary Σ_n -descent datum is part of the structure, averaging does not construct a symmetric bar complex. The available object is the braid-monodromic ordered local system on $\text{Conf}_n^{\text{ord}}(X)$.

Proof. Clause (i) is Corollary 27.4.4. Clause (ii) is precisely the descent equivalence of Proposition 27.4.3, with the projection written as the Reynolds idempotent for the twisted action. The kernel is the direct complement of the invariant summand over characteristic zero, so no quasi-isomorphism statement follows without an acyclicity hypothesis. Clause (iii) is the contrapositive of the strong-unitarity part of Proposition 27.4.3: Yang–Baxter monodromy gives a braid-group action, while symmetric descent requires the Coxeter relation $R_{12}(z)R_{21}(-z) = \text{id}$. $\square$

Remark 27.4.6 (Three bar complex variants and their filtrations). The symmetric chiral bar complex $\overline{B}^{\text{ch},\Sigma}(A)$, the ordered bar complex $\overline{B}^{\text{ch},\text{ord}}(A)$, and the Feigin–Ginzburg bar complex $\overline{B}^{\text{FG}}(A)$ (retaining only simple-pole residues) are related by two filtrations: a pole-order filtration on $\overline{B}^{\text{ch},\Sigma}(A)$ whose associated graded recovers $\overline{B}^{\text{FG}}(A)$, and the strong-unitary R -twisted descent $\overline{B}^{\text{ch},\text{ord}}(A) \rightarrow \overline{B}^{\text{ch},\Sigma}(A)$ of Proposition 27.4.3. At higher genus all three fuse via the Feynman transform of the modular operad (FCom for the chiral and Feigin–Ginzburg variants, FAss for the ordered variant).

Remark 27.4.7 (The R -matrix as Maurer–Cartan element). The classical r -matrix $r(z) \in \text{End}(\bar{A} \otimes \bar{A}) \otimes \mathcal{O}(*\Delta)$ defines a Maurer–Cartan element in the degree-2 component of the E_1 ordered convolution algebra (cf. the E_1 shadow obstruction tower in the body of the text). Writing

$$A_{\nabla} = \sum_{i < j} r_{ij}(z_i - z_j) dz_{ij}$$

on $\text{Conf}_n^{\text{ord}}(\mathbb{C})$, the flatness of $\nabla = d - A_{\nabla}$ is the Maurer–Cartan equation

$$d_{\text{dR}} A_{\nabla} - \frac{1}{2} [A_{\nabla}, A_{\nabla}] = 0,$$

equivalently $d_{\text{dR}} \omega + \frac{1}{2} [\omega, \omega] = 0$ for $\omega = -A_{\nabla}$. For logarithmic KZ residues, the d_{dR} term vanishes and the bracket term is exactly the Arnold relation for $d \log(z_i - z_j)$ together with the infinitesimal braid relations; in the spectral notation this is the CYBE (27.2). The YBE on $R(z)$ is the monodromy, hence exponentiated, form of this flatness equation. The R -matrix is the descent datum because the convolution dg Lie algebra governing Σ_n -equivariant structures on local systems over Conf_n is precisely the Gerstenhaber–Schack complex of bilinear operations, and Maurer–Cartan elements in it parametrise the nontrivial descents. Thus the entire apparatus of twisted descent is controlled by a single MC element in the degree-2 sector.

Remark 27.4.8 (Motivic interpretation of ordered-to-symmetric descent). The averaging map $\text{av}: \overline{B}^{\text{ch},\text{ord}}(A) \rightarrow \overline{B}^{\text{ch},\Sigma}(A)$ after a strong-unitary descent datum has been fixed is the R -twisted Reynolds projection from ordered chains to the descent invariants. Its kernel is the non-invariant ordered sector. For KZ-type examples this kernel contains the associator-dependent period data of ordered configuration-space integrals; the map is not, by itself, a theorem that every transcendental period in every coefficient system vanishes.

The ordered configuration space $\text{Conf}_k^{\text{ord}}(\mathbb{C})$ carries a canonical mixed Hodge structure whose periods are the iterated integrals of the Knizhnik–Zamolodchikov connection. The R -matrix monodromy of Proposition 27.4.3 is computed by these periods, and the resulting transcendental data is stratified by degree:

- At degree 2: the monodromy $R(z)$ of the flat connection $\nabla = d - r(z) dz$ involves $2\pi i$, a period of the Lefschetz motive $\mathbb{L}$ (weight 1).

- At degree 3: the Drinfeld associator Φ_{KZ} (the monodromy of the KZ connection on $\text{Conf}_3^{\text{ord}}(\mathbb{C})$) involves multiple zeta values $\zeta(2)$, $\zeta(3)$, $\zeta(2, 1)$, $\dots$ (periods of mixed Tate motives over $\mathbb{Z}$).
- At degree k : the iterated monodromy involves periods of mixed Tate motives of weight $\leq k - 1$, by the theorem of Brown [?brown-mzv].

The symmetric bar complex $\overline{B}^{\text{ch}, \Sigma}(A)$ retains the R -invariant part of this local system. In the standard families used in this chapter, the numerical shadows extracted after descent – κ , the complementarity scalar, and the finite shadow obstructions – are the rational trace invariants recorded elsewhere in the manuscript. The ordered kernel $\ker(\text{av})$ is the surplus sector: it carries the non-invariant KZ monodromy and associator classes before taking the symmetric shadow.

This is the arithmetic shadow of a structural phenomenon. Drinfeld’s Grothendieck–Teichmüller group $\widehat{GT}$ acts on the tower of KZ associators, equivalently on the pro-nilpotent completion of the ordered bar complex at each degree. The Deligne–Ihara conjecture identifies $\text{Lie}(\widehat{GT})$ with the free Lie algebra on generators in odd degrees ≥ 3 , one for each odd zeta value $\zeta(2n + 1)$. The ordered bar complex of a chiral algebra is a *representation* of this arithmetic symmetry group: the $\widehat{GT}$ -action permutes the associators that parametrise equivalent ordered-to-symmetric descents. Different choices of Drinfeld associator give different R -twisted Σ_n -actions with isomorphic but not identical descent data.

Thus the ordered bar complex is the natural carrier of the configuration-space period torsor, while the symmetric bar complex is the descended invariant shadow. The precise motivic claim proved here is this invariant/kernel statement; identifying the full graded motivic content of $\ker(\text{av})$ beyond the KZ mixed-Tate examples is a separate problem.

27.5 OPPOSITE-DUALITY, ANTI-INVOLUTIONS, AND ENVELOPING DUALITY

The second foundational phenomenon is order reversal. It transforms opposite multiplication on the algebra side into opposite deconcatenation on the bar side.

THEOREM 27.5.1 (*Opposite-duality for ordered bar coalgebras*). Let A be a strongly admissible associative chiral algebra. There is a canonical isomorphism of coaugmented conilpotent dg coalgebras

$$\mathbf{R}_A : \overline{B}^{\text{ch}}(A^{\text{op}}) \xrightarrow{\sim} \overline{B}^{\text{ch}}(A)^{\text{cop}}.$$

If A is finite-type Koszul so that linear duality returns an associative chiral algebra, then

$$(A^{\text{op}})^! \simeq (A^!)^{\text{op}}.$$

Proof. On desuspended bar words define

$$\mathbf{R}_A[s^{-1}a_1 | \dots | s^{-1}a_n] = (-1)^{\sum_{i < j} (|a_i|+1)(|a_j|+1)} [s^{-1}a_n | \dots | s^{-1}a_1].$$

Geometrically, this is induced by the order-reversal involution on the ordered configuration space.

The bar differential is the alternating sum of adjacent collision maps. The i -th face for A^{op} multiplies the i -th and $(i + 1)$ -st slots in the opposite order. Reversal carries that face to the $(n - i)$ -th face for A with exactly the sign written above. Hence $\mathbf{R}_A$ is a chain map.

The coproduct on $\overline{B}^{\text{ch}}(A)$ is deconcatenation. Reversal sends a cut after the p -th letter to a cut before the $(n - p)$ -th letter. Therefore

$$\Delta \circ \mathbf{R}_A = \tau \circ (\mathbf{R}_A \otimes \mathbf{R}_A) \circ \Delta,$$

where τ flips the tensor factors, which is exactly the statement that the target is the opposite coalgebra. The claim about linear duals follows because linear duality exchanges opposite coproduct with opposite product. $\square$

COROLLARY 27.5.2 (*Anti-involutions survive duality*). Any anti-involution $\iota : A \rightarrow A^{\text{op}}$ induces an anti-involution

$$\iota^! : A^! \rightarrow (A^!)^{\text{op}}.$$

If $\iota^2 = \text{id}$, then $(\iota^!)^2 = \text{id}$.

Proof. Apply Theorem 27.5.1 to the anti-involution $\iota : A \rightarrow A^{\text{op}}$. Koszul duality is contravariant, so it gives a morphism $(A^{\text{op}})^! \rightarrow A^!$. Using the canonical identification $(A^{\text{op}})^! \cong (A^!)^{\text{op}}$ from the same theorem, this is exactly the required anti-involution $\iota^! : A^! \rightarrow (A^!)^{\text{op}}$. Functoriality gives $(\iota^!)^2 = (\iota^2)^!$, so $\iota^2 = \text{id}$ implies $(\iota^!)^2 = \text{id}$. $\square$

Remark 27.5.3 (*Symmetric Verdier algebra and the ordered opposite*). Verdier duality for the symmetric Ran bar forms the algebra

$$K_X(\mathcal{A}) := \mathbb{D}_{\text{Ran}} \bar{B}_X^{\text{ch}}(\mathcal{A}).$$

A Koszul-pair datum supplies the separate algebra map $\nu_{\mathcal{A}} : K_X(\mathcal{A}) \rightarrow \mathcal{A}^!$. The ordered bar lives on $\text{Conf}_n^{\leq}(X)$ and carries the *opposite-coalgebra duality* of Theorem 27.5.1: the reversal involution R_A provides $\bar{B}^{\text{ord}}(\mathcal{A})^{\text{op}} \simeq \bar{B}^{\text{ord}}(\mathcal{A}^{\text{op}})$, which is the ordered noncommutative comparison available in the present ambient. A full ribbon-Ran enhancement would extend Verdier duality to ordered configurations; its construction is an open problem.

LEMMA 27.5.4 (*Closure of admissibility under opposite and enveloping constructions*). If A is strongly admissible, then so are A^{op} and $A^e = A \otimes^{\text{ch}} A^{\text{op}}$.

Proof. Passing from A to A^{op} does not change the underlying filtered vector space, augmentation, or completeness data; it only reverses the order of multiplication. Hence every clause in the definition of strong admissibility is checked by the same filtration and continuity estimates for the opposite product. For $A^e = A \otimes^{\text{ch}} A^{\text{op}}$, the completed tensor product of two strongly admissible filtered objects is again complete, exhaustive, and compatible with the bar construction degreewise. Therefore both A^{op} and A^e satisfy the same admissibility package. $\square$

COROLLARY 27.5.5 (*Enveloping duality*). Let A be strongly admissible, and assume (A, A^{op}) is EZ-admissible. Set $C = \bar{B}^{\text{ch}}(A)$. Then there is a canonical quasi-isomorphism of conilpotent dg coalgebras

$$\bar{B}^{\text{ch}}(A^e) \xrightarrow{\sim} C^e = C \hat{\otimes} C^{\text{cop}}.$$

If A is finite-type Koszul, then

$$(A^e)^! \simeq (A^!)^e.$$

Proof. By the ordered shuffle theorem,

$$\bar{B}^{\text{ch}}(A^e) = \bar{B}^{\text{ch}}(A \otimes^{\text{ch}} A^{\text{op}}) \xrightarrow{\sim} \bar{B}^{\text{ch}}(A) \hat{\otimes} \bar{B}^{\text{ch}}(A^{\text{op}}).$$

Now apply Theorem 27.5.1 to the second factor:

$$\bar{B}^{\text{ch}}(A^{\text{op}}) \xrightarrow{\sim} \bar{B}^{\text{ch}}(A)^{\text{cop}}.$$

This proves the coalgebra statement. The algebra statement follows after finite-type linear duality. $\square$

27.6 THE TWO-SIDED TWISTED BICOMODULE AND THE TANGENT BAR CONSTRUCTION

An $\mathcal{A}$ -bimodule has two coalgebra-side incarnations: differentiation of the bar construction at a square-zero extension, and twisting a two-sided tensor product by the universal twisting cochain. They coincide.

Definition 27.6.1 (Two-sided twisted bicomodule). Let $\mathcal{A}$ be strongly admissible, let $C = \overline{B}^{\text{ch}}(\mathcal{A})$, and let M be an $\mathcal{A}$ -bimodule. Define the *two-sided twisted bicomodule*

$$\mathbb{K}_A^{\text{bi}}(M) := C \widehat{\otimes} M \widehat{\otimes} C$$

with differential

$$d_{\mathbb{K}} = d_C \otimes 1 \otimes 1 + 1 \otimes d_M \otimes 1 + 1 \otimes 1 \otimes d_C + d_L + d_R,$$

where

$$\begin{aligned} d_L(c \otimes m \otimes d) &= \sum (-1)^{|c|} c_{(1)} \otimes \tau(c_{(2)}) \cdot m \otimes d, \\ d_R(c \otimes m \otimes d) &= \sum (-1)^{|c|+|m|} c \otimes m \cdot \tau(d_{(1)}) \otimes d_{(2)}, \end{aligned}$$

Here $\Delta(c) = \sum c_{(1)} \otimes c_{(2)}$ and $\Delta(d) = \sum d_{(1)} \otimes d_{(2)}$. These are the desuspended two-sided twisting signs: the left term moves the twisting cochain past the first coalgebra leg, and the right term moves it past both the left coalgebra leg and the middle bimodule factor. The left and right C -coactions are induced by comultiplication on the two outer factors.

LEMMA 27.6.2. $\mathbb{K}_A^{\text{bi}}(M)$ is a dg C -bicomodule.

Proof. The untwisted part of the differential squares to zero. The quadratic terms in d_L and in d_R vanish by the Maurer–Cartan equation

$$d\tau + \tau \star \tau = 0.$$

The mixed commutator $d_L d_R + d_R d_L$ vanishes because the left and right $\mathcal{A}$ -actions on the bimodule M commute. Compatibility with the bicomodule structure is immediate from coassociativity of the coproduct on the outer C -factors. $\square$

Definition 27.6.3 (Square-zero extension and one-defect bar complex). Let M be an $\mathcal{A}$ -bimodule and form the square-zero extension

$$A_\varepsilon := A \oplus \varepsilon M, \quad \varepsilon^2 = 0.$$

Inside the reduced ordered bar complex $\overline{B}^{\text{ch}}(A_\varepsilon)$, let $T_A^{\text{bar}}(M)$ be the subcomplex spanned by bar words containing exactly one εM -slot. We call this the *one-defect ordered bar complex*.

PROPOSITION 27.6.4. Modulo ε^2 , there is a canonical decomposition

$$\overline{B}^{\text{ch}}(A_\varepsilon) \cong \overline{B}^{\text{ch}}(A) \oplus \varepsilon T_A^{\text{bar}}(M).$$

The one-defect piece $T_A^{\text{bar}}(M)$ is naturally a C -bicomodule.

Proof. A reduced bar word in $\overline{B}^{\text{ch}}(A_\varepsilon)$ contains some number of εM -slots. Since $\varepsilon^2 = 0$, any word with at least two such slots vanishes modulo ε^2 . Therefore only the zero-defect and one-defect pieces survive.

The bar differential merges adjacent slots. Multiplying two ordinary A -slots remains in A . Multiplying an A -slot with the unique M -slot remains in M by the bimodule structure. There is no nonzero product of two defect slots. Hence the one-defect sector is a subcomplex. Deconcatenation cuts a one-defect word into a defect-free part and a one-defect part, or vice versa, so the one-defect sector is naturally a bicomodule over the ordinary bar coalgebra $C = \overline{B}^{\text{ch}}(A)$. $\square$

THEOREM 27.6.5 (*Tangent identification*). There is a canonical isomorphism of dg C -bicomodules

$$T_A^{\text{bar}}(M) \xrightarrow{\sim} \mathbb{K}_A^{\text{bi}}(M).$$

Equivalently, the one-defect ordered bar complex of a square-zero extension is exactly the two-sided twisted bicomodule of the defect bimodule.

Proof. As a graded object,

$$C = \bigoplus_{p \geq 0} (s^{-1} \tilde{A})^{\otimes p},$$

hence

$$C \widehat{\otimes} M \widehat{\otimes} C \cong \bigoplus_{p, q \geq 0} (s^{-1} \tilde{A})^{\otimes p} \otimes M \otimes (s^{-1} \tilde{A})^{\otimes q}.$$

This is in tautological bijection with one-defect bar words

$$[a_1 | \cdots | a_p | m | a_{p+1} | \cdots | a_{p+q}]$$

in which the unique defect sits between a left bar segment of length p and a right bar segment of length q .

Under this identification, the ordinary bar differential on the left segment and the right segment matches the internal bar differential coming from the two outer copies of C , while the two bar faces adjacent to the defect slot match exactly the two twisting terms d_L and d_R . Therefore the differentials agree. Deconcatenation also agrees on the nose, because cutting a one-defect word is the same as cutting the left and right bar segments around the unique defect. $\square$

COROLLARY 27.6.6 (*Infinitesimal dual coalgebra*). Modulo ε^2 , the bar coalgebra of the square-zero extension is

$$\overline{B}^{\text{ch}}(A_\varepsilon) \cong C \oplus \varepsilon \mathbb{K}_A^{\text{bi}}(M).$$

If A is finite-type Koszul, then after linear duality

$$(A_\varepsilon)^! \cong A^! \oplus \varepsilon M^! \quad (\text{mod } \varepsilon^2),$$

where

$$M^! := \Omega_C^{\text{bi}}(\mathbb{K}_A^{\text{bi}}(M)).$$

Proof. Proposition 27.6.4 identifies the ε -linear summand of $\overline{B}^{\text{ch}}(A_\varepsilon)$ with the one-defect bar complex. Theorem 27.6.5 identifies that one-defect complex with the bicomodule $\mathbb{K}_A^{\text{bi}}(M)$, so modulo ε^2 the bar coalgebra splits as $C \oplus \varepsilon \mathbb{K}_A^{\text{bi}}(M)$. If A is finite-type Koszul, linear duality and first-order cobar reconstruction carry the ε -summand to $M^! = \Omega_C^{\text{bi}}(\mathbb{K}_A^{\text{bi}}(M))$, giving $(A_\varepsilon)^! \cong A^! \oplus \varepsilon M^! \pmod{\varepsilon^2}$. $\square$

PROPOSITION 27.6.7 (*Infinitesimal annular variation*). Modulo ε^2 one has

$$\mathrm{HH}_\bullet^{\mathrm{ch}}(A_\varepsilon) \cong \mathrm{HH}_\bullet^{\mathrm{ch}}(A) \oplus \varepsilon \mathrm{HH}_\bullet^{\mathrm{ch}}(A, M).$$

On the coalgebra side this becomes

$$\mathrm{coHH}_\bullet^{\mathrm{ch}}(\overline{B}^{\mathrm{ch}}(A_\varepsilon)) \cong \mathrm{coHH}_\bullet^{\mathrm{ch}}(C) \oplus \varepsilon \mathrm{coHH}_\bullet^{\mathrm{ch}}(C, \mathbb{K}_A^{\mathrm{bi}}(M)).$$

Proof. The chiral Hochschild complex of the square-zero extension decomposes, modulo ε^2 , into the sector with no defect and the sector with exactly one defect; the second computes chiral Hochschild homology with coefficients in M . The coalgebra statement follows from Corollary 27.6.6 and the coHochschild identification proved later in Theorem 27.8.1. $\square$

27.7 PBW-COMPLETE TWO-SIDED KOSZUL DUALITY

One-sided module/comodule duality extends to the two-sided theory by passing from A to its enveloping algebra A^e and applying Corollary 27.5.5.

Definition 27.7.1 (*PBW-complete and coderived bicomodule categories*). Let A be strongly admissible and set $C = \overline{B}^{\mathrm{ch}}(A)$.

- (a) $D_{\mathrm{bi}}^{\mathrm{pbw}}(A)$ denotes the derived category of PBW-complete A -bimodules obtained from complete semifree A^e -resolutions.
- (b) $D_{\mathrm{bi}}^{\mathrm{co}}(C)$ denotes the coderived category of conilpotent C -bicomodules. Equivalently, by Lemma 27.2.6, it is the coderived category of left C^e -comodules.

Definition 27.7.2 (*Two-sided twisted cobar*). Let N be a C -bicomodule. Define

$$\Omega_C^{\mathrm{bi}}(N) := A \widehat{\otimes} N \widehat{\otimes} A$$

with the differential dual to the one in Definition 27.6.1.

THEOREM 27.7.3 (*PBW-complete bimodule/bicomodule equivalence*). Let A be strongly admissible, and assume (A, A^{op}) is EZ-admissible. Set $C = \overline{B}^{\mathrm{ch}}(A)$. Then there is an exact equivalence

$$\mathbb{K}_A^{\mathrm{bi}} : D_{\mathrm{bi}}^{\mathrm{pbw}}(A) \xrightarrow{\sim} D_{\mathrm{bi}}^{\mathrm{co}}(C)$$

with inverse Ω_C^{bi} . In the curved regime the same statement holds after replacing the ordinary derived category on the algebra side by the corresponding completed contraderived/coderived version.

Proof. By the enveloping algebra formalism, A -bimodules are left A^e -modules. By Corollary 27.5.5,

$$\overline{B}^{\mathrm{ch}}(A^e) \xrightarrow{\sim} C^e.$$

Apply the one-sided module/comodule Koszul duality from Hypothesis 27.2.3(II) to the associative chiral algebra A^e . This gives an equivalence between complete A^e -modules and conilpotent C^e -comodules. Since left C^e -comodules are the same as C -bicomodules by Lemma 27.2.6, we obtain the asserted equivalence.

The functor is precisely the two-sided twisted bar construction

$$M \mapsto C \widehat{\otimes} M \widehat{\otimes} C,$$

because that is the one-sided bar functor for the algebra A^e rewritten using the enveloping identification. The inverse is the corresponding two-sided cobar functor. $\square$

THEOREM 27.7.4 (*Diagonal correspondence*). Under the equivalence of Theorem 27.7.3, the diagonal bimodule ${}_A A_A$ is sent to the diagonal bicomodule C_Δ . Equivalently,

$$\mathbb{K}_A^{\text{bi}}(A) \simeq C_\Delta$$

in $D_{\text{bi}}^{\text{co}}(C)$.

Proof. By definition,

$$\mathbb{K}_A^{\text{bi}}(A) = C \widehat{\otimes} A \widehat{\otimes} C$$

with the two-sided twisting differential.

First contract the left half: the standard bar–cobar counit resolution yields a quasi-isomorphism

$$C \widehat{\otimes}_\tau A \xrightarrow{\sim} \mathbf{1}$$

compatible with the right C -coaction. Hence

$$\mathbb{K}_A^{\text{bi}}(A) \simeq C$$

as a right C -comodule.

Similarly, contracting the right half using

$$A \widehat{\otimes}_\tau C \xrightarrow{\sim} \mathbf{1}$$

gives

$$\mathbb{K}_A^{\text{bi}}(A) \simeq C$$

as a left C -comodule.

To identify the opposite coactions, filter $\mathbb{K}_A^{\text{bi}}(A)$ by total coradical degree in the two outer copies of C . On the associated graded the twisting terms disappear, and the bicomodule structure is literally the left and right coproducts on the two outer factors. Under either of the two contractions above, the associated graded collapses to a single copy of C , and the surviving left and right coactions are exactly the two legs of Δ_C . Because the filtration is complete and bounded below in the strongly admissible regime, this associated-graded identification lifts to the filtered complex. Therefore the resulting bicomodule is C_Δ . $\square$

COROLLARY 27.7.5 (*The diagonal is the unit for composition*). For every $X \in D_{\text{bi}}^{\text{co}}(C)$ there are canonical isomorphisms

$$C_\Delta \square_C^{\mathbf{R}} X \simeq X \simeq X \square_C^{\mathbf{R}} C_\Delta.$$

Proof. Transport the tautologies

$$A \otimes_A^{\mathbf{L}} M \simeq M \simeq M \otimes_A^{\mathbf{L}} A$$

for A -bimodules along Theorem 27.7.3 and use Theorem 27.7.4. $\square$

COROLLARY 27.7.6 (*Tensor–cotensor gluing*). For all $M, N \in D_{\text{bi}}^{\text{pbw}}(A)$ there is a canonical isomorphism

$$\mathbb{K}_A^{\text{bi}}(M \otimes_A^{\mathbf{L}} N) \simeq \mathbb{K}_A^{\text{bi}}(M) \square_C^{\mathbf{R}} \mathbb{K}_A^{\text{bi}}(N)$$

in $D_{\text{bi}}^{\text{co}}(C)$.

Proof. Theorem 27.7.3 identifies the derived category of PBW-complete bimodules with the coderived category of C -bicomodules. Under this equivalence, the relative tensor product over A is sent to the relative cotensor product over C because both are computed by the same two-sided bar resolution transported through $\mathbb{K}_A^{\text{bi}}$. Applying the equivalence to $M \otimes_A^{\mathbf{L}} N$ therefore yields the displayed isomorphism $\mathbb{K}_A^{\text{bi}}(M) \square_C^{\mathbf{R}} \mathbb{K}_A^{\text{bi}}(N)$. $\square$

Remark 27.7.7. Corollary 27.7.6 is the coalgebraic gluing law for intervals. The diagonal bicomodule C_Δ is therefore the universal boundary condition for interval composition.

27.8 CHIRAL HOCHSCHILD–COHOCHSCHILD DUALITY

Annular traces and centers on the algebra side are identified with coHochschild theories of the bar coalgebra.

THEOREM 27.8.1 (*Associative chiral Hochschild/coHochschild homology*). Let A be strongly admissible, let (A, A^{op}) be EZ-admissible, and set $C = \overline{B}^{\text{ch}}(A)$. Then for every complete A -bimodule M there is a canonical isomorphism

$$\text{HH}_\bullet^{\text{ch}}(A, M) \simeq \text{coHH}_\bullet^{\text{ch}}(C, \mathbb{K}_A^{\text{bi}}(M)).$$

In particular,

$$\text{HH}_\bullet^{\text{ch}}(A) \simeq \text{coHH}_\bullet^{\text{ch}}(C) \simeq C_\Delta \square_{C^e}^{\mathbf{R}} C_\Delta.$$

Proof. By definition,

$$\text{HH}_\bullet^{\text{ch}}(A, M) = \text{Tor}_\bullet^{A^e}(A, M).$$

Apply the equivalence of Theorem 27.7.3 to the pair (A, M) . The diagonal bimodule A goes to C_Δ by Theorem 27.7.4, and M goes to $\mathbb{K}_A^{\text{bi}}(M)$ by definition. Derived tensor over A^e is transported to derived cotensor over C^e . Therefore

$$\text{Tor}_\bullet^{A^e}(A, M) \simeq \text{Cotor}_\bullet^{C^e}(C_\Delta, \mathbb{K}_A^{\text{bi}}(M)),$$

which is the stated formula. Taking $M = A$ yields the second assertion. $\square$

THEOREM 27.8.2 (*Associative chiral Hochschild/coHochschild cohomology*). Under the same hypotheses, for every complete A -bimodule M there is a canonical isomorphism

$$\text{HH}_{\text{ch}}^\bullet(A, M) \simeq \text{coHH}_{\text{ch}}^\bullet(C, \mathbb{K}_A^{\text{bi}}(M)).$$

In particular,

$$\text{HH}_{\text{ch}}^\bullet(A) \simeq \text{coHH}_{\text{ch}}^\bullet(C) = \text{Coext}_{C^e}^\bullet(C_\Delta, C_\Delta).$$

Proof. Derived Hom is preserved by the equivalence of Theorem 27.7.3. Therefore

$$\text{RHom}_{A^e}(A, M) \simeq \text{RHom}_{C^e}(C_\Delta, \mathbb{K}_A^{\text{bi}}(M)),$$

which is the desired coHochschild cohomology complex. The specialization to $M = A$ follows from the diagonal correspondence. $\square$

COROLLARY 27.8.3 (*The annulus as self-cotrace*). The annular closed object attached to the universal boundary condition C_Δ is the coHochschild object

$$\mathcal{H}_C^{\text{cl}} := C_\Delta \square_{C^\epsilon}^{\mathbf{R}} C_\Delta \simeq \text{coHH}_\bullet^{\text{ch}}(C) \simeq \text{HH}_\bullet^{\text{ch}}(A).$$

Proof. Take $M = A$ in Theorem 27.8.1. Then the diagonal bimodule ${}_A A_A$ is carried to the diagonal bicomodule C_Δ , and the resulting coHochschild object is $C_\Delta \square_{C^\epsilon}^{\mathbf{R}} C_\Delta$. This is exactly the closed annulus object $\mathcal{H}_C^{\text{cl}}$, so the three descriptions agree. $\square$

COROLLARY 27.8.4 (*Cap action*). There is a canonical action

$$\text{coHH}_\bullet^{\text{ch}}(C) \square_{C^\epsilon}^{\mathbf{R}} C_\Delta \longrightarrow C_\Delta$$

obtained by transporting the chiral Hochschild cap action

$$\text{HH}_\bullet^{\text{ch}}(A) \otimes A \longrightarrow A$$

across the equivalence of Theorem 27.7.3.

Proof. View the classical Hochschild cap action as a morphism in the derived category of A -bimodules. Theorem 27.7.3 transports A to C_Δ and transports chiral Hochschild homology to $\text{coHH}_\bullet^{\text{ch}}(C)$. Under the same equivalence, the tensor operation on the algebra side becomes the cotensor operation on the coalgebra side, so the cap action becomes the displayed map $\text{coHH}_\bullet^{\text{ch}}(C) \square_{C^\epsilon}^{\mathbf{R}} C_\Delta \rightarrow C_\Delta$. $\square$

Remark 27.8.5. The cohomology theorem is the center theorem. The homology theorem is the annulus theorem. Together they say that the algebraic center and algebraic trace of A can be read directly from the coalgebraic diagonal C_Δ .

27.9 THE DIAGONAL BICOMODULE AS UNIVERSAL BOUNDARY CONDITION

The boundary side carries two operations. Interval composition is realized by derived cotensor (Corollary 27.7.6). The ordered pair-of-pants is the transport of the external tensor product of bimodules. The second operation is inherently ordered: without extra structure, it is *not* symmetric.

Definition 27.9.1 (Ordered fusion product). Let $X, Y \in D_{\text{bi}}^{\text{co}}(C)$. Define

$$X \star Y := \mathbb{K}_A^{\text{bi}} \left(\Omega_C^{\text{bi}}(X) \widehat{\otimes} \Omega_C^{\text{bi}}(Y) \right),$$

where $\widehat{\otimes}$ is the completed tensor product of bimodules with outer A -actions: the left A -action is on the first factor and the right A -action is on the second factor. We call $\star$ the *ordered fusion product*.

Remark 27.9.2. The adjective “ordered” is essential. Unless further symmetry data are supplied, $\star$ is only a monoidal product reflecting the ordering of incoming open boundaries. It is the algebraic shadow of an ordered pair-of-pants, not yet of the fully symmetric open cobordism category.

THEOREM 27.9.3 (*Ordered pair-of-pants algebra*). The diagonal bicomodule C_Δ carries a canonical associative algebra structure with respect to the ordered fusion product:

$$\mu_P : C_\Delta \star C_\Delta \longrightarrow C_\Delta, \quad \eta_P : \mathbf{I}_\star \longrightarrow C_\Delta,$$

where $\mathbf{I}_\star := \mathbb{K}_A^{\text{bi}}(k)$ is the image of the trivial bimodule.

Proof. By Theorem 27.7.4, $C_\Delta \simeq \mathbb{K}_A^{\text{bi}}(A)$. The multiplication and unit of the algebra A ,

$$\mu_A : A \widehat{\otimes} A \rightarrow A, \quad \eta_A : k \rightarrow A,$$

transport across $\mathbb{K}_A^{\text{bi}}$ to maps

$$\mu_P : C_\Delta \star C_\Delta \rightarrow C_\Delta, \quad \eta_P : \mathbf{I} \star \rightarrow C_\Delta.$$

Associativity and unitality follow immediately from associativity and unitality of A . $\square$

Definition 27.9.4 (Ordered open trace formalism). An ordered genus-zero open trace formalism consists of:

- (i) a composition product $\square_C^{\mathbf{R}}$ with unit object C_Δ ,
- (ii) an ordered fusion product $\star$,
- (iii) an associative algebra structure $(C_\Delta, \mu_P, \eta_P)$ for $\star$,
- (iv) a closed object $\mathcal{H}_C^{\text{cl}}$ obtained by annular closure,
- (v) an annulus action of $\mathcal{H}_C^{\text{cl}}$ on C_Δ ,

subject to the sewing relations induced from the algebra side.

THEOREM 27.9.5 (Ordered genus-zero open trace formalism). The data

$$(D_{\text{bi}}^{\text{co}}(C), \square_C^{\mathbf{R}}, C_\Delta, \star, \mu_P, \eta_P, \mathcal{H}_C^{\text{cl}})$$

constitute an ordered genus-zero open trace formalism. More precisely:

- (a) C_Δ is the unit for interval composition $\square_C^{\mathbf{R}}$.
- (b) $(C_\Delta, \mu_P, \eta_P)$ is an associative algebra object for ordered fusion.
- (c) Annular closure is

$$\mathcal{H}_C^{\text{cl}} \simeq \text{coHH}_\bullet^{\text{ch}}(C).$$

- (d) The annulus acts on the boundary object by the action of Corollary 27.8.4.
- (e) All ordered genus-zero sewing identities are transported from the corresponding identities for A -bimodules.

Proof. Statement (a) is Corollary 27.7.5. Statement (b) is Theorem 27.9.3. Statement (c) is Corollary 27.8.3. Statement (d) is Corollary 27.8.4. Finally, every ordered genus-zero sewing relation on the coalgebra side is the image under the equivalence $\mathbb{K}_A^{\text{bi}}$ of the corresponding relation on the algebra side. $\square$

Remark 27.9.6 (Ordered boundary symmetry). The theorem gives the algebraic ordered open package. A symmetric one-brane open TCFT requires additional structure symmetrising ordered fusion: either a boundary symmetry datum or a geometric realisation by bordered configuration spaces.

27.9.1 Calabi–Yau transport

The ordered open trace formalism acquires a Frobenius structure under a Calabi–Yau hypothesis on A .

Definition 27.9.7 (Complete chiral Calabi–Yau structure). A strongly admissible associative chiral algebra A is called d -Calabi–Yau if:

- (a) A is perfect as an A^e -module, and
- (b) there is an isomorphism in $D_{\text{bi}}^{\text{pbw}}(A)$

$$\varphi_A : A \xrightarrow{\sim} \text{RHom}_{A^e}(A, A^e)[d].$$

Equivalently, A carries a nondegenerate d -shifted derived trace pairing.

THEOREM 27.9.8 (Shifted ordered Frobenius structure). Assume A is d -Calabi–Yau. Then the underlying complex of C_Δ carries a canonical d -shifted ordered Frobenius structure. More precisely:

- (i) the ordered pair-of-pants multiplication μ_P and unit η_P are as above;
- (ii) there is a trace

$$\varepsilon_P : C_\Delta \rightarrow k[-d]$$

transported from the Calabi–Yau trace on A ;

- (iii) there is a coproduct

$$\Delta_P : C_\Delta \rightarrow C_\Delta \star C_\Delta[d]$$

adjoint to μ_P under ε_P ;

- (iv) the ordered Frobenius identities

$$(\mu_P \star \text{id}) \circ (\text{id} \star \Delta_P) = \Delta_P \circ \mu_P = (\text{id} \star \mu_P) \circ (\Delta_P \star \text{id})$$

hold.

Proof. On the algebra side, the Calabi–Yau structure identifies A with its bimodule dual shifted by d . Therefore multiplication

$$\mu_A : A \widehat{\otimes} A \rightarrow A$$

admits a unique adjoint coproduct

$$\Delta_A : A \rightarrow A \widehat{\otimes} A[d]$$

with respect to the trace pairing $\varepsilon_A : A \rightarrow k[-d]$; explicitly one may define Δ_A as the adjoint of μ_A under φ_A . The ordered Frobenius identities are formal consequences of associativity of μ_A and the nondegeneracy of the pairing.

Transport the entire package $(\mu_A, \eta_A, \varepsilon_A, \Delta_A)$ across the equivalence $\mathbb{K}_A^{\text{bi}}$ and use Theorem 27.7.4. The resulting structure maps are $\mu_P, \eta_P, \varepsilon_P, \Delta_P$, and all identities are preserved because the equivalence preserves composition. $\square$

COROLLARY 27.9.9 (Cardy operator on the coalgebra side). Under the hypotheses of Theorem 27.9.8, the ordered annulus endomorphism of the universal boundary object is

$$\text{Ann}_{C_\Delta} := \mu_P \circ \Delta_P \in \text{End}(C_\Delta)[d].$$

Its annular closure factors through the closed object

$$\mathcal{H}_C^{\text{cl}} \simeq \text{coHH}_\bullet^{\text{ch}}(C).$$

Proof. For a Calabi–Yau algebra, the open annulus operator is the composite $\mu_A \circ \Delta_A$ on the diagonal bimodule. Applying $\mathbb{K}_A^{\text{bi}}$ transports the diagonal bimodule to C_Δ and transports multiplication and comultiplication to the ordered pair-of-pants maps μ_P and Δ_P . Hence the ordered annulus endomorphism on the coalgebra side is $\mu_P \circ \Delta_P$. Corollary 27.8.3 identifies its annular closure with $\mathcal{H}_C^{\text{cl}} \simeq \text{coHH}_\bullet^{\text{ch}}(C)$. $\square$

27.10 A MASTER THEOREM AND ITS CONCEPTUAL FORM

The preceding results assemble into a single statement.

THEOREM 27.10.1 (*Master theorem*;). Let A be a strongly admissible augmented associative chiral algebra on X , assume (A, A^{op}) is EZ-admissible, and set

$$C := \overline{B}^{\text{ch}}(A).$$

Then:

- (1) **Ordered shuffle.** There is a quasi-isomorphism of conilpotent dg coalgebras

$$\overline{B}^{\text{ch}}(A \otimes^{\text{ch}} B) \simeq \overline{B}^{\text{ch}}(A) \widehat{\otimes} \overline{B}^{\text{ch}}(B)$$

for every EZ-admissible partner B .

- (2) **Opposite-duality.** There is a canonical isomorphism

$$\overline{B}^{\text{ch}}(A^{\text{op}}) \simeq \overline{B}^{\text{ch}}(A)^{\text{cop}}.$$

- (3) **Enveloping duality.** There is a canonical quasi-isomorphism

$$\overline{B}^{\text{ch}}(A^e) \simeq C^e.$$

- (4) **Two-sided bimodule/bicomodule duality.** There is an exact equivalence

$$D_{\text{bi}}^{\text{pbw}}(A) \simeq D_{\text{bi}}^{\text{co}}(C).$$

- (5) **Diagonal correspondence.** Under this equivalence one has

$${}_A A_A \longleftrightarrow C_\Delta.$$

- (6) **Composition.** The diagonal bicomodule is the unit for derived cotensor:

$$C_\Delta \square_C^{\mathbf{R}} X \simeq X \simeq X \square_C^{\mathbf{R}} C_\Delta.$$

- (7) **chiral Hochschild/coHochschild homology.** For every complete A -bimodule M ,

$$\text{HH}_\bullet^{\text{ch}}(A, M) \simeq \text{coHH}_\bullet^{\text{ch}}(C, \mathbb{K}_A^{\text{bi}}(M)).$$

- (8) **chiral Hochschild/coHochschild cohomology.** For every complete A -bimodule M ,

$$\text{HH}_\bullet^{\text{ch}}(A, M) \simeq \text{coHH}_\bullet^{\text{ch}}(C, \mathbb{K}_A^{\text{bi}}(M)).$$

(9) **Tangent theory.** For a square-zero extension $A_\varepsilon = A \oplus \varepsilon M$,

$$\overline{B}^{\text{ch}}(A_\varepsilon) \cong C \oplus \varepsilon \mathbb{K}_A^{\text{bi}}(M) \pmod{\varepsilon^2}.$$

(10) **Ordered open trace formalism.** The coalgebraic boundary object C_Δ carries ordered pair-of-pants, annulus, and composition operations transported from the algebra side, and if A is d -Calabi–Yau then the underlying complex of C_Δ becomes a d -shifted ordered Frobenius object.

Proof. This is a summary of Theorems 27.3.3, 27.5.1, 27.7.3, 27.7.4, 27.8.1, 27.8.2, 27.6.5, and 27.9.5, together with Corollaries 27.5.5, 27.7.5, and 27.6.6, and Theorem 27.9.8. $\square$

27.II CONFIGURATION SPACE GEOMETRY OF THE ORDERED BAR COMPLEX

The master theorem packages the ordered bar complex as an abstract dg coalgebra. The product $\text{FM}_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R})$ gives it a concrete body: the bar differential comes from the holomorphic factor, the coproduct from the topological factor.

27.II.1 Ordered configuration spaces

Definition 27.II.1 (Ordered real configuration space). For $k \geq 1$, the *ordered real configuration space* is

$$\text{Conf}_k^<(\mathbb{R}) := \{(t_1, \dots, t_k) \in \mathbb{R}^k \mid t_1 < t_2 < \dots < t_k\}.$$

This is a single open convex cell in $\mathbb{R}^k$, hence contractible.

PROPOSITION 27.II.2 (*Topology of ordered real configurations*;). (i) $\text{Conf}_k^<(\mathbb{R})$ is contractible (it is a connected component of $\text{Conf}_k^{\text{ord}}(\mathbb{R})$, which consists of $k!$ contractible chambers).

(ii) The natural projection $\pi_k: \text{Conf}_k^{\text{ord}}(\mathbb{R}) \rightarrow \text{Conf}_k(\mathbb{R})/\Sigma_k$ is a $k!$ -sheeted covering. The fibre over a point $\{t_1, \dots, t_k\} \in \text{Conf}_k(\mathbb{R})/\Sigma_k$ consists of the $k!$ orderings of the t_i .

(iii) $\text{Conf}_k^<(\mathbb{R})$ is a fundamental domain for the Σ_k -action: every unordered configuration can be uniquely ordered. This discreteness (each fibre is a set, not a path-connected space) is the geometric reason that the E_1 -structure (associativity) carries no homotopy-coherence data beyond the sequence of associahedra.

Proof. Part (i): $\text{Conf}_k^<(\mathbb{R})$ is cut out by the strict linear inequalities $t_1 < t_2 < \dots < t_k$ inside $\mathbb{R}^k$, so it is an open convex cell and hence contractible. Permuting coordinates gives the other $k!$ chambers of $\text{Conf}_k^{\text{ord}}(\mathbb{R})$, and these chambers are disjoint because two different orderings cannot hold simultaneously. Part (ii): the Σ_k -action on $\text{Conf}_k^{\text{ord}}(\mathbb{R})$ is free, and quotienting by that action forgets the ordering while retaining the underlying set of points, so the fibre over an unordered configuration is exactly its $k!$ orderings. Part (iii): every unordered configuration admits a unique increasing representative, namely the one obtained by sorting its points from left to right. Thus $\text{Conf}_k^<(\mathbb{R})$ is a fundamental domain, and the fact that the fibre is discrete explains why the ordered theory carries only E_1 -type coherence. $\square$

Definition 27.II.3 (Ordered holomorphic configuration space). For a smooth curve X and $k \geq 1$, the *ordered configuration space* is

$$\text{Conf}_k^{\text{ord}}(X) := \{(z_1, \dots, z_k) \in X^k \mid z_i \neq z_j \text{ for all } i \neq j\}.$$

The symmetric group Σ_k acts freely by permuting coordinates. The unordered configuration space is the quotient: $\text{Conf}_k(X) = \text{Conf}_k^{\text{ord}}(X)/\Sigma_k$. For $X = \mathbb{C}$: $\pi_1(\text{Conf}_k^{\text{ord}}(\mathbb{C})) = P_k$, the pure braid group; $\pi_1(\text{Conf}_k(\mathbb{C})) = B_k$, the full braid group.

27.11.2 The product space and its operadic role

Construction 27.11.4 (The $SC^{\text{ch},\text{top}}$ operation space). The two-coloured Swiss-cheese operad $SC^{\text{ch},\text{top}}$ has operation spaces

$$SC^{\text{ch},\text{top}}(k, m) = FM_k(\mathbb{C}) \times E_1(m),$$

where $FM_k(\mathbb{C})$ is the Fulton–MacPherson compactification of $\text{Conf}_k(\mathbb{C})$ (the chiral, holomorphic factor) and $E_1(m)$ is the little-intervals operad (the coassociative, topological factor). Concretely, $E_1(m) \simeq \text{Conf}_m^<(\mathbb{R})$ up to translation and scaling, which is contractible.

For the ordered bar complex of an E_1 -chiral algebra, the relevant spaces at tensor degree k are

$$FM_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R}).$$

A bar element of degree k is parametrised by this product: the coordinates $z_1, \dots, z_k \in \mathbb{C}$ live on the holomorphic curve, while the ordering $t_1 < t_2 < \dots < t_k$ records the position in the topological direction $\mathbb{R}_t$. The bar differential acts in the $\mathbb{C}$ -direction (extracting OPE residues); the deconcatenation coproduct acts in the $\mathbb{R}$ -direction (cutting the ordered sequence).

Remark 27.11.5 (The two colours). The product $FM_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R})$ is the geometric fingerprint of a 3d holomorphic-topological field theory on $\mathbb{C}_z \times \mathbb{R}_t$: observables factorise holomorphically in z and associatively in t . The bar differential is the chiral (holomorphic) component. The bar coproduct is the coassociative (topological) component.

Remark 27.11.6 (Codimension-one generators for $SC^{\text{ch},\text{top}}$). The construction above gives the operation space, not yet a minimal generators-and-relations presentation, and by itself it does not equip the ordered bar complex with a full Swiss-cheese algebra structure. On compactified models the codimension-1 generator families are:

- (i) closed collision faces $\partial_S FM_k(\mathbb{C})$ with $|S| \geq 2$;
- (ii) open interval-splitting faces in a Stasheff compactification of $E_1(m)$, equivalently cuts of the ordered open inputs into consecutive blocks;
- (iii) in the mixed space $FM_k(\mathbb{C}) \times E_1(m)$, the product faces $\partial_S FM_k(\mathbb{C}) \times E_1(m)$ and $FM_k(\mathbb{C}) \times F$, with F an interval-splitting face as in (ii).

The codimension-2 relations are the intersections of these faces: Arnold–Orlik–Solomon in the closed factor, Stasheff associativity in the open factor, and mixed commuting squares comparing a closed collision with an open split.

27.11.3 The ordered FM compactification

Construction 27.11.7 (Ordered Fulton–MacPherson partial compactification). The ordered FM object used by the ordered bar differential is the associahedral partial Fulton–MacPherson compactification $\overline{FM}_k^{\text{ord}}(\mathbb{C})$, defined as the iterated real oriented blowup of $\text{Conf}_k^{\text{ord}}(\mathbb{C})$ along the *consecutive-block* diagonals

$$D_I = \{z_i = z_j : i, j \in I\}, \quad I = \{a, a+1, \dots, b\}, \quad |I| \geq 2.$$

It is a partial compactification, not the full labelled Fulton–MacPherson compactification. In the full compactification one blows up every diagonal $D_S = \{z_i = z_j : i, j \in S\}$ for every subset $S \subseteq \{1, \dots, k\}$ with $|S| \geq 2$; the ordered bar keeps only the consecutive-block faces because only adjacent words may be contracted by the associative bar differential.

The codimension-one boundary faces correspond to *consecutive* collisions $z_i \rightarrow z_{i+1}$, not to arbitrary subsets. A non-consecutive collision such as $z_1 \rightarrow z_3$ (with z_2 remaining separated) is not a codimension-one face of the ordered compactification.

Low-degree examples.

For $k = 2$: $\overline{\text{FM}}_2^{\text{ord}}(\mathbb{C}) \cong \overline{\mathbb{C}}$ (the Riemann sphere), with a single boundary divisor $D_{1,2} = \{z_1 = z_2\}$.

For $k = 3$: two codimension-one faces: $D_{1,2}$ (first pair collides) and $D_{2,3}$ (last pair collides). The full-FM divisor $D_{\{1,3\}}$ (first and third collide while the middle point remains separated) is not a boundary face of the ordered partial model. The codimension-two ordered corner is the total consecutive collision $D_{\{1,2,3\}}$, reached by letting the two adjacent faces meet. This is the associahedron K_3 : a line segment with two endpoints.

27.II.4 Boundary strata: planted forests

Construction 27.II.8 (Boundary stratification by planted forests). The boundary strata of $\overline{\text{FM}}_k^{\text{ord}}(\mathbb{C})$ are indexed by *planted forests*: ordered sequences of planar rooted trees.

A *planted forest* $F = (T_1, T_2, \dots, T_r)$ is an *ordered* sequence of planar rooted trees whose leaves, read from left to right across all trees, are labelled $1, 2, \dots, k$ in order. The trees $T_1, \dots, T_r$ correspond to the r clusters of points that remain separated at the given codimension; within each tree, the internal vertices record the collision history of points within that cluster.

The stratum indexed by F is the product

$$\partial_F \overline{\text{FM}}_k^{\text{ord}}(\mathbb{C}) \cong \prod_{j=1}^r \overline{\text{FM}}_{|T_j|}^{\text{ord}}(\mathbb{C}),$$

where $|T_j|$ is the number of leaves of T_j .

For the codimension-one faces: each is indexed by a forest with $k-1$ trees, $k-2$ of which are single leaves and one of which is a single binary tree with two leaves. Concretely, the face $D_{i,i+1}$ corresponds to the forest in which points i and $i+1$ form a binary tree (they collide) and all other points are isolated.

Contrast with the unordered case. In the unordered FM compactification, boundary strata are indexed by *trees* (rooted trees with unordered children). In the ordered case, the strata are indexed by *planted forests* (ordered sequences of planar trees): the ordering of trees within the forest records the linear order on the topological direction.

27.II.5 The bar differential from collision residues

Construction 27.II.9 (Bar differential). Let $\mathcal{A}$ be a strongly admissible E_1 -chiral algebra with structure constants $e_{I(n)} e_J = \sum_K c_{IJ;n}^K e_K$ relative to a homogeneous basis $\{e_I\}$ of the augmentation ideal $\tilde{\mathcal{A}}$. The bar differential on $\overline{B}^{\text{ch,ord}}(\mathcal{A})$ decomposes as

$$d_{\overline{B}^{\text{ch,ord}}} = d_{\text{int}} + \sum_{i=1}^{k-1} d_{i,i+1},$$

where:

- d_{int} applies the internal differential of $\mathcal{A}$ to each tensor factor.
- $d_{i,i+1}$ extracts the collision residue at the codimension-one stratum $D_{i,i+1} = \{z_i = z_{i+1}\}$, using the ordered logarithmic propagator $\eta_{i,i+1} = d \log(z_i - z_{i+1})$.

Explicitly, let $|a|$ denote cohomological degree and use the desuspended binary operation

$$b_2^{(n)}(s^{-1}a \otimes s^{-1}b) := (-1)^{|a|} s^{-1}(a_{(n)}b).$$

The coderivation extension gives the component $d_{i,i+1}^{(n)}$ on a bar word $[s^{-1}e_{I_1} | \cdots | s^{-1}e_{I_k}]$ by contracting the i -th and $(i+1)$ -st slots via all OPE products:

$$d_{i,i+1}^{(n)}[s^{-1}e_{I_1} | \cdots | s^{-1}e_{I_k}] = (-1)^{\sum_{q < i} (|e_{I_q}| - 1) + |e_{I_i}|} \sum_K c_{I_i I_{i+1} n}^K [s^{-1}e_{I_1} | \cdots | s^{-1}e_K | \cdots | s^{-1}e_{I_k}] \otimes [\delta_{D_{i,i+1}}^{(n)}],$$

where the contracted pair is replaced by a single slot and $[\delta_{D_{i,i+1}}^{(n)}]$ is the n -th residue class at the collision divisor. Thus $d_{i,i+1} = \sum_n d_{i,i+1}^{(n)}$. The internal differential is the coderivation extending $b_1(s^{-1}a) = -s^{-1}(d_A a)$, with the same prefix sign $\sum_{q < i} (|e_{I_q}| - 1)$.

The sum runs only over *consecutive* collisions $i, i+1$: this is the ordered constraint. In the unordered bar complex (Vol. I, Theorem A), one sums over all pairs $\{i, j\}$ and then takes Σ_k -coinvariants.

The identity $d^2 = 0$ follows from Stokes' theorem applied to the boundary strata of $\overline{\text{FM}}_k^{\text{ord}}(\mathbb{C})$: the codimension-two strata receive the two adjacent parenthesisations of the same consecutive block, and the algebraic content of their cancellation is the desuspended Stasheff identity for the OPE operations m_k^{ch} . In the strict associative case this is ordinary associativity of m_2 ; with higher OPE modes retained it is the consecutive-block projection of the Borchers identities.

Remark 27.11.10 (Ordered vs. FG bar: the all-modes clause). The sum over all OPE modes n in the bar differential (eq. above) distinguishes the ordered bar from the Francis–Gaitsgory bar, which retains only the $n = 0$ slot. The higher-mode contributions are recorded on ordered bar words via the tensor decorations $[\delta_D^{(n)}]$; equivalently, scalar-valued higher-mode residues contribute to the curvature m_0 of the curved bar coalgebra (see the Heisenberg case, Theorem 27.12.1), while field-valued higher-mode residues feed spectral $\mathcal{A}_\infty$ -corrections m_k at degree $k \geq 3$ (see the Virasoro case, §27.15). In every case the ordered bar extracts *all* OPE modes; the convention chosen here differs from the raw-OPE presentation on the right-hand side of the classical Laurent expansion by the single d log absorption step.

27.11.6 The deconcatenation coproduct

Construction 27.11.11 (Deconcatenation coproduct). The ordered bar coalgebra carries a coassociative coproduct Δ defined by *deconcatenation*: cutting the ordered sequence at every possible position. For a bar word of length k :

$$\Delta[s^{-1}e_{I_1} | \cdots | s^{-1}e_{I_k}] = \sum_{p=0}^k [s^{-1}e_{I_1} | \cdots | s^{-1}e_{I_p}] \otimes [s^{-1}e_{I_{p+1}} | \cdots | s^{-1}e_{I_k}],$$

where the $p = 0$ and $p = k$ terms produce the coaugmentation.

This coproduct is the topological structure: it comes from the ordered configuration space $\text{Conf}_k^<(\mathbb{R})$ by cutting the ordered real line at a point between t_p and t_{p+1} . The p points to the left form one ordered subconfiguration; the $k-p$ points to the right form another. The coassociativity of Δ is the associativity of interval composition.

Contrast with the holomorphic differential. The bar differential d extracts residues in the holomorphic direction (collisions of points on $\mathbb{C}$). The coproduct Δ cuts in the topological direction (splitting the ordered sequence on $\mathbb{R}$). Together, the pair (d, Δ) encodes both components of the E_1 -chiral coalgebra:

Structure	Direction	Geometric source
Bar differential d	holomorphic ($\mathbb{C}_z$)	OPE residues on $\mathrm{FM}_k(\mathbb{C})$
Coproduct Δ	topological ($\mathbb{R}_t$)	Deconcatenation of $\mathrm{Conf}_k^<(\mathbb{R})$

27.II.7 The covering space frame

Construction 27.II.12 (Ordered-to-unordered covering). The projection

$$\pi_k: \mathrm{Conf}_k^{\mathrm{ord}}(\mathbb{C}) \longrightarrow \mathrm{Conf}_k(\mathbb{C}) = \mathrm{Conf}_k^{\mathrm{ord}}(\mathbb{C})/\Sigma_k$$

is a principal Σ_k -bundle, étale with fibre Σ_k . The fibre is a $k!$ -element set.

In the topological direction, the analogous covering $\mathrm{Conf}_k^{\mathrm{ord}}(\mathbb{R}) \rightarrow \mathrm{Conf}_k(\mathbb{R})/\Sigma_k$ is also a $k!$ -sheeted covering, but here it is trivialised by the total order on $\mathbb{R}$: the component $\mathrm{Conf}_k^<(\mathbb{R})$ is a fundamental domain. This triviality is why the topological direction carries an E_1 -structure (associative, no higher coherences from the covering) while the holomorphic direction carries monodromy (the R -matrix).

The bar complex at tensor degree k defines a local system $\mathcal{F}_k^{\mathrm{ord}}$ on $\mathrm{Conf}_k^{\mathrm{ord}}(\mathbb{C})$ whose stalk at $(z_1, \dots, z_k)$ is $(s^{-1}\tilde{\mathcal{A}})^{\otimes k}$, with flat connection induced by the residue differential d_{res} . The R -matrix is the monodromy of this flat connection.

To descend $\mathcal{F}_k^{\mathrm{ord}}$ from ordered to unordered configurations requires a Σ_k -equivariant structure: isomorphisms $R_\sigma: \mathcal{F}_k^{\mathrm{ord}}|_{(z_1, \dots, z_k)} \xrightarrow{\sim} \mathcal{F}_k^{\mathrm{ord}}|_{(z_{\sigma(1)}, \dots, z_{\sigma(k)})}$ for each $\sigma \in \Sigma_k$, satisfying the cocycle condition and compatible with the flat connection.

In the pole-free symmetric case the equivariant structure is canonical: $R_\sigma = \epsilon(\sigma) \cdot \tau_\sigma$, where τ_σ permutes tensor factors and $\epsilon(\sigma)$ is the desuspended Koszul sign. The descent then recovers the ordinary Σ_k -coinvariant bar complex (Vol. I, Theorem A).

For a singular or genuinely ordered E_1 -chiral algebra, the equivariant structure must be constructed from the OPE data. This construction is the R -matrix. The Yang–Baxter equation supplies the braid-group action; the further strong-unitarity condition is what allows the action to factor through Σ_k and hence to produce the symmetric bar.

Remark 27.II.13 (Why ordered spaces). The use of ordered versus unordered configuration spaces reflects the operadic symmetry of the algebra:

- An E_∞ -chiral algebra has operations that are Σ_n -equivariant: the factorisation structure is defined on the *unordered* configuration space $\mathrm{Conf}_k(X)/\Sigma_k$. The ordering on the bar complex is a computational convenience that can be quotiented out.
- An E_1 -algebra (an associative chiral algebra, a quantum vertex algebra in the sense of Etingof–Kazhdan) has operations indexed by *ordered* compositions: its bar complex uses $\mathrm{Conf}_k^{\mathrm{ord}}(X)$. The ordering records the topological direction: in $\mathbb{C}_z \times \mathbb{R}_t$, points along $\mathbb{R}_t$ are ordered by time, and the E_1 -structure is the time-ordered product.
- The Swiss-cheese operad $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ uses *both*: unordered configurations in the holomorphic direction (chiral component) and ordered configurations in the topological direction (coassociative component). The ordered bar complex of a vertex algebra, which is E_∞ -chiral, uses the ordered configuration space for the E_1 /coassociative component of $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$; this is the topological direction, not a claim that the algebra is nonlocal. The holomorphic component remains E_∞ .

The R -matrix $R(z) \in \text{End}(V \otimes V)((z))$ is the data needed to pass from ordered to unordered configurations in the holomorphic direction: it is the monodromy of the local system on $\text{Conf}_2^{\text{ord}}(\mathbb{C})$ around the generator of $\pi_1 = \mathbb{Z}$.

The first test case is the Heisenberg chiral algebra at level k .

27.12 THE HEISENBERG ORDERED BAR COMPLEX

Let $V = \mathbb{C} \cdot J$ be the one-dimensional vector space spanned by the Heisenberg current, let $k \in \mathbb{C}$ be the level, and let $\mathcal{H}_k$ be the Heisenberg chiral algebra with OPE

$$J(z)J(w) \sim \frac{k}{(z-w)^2}.$$

The Heisenberg algebra is E_∞ -chiral: it is a local vertex algebra with Σ_n -equivariant factorization structure. Its OPE has a double pole, but poles do not break E_∞ -locality.

The ordered bar complex $\overline{B}^{\text{ch}}(\mathcal{H}_k)$ is the cofree conilpotent coalgebra on the desuspension $s^{-1}\overline{\mathcal{H}}_k$, with the ordering of tensor factors recording the linear order $t_1 < \cdots < t_n$ on $\mathbb{R}$. We compute the complex degree by degree.

THEOREM 27.12.1 (*The Heisenberg ordered bar complex;*). The ordered bar complex $\overline{B}^{\text{ch}}(\mathcal{H}_k)$ is a curved cofree conilpotent dg coalgebra $(T^c(s^{-1}V), d_{\overline{B}^{\text{ch}}}, m_o, \Delta)$ carrying the following data:

(1) **Curvature.** The degree-0 component is

$$m_o = k \cdot |o\rangle \in \overline{B}_o^{\text{ch}}(\mathcal{H}_k),$$

the constant extracted from the double-pole coefficient $J_{(1)}J = k$. This is the genus-zero Heisenberg curvature $\kappa(\mathcal{H}_k) = k$ of the Vol. I landscape census.

- (2) **Degree 1.** $\overline{B}_1^{\text{ch}}(\mathcal{H}_k) = \mathbb{C} \cdot [s^{-1}J]$, with $d_{\overline{B}^{\text{ch}}}[s^{-1}J] = o$ (the linear bar differential is binary; a single element has no adjacent pair to collide).
- (3) **Degree 2.** $\overline{B}_2^{\text{ch}}(\mathcal{H}_k) = \mathbb{C} \cdot [s^{-1}J | s^{-1}J]$, a *single* generator (the ordered complex retains the linear order; there is no Σ_2 -identification). The linear bar differential vanishes:

$$d_{\overline{B}^{\text{ch}}}[s^{-1}J | s^{-1}J] = o,$$

because the contraction of the two adjacent J -slots into a *single* bar slot must land in the augmentation ideal $\overline{\mathcal{H}}_k$, whereas the only nonvanishing OPE mode of two J 's is the central scalar $J_{(1)}J = k \in \mathbb{C}$. The scalar escapes the augmentation ideal entirely and is collected in the curvature m_o upstream (item (1)), not in the linear differential d_* .

- (4) **Degree n .** $\overline{B}_n^{\text{ch}}(\mathcal{H}_k) = \mathbb{C} \cdot [s^{-1}J | \cdots | s^{-1}J]$ (n copies), with $d_{\overline{B}^{\text{ch}}} = o$ on every element. The argument is uniform: each adjacent collision either lands in a scalar (contributing to m_o) or vanishes, so no contribution survives in the augmentation ideal at positive degree.

- (5) **Coproduct.** The deconcatenation coproduct Δ on $\overline{B}^{\text{ch}}(\mathcal{H}_k)$ is

$$\Delta[s^{-1}J | \cdots | s^{-1}J] = \sum_{i=0}^n [s^{-1}J | \cdots | s^{-1}J]_i \otimes [s^{-1}J | \cdots | s^{-1}J]_{n-i},$$

where the subscript denotes the number of tensor factors. This is the tensor coalgebra coproduct, encoding interval-cutting in $\mathbb{R}$.

- (6) **Curved E_1 -chiral coalgebra structure.** The ordered bar coalgebra is the curved cofree object $(T^c(s^{-1}V), d_1 = 0, m_o = k|o\rangle, \Delta)$: the linear differential vanishes identically, but the degree-0 curvature $m_o = k|o\rangle$ is non-zero. The associated R-matrix $R(z) = e^{k\hbar/z}$ (Theorem 27.12.3) is the exponentiated form of the curvature seen on the ordered configuration space.

Proof. Heisenberg has the single generator J and the unique nonvanishing OPE mode $J_{(1)}J = k$, which is a scalar. The linear bar differential $d_1: \bar{B}_n^{\text{ch}} \rightarrow \bar{B}_{n-1}^{\text{ch}}$ contracts an adjacent pair of slots into a single slot of the augmentation ideal $\tilde{\mathcal{H}}_k$. The only output available from $J \cdot J$ contractions is the scalar k , which lies outside $\tilde{\mathcal{H}}_k$; hence $d_1 = 0$ on every bar word. The scalar contribution is collected separately in the degree-0 component, giving $m_o = k|o\rangle$.

The deconcatenation coproduct is manifestly coassociative (it is the tensor coalgebra structure), and the curved bar identity reduces to $d_1 \circ d_1 = [m_o, -]_o$, both sides of which vanish on the augmentation ideal. $\square$

Remark 27.12.2 (Curvature, not differential). The mode $J_{(1)}J = k$ is the genus-zero curvature of the ordered Heisenberg bar coalgebra: it lives in the degree-0 component m_o , not in the linear differential d_1 . In the *symmetric* bar complex $\bar{B}^{\Sigma}(\mathcal{H}_k)$ (Vol I, Theorem A) the same datum is conventionally recorded by $d_{\bar{B}}[s^{-1}J | s^{-1}J] = k$, viewing the constant k as the value of d on the ground field copy inside the symmetric bar. In the ordered complex the constant is collected upstream in m_o , and the corresponding holonomy on ordered configuration space is the R-matrix $R(z) = e^{k\hbar/z}$ (Theorem 27.12.3). The three pictures are equivalent presentations of the same genus-zero datum $\kappa(\mathcal{H}_k) = k$.

THEOREM 27.12.3 (Collision residue and R-matrix;). Let $z = z_1 - z_2$ denote the relative coordinate on $C_2^<(\mathbb{C})$. The collision residue of the Heisenberg double-pole OPE is

$$r_{\mathcal{H}}^{\text{coll}}(z) = \frac{k \Omega_{\mathcal{H}}}{z}, \quad \Omega_{\mathcal{H}} := J \otimes J, \quad (27.6)$$

a tensor-valued *simple* pole obtained from the OPE double pole $k/(z_1 - z_2)^2$ by one step of $d \log$ absorption ($d \log$ lowers every OPE pole order by one). The scalar k/z is only the J, J matrix coefficient of (27.6).

The unit-charge coefficient of the flat connection on the trivial bundle over $C_2^<(\mathbb{C})$ determined by the bar propagator is

$$\nabla_{\text{unit}} = d - (r_{\mathcal{H}}^{\text{coll}}(z))_{J,J} dz = d - (k/z) dz,$$

and its monodromy around the origin is

$$\text{Mon}_o(\nabla_{\text{unit}}) = e^{-2\pi i k}$$

(treating $k \in \mathbb{C}$ as a generic continuous parameter).

The spectral R-matrix on modules is

$$R(z) = e^{k\hbar/z} \quad (\text{nontrivial}).$$

Since $\mathcal{H}_k$ is E_{∞} -chiral, this R-matrix is *derived* from the local OPE via the monodromy of ∇_{unit} , not independent input. The Yang–Baxter equation is satisfied by the tensor residue $\Omega_{\mathcal{H}}$ because the Heisenberg current Lie algebra is abelian; after evaluating on Fock charges the resulting $R(z)$ is scalar.

Proof. The OPE mode expansion is $J(z)J(w) = \sum_{n \geq 0} J_{(n)}J \cdot (z-w)^{-n-1}$, with the unique nonvanishing mode $J_{(1)}J = k$ giving the double-pole coefficient. Pairing the OPE density $k(z-w)^{-2}dz$ against the bar kernel $d \log(z-w)$ on $\text{FM}_2(\mathbb{C})$ and using $d \log(z-w) = -dw/(z-w)$ absorbs one power of $(z-w)^{-1}$, producing the simple-pole residue kernel $k\Omega_{\mathcal{H}}(z-w)^{-1}dz$ on the ordered configuration space. Writing $z = z_1 - z_2$ for the relative coordinate, $r_{\mathcal{H}}^{\text{coll}}(z) = k\Omega_{\mathcal{H}}/z$ as claimed.

The unit-charge coefficient connection $\nabla_{\text{unit}} = d - (k/z)dz$ on the trivial line bundle over $\mathbb{C}^\times$ has flat sections $f(z) = z^k$; the associated parallel transport around $\gamma: z \mapsto e^{2\pi i t}z$ multiplies flat sections by $e^{2\pi i k}$, so the monodromy acting on parallel-transported vectors is $e^{-2\pi i k}$.

The spectral R -matrix is obtained by the Kohno exponentiation of the connection. On Fock modules $\mathcal{F}_\mu \otimes \mathcal{F}_\nu$ the Casimir collapses to the scalar $\mu\nu k$, and the path-ordered exponential reduces to the ordinary exponential $R(z) = \exp(\oint r_{\mathcal{H}}^{\text{coll}}(z) dz) = e^{k\hbar/z}$ in the spectral variable, where $\hbar = \mu\nu$. The computation is scalar throughout after this rank-one evaluation. $\square$

Remark 27.12.4 (Non-triviality). The Heisenberg R -matrix $R(z) = e^{k\hbar/z}$ is *not* the trivial permutation $R = \tau$. For a generic level k and generic Fock charges, $R(z)$ is a non-identity scalar exponential series in $1/z$. The collision residue is the tensor $k\Omega_{\mathcal{H}}/z$, whose rank-one coefficient is derived from the OPE double pole ($d \log$ absorption); attempting to read the R -matrix off the raw OPE without applying the step gives the incorrect answer k/z^2 and hence a wrong pole structure.

THEOREM 27.12.5 (Open-colour Koszul dual: the abelian Yangian;). The ordered (coassociative) Koszul dual of $\mathcal{H}_k$ is the abelian Yangian

$$\mathcal{H}_k^{\text{l,ord}} \simeq Y(\mathfrak{u}(1)) \simeq \mathbb{C}[h_0, h_1, h_2, \dots],$$

the polynomial algebra on generators h_n of degree $n+1$, with product inherited from the continuous graded linear dual of the deconcatenation coproduct. The spectral-parameter presentation identifies $h_n = \partial_u^n h(u)|_{u=0}$, where $h(u) = \sum_{n \geq 0} h_n u^{-n-1}$ is the generating current of the Yangian.

Proof. Since the bar differential vanishes on $\overline{B}^{\text{ch}}(\mathcal{H}_k)$ and each spectral graded piece is finite-dimensional, the Koszul dual is the continuous graded linear dual of the bar coalgebra:

$$\mathcal{H}_k^{\text{l,ord}} = (\overline{B}^{\text{ch}}(\mathcal{H}_k))^\vee = (T^c(s^{-1}V))^\vee \simeq T(sV^\vee) \simeq \mathbb{C}[h],$$

where $h = (s^{-1}J)^\vee$ is the dual generator. The coalgebra $T^c(s^{-1}V)$ has deconcatenation coproduct; dualizing produces the concatenation (polynomial) product on $T(sV^\vee) = \mathbb{C}[h]$.

Since V is one-dimensional and $d_{\overline{B}^{\text{ch}}} = 0$, the Koszul dual algebra is freely generated by h with no relations. Restoring the spectral grading from the FM configuration-space stratification, the degree- n component corresponds to $\text{FM}_n(\mathbb{C})$, giving the generators $h_0, h_1, h_2, \dots$ of the abelian Yangian $Y(\mathfrak{u}(1))$.

Equivalently: the Koszul dual is the endomorphism algebra of the line operator b in the coassociative line category $\mathcal{C}_{\text{line}}$. The line category $\mathcal{C}_{\text{line}} \simeq \mathcal{H}_{-k}\text{-mod}$ is equivalent to modules over the negative-level Heisenberg, but the ordered Koszul dual $\mathcal{H}_k^{\text{l,ord}} = Y(\mathfrak{u}(1)) \simeq \mathbb{C}[h_0, h_1, \dots]$ is categorically distinct from $\mathcal{H}_{-k}$ as a chiral algebra (not $\mathcal{H}_{-k}$; they share the same modular characteristic $\kappa = -k$ but differ as algebras). $\square$

THEOREM 27.12.6 (Formality: class G, shadow depth 2;). The Heisenberg ordered bar complex is formal: the A_∞ -structure on $H^\bullet(\overline{B}^{\text{ch}}(\mathcal{H}_k))$ has $m_k = 0$ for all $k \geq 3$. The Heisenberg belongs to class G (shadow depth $r_{\text{max}} = 2$, the minimum for a nontrivial chiral algebra).

Proof. Since $d_{\overline{B}^{\text{ch}}} = 0$, the bar complex is its own cohomology. There is nothing to transfer: the A_∞ -structure on cohomology inherits the trivial differential and the deconcatenation coproduct, with all higher operations vanishing. The vanishing of $m_{k \geq 3}$ is equivalent to saying that the OPE has a single pole order (the double pole), and the collision residue $r_{\mathcal{H}}^{\text{coll}} = k\Omega_{\mathcal{H}}/z$ has a simple pole, which falls in class G. $\square$

Remark 27.12.7 (Contrast with the chiral (symmetric) Koszul dual). The chiral Koszul dual of $\mathcal{H}_k$ (Vol I) is the curved second-kind commutative chiral algebra

$$\mathcal{H}_k^{1,\text{ch}} = (\text{Sym}^{\text{ch}}(V^*[1]), m_0 = -k\omega),$$

a free commutative associated-graded algebra on one shifted generator with curvature. The ordered Koszul dual $Y(\mathfrak{u}(1))$ carries strictly more structure: the spectral parameter u (arising from the FM stratification in the ordered complex) is invisible in the symmetric Koszul dual. The passage from ordered to symmetric is R -matrix-twisted Σ_n -coinvariants: since $R(z) = e^{kh/z} \neq \tau$ (the Koszul sign), the descent $\overline{B}^{\text{ch}}(\mathcal{H}_k) \rightarrow \overline{B}^{\Sigma}(\mathcal{H}_k)$ is genuinely twisted, and the spectral parameter information is lost in the quotient (absorbed into the bar differential of $\overline{B}^{\Sigma}$, where $d_{\overline{B}}[s^{-1}J | s^{-1}J] = k \neq 0$).

This is the three-tier picture in its simplest instance: the Heisenberg lives in tier (ii) (E_∞ -chiral with $R(z) \neq \tau$, derived from the local OPE). Tier (i) would require $R(z) = \tau$ (no OPE poles); tier (iii) would require $R(z)$ to be independent input (genuinely E_1).

Remark 27.12.8 (The Heisenberg as prototype). The Heisenberg ordered bar complex is the simplest instance of a general pattern. Each subsequent family generalises exactly one aspect of the structure, while preserving the others.

- (i) $\beta\gamma$ system (§27.24): The underlying vector space grows from $\dim V = 1$ to $\dim V = 2$, and the pole-valued collision residue drops: the d log kernel absorbs the simple OPE pole. The regular contact operator Θ satisfies $\Theta^2 = 0$, and the bar differential remains trivial ($d_{\overline{B}^{\text{ch}}} = 0$) because the zeroth mode product $\beta_{(0)}\gamma = 1$ is a scalar, not a new generator. Formality persists: shadow depth is $r_{\max} = 4$ (class C).
- (ii) *Affine* $\widehat{\mathfrak{g}}_k$ (§27.16.1): The rank-one tensor residue $k\Omega_{\mathcal{H}}/z$ becomes the trace-form Casimir kernel $k\Omega_{\mathfrak{t}}/z \in \mathfrak{g} \otimes \mathfrak{g}(z^{-1})$. The scalar R -matrix $e^{kh/z}$ becomes the Yang R -matrix $1 + \Omega/((k + h^\vee)z) + O((k + h^\vee)^{-2})$ after KZ rescaling. The abelian Yangian $Y(\mathfrak{u}(1))$ becomes $Y_h(\mathfrak{g})$. The bar differential acquires nontrivial components from $[X, Y]_{(0)} \neq 0$, but formality persists: shadow depth is $r_{\max} = 3$ (class L).
- (iii) *Virasoro* (§27.15): The double OPE pole becomes quartic: $T(z)T(w) \sim (c/2)/(z-w)^4 + \dots$. The simple current residue $k\Omega_{\mathcal{H}}/z$ becomes the triple-pole residue $(c/2)/z^3 + 2T/z$. Formality breaks: $m_k \neq 0$ for all $k \geq 3$, so the A_∞ -structure is genuinely infinite. Shadow depth is $r_{\max} = \infty$ (class M). The nontrivial Yangian structure collapses to a single generator T , but the non-formal bar differential compensates: the complexity migrates from the algebra's rank to the differential's depth.

The four classes resolve as follows. The Heisenberg is class G (shadow depth 2, formal, scalar). The $\beta\gamma$ system is class C (shadow depth 4, formal, regular nilpotent contact). The affine is class L (shadow depth 3, formal, matrix). The Virasoro is class M (shadow depth ∞ , non-formal, collapsed rank). Each step from Heisenberg to Virasoro escalates exactly one structural parameter while the rest of the ordered bar architecture remains intact.

27.13 THE DRINFELD PRESENTATION OF $Y_{\hbar}(\mathfrak{sl}_2)$

The ordered bar complex $\overline{B}^{\text{ch}}(V_k(\mathfrak{sl}_2))$ produces the Yang R -matrix, the RTT presentation, and the Gauss decomposition. The *Drinfeld presentation* (the generating-current form that reveals the Yangian as a deformation of the current algebra $U(\mathfrak{sl}_2[t])$) emerges from the ordered bar data. The affine vertex algebra $V_k(\mathfrak{sl}_2)$ is E_{∞} -chiral (it is a local vertex algebra with Σ_n -equivariant factorisation structure); the Yangian $Y_{\hbar}(\mathfrak{sl}_2)$ is the ordered Koszul dual living on the open boundary $\mathbb{R}_t$.

GENERATORS

The Drinfeld generators are obtained from the Gauss decomposition of the transfer matrix $T(u) = F(u)K(u)E(u)$, where $F(u)$ is lower-triangular unipotent, $K(u) = \text{diag}(k_1(u), k_2(u))$ is diagonal, and $E(u)$ is upper-triangular unipotent. Define the Drinfeld currents:

$$\begin{aligned} E(u) &= \sum_{r \geq 0} E_r u^{-r-1}, \\ F(u) &= \sum_{r \geq 0} F_r u^{-r-1}, \\ H(u) &= 1 + \hbar \sum_{r \geq 0} H_r u^{-r-1} = \frac{k_1(u)}{k_2(u)}. \end{aligned}$$

The modes $\{E_r, F_r, H_r\}_{r \geq 0}$ generate $Y_{\hbar}(\mathfrak{sl}_2)$ as an associative algebra. At $\hbar = 0$, the identification $E_r \mapsto e \otimes t^r, F_r \mapsto f \otimes t^r, H_r \mapsto h \otimes t^r$ recovers $U(\mathfrak{sl}_2[t])$.

THE DRINFELD RELATIONS FROM THE BAR COMPLEX

THEOREM 27.13.1 (*Drinfeld presentation of $Y_{\hbar}(\mathfrak{sl}_2)$*). The Yangian $Y_{\hbar}(\mathfrak{sl}_2)$, with $\hbar = 1/(k+2)$, is the associative algebra generated by $\{E_r, F_r, H_r\}_{r \geq 0}$ subject to the relations:

$$(D1) \quad [H_r, H_s] = 0 \text{ for all } r, s \geq 0.$$

$$(D2) \quad [H(u), E(v)] = \frac{2\hbar}{u-v} (E(u) - E(v)).$$

$$(D3) \quad [H(u), F(v)] = -\frac{2\hbar}{u-v} (F(u) - F(v)).$$

$$(D4) \quad [E(u), F(v)] = \frac{1}{u-v} (H(u) - H(v)).$$

$$(D5) \quad (u-v) [E(u), E(v)] = \hbar (E(u)E(v) + E(v)E(u)) \text{ (deformed Serre relation).}$$

$$(D6) \quad (u-v) [F(u), F(v)] = -\hbar (F(u)F(v) + F(v)F(u)) \text{ (deformed Serre relation).}$$

Proof. Relations (D1)–(D4) are extracted from the Gauss decomposition of the RTT equation $R_{12}(u-v)T_1(u)T_2(v) = T_2(v)T_1(u)R_{12}(u-v)$. The key step is the factorisation $T(u) = F(u)K(u)E(u)$: the diagonal entries produce (D1), the off-diagonal–diagonal cross-terms produce (D2)–(D3), and the purely off-diagonal cross-terms produce (D4).

For (D1): the RTT relations $[A(u), A(v)] = 0 = [D(u), D(v)]$ imply that $k_1(u), k_2(u)$ (and hence $H(u) = k_1(u)/k_2(u)$) generate a commutative subalgebra.

For (D2): the RTT relation $(u-v)[A(u), B(v)] = A(v)B(u) - A(u)B(v)$, rewritten via Gauss decomposition in terms of $H(u)$ and $E(u)$, yields the stated current-algebra relation. Expanding $A(u) = k_1(u)(1 + F(u)k_2(u)k_1(u)^{-1}E(u))$ and $B(u) = k_1(u)E(u)$, the diagonal factor cancels between left and right sides, and the residual identity in the off-diagonal is precisely (D2). Relation (D3) follows by the same argument applied to $(u-v)[A(u), C(v)] = C(v)A(u) - C(u)A(v)$.

For (D4): the RTT relation $(u-v)[B(u), C(v)] = D(v)A(u) - D(u)A(v)$ extracts, via Gauss decomposition, to $(u-v)[E(u), F(v)] = H(u) - H(v)$.

For (D5) and (D6): the RTT relation $[B(u), B(v)] = 0$ encodes $[E(u), E(v)]$ modulo diagonal factors. The precise computation: $[B(u), B(v)] = 0$ with $B(u) = k_1(u) E(u)$ gives, after extracting the non-commuting diagonal, $(u-v)[E(u), E(v)] = \hbar(E(u)E(v) + E(v)E(u))$. The sign in (D6) follows from $[C(u), C(v)] = 0$ by the same argument with F in place of E .

Every relation is a direct algebraic consequence of the RTT presentation, itself extracted from the degree-2 bar differential and the Yang R -matrix $R(u) = u I + P$. $\square$

Remark 27.13.2 (Provenance from the bar complex). The chain of identifications is:

$$\text{OPE of } \widehat{\mathfrak{sl}}_2 \xrightarrow{\text{bar differential}} r(z) = \frac{\hbar \Omega}{z} \xrightarrow{\text{exponentiation}} R(u) = u I + P \xrightarrow{\text{RTT}} \text{(D1)–(D6)}.$$

The first arrow is (the d log kernel absorbs one pole from the affine double-pole OPE); the second is the monodromy of the Kohn connection on $\text{Conf}_2^{\text{ord}}(\mathbb{C})$ specialised to the fundamental representation; the third is the Gauss decomposition. The entire Drinfeld presentation is a derived algebraic consequence of the OPE of $V_k(\mathfrak{sl}_2)$.

GAUSS DECOMPOSITION

PROPOSITION 27.13.3 (Gauss decomposition). The transfer matrix $T(u) = \begin{pmatrix} A(u) & B(u) \\ C(u) & D(u) \end{pmatrix}$ factors uniquely as

$$T(u) = \underbrace{\begin{pmatrix} 1 & 0 \\ F(u) & 1 \end{pmatrix}}_{F(u)} \cdot \underbrace{\begin{pmatrix} k_1(u) & 0 \\ 0 & k_2(u) \end{pmatrix}}_{K(u)} \cdot \underbrace{\begin{pmatrix} 1 & E(u) \\ 0 & 1 \end{pmatrix}}_{E(u)},$$

with $A(u) = k_1(u) + F(u) k_2(u) E(u)$, $B(u) = k_1(u) E(u)$, $C(u) = F(u) k_2(u)$, $D(u) = k_2(u)(1 + F(u) E(u))$. The Drinfeld Cartan current is the ratio $H(u) = k_1(u)/k_2(u)$.

Proof. The upper-triangular unipotent factor is determined by $E(u) = k_1(u)^{-1} B(u)$; the lower-triangular unipotent factor by $F(u) = C(u) k_2(u)^{-1}$; the diagonal entries by $k_2(u) = D(u) - C(u) A(u)^{-1} B(u)$ (the Schur complement) and $k_1(u) = A(u) - B(u) D(u)^{-1} C(u)$. The quantum determinant $\text{qdet } T(u) = k_1(u) k_2(u - \hbar)$ is central in $Y_{\hbar}(\mathfrak{sl}_2)$, confirming the factorisation is well-defined over the Yangian. $\square$

TWISTED COPRODUCT ON DRINFELD GENERATORS

THEOREM 27.13.4 (Twisted coproduct). The twisted coproduct $\Delta_z: Y_{\hbar}(\mathfrak{sl}_2) \rightarrow Y_{\hbar}(\mathfrak{sl}_2) \otimes Y_{\hbar}(\mathfrak{sl}_2)$ acts on the Drinfeld generators as:

$$\Delta_z(H(u)) = H(u) \otimes H(u-z), \quad (27.7)$$

$$\Delta_z(E(u)) = E(u) \otimes 1 + H(u-z) \otimes E(u-z), \quad (27.8)$$

$$\Delta_z(F(u)) = 1 \otimes F(u-z) + F(u) \otimes H(u-z)^{-1}. \quad (27.9)$$

At $z = 0$ this recovers the standard Hopf coproduct of $Y_{\hbar}(\mathfrak{sl}_2)$.

Proof. The RTT coproduct is $\Delta_z(T(u)) = T(u) \dot{\otimes} T(u-z)$ (matrix multiplication in the auxiliary space, with spectral parameter shifted by z in the second tensor factor). Applying Gauss decomposition to both sides:

$$\Delta_z(T(u)) = F(u) K(u) E(u) \dot{\otimes} F(u-z) K(u-z) E(u-z).$$

The diagonal entry gives $\Delta_z(K(u)) = K(u) \otimes K(u-z)$, whence (27.7) follows by taking the ratio k_1/k_2 . The off-diagonal entry $\Delta_z(B(u)) = A(u) \otimes B(u-z) + B(u) \otimes D(u-z)$, rewritten via $B = k_1 E$ and $A = k_1 + F k_2 E$, yields (27.8) after extracting the k_1 factor. Equation (27.9) follows by the analogous computation on $C(u) = F(u) k_2(u)$. $\square$

Remark 27.13.5 (Factorisation-algebraic origin of Δ_z). The spectral parameter z is the relative position along $\mathbb{R}_t$: it is the topological interval coordinate of the $\text{SC}^{\text{ch}, \text{top}}$ -structure. The twisted coproduct Δ_z is the factorisation product of line operators at positions t_1 and $t_2 = t_1 + z$ on the topological interval. The formula $\Delta_z(T(u)) = T(u) \dot{\otimes} T(u-z)$ is the bar-coalgebra deconcatenation specialised to degree 2 in the ordered bar complex. At $z = 0$ the two insertion points collide and one recovers the ordinary (untwisted) Hopf coproduct.

PBW BASIS AND HILBERT SERIES

THEOREM 27.13.6 (*PBW theorem for $Y_{\hbar}(\mathfrak{sl}_2)$*). The ordered monomials

$$\{f_{r_1} \cdots f_{r_a} h_{s_1} \cdots h_{s_b} e_{t_1} \cdots e_{t_c} \mid 0 \leq r_1 \leq \cdots \leq r_a, 0 \leq s_1 \leq \cdots \leq s_b, 0 \leq t_1 \leq \cdots \leq t_c\}$$

form a basis of $Y_{\hbar}(\mathfrak{sl}_2)$ over $\mathbb{C}$. The Hilbert series with respect to the grading $\deg(X_r) = r$ is

$$\text{HS}_{Y_{\hbar}(\mathfrak{sl}_2)}(q) = \prod_{d \geq 0} \frac{1}{(1 - q^d)^3}.$$

Proof. The PBW property follows from the Drinfeld relations (D1)–(D6) by a standard diamond lemma argument: the leading terms of (D2)–(D6) (in the degree-lexicographic order $f_{r_1} \cdots h_{s_1} \cdots e_{t_1} \cdots$) show that every out-of-order monomial reduces to a sum of ordered monomials of equal or lower total degree. The three families of generators $\{e_r\}_{r \geq 0}$, $\{f_r\}_{r \geq 0}$, $\{h_r\}_{r \geq 0}$ each contribute a factor of $\prod_{d \geq 0} (1 - q^d)^{-1}$ to the Hilbert series, giving the stated product formula. The PBW basis is compatible with the filtration $F_{\leq n} Y_{\hbar}(\mathfrak{sl}_2) = \langle X_{r_1} \cdots X_{r_k} \mid r_1 + \cdots + r_k \leq n \rangle$, and the associated graded is $\text{gr } Y_{\hbar}(\mathfrak{sl}_2) \simeq U(\mathfrak{sl}_2[t])$. $\square$

CLASSICAL LIMIT: COMPARISON WITH $U(\mathfrak{sl}_2[t])$

THEOREM 27.13.7 (*Classical limit*). At $\hbar = 0$, the Yangian $Y_{\hbar}(\mathfrak{sl}_2)$ degenerates to the universal enveloping algebra of the current Lie algebra $\mathfrak{sl}_2[t] = \mathfrak{sl}_2 \otimes \mathbb{C}[t]$. Explicitly:

- (i) Relations (D2)–(D3) at $\hbar = 0$ become $[H(u), E(v)] = 0 = [H(u), F(v)]$ after clearing denominators and passing to modes, yielding $[h_r, e_s] = 2e_{r+s}$, $[h_r, f_s] = -2f_{r+s}$ the current-algebra Lie brackets $[h \otimes t^r, e \otimes t^s] = 2(e \otimes t^{r+s})$.
- (ii) Relation (D4) at $\hbar = 0$ becomes $[E_r, F_s] = H_{r+s}$, i.e. $[e \otimes t^r, f \otimes t^s] = h \otimes t^{r+s}$.
- (iii) Relations (D5)–(D6) at $\hbar = 0$ become $[E(u), E(v)] = 0 = [F(u), F(v)]$ after clearing $(u-v)$ the Serre relation for $\mathfrak{sl}_2[t]$ (abelian root spaces).
- (iv) The twisted coproduct Δ_z at $\hbar = 0$ degenerates to the cocommutative coproduct $\Delta(X_r) = X_r \otimes 1 + 1 \otimes X_r$ of $U(\mathfrak{sl}_2[t])$.

The PBW filtration on $Y_{\hbar}(\mathfrak{sl}_2)$ has associated graded $\text{gr } Y_{\hbar}(\mathfrak{sl}_2) \cong U(\mathfrak{sl}_2[t])$, confirming that the Yangian is a filtered deformation of the current algebra, with deformation parameter $\hbar = 1/(k+2)$ sourced by the level of the affine input $V_k(\mathfrak{sl}_2)$.

Proof. Setting $\hbar = 0$ in relations (D1)–(D6) is immediate. For (i): (D2) becomes $[H(u), E(v)] = 0$ at $\hbar = 0$; expanding $H(u) = 1 + \hbar \sum H_r u^{-r-1}$ and taking the leading $\hbar$ -linear term recovers $[h_r, e_s] = 2e_{r+s}$. For (ii): (D4) is $\hbar$ -independent. For (iii): the right-hand side of (D5) vanishes at $\hbar = 0$, giving $[E(u), E(v)] = 0$. For (iv): the shift $u \mapsto u - z$ in the second tensor factor of Δ_z is the spectral-parameter manifestation of the coproduct; at $\hbar = 0$ the modes become primitive. The associated-graded statement follows from the PBW theorem (Theorem 27.13.6). $\square$

Remark 27.13.8 (The deformation parameter and the level). The identification $\hbar = 1/(k+2)$ belongs to the KZ-normalized spectral connection, not to the trace-form collision residue. The affine OPE $J^a(z)J^b(w) \sim k \kappa^{ab}/(z-w)^2 + f^{ab}_c J^c/(z-w)$ gives the trace-form collision residue $r^{\text{coll}}(z) = k\Omega_{\text{tr}}/z$ after the $d \log$ kernel absorbs one pole order. The KZ connection rescales the Casimir-and-coupling package to $r^{\text{KZ}}(z) = \Omega/((k+h^\vee)z)$, with $h^\vee = 2$ for $\mathfrak{sl}_2$. At the critical level $k = -h^\vee = -2$, the parameter $\hbar$ diverges and the Yangian construction degenerates: this is the ordered-bar reflection of the Sugawara obstruction at critical level.

27.14 THE DOUBLE BAR AND WHAT IT RECOVERS

The ordered Koszul dual of $\widehat{\mathfrak{g}}_k$ is $Y_{\hbar}(\mathfrak{g})$. What is the ordered Koszul dual of $Y_{\hbar}(\mathfrak{g})$?

If ordered Koszul duality were an involution (as the full $\text{SC}^{\text{ch}, \text{top}}$ duality is (Theorem 27.14.2 below), then $\overline{B}^{\text{ch}, \text{ord}}(Y_{\hbar}(\mathfrak{g}))$ would recover $\widehat{\mathfrak{g}}_k$. It does not.

The ordered double bar recovers $U(\mathfrak{g}[t])$ *without* the central extension. The level k is invisible because it enters the Yangian as $\hbar = 1/(k+h^\vee)$, not as an OPE pole: the spectral R -matrix $R(u) = 1 + \hbar \Omega/u + O(\hbar^2)$ has only a simple pole, so the $d \log$ propagator of the ordered bar extracts the Lie bracket of $\mathfrak{g}[t]$ and nothing more. The double pole that *creates* the central extension lives in the holomorphic OPE on $\text{FM}_2(\mathbb{C})$ (the closed colour), and no iteration of the open bar can reach it.

THEOREM 27.14.1 (*Central extension is invisible to the ordered double bar*). Let $\mathfrak{g}$ be a simple Lie algebra and let $A = \widehat{\mathfrak{g}}_k$ at non-critical level. The ordered double Koszul dual satisfies

$$(A^!_{\text{line}})_{\text{line}}^! \simeq U(\mathfrak{g}[t]), \quad \text{not } \widehat{\mathfrak{g}}_k.$$

Proof. The level k of $\widehat{\mathfrak{g}}_k$ enters the ordered Koszul dual $Y_{\hbar}(\mathfrak{g})$ as the scalar $\hbar = 1/(k+h^\vee)$. The holomorphic double pole $k \delta^{ab}/(z-w)^2$ (the source of the central term $k n \delta_{n+m,0}$ in the mode algebra) does not survive as a double pole in the spectral variable: the Yangian R -matrix $R(u) = 1 + \hbar r(u) + O(\hbar^2)$ has its singularity at $u = 0$ with a *simple* pole $r(u) = \Omega/u$, where $\Omega = \sum_a T^a \otimes T^a$ is the Casimir tensor.

The ordered bar differential of $Y_{\hbar}(\mathfrak{g})$ uses the propagator $d \log(u_i - u_j)$ on $\text{Conf}_n^<(\mathbb{A}_u^1)$. By the $d \log$ absorption principle, a simple spectral pole yields the zeroth product $a_{(\circ)} b$; a double pole would yield a derivative term $a_{(\circ)} b$ carrying the central extension. But the spectral OPE has no double pole. Degree by degree:

Degree 1. Yangian generators E_n, F_n, H_n map to current modes J_n^a . At the first bar stage, the cohomology is therefore the desuspended current Lie algebra:

$$H^*(s^{-1}\tilde{Y}_{\hbar}, d_{\text{bar}}) = s^{-1}\mathfrak{g} \quad (\text{concentrated in cohomological degree } 1).$$

Degree 2. The spectral OPE $[E(u), F(v)] \sim \hbar/(u-v) \cdot (\dots)$ has only simple poles, so

$$d_{\text{bar}}(s^{-1}E_n \otimes s^{-1}F_m) = s^{-1}[E_n, F_m] = s^{-1}H_{n+m},$$

with no central term. For the E – E component, the pole at $u-v = \hbar$ is shifted off the collision diagonal, giving $d_{\text{res}}(s^{-1}E \otimes s^{-1}E) = 0$, i.e. $[e, e] = 0$ in $\mathfrak{g}[t]$.

Degree 3. $d^2 = 0$ reduces to the classical Yang–Baxter equation for $r(u) = \Omega/u$, which holds by the Jacobi identity for $\mathfrak{g}$.

Hence the bar differential recovers only the Lie bracket of $\mathfrak{g}[t]$, not the central extension. $\square$

The loss is not a failure of the machinery; it is a precise diagnosis of what each colour carries.

THEOREM 27.14.2 (*Two-colour double Koszul duality is involutive*). Let $\mathcal{A}$ be a strongly admissible E_∞ -chiral algebra on a curve X . The full $\text{SC}^{\text{ch}, \text{top}}$ double Koszul duality satisfies $(\mathcal{A}^!)^! \simeq \mathcal{A}$, recovering all central extensions and higher-pole data.

Proof. The full duality operates on both components: the *chiral component* (symmetric bar $\overline{B}^\Sigma(\mathcal{A})$ on $\text{Ran}(X)/\Sigma_n$, dualised by D_{Ran}) carries the holomorphic OPE including the double pole; the *coassociative component* (ordered bar $\overline{B}^{\text{ch}, \text{ord}}(\mathcal{A})$ on $\text{Conf}_n^<(\mathbb{R})$, dualised by linear duality) carries the spectral data. Verdier/Ran duality preserves the full pole structure, so the double pole survives. The bar–cobar involution $\Omega(\overline{B}^{\text{ch}}(\Omega(\overline{B}^{\text{ch}}(\mathcal{A})))) \simeq \mathcal{A}$ (Hypothesis 27.2.3(I), applied twice) then recovers $\mathcal{A}$ in its entirety. For $\widehat{\mathfrak{g}}_k$ the chiral Verdier–Koszul dual is $\text{CE}^{\text{ch}}(\widehat{\mathfrak{g}}_{-k-2\hbar^\vee})$; its scalar shadow has the Feigin–Frenkel dual level, and the second application returns to $\widehat{\mathfrak{g}}_k$ with the central extension intact. $\square$

COROLLARY 27.14.3 (*Non-redundancy of the two colours*). For any E_∞ -chiral algebra $\mathcal{A}$ with non-trivial OPE poles, the open and closed bar complexes carry genuinely non-redundant information. Neither colour alone recovers $\mathcal{A}$ by iterating Koszul duality: the ordered double bar loses the central extension (Theorem 27.14.1), while the chiral symmetric bar does not determine the R -matrix monodromy for the ordered-to-unordered descent (Proposition 27.4.3).

Proof. The ordered colour alone is insufficient by Theorem 27.14.1: iterating the ordered bar–cobar construction forgets the double-pole central extension data. The symmetric chiral colour alone is also insufficient by Proposition 27.4.3: it retains the holomorphic OPE data but does not recover the ordered R -matrix monodromy needed for descent from the ordered to the unordered picture. These two failures are complementary, so the open and closed colours carry genuinely different information and both are needed to recover $\mathcal{A}$. $\square$

Remark 27.14.4 (*The chiral–coassociative architecture at a glance*). The double-bar computation for $\widehat{\mathfrak{sl}}_{2,k}$ distils the architecture:

	Chiral (holomorphic)	Coassociative (topological)
Pole order	double: $k/(z-w)^2$	simple: $\hbar/(u-v)$
Extracted datum	central extension	Lie bracket of $\mathfrak{g}[t]$
Double KD output	$\widehat{\mathfrak{g}}_k$ (full)	$U(\mathfrak{g}[t])$ (no central ext.)

The two components of the E_1 -chiral bar carry genuinely non-redundant information. The coassociative component sees the Yangian; the chiral component sees the level. Neither alone recovers the algebra; the central extension is the datum that forces both components to be present.

27.15 THE VIRASORO ORDERED BAR COMPLEX AND THE GRAVITATIONAL YANGIAN

The affine Yangian $Y_{\hbar}(\mathfrak{sl}_2)$ has three independent generator families $E(u)$, $F(u)$, $H(u)$. The Virasoro algebra has one generator T . What happens to the Yangian when the input has a single generator of spin greater than 1?

The answer is forced by two structural features (a triple-pole collision residue and a single-generator mode collapse) whose interplay produces an object that is simultaneously trivial as a Lie algebra and infinitely non-formal as an A_{∞} algebra. The Virasoro OPE is

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}.$$

TRIPLE-POLE RESIDUE

The bar complex uses the propagator $d \log(z-w) = dz/(z-w)$, which absorbs one power of the pole in each OPE term. The quartic pole becomes a triple pole; the double pole becomes a simple pole; the simple pole is absorbed entirely and feeds the bar differential $d_{\overline{B}^{\text{ch}}} [s^{-1}T | s^{-1}T] = s^{-1}(T_{(0)}T) = s^{-1}(\partial T)$.

PROPOSITION 27.15.1 (*Virasoro collision residue*;). The collision residue r -matrix of Vir_c is

$$r^{\text{coll}}(z) = \frac{c/2}{z^3} \mathbf{I} \otimes \mathbf{I} + \frac{2T}{z} \otimes \mathbf{I}. \quad (27.10)$$

This is a **triple-pole** r -matrix: the leading singularity z^{-3} is unprecedented in the affine case, where $r_{\text{KM}}^{\text{coll}}(z) = k \Omega_{\mathfrak{g}}/z$ is a simple pole (Theorem 27.12.1). The two depth components (the central scalar $(c/2)/z^3$ and the field-valued $2T/z$) play entirely different roles: the central term controls curvature, while the field-valued term generates the non-associative cascade.

Proof. The Virasoro OPE has singular terms of orders 4, 2, and 1. Passing to the collision-residue kernel removes one pole order because the bar propagator contributes a $d \log$ factor, so these become poles of orders 3, 1, and 0. The regular part is absorbed into the ordinary bar differential $d_{\overline{B}^{\text{ch}}}$. The remaining singular pieces are exactly the two terms displayed in (27.10), with the cubic pole coming from the central term and the simple pole from the field T . $\square$

The collision residue satisfies the classical Yang–Baxter equation.

PROPOSITION 27.15.2 (*Virasoro CYBE*;). The collision residue (27.10) satisfies

$$[r^{12}(u), r^{13}(u+v)] + [r^{12}(u), r^{23}(v)] + [r^{13}(u+v), r^{23}(v)] = 0. \quad (27.11)$$

Proof. Write $r(z) = \frac{c/2}{z^3} \mathbf{I} \otimes \mathbf{I} + \frac{2T}{z} \otimes \mathbf{I} + \frac{2}{z} \mathbf{I} \otimes T$. The cubic central term commutes with every tensor factor, so it contributes nothing to the three commutators in (27.11). For the simple-pole part, the Laplace transform identifies the CYBE with the Jacobi identity for the Virasoro PVA bracket $\{T_{\lambda}T\} = \partial T + 2T\lambda + \frac{c}{12}\lambda^3$. The three commutators in the CYBE are precisely the three Jacobi terms, so their sum vanishes. $\square$

MODE COLLAPSE

Now the single-generator structure exerts its force.

THEOREM 27.15.3 (*Gravitational Yangian collapse;*). Let $c' = 26 - c$ denote the Koszul dual central charge. Define the level- r generators on $\text{Vir}_{c'}$ by

$$\mathsf{T}_n^{(r)} := \binom{n+r-1}{r} L_{-n-r}, \quad \Omega_r = \sum_{n \in \mathbb{Z}} \mathsf{T}_n^{(r)} \otimes L_n,$$

so that $r(z) = \sum_{r \geq 0} \Omega_r z^{-r-1}$. Then:

- (i) *Linear dependence.* For every $r \geq 1$ and $n \in \mathbb{Z}$, $\mathsf{T}_n^{(r)} = \binom{n+r-1}{r} L_{-n-r}$ is a scalar multiple of a single Virasoro mode. There is no independent Yangian partner at any level.
- (ii) *Lie-algebraic isomorphism.* $Y^{\text{dg}}(\text{Vir}_c) \cong \text{Vir}_{c'}$ as Lie algebras. The entire Yangian Lie structure collapses.
- (iii) *All-level bracket.*

$$[\mathsf{T}_m^{(r)}, \mathsf{T}_n^{(s)}] = \binom{m+r-1}{r} \binom{n+s-1}{s} [(n+s-m-r) L_{-m-n-r-s} - \frac{c'}{12} ((m+r)^3 - (m+r)) \delta_{m+n+r+s,0}],$$

which reduces to a single Virasoro commutator.

Proof. Part (i) is the entire argument: because T has conformal weight 2, the mode L_{-n-r} depends only on the sum $n+r$. The level index r splits this sum but adds no new degree of freedom. In the affine Yangian, level-1 generators (e_1, f_1, h_1) are linearly independent of (e_0, f_0, h_0) because $\dim \mathfrak{g} \geq 3$ generators of spin 1 each have an independent mode family. Here the single spin-2 generator forces all levels into the same Virasoro mode lattice. Part (ii) follows: the generators $\{\mathsf{T}_n^{(r)}\}_{n,r}$ span $\{L_m\}_{m \in \mathbb{Z}}$, which is $\text{Vir}_{c'}$. Part (iii) is a direct computation using the Virasoro commutator $[L_{-m-r}, L_{-n-s}] = (n+s-m-r) L_{-m-n-r-s} + \frac{c'}{12} ((m+r)^3 - (m+r)) \delta_{m+n+r+s,0}$. $\square$

The collapse is absolute: the gravitational Yangian has no independent higher-level data, no non-primitive coproduct, no Drinfeld partners. As a Lie algebra it is just Vir_{26-c} .

INFINITE A_∞ TOWER

Despite the Lie-algebraic collapse, the T -line remembers higher homotopy. The cubic Stasheff operation is computed directly; the all-order assertion is a statement about survival of the transferred shadow classes.

THEOREM 27.15.4 (*Virasoro non-formality;*). For the universal Virasoro family over $\mathbb{Q}(c)$, the T -line transferred shadow operations are nonzero in all degrees $k \geq 3$. For a fixed central charge c_0 , the same conclusion holds only after the specialisations of those rational obstruction classes remain nonzero for all k . In every specialization with $m_3 \neq 0$, the ordered bar complex is not formal.

Proof. The degree-3 associator is computed directly from the PVA λ -bracket. The Stasheff identity at degree 3 requires $m_3 = -A_3$ where

$$A_3(T, T, T; \lambda_{12}, \lambda_{23}) = -\{T_{\lambda_{23}}\{T_{\lambda_{12}}T\}\} = \frac{c}{12} \lambda_{23}^3 (2\lambda_{12} + \lambda_{23}) + (T\text{-dependent terms}).$$

The scalar contact term $\frac{c}{12} \lambda_{23}^3 (2\lambda_{12} + \lambda_{23})$ is nonzero for $c \neq 0$, and the T -dependent terms coming from $T_{(1)}T = 2T$ are nonzero in the universal Virasoro OPE. Hence m_3 is nonzero outside the corresponding specialization locus. The all-order statement is not a formal consequence of this single self-loop. It is the universal non-cancellation statement proved on the T -line by Theorem ???: each higher shadow coefficient has a nonzero leading Laurent term over $\mathbb{Q}(c)$. Specialising c may kill individual rational classes; a fixed central charge therefore needs the stated non-cancellation check. $\square$

Remark 27.15.5 (What non-formality is not). Three distinct things are being kept apart here.

- (i) *Non-formality* is a property of the A_∞ -chiral structure on Vir_c transferred to bar cohomology. The universal T -line has nonzero transferred operations in all degrees; a fixed central charge must be checked after specialization. It does *not* say Vir_c is non-Koszul. Vir_c is chirally Koszul at every non-critical central charge: the bar cohomology $H^\bullet(\overline{B}^{\text{ch}}(\text{Vir}_c))$ is concentrated in bar degree 1 by PBW universality and single-generator freeness. Koszulness (bar concentration) and A_∞ formality (vanishing of transferred higher operations) are different properties. Virasoro is Koszul but A_∞ non-formal.
- (ii) E_1 *versus* E_∞ is the question of locality. Vir_c is and remains E_∞ -chiral: local, with Σ_n -equivariant factorization. The ordered bar complex applies the E_1 -Koszul duality *functor* to the E_∞ input; non-formality of the output does not make the input non-local. Having OPE poles never breaks E_∞ .
- (iii) *The R -matrix is derived*, not independent input: $R(z)$ is obtained as the monodromy of the Kohno connection built from the collision residue r^{coll} , and the $d \log$ absorption step sets the correct pole structure.

CURVATURE

PROPOSITION 27.15.6 (*Gravitational Yangian curvature;*). The curvature of the gravitational dg-shifted Yangian is

$$\kappa(Y^{\text{dg}}(\text{Vir}_c)) = \frac{26 - c}{2}.$$

Two central charges are distinguished:

- (i) *Critical string* ($c = 26$): $\kappa = 0$. The gravitational Yangian is flat; $F_g = 0$ for all $g \geq 1$ (UNIFORM-WEIGHT). This is anomaly cancellation.
- (ii) *Koszul self-dual* ($c = 13$): $\kappa = 13/2$. The Koszul involution $c \mapsto 26 - c$ fixes $c = 13$, so $\text{Vir}_{13}^1 = \text{Vir}_{13}$. The genus tower is invariant under $c \mapsto 26 - c$ (gravitational S-duality) with $F_g(\text{Vir}_{13}) = \frac{13}{2} \lambda_g^{\text{FP}}(\text{UNIFORM} - \text{WEIGHT}) \neq 0$.

Proof. Volume I Theorem D gives the Virasoro curvature formula $\kappa(\text{Vir}_c) = c/2$. By Theorem 27.15.3, the gravitational dg-shifted Yangian is identified with the Koszul dual Vir_{26-c} . Applying the same curvature formula to that dual central charge gives

$$\kappa(Y^{\text{dg}}(\text{Vir}_c)) = \kappa(\text{Vir}_{26-c}) = \frac{26 - c}{2}.$$

Substituting $c = 26$ and $c = 13$ yields the critical and self-dual cases listed in the statement. $\square$

THE GAUGE-GRAVITY DICHOTOMY

The three mechanisms assemble into a single structural dichotomy.

COROLLARY 27.15.7 (*Gauge-gravity complexity dichotomy;*). The two standard HT families occupy opposite corners of the (A_∞, Δ) -complexity plane:

	A_∞ products m_k ($k \geq 3$)	coproduct Δ_z
Gauge (KM, class L)	$m_k = 0$ (formal)	nontrivial Yangian Δ_z
Gravity (Vir, conditional class M)	$m_3 \neq 0$, $m_k \neq 0$ universally on the T -line	strictly primitive Δ_z

The dichotomy is controlled by two inputs:

- (1) *Pole order.* Double OPE pole $\Rightarrow$ simple collision residue $\Rightarrow$ class **L** $\Rightarrow$ formal. Quartic OPE pole $\Rightarrow$ triple collision residue $\Rightarrow$ conditional class **M** $\Rightarrow$ non-formal after T -line non-cancellation.
- (2) *Generator count.* $\dim \mathfrak{g}$ generators of spin 1 $\Rightarrow$ independent Yangian partners $\Rightarrow$ nontrivial coproduct. One generator of spin 2 $\Rightarrow$ collapse (Theorem 27.15.3) $\Rightarrow$ primitive coproduct.

Drinfeld–Sokolov reduction transports class **L** to the conditional class **M** corridor: the Sugawara construction manufactures the quartic pole from the affine double pole, and the resolvent tree formula supplies the candidate higher operations. Their all-order survival is precisely the T -line non-cancellation hypothesis.

Proof. The A_∞ column: class **L** is formal by pole-order classification, and the gravity line is non-formal on the universal T -line by Theorem 27.15.4. The coproduct column: the Yangian coproduct is non-primitive for gauge theory (Theorem 27.16.1) and strictly primitive for gravity by Theorem 27.15.8. $\square$

GRAVITATIONAL COPRODUCT PRIMITIVITY

The corollary’s coproduct column rests on a structural vanishing that deserves its own statement. The DS-transferred coproduct on Vir_c has no non-primitive corrections at any degree; the mechanism is ghost-number filtration, not a cancellation.

THEOREM 27.15.8 (*Virasoro generator coproduct primitivity*;). Let Δ_z^{Vir} denote the coproduct on the Virasoro algebra obtained by Drinfeld–Sokolov reduction from the affine coproduct on $\widehat{\mathfrak{sl}}_2$, on the principal DS ghost-zero projection surface. Then the linear component is primitive on the Virasoro generator:

$$(p \otimes p) \circ \Delta_z^{\text{Vir}}(T) = T \otimes 1 + 1 \otimes T,$$

where p is the projection to ghost number 0. The all-degree vanishing of nonlinear generator-level coproduct components is the conditional signed ghost-defect statement isolated in Volume II, Theorem ??.

Proof. The displayed formula is the degree-one generator computation: the split affine Casimir terms contain weight-one current factors, and the projection $p \otimes p$ to the Virasoro ghost-zero cohomology kills them. Nonlinear HPL coproduct corrections require the signed tree count of the Volume II theorem. The slogan $\text{gh}(h) = -1$ is not by itself the proof of all arities. $\square$

Remark 27.15.9 (*The (m, Δ) -complexity plane*). The contrast between product and coproduct complexity is absolute. The transferred product m_z^{Vir} is infinitely complicated: the full A_∞ tower is nonzero at all degrees (class **M**, shadow depth $r_{\max} = \infty$). The transferred coproduct is generator-trivial on the signed ghost-defect surface. In the (m, Δ) -complexity plane, gravity sits at $(\infty, 0)$: infinite product complexity, zero coproduct complexity. Gauge theory (affine Kac–Moody) sits at $(3, \text{nonzero})$: finite product complexity (class **L**), nontrivial coproduct. The Sugawara embedding confirms this: the affine coproduct applied to the Sugawara stress tensor $T = \kappa^{ab} J_a J_b / (2(k + h^\vee))$ produces a nontrivial cross term

$$\Delta_z^{\text{KM}}(T) - T \otimes 1 - 1 \otimes T = \frac{\Omega}{(k + h^\vee)z}, \quad \Omega = \kappa^{ab} J_a \otimes J_b.$$

Primitivity is a genuine consequence of DS reduction, not a triviality of Virasoro. The physical content: gravity does not produce particles. It braids them, curves their propagators, and dresses them with an infinite tower of higher products, but the coproduct, which governs particle creation from the vacuum, is trivial. This is the coalgebraic shadow of the no-hair theorem: the gravitational sector has no nontrivial coalgebra structure at any degree.

Remark 27.15.10 (Summary of the gravitational dg-shifted Yangian). $Y^{\text{dg}}(\text{Vir}_c)$ is Vir_{26-c} equipped with: (a) the infinite A_∞ tower $\{m_k\}_{k \geq 3}$ (class **M**); (b) primitive coproduct $\Delta_z(x) = \tau_z(x) \otimes 1 + 1 \otimes x$; (c) triple-pole collision residue $r(z) = (c'/2)/z^3 + 2T/z$; (d) curvature $\kappa = (26 - c)/2$. The Lie-algebraic Yangian structure is trivial (all levels collapse); the entire nontrivial content resides in the A_∞ tower. The gravitational Yangian is a *curved* A_∞ -deformation of $U(\text{Vir}_{26-c})$, not a filtered deformation of $U(\text{Witt}[t])$.

27.16 THE UNIVERSAL KAC–MOODY YANGIAN THEOREM

The full nonabelian Kac–Moody family yields the definitive result. For every simple Lie algebra $\mathfrak{g}$ and non-critical level $k \neq -h^\vee$, the E_1 -chiral Koszul dual is the Yangian $Y_h(\mathfrak{g})$. This is the ordered analogue of Theorem ??, which gives the symmetric Koszul duality $\widehat{\mathfrak{g}}_k^\dagger \simeq \text{CE}^{\text{ch}}(\widehat{\mathfrak{g}}_{-k-2h^\vee})$.

All affine Kac–Moody algebras $\widehat{\mathfrak{g}}_k$ are E_∞ -chiral: they are local vertex algebras with Σ_n -equivariant factorization structure. The OPE poles do not break E_∞ -locality.

27.16.1 The ordered bar complex of $\widehat{\mathfrak{g}}_k$

Fix a simple Lie algebra $\mathfrak{g}$ with invariant form $(\cdot, \cdot)$ normalised so that $(\theta|\theta) = 2$ for the highest root θ , dual Coxeter number $h^\vee$, and structure constants f^{ab}_c in an orthonormal basis $\{T^a\}_{a=1}^{\dim \mathfrak{g}}$. Let $\widehat{\mathfrak{g}}_k$ be the affine vertex algebra at level $k \neq -h^\vee$, with OPE

$$J^a(z) J^b(w) \sim \frac{k(T^a, T^b)}{(z-w)^2} + \frac{f^{ab}_c J^c(w)}{z-w}. \quad (27.12)$$

Write $\hbar = 1/(k + h^\vee)$ for the deformation parameter (well-defined away from critical level) and

$$\Omega = \sum_{a=1}^{\dim \mathfrak{g}} T^a \otimes T^a \in \mathfrak{g} \otimes \mathfrak{g}$$

for the quadratic Casimir tensor.

THEOREM 27.16.1 (*Conditional universal Kac–Moody Yangian criterion*;). Assume the root-sector strictification package of Theorem 27.17.8 and the R -twisted descent package of Proposition 27.4.3. For every simple Lie algebra $\mathfrak{g}$ and non-critical level $k \neq -h^\vee$, the E_1 -chiral Koszul dual of the affine vertex algebra $\widehat{\mathfrak{g}}_k$ is the dg-shifted Yangian:

$$A_{\text{line}}^{\text{l,ord}}(\widehat{\mathfrak{g}}_k) \simeq Y_{\hbar}^{\text{dg}}(\mathfrak{g}) \simeq Y_{\hbar}(\mathfrak{g}), \quad \hbar = \frac{1}{k + h^\vee},$$

where the second equivalence is the spectral Drinfeld strictification (Theorem 27.17.8), which identifies the dg-shifted Yangian with the classical Yangian as strict associative algebras. The duality is:

- (1) functorial in $\mathfrak{g}$ (respects Lie algebra homomorphisms);
- (2) compatible with the symmetric Koszul duality $\widehat{\mathfrak{g}}_k^\dagger \simeq \text{CE}^{\text{ch}}(\widehat{\mathfrak{g}}_{-k-2h^\vee})$ via R -twisted Σ_n -descent (Proposition 27.4.3);
- (3) valid for all nine infinite families and exceptional types (Table 27.1).

Proof. The proof has five steps.

Step 1: Collision residue and KZ normalization. The OPE (27.12) has a double pole $k(T^a, T^b)/(z-w)^2$ and a simple pole $f^{ab}_c J^c(w)/(z-w)$. The bar kernel $d \log(z-w)$ absorbs one power, so the

collision residue in trace-form normalization is $r^{\text{coll}}(z) = k\Omega_{\text{tr}}/z$. After the Casimir-and-coupling rescaling used by the KZ connection, the spectral classical r -matrix is

$$r_{12}^{\text{KZ}}(z) = \frac{\Omega_{12}}{(k + h^\vee)z} = \frac{\hbar \Omega_{12}}{z}. \quad (27.13)$$

The simple-pole bracket channel supplies the bar differential in Step 2; it is not a pole-valued collision-residue term in (27.13).

Step 2: Bar differential at degree 2. The ordered bar differential on $\overline{B}_2^{\text{ch,ord}}(\widehat{\mathfrak{g}}_k)$ extracts the Lie bracket from the simple-pole collision:

$$d_{\overline{B}}^{\text{ch}}[s^{-1}J^a | s^{-1}J^b] = f^{ab}{}_c [s^{-1}J^c]. \quad (27.14)$$

This is the Lie bracket $[T^a, T^b] = f^{ab}{}_c T^c$ of $\mathfrak{g}$. At degree 2, the ordered bar complex reproduces the Chevalley–Eilenberg complex of $\mathfrak{g}$. The double-pole term $k(T^a, T^b)/(z - w)^2$ contributes through the trace-form residue $k\Omega_{\text{tr}}/z$, equivalently through the KZ-normalized spectral datum $\Omega/((k + h^\vee)z)$, to the R -matrix, not to the bar differential (this is the ordered/symmetric distinction: in the symmetric bar complex, the same data appears in the bar differential as the curvature $m_o = \frac{k+h^\vee}{2h^\vee}\kappa$).

Step 3: $d^2 = 0$ at degree 3 is the CYBE. The bar differential satisfies $d^2 = 0$ on the ordered bar complex. At degree 3, this condition applied to $[s^{-1}J^a | s^{-1}J^b | s^{-1}J^c]$ is equivalent to the *classical Yang–Baxter equation* for the KZ-normalized r -matrix $r^{\text{KZ}}(z) = \Omega/((k + h^\vee)z)$:

$$[r_{12}(z_1 - z_2), r_{13}(z_1 - z_3)] + [r_{12}(z_1 - z_2), r_{23}(z_2 - z_3)] + [r_{13}(z_1 - z_3), r_{23}(z_2 - z_3)] = 0.$$

Substituting $r_{ij}(z) = \Omega_{ij}/((k + h^\vee)z)$, the three terms become proportional to $f^{a[b}{}_c f^{c]e}{}_d$, and the vanishing is exactly the Jacobi identity for $\mathfrak{g}$. Thus $d^2 = 0$ holds unconditionally for every simple $\mathfrak{g}$.

Step 4: Complete strictification. The spectral Drinfeld class $[\delta] \in H^2(\mathfrak{g}, \mathfrak{g} \otimes \mathfrak{g})$ measures the obstruction to strictifying the $\mathcal{A}_\infty$ -Yangian to a strict associative algebra. For every simple Lie algebra $\mathfrak{g}$, the root spaces are one-dimensional (root-space one-dimensionality), so the relevant H^2 group decomposes into root sectors: each sector is one-dimensional, and the Jacobi identity forces the cocycle $[\delta]$ to be a coboundary in every sector. The class therefore vanishes:

$$[\delta] = 0 \quad \text{for all simple } \mathfrak{g}.$$

This is the strictification mechanism: the Yangian $Y_h(\mathfrak{g})$ is a *strict* associative algebra.

Step 5: Identification of the Koszul dual. The cohomology $H^\bullet(\overline{B}^{\text{ch,ord}}(\widehat{\mathfrak{g}}_k))$ with the dual multiplication (from dualising the deconcatenation coproduct) is the RTT presentation of the Yangian $Y_h(\mathfrak{g})$: the degree-1 generators are the currents $\{T_n^a\}_{a,n}$, the degree-2 relations are the RTT relations $R(u - v)T_1(u)T_2(v) = T_2(v)T_1(u)R(u - v)$ with R -matrix $R(u) = 1 + \hbar\Omega/u$, and the strictification of Step 4 ensures no higher $\mathcal{A}_\infty$ corrections. By the Drinfeld theorem, this is $Y_h(\mathfrak{g})$. $\square$

27.16.2 Data for all simple types

In every case the curvature of the E_1 -chiral Koszul dual is

$$\kappa(Y_h(\mathfrak{g})) = -\kappa(\widehat{\mathfrak{g}}_k) = -\frac{\dim(\mathfrak{g}) \cdot (k + h^\vee)}{2h^\vee},$$

the negation of the affine curvature. The KM complementarity identity $\kappa(\widehat{\mathfrak{g}}_k) + \kappa(Y_h(\mathfrak{g})) = 0$ holds specifically for Kac–Moody and free-field families and does *not* generalise: for Virasoro one has $\kappa(\text{Vir}_c) + \kappa(\text{Vir}_{26-c}) = 13$, and for $\mathcal{W}_3$ one has $\kappa(\mathcal{W}_3^k) + \kappa(\mathcal{W}_3^{k'}) = 250/3$ (cf. Theorem D of Volume I).

TABLE 27.1: Ordered Koszul duality data for the simple Kac–Moody family. All entries follow from Theorem 27.16.1.

Type	$\mathfrak{g}$	$\dim \mathfrak{g}$	$h^\vee$	Fund. repr. dim	$\hbar$	$\kappa(Y_\hbar(\mathfrak{g}))$
A_n	$\mathfrak{sl}_{n+1}$	$n^2 + 2n$	$n + 1$	$n + 1$	$\frac{1}{k+n+1}$	$-\frac{(n^2+2n)(k+n+1)}{2(n+1)}$
B_n	$\mathfrak{so}_{2n+1}$	$n(2n+1)$	$2n-1$	$2n+1$	$\frac{1}{k+2n-1}$	$-\frac{n(2n+1)(k+2n-1)}{2(2n-1)}$
C_n	$\mathfrak{sp}_{2n}$	$n(2n+1)$	$n+1$	$2n$	$\frac{1}{k+n+1}$	$-\frac{n(2n+1)(k+n+1)}{2(n+1)}$
D_n	$\mathfrak{so}_{2n}$	$n(2n-1)$	$2n-2$	$2n$	$\frac{1}{k+2n-2}$	$-\frac{n(2n-1)(k+2n-2)}{2(2n-2)}$
E_6	$\mathfrak{e}_6$	78	12	27	$\frac{1}{k+12}$	$-\frac{78(k+12)}{24}$
E_7	$\mathfrak{e}_7$	133	18	56	$\frac{1}{k+18}$	$-\frac{133(k+18)}{36}$
E_8	$\mathfrak{e}_8$	248	30	248	$\frac{1}{k+30}$	$-\frac{248(k+30)}{60}$
F_4	$\mathfrak{f}_4$	52	9	26	$\frac{1}{k+9}$	$-\frac{52(k+9)}{18}$
G_2	$\mathfrak{g}_2$	14	4	7	$\frac{1}{k+4}$	$-\frac{14(k+4)}{8}$

Remark 27.16.2 (Casimir tensor for each type). In the fundamental representation, the Casimir tensor $\Omega \in \mathfrak{g} \otimes \mathfrak{g}$ acts as:

- (a) *Type A_n .* $\Omega = P - \frac{1}{n+1} I \otimes I$, where $P \in \text{End}(\mathbb{C}^{n+1} \otimes \mathbb{C}^{n+1})$ is the permutation operator.
- (b) *Types B_n, D_n .* $\Omega = P - K$, where $K_{ij,kl} = \delta_{ik'} \delta_{jl'}$ is the contraction with the invariant bilinear form (using the index convention $i' = 2n+2-i$ for B_n , $i' = 2n+1-i$ for D_n).
- (c) *Type C_n .* $\Omega = P - K$, where $K_{ij,kl} = J_{ik} J_{jl}$ involves the symplectic form J .
- (d) *Exceptional types.* Ω is determined by the structure constants f^{ab}_c via $\Omega = \sum_a T^a \otimes T^a$ in any orthonormal basis; explicit matrix forms follow from the Chevalley basis.

Remark 27.16.3 (Relation to Drinfeld–Kohno and quantum groups). The Kohno connection (27.1) for $\widehat{\mathfrak{g}}_k$ takes the form $\nabla = d - \hbar \sum_{i < j} \Omega_{ij} dz_{ij}/z_{ij}$, which is the Knizhnik–Zamolodchikov connection at level k . Its monodromy representation is a braid-group representation. The Drinfeld–Kohno theorem identifies this braided representation, after a choice of associator and the standard half-monodromy normalisation

$$q = e^{\pi i / (k + h^\vee)},$$

with the braid representation coming from the universal R -matrix of $U_q(\mathfrak{g})$. The Yangian appears on the ordered line side before exponentiation: finite-dimensional evaluation modules for $Y_\hbar(\mathfrak{g})$ carry the rational matrix $R(u) = 1 + \hbar \Omega/u + O(\hbar^2)$, and this additive spectral datum is compatible with the KZ normalisation under the trigonometric/rational degeneration. Thus the ordered bar complex refines the KZ connection at chain level; it does not assert that KZ monodromy factors through the Yangian as an algebra, nor does it prove a category- $\mathcal{O}$ equivalence.

Remark 27.16.4 (The pole-order dichotomy). The Kac–Moody OPE has a double pole and a simple pole. The $d \log$ kernel absorbs one power, leaving a collision residue with a simple pole $k\Omega_{\text{tr}}/z$ in trace-form normalization, equivalently the KZ-normalized spectral term $\Omega/((k + h^\vee)z)$. The simple-pole Lie

bracket channel supplies the bar differential; it is not a pole-valued collision-residue term. This places all $\widehat{\mathfrak{g}}_k$ in class L (double-pole OPE, simple-pole collision residue, finite shadow depth). By contrast, the Virasoro OPE has a quartic pole, giving a triple-pole collision residue and class M (infinite shadow depth). Under DS reduction $\widehat{\mathfrak{g}}_k \rightarrow \mathcal{W}_k(\mathfrak{g})$, the pole-order escalation transports class L to class M via Sugawara.

Remark 27.16.5 (Kac–Moody multiplicity boundary). Theorem 27.16.1 covers the finite-dimensional simple case only under its strictification and descent hypotheses. The remaining boundary is Kac–Moody algebras $\widehat{\mathfrak{g}}_k$ for $\mathfrak{g}$ a Kac–Moody Lie algebra (not finite-dimensional simple): for affine or indefinite Kac–Moody algebras, root multiplicities can exceed one, the root-space one-dimensionality argument of Step 4 fails, and the strictification mechanism requires new input.

Remark 27.16.6 (Line-side square-root convention at nonzero curvature;). The scalar Verdier conductor of Theorem C is the additive invariant $K^\kappa(A, A^!) = \kappa(A) + \kappa(A^!)$. A line-operator comparison introduces a different, presentation-dependent product

$$P_{\text{line}}^\kappa(A) := \kappa_{\text{vert}}(A) \kappa_{\text{line}}(A_{\text{line}}^!).$$

Here both factors belong to the same trace convention and require an independently constructed line-side dual. On the locus $P_{\text{line}}^\kappa(A) \in \mathbb{C}^\times$, a choice of square root defines a deformation parameter by

$$\hbar^2 P_{\text{line}}^\kappa(A) = -1.$$

Thus the displayed equation records the chosen line-side normalisation; its mathematical content lies in an independent construction of P_{line}^κ and of $\hbar$. The zero-product lanes, including the computed Heisenberg and affine additive conductors, carry their trace normalisation directly.

For the K_3 lattice, the exact arithmetic statement is $2c_+ = 2 \cdot 4 = 8$ for the Mukai lattice of signature $(4, 20)$. Identifying this integer with a chiral conductor requires the comparison package H_B ; identifying it further with P_{line}^κ requires a compact Hall object, its line-side dual, and a common trace form. Under those hypotheses the chosen branch gives $\hbar^2 = -1/8$. The computed additive conductors in Volume I are $\{0, 13, 250/3\}$. The BP value $25/3$ and the Mukai value 8 remain separate open comparison ledgers.

27.17 SPECTRAL DRINFELD STRICTIFICATION

The ordered bar complex of a dg-shifted Yangian carries a filtered A_∞ structure. The question of whether this A_∞ structure can be straightened to a genuine associative structure with spectral parameter is controlled by a cohomological obstruction: the *spectral Drinfeld class*. This obstruction vanishes for all simple Lie algebras.

27.17.1 The obstruction class

Definition 27.17.1 (Spectral Drinfeld class at filtration p). Let A be a filtered dg-shifted Yangian carrying a spectral quasi-factorization datum with quasi-associator

$$\Phi(w, z) = 1 + \phi_p(w, z) \pmod{F^{p+1}},$$

where ϕ_p is the first nontrivial term at filtration p . The spectral cochain complex is defined by

$$C_{\text{spec}}^2(A) = \{g(u) \in A^{\widehat{\otimes} 2}\}, \quad C_{\text{spec}}^3(A) = \{\phi(w, z) \in A^{\widehat{\otimes} 3}\},$$

with linearized spectral differential

$$(\delta g)(w, z) = 1 \otimes g(z) + (\text{id} \otimes \Delta_z)g(w) - (\Delta_w \otimes \text{id})g(z) - g(w) \otimes 1.$$

The *spectral Drinfeld class at filtration p* is

$$\mathfrak{D}_{\text{spec}}(A, \Omega)|_{F^p} := [\phi_p] \in H_{\text{spec}}^3(\text{gr}^p A).$$

Remark 27.17.2 (Interpretation). The spectral Drinfeld class measures the failure of the A_∞ bar-complex structure to strictify to a genuine associative product with spectral parameter. At each filtration $p \geq 2$, the pentagon relation on the quasi-associator linearizes: ϕ_p is a 3-cocycle, a spectral twist shifts it by a coboundary, and the class $[\phi_p] \in H_{\text{spec}}^3(\text{gr}^p A)$ is the intrinsic obstruction. If $[\phi_p] = 0$ for all $p \geq 2$, an iterative filtered twist produces $\Phi^G = 1$, and the quasi-factorization datum strictifies to a genuine spectral factorization R -matrix.

27.17.2 Root-space one-dimensionality

The key structural input is a classical theorem about the root structure of simple Lie algebras: every root space is one-dimensional. This forces the spectral Drinfeld class, which is valued in root spaces, to be a scalar, and a scalar is determined by a single equation.

THEOREM 27.17.3 (*Root-space one-dimensionality*;). Let $\mathfrak{g}$ be a simple Lie algebra. For any subset $S = \{\alpha_1, \dots, \alpha_n\}$ of simple roots such that $\alpha = \sum_{i=1}^n \alpha_i$ is a root of $\mathfrak{g}$, the multilinear degree- n space

$$\text{span}\{\text{Lie monomials in } E_{\alpha_1}, \dots, E_{\alpha_n} \text{ using each exactly once}\} \subseteq \mathfrak{g}_\alpha$$

is one-dimensional.

Proof. Every multilinear Lie monomial in $E_{\alpha_1}, \dots, E_{\alpha_n}$ has weight $\alpha_1 + \dots + \alpha_n = \alpha$ (since each bracket adds the weights of its arguments). Therefore all such monomials lie in the root space $\mathfrak{g}_\alpha$. In a simple Lie algebra, every root has multiplicity one: $\dim \mathfrak{g}_\alpha = 1$. Hence the multilinear space is at most one-dimensional.

It remains to verify that at least one multilinear monomial is nonzero. Since α is a root and the simple roots α_i are linearly independent, there exists an ordering $\alpha_{i_1}, \dots, \alpha_{i_n}$ and a sequence of partial sums $\beta_k = \alpha_{i_1} + \dots + \alpha_{i_k}$ such that each β_k is a root (this follows from the connectedness of the support of α in the Dynkin diagram and the standard theory of root strings). The iterated bracket $[E_{\alpha_{i_1}}, [E_{\alpha_{i_2}}, \dots, E_{\alpha_{i_n}}] \dots]$ is then nonzero (each intermediate bracket lands in a nonzero root space). $\square$

27.17.3 The Jacobi collapse lemma

When root spaces are one-dimensional, multilinear Lie monomials in root vectors are necessarily proportional: the target space has no room for independent contributions. The mechanism by which the free Lie algebra's higher-dimensional multilinear spaces collapse to one dimension inside $\mathfrak{g}$ is the Jacobi identity.

The simplest nontrivial case is the D_4 star: four simple roots $\alpha_1, \alpha_2, \alpha_3, \alpha_c$ with α_c adjacent to each of $\alpha_1, \alpha_2, \alpha_3$, and the α_i mutually non-adjacent. In the free Lie algebra modulo non-adjacency commutation, the multilinear degree-4 space is two-dimensional. In $\mathfrak{g}$, the Jacobi identity collapses it to one.

LEMMA 27.17.4 (*Jacobi collapse for star sectors*;). Let X_1, X_c, X_2, X_3 be root vectors in a Lie algebra $\mathfrak{g}$ with $[X_1, X_2] = [X_1, X_3] = [X_2, X_3] = 0$ (the D_4 -star commutation relations). Define

$$A = [[X_2, [X_1, X_c]], X_3], \quad B = [[X_3, [X_1, X_c]], X_2].$$

Then $A = B$.

Proof. Apply the Jacobi identity to (X_2, X_c, X_3) :

$$[X_2, [X_c, X_3]] + [X_c, [X_3, X_2]] + [X_3, [X_2, X_c]] = 0.$$

Since $[X_2, X_3] = 0$, the middle term vanishes, giving

$$[X_2, [X_c, X_3]] = [X_3, [X_c, X_2]].$$

Now expand A and B using Jacobi and $[X_1, X_2] = [X_1, X_3] = 0$:

$$\begin{aligned} A &= [[X_2, [X_1, X_c]], X_3] = [X_2, [[X_1, X_c], X_3]] - [[X_1, X_c], [X_2, X_3]] \\ &= [X_2, [[X_1, X_c], X_3]] \quad (\text{since } [X_2, X_3] = 0) \\ &= [X_2, [X_1, [X_c, X_3]]] - [X_2, [X_c, [X_1, X_3]]] \\ &= [X_2, [X_1, [X_c, X_3]]] \quad (\text{since } [X_1, X_3] = 0) \\ &= [[X_2, X_1], [X_c, X_3]] + [X_1, [X_2, [X_c, X_3]]] \\ &= [X_1, [X_2, [X_c, X_3]]] \quad (\text{since } [X_1, X_2] = 0). \end{aligned}$$

The identical computation with $2 \leftrightarrow 3$ gives $B = [X_1, [X_3, [X_c, X_2]]]$. The displayed Jacobi consequence gives $[X_2, [X_c, X_3]] = [X_3, [X_c, X_2]]$, hence $A = B$. $\square$

Remark 27.17.5 (Root multiplicity one as structural inevitability). The Jacobi collapse lemma is not a clever computation that happens to kill the obstruction. The point is that the obstruction *has nowhere to live*.

The spectral Drinfeld class at filtration n , restricted to the root sector $\alpha = \sum \alpha_i$, is a cohomology class valued in $\mathfrak{g}_\alpha$. Root multiplicity one says $\dim \mathfrak{g}_\alpha = 1$. A cohomology class valued in a one-dimensional space is a scalar. A scalar is determined by a single equation. The coproduct rigidity provides that equation.

The free Lie algebra on the simple root vectors, modulo non-adjacency commutation, may have higher-dimensional multilinear spaces (the D_4 star has $\dim = 2$). But in $\mathfrak{g}$ the Jacobi identity collapses them (Lemma 27.17.4). This collapse is not an accident: it is the shadow of root multiplicity one, which is itself a theorem about the representation theory of $\mathfrak{sl}_2$ -triples.

27.17.4 The beta-integral coefficient

The BCH expansion of $\log(e^{X_1} \cdots e^{X_n})$ produces the universal coefficient at each filtration. This coefficient is determined by the Dynkin projection.

THEOREM 27.17.6 (Dynkin coefficient via the beta integral;). Let $X_1, \dots, X_n$ satisfy the path commutation relations $[X_i, X_j] = 0$ for $|i - j| \geq 2$. Then the multilinear $X_1 \cdots X_n$ -part of the ordered Baker–Campbell–Hausdorff product is

$$\text{mult}_{X_1 \cdots X_n} \log(e^{X_1} e^{X_2} \cdots e^{X_n}) = \frac{1}{n} [X_1, [X_2, \dots, [X_{n-1}, X_n] \cdots]],$$

where the coefficient $1/n$ arises from the beta integral

$$\frac{1}{n} = \int_0^1 (1-t)^{n-1} dt.$$

This is the unique coefficient forced by the BCH formula: the Dynkin projection $D_n = \frac{1}{n} \ell_n$ applied to the ordered concatenation $X_1 \otimes \cdots \otimes X_n$.

Proof. The multilinear part is $c_n \cdot [X_1, [X_2, \dots, X_n] \cdots]$ for a unique scalar c_n (the multilinear Lie space is one-dimensional by root-space one-dimensionality in $\mathfrak{g}$, or by the path one-dimensionality theorem in the free Lie algebra quotient). We determine c_n by extracting the coefficient of the concatenation monomial $X_1 \cdot X_2 \cdots X_n$ in the universal enveloping algebra.

Step 1: Coefficient in the Lie bracket. In the universal enveloping algebra, the right-normed bracket $[X_1, [X_2, \dots, [X_{n-1}, X_n] \cdots]]$ has leading term $X_1 X_2 \cdots X_n$ with coefficient $+1$.

Step 2: Coefficient in the BCH logarithm. The multilinear part of $e^{X_1} \cdots e^{X_n}$ in the free associative algebra is $X_1 \cdots X_n$. The coefficient of $X_1 \cdots X_n$ in $\log(e^{X_1} \cdots e^{X_n})$, computed via $\log(1 + A) = \sum_{k \geq 1} (-1)^{k+1} A^k / k$, counts compositions of n into k parts:

$$\text{coeff of } X_1 \cdots X_n \text{ in } \log(P) = \sum_{k=1}^n \frac{(-1)^{k+1}}{k} \binom{n-1}{k-1}.$$

Step 3: The beta integral.

$$\begin{aligned} \sum_{k=1}^n \frac{(-1)^{k+1}}{k} \binom{n-1}{k-1} &= \sum_{j=0}^{n-1} \frac{(-1)^j}{j+1} \binom{n-1}{j} = \sum_{j=0}^{n-1} \binom{n-1}{j} (-1)^j \int_0^1 t^j dt \\ &= \int_0^1 \sum_{j=0}^{n-1} \binom{n-1}{j} (-t)^j dt = \int_0^1 (1-t)^{n-1} dt = \frac{1}{n}. \end{aligned}$$

Combining Steps 1–3: $c_n \cdot 1 = \frac{1}{n}$, hence $c_n = \frac{1}{n}$. $\square$

Remark 27.17.7 (The Dynkin projection as coassociative counit). The coefficient $1/n$ is the Dynkin projection $D_n: T^n(V) \rightarrow \text{Lie}^n(V)$, $D_n = \frac{1}{n} \ell_n$, applied to the ordered concatenation. The bar-cobar counit $\varepsilon: \Omega(\bar{B}^{\text{ch}}(\mathcal{A})) \rightarrow \mathcal{A}$ extracts the chiral algebra from its bar complex (a chiral operation on $\text{FM}_k(\mathbb{C})$). The Dynkin projection extracts the Lie element from the tensor algebra (a coassociative operation on $\text{Conf}_n(\mathbb{R})$). Both are extraction maps from a cofree object to the generating algebra, controlled by the same combinatorial identity: the logarithm of the ordered exponential. The coefficient $1/n$ is the quantitative expression of how much Lie content survives the ordered tensor product, the same content that the bar-cobar adjunction computes in the chiral setting.

27.17.5 Complete strictification

THEOREM 27.17.8 (Root-sector strictification criterion for simple Lie algebras;). Let $\mathfrak{g}$ be a simple Lie algebra of any type. Assume that the spectral Drinfeld class localizes root-sector by root-sector, and that in each nonzero root sector the product coefficient and coproduct coefficient are identified by the Dynkin idempotent and the coproduct rigidity equation. Then the spectral Drinfeld class vanishes at every filtration:

$$\mathfrak{D}_{\text{spec}}(A, \Omega) \Big|_{F^p} = 0 \quad \text{for all } p \geq 2.$$

In particular, whenever a residue-bounded complete dg-shifted Yangian over $\mathfrak{g}$ carries a spectral quasi-factorization datum, that datum strictifies to a genuine spectral factorization realization. The dg-shifted Yangian $Y_h^{\text{dg}}(\mathfrak{g})$ carries a strict filtered algebra structure.

Proof. The proof proceeds by analysing the spectral Drinfeld class sector by sector. At filtration p , each root sector of type $\alpha = \sum_{i=1}^p \alpha_i$ (where the α_i are simple roots) contributes independently.

Case 1: α is not a root. If $\alpha = \sum \alpha_i$ is not a root of $\mathfrak{g}$, then the root space $\mathfrak{g}_\alpha = 0$ and every multilinear Lie monomial in $\{E_{\alpha_i}\}$ vanishes. The sector contributes nothing.

Case 2: α is a root (path-type sectors). The spectral Drinfeld class restricted to the root sector lives in $\mathfrak{g}_\alpha$. By Theorem 27.17.3, $\dim \mathfrak{g}_\alpha = 1$. The multilinear BCH computation (Theorem 27.17.6) gives a unique coefficient $1/p$ for the product side. The coproduct rigidity gives a unique equation for the coproduct side. Since both sides are scalars in the same one-dimensional space, equality reduces to a single identity (the same identity that holds at filtrations 2 and 3) and the obstruction class vanishes.

Case 3: Non-path sectors (e.g., the D_4 star). Root-space one-dimensionality (Theorem 27.17.3) forces the multilinear BCH contribution to be a scalar multiple of the unique generator of $\mathfrak{g}_\alpha$. The Jacobi collapse lemma (Lemma 27.17.4) ensures that the two-dimensional free Lie space collapses to one dimension in $\mathfrak{g}$, so the only surviving contribution is the iterated bracket $[E_{\alpha_1}, [E_{\alpha_2}, \dots]]$, whose coefficient in the BCH expansion is $1/p$ by the Dynkin formula.

The inductive strictification. Therefore no root sector at any filtration carries an independent obstruction class. The spectral Drinfeld class vanishes at every filtration. Starting from any spectral quasi-factorization datum, a filtered twist kills the first nontrivial quasi-associator term at each filtration. Iterating filtration by filtration produces a twist with trivial quasi-associator, hence a genuine spectral factorization realization. $\square$

Remark 27.17.9 (The role of root multiplicity one). The criterion has the form of a *root-multiplicity-one rigidity principle*: the spectral Drinfeld obstruction to strictifying a dg-shifted Yangian vanishes after the spectral class has been localized to one-dimensional root sectors.

The bar complex $\overline{B}^{\text{ord}}(\mathcal{A})$ is an E_1 coassociative coalgebra; the $\text{SC}^{\text{ch}, \text{top}}$ datum emerges at the level of the chiral derived center, as the pair $(C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A})$ (Theorem 27.10.1). The root-sector strictification criterion says that, once the spectral quasi-factorization package and the coefficient comparison have been constructed, the passage from quasi to strict is forced inside each simple root sector. Just as the Decomposition Theorem (purity of IC complexes) makes the Hecke algebra arise inevitably from the geometry of G/B , root multiplicity one makes the strictification step a Lie-theoretic calculation rather than a scalar shadow identity.

Remark 27.17.10 (What fails for Kac–Moody algebras with root multiplicities > 1). For Kac–Moody algebras whose root lattice contains roots with multiplicity > 1 (e.g., imaginary roots of indefinite Kac–Moody algebras), root-space one-dimensionality fails. The Jacobi collapse mechanism no longer forces multilinear Lie monomials to be proportional, and the spectral Drinfeld obstruction class can live in a space of dimension > 1 . In such cases, the coproduct rigidity provides fewer equations than unknowns, and genuine obstructions could survive.

The boundary admits a precise stratification: the obstruction vanishes in all root sectors where root multiplicity one holds (all roots of simple Lie algebras, real roots of affine Lie algebras), and the remaining sectors are exactly those with higher multiplicity.

For untwisted affine Lie algebras $\widehat{\mathfrak{g}}$, the real roots $\alpha + n\delta$ have multiplicity 1 (so the root-sector criterion applies after the same localization hypotheses), while the imaginary roots $n\delta$ have multiplicity $\ell = \text{rank}(\mathfrak{g})$. The imaginary sectors are abelian (elements within a single $\mathfrak{g}_{n\delta}$ commute), and a Cartan gauge-twist argument should absorb the defect. The mixed real-plus-imaginary sectors require a separate analysis. Complete strictification for affine types therefore remains conjectural pending the detailed imaginary-sector computation.

Remark 27.17.11 (Borcherds lift as strictification device). The strictification criterion 27.17.8 rests on two logically separable inputs: (i) one-dimensionality of root spaces, and (ii) Jacobi-driven collapse of multilinear free Lie spaces onto a single generator (Lemma 27.17.4). Input (ii) is a *structural* consequence of (i): whenever $\dim \mathfrak{g}_\alpha = 1$, every multilinear Lie monomial valued in $\mathfrak{g}_\alpha$ is a scalar multiple of a single iterated bracket, and the Jacobi identity among the simple roots provides the unique scalar equation that fixes it. The *mechanism*, Jacobi-star-sector killing, generalizes to any Lie (super)algebra whose root multiplicity structure can be encoded so that each root sector becomes one-dimensional *after an auxiliary grading*. A Borcherds generalized Kac–Moody superalgebra supplies exactly this grading: a root of multiplicity m_α on the bosonic Kac–Moody side is replaced by a single root of multiplicity 1 on the Borcherds superalgebra side, with the m_α -fold degeneracy absorbed into an internal Λ -grading that couples to super-parity [?Borcherds1988, ?Borcherds1992]. This is the content of the no-ghost theorem for lattice vertex algebras: physical states carry a natural $\mathbb{Z}_{\geq 0}$ -level grading, and imaginary-root degeneracies are exactly the dimension of the level- m_α string Hilbert space, which resolves after quantization by the (b, c) -ghost super-extension.

The lift is not uniform across Kac–Moody types. Three regimes must be distinguished:

- (i) *Finite and affine types with real roots.* All real roots α satisfy $\dim \mathfrak{g}_\alpha = 1$; Theorem 27.17.8 applies in the real-root sectors only after the spectral class has been localized there. The Borcherds lift is trivial (identity) on these sectors.
- (ii) *Affine types, imaginary roots $n\delta$.* The imaginary root space is abelian of dimension $\ell = \text{rank}(\mathfrak{g})$. The Borcherds lift replaces $\mathfrak{g}_{n\delta}$ by a single generator carrying a $\mathbb{Z}^\ell$ -grading, and the Jacobi-collapse argument extends verbatim to the super-extension because abelian sectors contribute no bracket. A Cartan gauge-twist absorbs the diagonal defect; the mixed real-plus-imaginary star sectors reduce to the real-root argument after projection.
- (iii) *Hyperbolic and generalized Kac–Moody types.* Imaginary roots appear with multiplicities $m_\alpha > 1$ governed by Borcherds’s denominator identity or the Frenkel–Kac–Segal vertex construction (e.g. the Monster Lie algebra $\mathfrak{m}$ [?Borcherds1992] and the Fake Monster $\mathfrak{m}_{\text{fake}}$ [?Borcherds1990]). In these cases the super-lift is nontrivial and the Jacobi-collapse identity must be proved inside the super-bracket after imaginary-root expansion.

Conjecture 27.17.12 (Kac–Moody strictification via the Borcherds lift;). Let $\mathfrak{g}$ be a symmetrizable Kac–Moody algebra (finite, affine, hyperbolic, or generalized) with root lattice Q and imaginary-root multiplicity function $m: Q \rightarrow \mathbb{Z}_{\geq 0}$. Let $\mathfrak{g}^{\text{super}}$ denote the Borcherds superalgebra obtained by replacing each imaginary root space $\mathfrak{g}_\alpha$ of multiplicity $m_\alpha > 1$ with a single generator E_α carrying an internal Λ_α -grading of rank m_α coupled to super-parity $|E_\alpha| \equiv m_\alpha \pmod{2}$, subject to the Borcherds denominator identity for the universal enveloping.

Then $\mathfrak{g}^{\text{super}}$ satisfies a super-analogue of root multiplicity one in the sense that every Λ -homogeneous root sector is one-dimensional, and the super-Jacobi identity collapses every multilinear bracket valued in a Λ -homogeneous sector to the unique iterated super-bracket. Consequently the spectral Drinfeld class of the dg-shifted Yangian $Y_h^{\text{dg}}(\mathfrak{g}^{\text{super}})$ vanishes at every filtration, and the strictification theorem descends to $Y_h^{\text{dg}}(\mathfrak{g})$ via the bosonic projection $\mathfrak{g}^{\text{super}} \rightarrow \mathfrak{g}$.

Three test sectors fix the present boundary of the conjecture. For untwisted affine $\widehat{\mathfrak{g}}$, the super-lift is the trivial extension by the $\mathbb{Z}^\ell$ -graded Heisenberg of the imaginary-root tower, and the Cartan gauge-twist of Remark 27.17.10 is the bosonic projection of a super-Jacobi collapse; on $\widehat{\mathfrak{sl}}_2$ the imaginary roots $n\delta$ carry a single $\alpha^\vee$ and the super-extension is trivial. For the Fake Monster $\mathfrak{m}_{\text{fake}} = \text{Lie}(V_\Lambda^{\text{phys}})$

[?Borcherds1990], the lattice vertex algebra V_Λ for $\Lambda = \Pi_{25,1}$ and the no-ghost theorem supply an explicit Λ -grading on the imaginary-root spaces. For the Monster Lie algebra $\mathfrak{m}$, the Borcherds denominator $p^{-1} \prod_{(m,n)>0} (1 - p^m q^n)^{c(mn)} = j(p) - j(q)$ [?Borcherds1992] presents each imaginary-root sector as $c(mn)$ -dimensional and hence as a single super-generator at level $c(mn)$ after the auxiliary grading is installed.

The remaining condition is the generic hyperbolic Kac–Moody case, where the Borcherds lift has not been made explicit. The first decisive computations are the untwisted $\widehat{\mathfrak{sl}}_2$ case at a generic non-critical level and the lowest Monster imaginary-root sector $[E_{(1,1)}, E_{(1,1)}]$ with $\dim \mathfrak{m}_{(1,1)} = c(1) = 196884$.

Remark 27.17.13 (Hall–Drinfeld double as fourth taxonomic slot beyond Yangian). Under the strictification package of Theorem 27.17.8, the finite-dimensional simple case produces $Y_h(\mathfrak{g})$ as a classical Yangian because the Cartan datum of every simple finite-dimensional $\mathfrak{g}$ carries a Kac–Moody grading, a Weyl group, and a Drinfeld J-presentation. None of these inputs survives on the BKM side of the K_3 chiral landscape surveyed in Part ?? and developed cross-volume: the BKM companion object sometimes called a “ K_3 Yangian” in shorthand, under the Vol III CY-to-chiral two-stage factorisation $\Phi_3^{(\Sigma_2, C)} = \mathrm{Sp}_{\Sigma_2, C}^{\mathrm{ch}} \circ \Phi_3^{\mathrm{FA}}$, on the K_3 -fibre stage-2 shadow of $\Phi_3^{\mathrm{FA}}(D^b(\mathrm{Coh}(K_3 \times E)))$ (Vol III Chapter ??, Theorem ??, and Remark ??), is not a Yangian at all, but the compact Hall–Drinfeld double

$$D_h(Y_{h, \mathrm{crit}}^{\mathrm{Hall}, +}(K_3 \times E)),$$

formed in Vol III finite windows from the reduced compact Hall source, the Serre-dual negative half, the Euler–Hall pairing, the Mukai Cartan torus, and the radical quotient. The finite Rees hCS–Hall comparison gives bounded Rees Hall classes and comparison maps; it is not by itself this compact double and does not prove its Borcherds recognition. The Cartan lives inside a Manin pair $(\mathfrak{g}_{\Delta_5}, \mathfrak{n}_+^{\mathrm{imag}} + \mathfrak{h}^{\mathrm{imag}, \mathrm{rk} 23})$ whose ambient metric has signature $(2, 1)$ on the imaginary directions; this signature *forbids* the Lagrangian decomposition of a Manin triple, so this Hall–Drinfeld double has no classical Manin-triple RTT presentation on a real root ladder. The chiral Hall–Drinfeld double therefore occupies a taxonomic slot genuinely distinct from the three classical slots of this chapter: it is neither a Drinfeld–Jimbo quantum group, nor a Yangian, nor an RTT algebra, nor a Manin-triple quasi-Hopf algebra. The strictification theorem of this chapter does *not* claim coverage of this fourth slot; the Kac–Moody multiplicity boundary of Remark 27.16.5 widens, beyond root-multiplicity breakdown, into the BKM regime where the Cartan signature itself obstructs the classical double.

Remark 27.17.14 (Identification of the chiral quantum group undergirding the K_3 BKM: chain-level naming). Three candidate names circulate in the literature for the chiral quantum group undergirding the K_3 BKM / Siegel bialgebra: (i) an affine K_3 Yangian $Y_h(\widehat{\mathfrak{g}}_{\Delta_5})$, (ii) an elliptic Yangian on the twisted torus, and (iii) the Feigin–Odesskii quantum-toroidal algebra $U_{q_1, q_2}(\widehat{\mathfrak{gl}}_1)$. None matches the global object. The Koszul-duality structure of the ordered bar complex selects a fourth object, and the selection is fixed by the same gauge-invariant calculation that identifies the Igusa form Δ_5 .

Rejection of the three candidates. (i) $Y_h(\widehat{\mathfrak{g}}_{\Delta_5})$ does not exist as a Drinfeld object: the BKM Cartan is infinite-dimensional and contains infinitely many imaginary simple roots, so the Drinfeld J-presentation never closes (Remark 27.17.13). (ii) An elliptic Yangian on a single torus misses the 24-node discriminant of the K_3 fibration: the single- τ parameter cannot resolve the 24 independent Mukai-lattice directions. (iii) The Feigin–Odesskii quantum-toroidal algebra captures one node of the 24-node locus only; it is a *local* piece, not the global chiral quantum group.

Identification via the ordered Koszul pair. Apply the ordered bar–cobar construction, together with the R -twisted descent of Proposition 27.4.3, to the compact Hall–Drinfeld double $\mathcal{A} = \mathbf{H}_{\Delta_5}$, when the compact passage datum of Remark 27.17.13 has been supplied. The finite Rees hCS–Hall maps alone give only a bounded positive-half target and do not construct $\mathcal{A}$. The chain-level ordered Koszul dual $\mathcal{A}_{\text{line}}^! = (\mathcal{A}^i)^\vee$ is produced from the quadratic comparison $q_{\mathcal{A}}^{\text{ord}}: \mathcal{A}^i \rightarrow \overline{B}^{\text{ch,ord}}(\mathcal{A})$ by finite-type ordered linear duality and the opposite-coalgebra duality of Theorem 27.5.1 is, on the quadratic stratum R_{quad} of Remark ?? of Vol I, Ch. ??, the Chevalley–Eilenberg coalgebra $C_\star^{\text{CE}}(\mathfrak{g}_{\Delta_5})$ computed in the Schiffmann–Vasserot shuffle basis. On the full non-quadratic Borchers stratum R_{Borchers} , $\mathcal{A}_{\text{line}}^!$ acquires a curved perturbation whose curvature class is the Gritsenko–Nikulin denominator cocycle. The correct name for the resulting quantum group is therefore not “K₃ Yangian” but the *Drinfeld double of the curved Chevalley–Eilenberg coalgebra*

$$\mathbf{Q}_h^{\text{K}_3} := D_h(C_\star^{\text{CE,crv}}(\mathfrak{g}_{\Delta_5}); \omega_{\Delta_5}),$$

with curvature ω_{Δ_5} the Gritsenko–Nikulin 2-cocycle of the primitive BKM denominator line. In the theta-normalisation this line is Δ_5 with leading coefficient 64, while the monic Borchers product is $D_5 = 64^{-1}\Delta_5$. Hence $\Phi_{10}^{\text{un}} = \Delta_5^2$, $\Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2$, and $Z_{\text{OP/DI}}^X = -(\Phi_{10}^{\text{OP}})^{-1} = -4096 \Delta_5^{-2}$. These are scalar normalisations, not the compact Hall double and not the primitive denominator datum. The scalar 64 and its square are checked, with this normalisation, by `igusa-cusp-form/compute/verify_square_root.py` and `calabi-yau-quantum-groups/compute/lib/borchers_denom`. Those computations check the Borchers/Gritsenko coefficient normalisation, not compact Hall data. The denominator identity is (Gritsenko–Nikulin 1998, Theorem 2.1; Borchers 1992, Theorem 10.1).

Conditional line-side normalisation. The Mukai lattice has signature $(4, 20)$, hence the exact lattice integer $2c_+ = 8$. Supply the compact comparison package H_B , construct the line-side curvature in the same trace convention, and identify $P_{\text{line}}^\kappa = 2c_+$. The square-root convention of Remark 27.16.6 then gives

$$\hbar_{\text{K}_3}^2 = -\frac{1}{8}.$$

This equation is conditional on the three comparison inputs just listed. A proof of strict ordered bar–cobar closure at this branch is an additional obligation in the compact Hall programme.

Arthur-packet witness. The image of $\mathbf{Q}_{\hbar_{\text{K}_3}}^{\text{K}_3}$ under the Langlands correspondence for Sp_4 is the Arthur packet $\psi_{\Delta_{10}} = \phi_{\Delta_{E_6}} \boxtimes \text{Sym}^1$ of Vol III, Theorem ??. At the p -adic places the Hecke eigenvalues of the Saito–Kurokawa/Ikeda lift satisfy

$$\lambda_p(\Delta_{10}) = a_p(\Delta_{E_6}) + p^8 + p^9,$$

this being the Maass relation in Hecke-eigenvalue form (Andrianov 1974, Theorem 3.2; Ikeda 2001, Corollary 16.2); the $p^8 + p^9$ term is the signature-of-Sym¹ contribution to the Arthur parameter, and its presence is the *chain-level* witness that $R_{\text{Borchers}} \neq 0$ on the non-quadratic stratum. The Siegel form attached to this Arthur packet at level 1, weight 10, for $\text{Sp}_4(\mathbb{Z})$ is Igusa’s Δ_{10} , and not any other candidate (Eisenstein E_{10} is not cuspidal; Ikeda’s generic degree-4 lift produces Δ_{10} as its unique non-trivial output at $k = 10$; there is no “Schottky form J_8 ” at weight 10 to conflate with).

Under the compact passage datum, $\mathbf{Q}_h^{\text{K}_3}$ at $\hbar^2 = -1/8$ with Arthur parameter $\psi_{\Delta_{10}}$ is the object denoted here by the chiral quantum group undergirding the K₃ BKM. The unconditional conclusion needed in this volume is narrower and sharp: the Drinfeld–Yangian, single-torus elliptic–Yangian, and one-node quantum-toroidal names do not match the BKM Cartan, the 24-node Mukai-lattice discriminant,

or the compact double data; the constants 64 and 4096 normalise the Borchers denominator and its square, not the algebra object. The unquotiented compact Hall–Drinfeld/Borchers recognition remains conditional on the primitive comparison, PBW/no-extra-relations, radical faithfulness, centre, associator, and inverse-limit data named in Remark 27.17.13.

Remark 27.17.15 (Abelian at Lie, non-abelian at vertex). The BKM taxonomic slot of Remark 27.17.13 exhibits a splitting phenomenon absent in the affine lineage. At the level of the chiral bialgebra of generators and Lie brackets, the imaginary-root sectors of $\mathfrak{g}_\Delta$, *abelianise*: the Hall side produces 24 commuting copies of the Miki quantum toroidal algebra of $\mathfrak{gl}_1$, one per weight- $(1, 1)$ direction in the K_3 lattice. Non-abelianness is reinstated one level up, at the vertex-algebraic closure on the K_3 Fock space: Frenkel–Kac 1980 vertex closure glues the 24 toroidal copies into a single BKM-style chiral bialgebra whose non-abelian brackets appear only after passage through the vertex operators $e^{\alpha \cdot \phi}$. The G/L/C/M classification of Remark 27.28.3 therefore splits, on the K_3 input, into a two-layer tower: a class-**G** layer (abelian at Lie) and a class-**L** layer (non-abelian at vertex), stacked by the Frenkel–Kac closure.

27.18 WORKED EXAMPLE: $\mathfrak{sl}_3$ AT LEVEL k

The conditional criterion of Theorem 27.16.1 specializes to every simple Lie algebra once its hypotheses are verified. For $\mathfrak{g} = \mathfrak{sl}_3$ in explicit matrix-unit coordinates, the rank-2 phenomena invisible in the rank-1 ($\mathfrak{sl}_2$) case: adjacent-root triangle sectors, the coefficient $\frac{1}{2}$, the Serre relations from root-space vanishing, and the 9×9 R -matrix.

27.18.1 Root system and matrix-unit notation

The Lie algebra $\mathfrak{sl}_3$ has root system $\Phi = \{\pm\alpha_1, \pm\alpha_2, \pm(\alpha_1 + \alpha_2)\}$ of type A_2 , with simple roots α_1, α_2 and Cartan matrix

$$A = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}.$$

In the $\mathfrak{gl}_3$ matrix-unit basis we set

$$e_1 = E_{12}, \quad e_2 = E_{23}, \quad e_{12} = [e_1, e_2] = E_{13},$$

$$f_1 = E_{21}, \quad f_2 = E_{32}, \quad f_{12} = [f_2, f_1] = E_{31},$$

and $h_1 = E_{11} - E_{22}$, $h_2 = E_{22} - E_{33}$. The composite root generators satisfy

$$[e_1, e_2] = e_{12}, \quad [f_2, f_1] = f_{12}, \quad [f_1, f_2] = -f_{12}.$$

The affine vertex algebra $V_k(\mathfrak{sl}_3)$ has OPE

$$J^a(z) J^b(w) \sim \frac{k \kappa(a, b)}{(z - w)^2} + \frac{[a, b](w)}{z - w}$$

where κ is the Killing form normalised so that $\kappa(e_i, f_i) = 1$ and $\kappa(e_{12}, f_{12}) = 1$.

27.18.2 Degree-1 generators: the Drinfeld currents

The ordered bar complex $\overline{B}^{\text{ch,ord}}_\bullet(V_k(\mathfrak{sl}_3))$ has degree-1 generators $s^{-1}e_1, s^{-1}e_2, s^{-1}e_{12}, s^{-1}f_1, s^{-1}f_2, s^{-1}f_{12}, s^{-1}h_1, s^{-1}h_2$. The corresponding bar cohomology classes organise into Drinfeld generating functions for $Y_{\hbar}(\mathfrak{sl}_3)$ with $\hbar = 1/(k+3)$:

$$\begin{aligned} E_i(u) &= \sum_{r \geq 0} E_i^{(r)} u^{-r-1}, \quad i = 1, 2, \\ F_i(u) &= \sum_{r \geq 0} F_i^{(r)} u^{-r-1}, \\ H_i(u) &= 1 + \sum_{r \geq 0} H_i^{(r)} u^{-r-1}, \end{aligned}$$

where $u = 1/z$ is the spectral parameter. The zeroth modes $E_i^{(0)}, F_i^{(0)}, H_i^{(0)}$ generate a copy of $U(\mathfrak{sl}_3)$ inside $Y_{\hbar}(\mathfrak{sl}_3)$.

27.18.3 Degree-2 relations: Cartan matrix and Yangian deformation

The bar differential (27.14) specialises to

$$\begin{aligned} d_{\overline{B}^{\text{ch}}}(s^{-1}h_i \otimes s^{-1}e_j) &= A_{ij} s^{-1}e_j, \\ d_{\overline{B}^{\text{ch}}}(s^{-1}e_i \otimes s^{-1}f_j) &= \delta_{ij} s^{-1}h_i, \\ d_{\overline{B}^{\text{ch}}}(s^{-1}e_1 \otimes s^{-1}e_2) &= s^{-1}e_{12}, \\ d_{\overline{B}^{\text{ch}}}(s^{-1}f_2 \otimes s^{-1}f_1) &= s^{-1}f_{12}. \end{aligned}$$

The first two lines reproduce the Cartan relations $[H_i, E_j] = A_{ij}E_j$ and $[E_i, F_j] = \delta_{ij}H_i$ at leading order in the spectral parameter. The last two express the composite root as a bar boundary. The Yangian deformation appears at the next spectral order:

$$[H_i(u), E_j(v)] = \frac{A_{ij}}{u-v} E_j(v) + (\text{regular}), \quad [E_i(u), F_j(v)] = \frac{\delta_{ij}}{u-v} H_i(v) + (\text{regular}).$$

27.18.4 Degree-3 triangle sectors

This is the first genuinely rank-2 sector: the composite root $\alpha_1 + \alpha_2$ produces degree-3 bar elements that have no $\mathfrak{sl}_2$ analogue.

Definition 27.18.1 (Triangle sectors for $\mathfrak{sl}_3$). The degree-3 ordered bar complex $\overline{B}^{\text{ch,ord}}_3(V_k(\mathfrak{sl}_3))$ contains four *triangle sectors*, indexed by the composite root $\alpha_1 + \alpha_2$ and the two orderings of simple lowering (respectively raising) operators:

$$\begin{aligned} T_{12}^L &= E_{13}^{(1)} E_{21}^{(2)} E_{32}^{(3)}, & T_{21}^L &= E_{13}^{(1)} E_{32}^{(2)} E_{21}^{(3)}, \\ T_{12}^R &= E_{12}^{(1)} E_{23}^{(2)} E_{31}^{(3)}, & T_{21}^R &= E_{23}^{(1)} E_{12}^{(2)} E_{31}^{(3)}. \end{aligned}$$

The left triangles have the composite raising operator $e_{12} = E_{13}$ in the first tensor factor and the two simple lowering operators split across factors 2 and 3. The right triangles have the two simple raising operators in factors 1 and 2 and the composite lowering operator $f_{12} = E_{31}$ in factor 3.

THEOREM 27.18.2 (*Triangle coefficient for $\mathfrak{sl}_3$*). Let the two-body spectral functions be given by the rational ansatz $\rho_\alpha(u) = c_\alpha/u$, and define the triangle transport coefficient λ by

$$\Pi_{\langle T_{12}^L, T_{21}^L \rangle}((\text{id} \otimes \Delta_z) X_{\alpha_1 + \alpha_2}^{12}(w)) = \lambda(\rho_1(w) \rho_2(w+z) T_{12}^L - \rho_2(w) \rho_1(w+z) T_{21}^L).$$

Then the triangle coefficient is

$$\lambda = \frac{c_1 c_2}{2 c_{12}} = \frac{1}{2} = \int_0^1 (1-t) dt,$$

where the last equality identifies the coefficient as the $n = 2$ Euler beta integral $B(1, 2) = \int_0^1 (1-t)^{2-1} dt = 1/2$. In the normalised case $c_1 = c_2 = c_{12} = 1$, the coefficient is $\frac{1}{2}$ for both left and right triangles and both orderings: $\lambda_{12}^L = \lambda_{21}^L = \lambda_{12}^R = \lambda_{21}^R = \frac{1}{2}$.

Proof. The product side of the filtration-2 hexagon defect equation projects to the triangle sectors by commutator extraction. The only terms that contribute are

$$[E_1^{(1)} F_1^{(2)}, E_2^{(1)} F_2^{(3)}] = E_{12}^{(1)} F_1^{(2)} F_2^{(3)}$$

and

$$[E_2^{(1)} F_2^{(2)}, E_1^{(1)} F_1^{(3)}] = -E_{12}^{(1)} F_2^{(2)} F_1^{(3)},$$

where the signs arise from $[e_1, e_2] = e_{12}$ and $[e_2, e_1] = -e_{12}$. The logarithm of the ordered product of two-body exponentials gives

$$\Pi_{\langle T_{12}^L, T_{21}^L \rangle} \frac{1}{2} [S_{12}(w), S_{13}(w+z)] = \frac{1}{2} \rho_1(w) \rho_2(w+z) T_{12}^L - \frac{1}{2} \rho_2(w) \rho_1(w+z) T_{21}^L.$$

On the coproduct side, $X_{\alpha_1 + \alpha_2}$ is the unique composite root generator that can land in the triangle sector. The twisted coproduct on $X_{\alpha_1 + \alpha_2}^{12}(w)$ projects to the triangle sector with transport coefficient λ . Equating the two sides and substituting the rational ansatz $\rho_\alpha(u) = c_\alpha/u$ gives

$$\frac{c_{12}}{w} \cdot \frac{\lambda}{w+z} = \frac{1}{2} \cdot \frac{c_1}{w} \cdot \frac{c_2}{w+z},$$

whence $\lambda = c_1 c_2 / (2 c_{12})$. In the normalised case this is $1/2$. The integral representation follows from $B(1, 2) = \int_0^1 (1-t) dt = 1/2$. $\square$

Remark 27.18.3 (The triangle coefficient as BCH coefficient). The coefficient $1/2$ is the $n = 2$ instance of the universal n -gon coefficient $1/n$ supplied by the Vol. II n -gon localisation formula. At $n = 2$ the ordered BCH expansion $\log(e^X e^Y) = X + Y + \frac{1}{2}[X, Y] + \dots$ has $\frac{1}{2}$ as the coefficient of the first commutator term. This is not a coincidence: the triangle sector is the first commutator sector in the ordered bar complex. The integral $\int_0^1 (1-t)^{n-1} dt = 1/n$ provides a uniform derivation for all n , replacing case-by-case Baker–Campbell–Hausdorff algebra.

27.18.5 Serre relations from root-space vanishing

PROPOSITION 27.18.4 (*Serre relations from root-space vanishing*). The Serre relations of $Y_h(\mathfrak{sl}_3)$ arise from degree-3 bar cohomology by root-space obstruction. Specifically:

- (i) $2\alpha_1 + \alpha_2 \notin \Phi(\mathfrak{sl}_3)$, so $(\mathfrak{sl}_3)_{2\alpha_1 + \alpha_2} = 0$, which forces $[e_1, [e_1, e_2]] = 0$.

(ii) $\alpha_1 + 2\alpha_2 \notin \Phi(\mathfrak{sl}_3)$, so $(\mathfrak{sl}_3)_{\alpha_1+2\alpha_2} = 0$, which forces $[e_2, [e_2, e_1]] = 0$.

In the ordered bar complex, these correspond to the vanishing of the degree-3 bar differential on the would-be generators $s^{-1}e_1 \otimes s^{-1}e_1 \otimes s^{-1}e_2$ and $s^{-1}e_2 \otimes s^{-1}e_2 \otimes s^{-1}e_1$: the target root spaces are empty, so the bar differential has trivial image and the corresponding bar cohomology classes are zero. The spectral-parameter deformation promotes these to the Yangian Serre relations:

$$\text{Sym}_{u_1, u_2} [E_i(u_1), [E_i(u_2), E_j(v)]] = 0, \quad A_{ij} = -1.$$

Proof. Consider the degree-3 bar element $s^{-1}e_1 \otimes s^{-1}e_1 \otimes s^{-1}e_2$. The bar differential evaluates the nested commutator $[e_1, [e_1, e_2]] = [e_1, e_{12}]$. But $e_1 \in (\mathfrak{sl}_3)_{\alpha_1}$ and $e_{12} \in (\mathfrak{sl}_3)_{\alpha_1+\alpha_2}$, so the commutator would live in $(\mathfrak{sl}_3)_{2\alpha_1+\alpha_2}$. Since $2\alpha_1 + \alpha_2 \notin \Phi(\mathfrak{sl}_3)$ (the root system of A_2 contains only roots of height ≤ 2), this root space is zero, hence $[e_1, e_{12}] = 0$. The identical argument with $\alpha_1 \leftrightarrow \alpha_2$ gives $[e_2, e_{21}] = [e_2, [e_2, e_1]] = 0$.

For the Yangian deformation: the spectral OPE $E_i(u)E_i(v)$ has a pole shifted to $u - v = \hbar$ (off the collision diagonal), so the collision residue vanishes and $d_{\text{res}}(s^{-1}E_i \otimes s^{-1}E_i) = 0$. The degree-3 bar cocycle condition $d^2 = 0$ then forces the symmetrised nested commutator to vanish, giving the Yangian Serre relation. $\square$

27.18.6 The RTT presentation and the 9×9 R -matrix

THEOREM 27.18.5 (*RTT presentation for $Y_{\hbar}(\mathfrak{sl}_3)$ from the ordered bar complex;*). Let $V = \mathbb{C}^3$ be the defining representation of $\mathfrak{sl}_3$ and define the transfer matrix

$$T(u) = \sum_{a,b=1}^3 e_{ab} \otimes t^{ab}(u) \in \text{End}(V) \otimes Y_{\hbar}(\mathfrak{sl}_3)[[u^{-1}]],$$

where $t^{ab}(u)$ are the degree-1 bar cohomology generating functions. Then the consistency of the degree-3 ordered bar complex $\overline{B}_3^{\text{chord}}$ gives the RTT relation

$$R(u-v) T_1(u) T_2(v) = T_2(v) T_1(u) R(u-v), \quad (27.15)$$

where $R(u) \in \text{End}(V \otimes V)$ is the rational Yang R -matrix

$$R(u) = 1 + \frac{\hbar \Omega}{u} + O(u^{-2}), \quad \Omega = \sum_{a,b=1}^3 e_{ab} \otimes e_{ba},$$

acting on $V \otimes V \cong \mathbb{C}^9$. Here Ω is the $\mathfrak{sl}_3$ -Casimir in the tensor square of the defining representation (Remark 27.16.2(a) with $n = 2$), and e_{ab} are the standard matrix units of $\mathfrak{gl}_3$.

Proof. This is the A_2 specialisation of Theorem 27.16.1. The R -matrix arises from the monodromy of the flat connection $\nabla = d - r(z) dz$ on the ordered configuration space $C_2^<(\mathbb{C})$, where $r^{\text{KZ}}(z) = \Omega / ((k + \hbar^\vee)z)$ is the KZ-normalized classical r -matrix (27.13). The underlying trace-form collision residue is $k\Omega_{\text{tr}}/z$. The RTT relation (27.15) is equivalent to $d^2 = 0$ on $\overline{B}_3^{\text{chord}}$: the three-fold bar consistency intertwines two orderings of the first two tensor factors via the R -matrix and inserts a bar cohomology class in the third slot. The Yang–Baxter equation

$$R_{12}(u-v) R_{13}(u) R_{23}(v) = R_{23}(v) R_{13}(u) R_{12}(u-v)$$

follows from $d^3 = 0$ on $\overline{B}_4^{\text{chord}}$ and is checked directly for $R(u) = 1 + \hbar \Omega / u$ using the $\mathfrak{sl}_3$ Jacobi identity in the tensor cube $V^{\otimes 3} \cong \mathbb{C}^{27}$. $\square$

Remark 27.18.6 (The 9×9 versus 4×4 R -matrix). For $\mathfrak{sl}_2$ the R -matrix acts on $\mathbb{C}^2 \otimes \mathbb{C}^2 \cong \mathbb{C}^4$. For $\mathfrak{sl}_3$ it acts on $\mathbb{C}^3 \otimes \mathbb{C}^3 \cong \mathbb{C}^9$. The decomposition $\mathbb{C}^9 \cong \mathbf{6} \oplus \mathbf{3}$ (symmetric and exterior squares) is an eigenspace decomposition for the permutation $P = \sum e_{ab} \otimes e_{ba}$: eigenvalue $+1$ on $\text{Sym}^2(V)$ and -1 on $\wedge^2(V)$. The R -matrix $R(u) = 1 + \hbar P/u$ therefore has eigenvalues $1 + \hbar/u$ and $1 - \hbar/u$ on these two subspaces. The four triangle sectors $T_{12}^L, T_{21}^L, T_{12}^R, T_{21}^R$ are the components of the degree-3 bar complex that detect the off-diagonal $(\alpha_1 + \alpha_2)$ block of this R -matrix.

27.18.7 Strictification for $\mathfrak{sl}_3$

THEOREM 27.18.7 (*Vanishing of the spectral Drinfeld class for $\mathfrak{sl}_3$*). The spectral Drinfeld class $[\partial] \in H^2(\mathfrak{sl}_3, \text{End}(\mathfrak{sl}_3 \otimes \mathfrak{sl}_3))$ vanishes. Concretely:

- (i) At filtration 1 (Cartan sector), the defect is identically zero because the Cartan matrix A_{ij} has integer entries and the rational ansatz is already exact.
- (ii) At filtration 2 (triangle sector), the obstruction lives in the two-dimensional space spanned by T_{12}^L and T_{21}^L . The triangle coefficient $\lambda = 1/2$ satisfies the rigidity equations of Theorem 27.18.2, so the defect vanishes.
- (iii) At filtration ≥ 3 , the Serre relation $[e_1, [e_1, e_2]] = 0$ ensures vanishing target. Root-space one-dimensionality ($\dim(\mathfrak{sl}_3)_\alpha = 1$ for all $\alpha \in \Phi$) forces the remaining cochains to be coboundaries via the Jacobi collapse mechanism (Step 4 of Theorem 27.16.1).

Therefore $[\partial] = 0$ at every filtration, and $Y_\hbar(\mathfrak{sl}_3)$ is a strict associative algebra.

Proof. This is Step 4 of Theorem 27.16.1 specialised to A_2 . The filtration-by-filtration calculation above records what the general root-space one-dimensionality argument looks like when all root spaces are enumerated: Φ has exactly 6 roots, all of multiplicity one. $\square$

Remark 27.18.8 (Contrast with root multiplicities > 1). The vanishing of $[\partial]$ uses $\dim(\mathfrak{sl}_3)_\alpha = 1$ in an essential way. For Kac–Moody algebras with root multiplicities > 1 (e.g. the Monster Lie algebra), the endomorphism space at a root of multiplicity m is $\text{End}(\mathbb{C}^m)$, and the Jacobi collapse argument fails: the obstruction cochain has non-scalar entries that need not be coboundaries.

27.19 HIGHER-RANK PATTERN: THE $\mathfrak{sl}_4$ ROOT QUADRILATERAL

For $\mathfrak{sl}_4$ the Dynkin diagram is the path $\alpha_1 - \alpha_2 - \alpha_3$ of type A_3 , with positive roots

$$\Phi^+ = \{\alpha_1, \alpha_2, \alpha_3, \alpha_1 + \alpha_2, \alpha_2 + \alpha_3, \alpha_1 + \alpha_2 + \alpha_3\}.$$

In matrix-unit notation: $e_1 = E_{12}, e_2 = E_{23}, e_3 = E_{34}, e_{12} = E_{13}, e_{23} = E_{24}, e_{123} = E_{14}$.

Definition 27.19.1 (*Quadrilateral sectors*). The degree-4 ordered bar complex exhibits *quadrilateral sectors* associated to the maximal composite root $\alpha_1 + \alpha_2 + \alpha_3$. The left quadrilateral vector is

$$Q_{123}^L = E_{14}^{(1)} E_{21}^{(2)} E_{32}^{(3)} E_{43}^{(4)},$$

with permuted orderings of the simple lowering operators in factors 2, 3, 4.

THEOREM 27.19.2 (*Quadrilateral coefficient for $\mathfrak{sl}_4$*). Under the normalised rational ansatz, the quadrilateral transport coefficient is

$$\frac{1}{3} = \int_0^1 (1-t)^2 dt = B(1, 3),$$

the $n = 3$ instance of the universal n -gon coefficient $1/n$.

Proof. By the same method as Theorem 27.18.2, the product side of the filtration-3 hexagon defect gives

$$\frac{1}{3} [X_1, [X_2, X_3]],$$

where the coefficient $1/3$ arises from the Dynkin path BCH formula: $\log(e^{X_1}e^{X_2}e^{X_3})$ restricted to the multilinear part of the path $\alpha_1 \sim \alpha_2 \sim \alpha_3$ gives $\frac{1}{3}[X_1, [X_2, X_3]]$ (using $[X_1, X_3] = 0$ since α_1 and α_3 are non-adjacent). The integral representation is $\int_0^1 (1-t)^2 dt = \frac{1}{3}$.

On the coproduct side, $X_{\alpha_1+\alpha_2+\alpha_3}$ is the unique height-3 generator whose twisted coproduct projects to the quadrilateral sector. Equating coefficients gives the claim.

The Serre relations for $\mathfrak{sl}_4$ provide further constraints: $(\text{ad } e_i)^{1-A_{ij}}(e_j) = 0$ with $A_{ij} = -1$ for adjacent i, j and $A_{13} = 0$. The last condition gives $[e_1, e_3] = 0$: non-adjacent simple roots commute.

The strictification obstruction vanishes for $\mathfrak{sl}_4$ by root-space one-dimensionality (every root of A_3 has multiplicity 1), exactly as for $\mathfrak{sl}_3$. $\square$

Remark 27.19.3 (The beta-integral staircase). The pattern of n -gon coefficients

$$\frac{1}{n} = \int_0^1 (1-t)^{n-1} dt = B(1, n), \quad n = 2, 3, 4, \dots,$$

gives a staircase indexed by Dynkin path length:

$\mathfrak{sl}_N$	$N = 2$	$N = 3$	$N = 4$	$N = 5$
path length n	1	2	3	4
coefficient	1	1/2	1/3	1/4

At $n = 1$ (the $\mathfrak{sl}_2$ case), there is no triangle sector and the coefficient is 1: this is the degree-2 bar differential, which is the Lie bracket itself. The genuine rank-2 phenomenon begins at $n = 2$ with the coefficient $1/2$. Each step up the rank ladder introduces one additional nested commutator and one additional power of $(1-t)$ in the integrand. The beta integral provides a single uniform computation that replaces all the case-by-case Baker–Campbell–Hausdorff algebra.

For general simple $\mathfrak{g}$, the maximal Dynkin path length is the rank r , and the deepest n -gon coefficient is $1/r$. The strictification obstruction vanishes for all simple Lie algebras by root-space one-dimensionality (every root in a finite root system has multiplicity 1), confirming Theorem 27.16.1.

27.19.1 Explicit computations and R -matrices: types B_2, C_2, G_2

Table 27.1 records summary data for all types. We work out the three rank-2 families beyond type A , exhibiting root data, R -matrices in the fundamental representation, Serre relations, and strictification.

THEOREM 27.19.4 (Ordered bar complexes and Yangian R -matrices for rank-2 non- A types;). For each of the rank-2 types below, the trace-form collision residue is $k\Omega_{\text{tr}}/z$ and the KZ-normalized spectral r -matrix is $r^{\text{KZ}}(z) = \Omega/((k+h^\vee)z)$. Root-space one-dimensionality forces complete strictification, and the RTT relation $R_{12}(u-v)T_1(u)T_2(v) = T_2(v)T_1(u)R_{12}(u-v)$ generates the Yangian.

Type B_2 ($\mathfrak{so}_5$, $h^\vee = 3$, $V = \mathbb{C}^5$). Cartan matrix $\begin{pmatrix} 2 & -1 \\ -2 & 2 \end{pmatrix}$; positive roots $\alpha_1, \alpha_2, \alpha_1+\alpha_2, \alpha_1+2\alpha_2$; max height 3. The Casimir image on $V \otimes V$ is $\Omega_V = P - K$, where K is the trace contraction. The Zamolodchikov–Fateev R -matrix is

$$R(u) = u \cdot \text{id} + P - \frac{Q}{u + \varkappa}, \quad \varkappa = \frac{N-2}{2} = \frac{3}{2}, \quad (27.16)$$

with eigenvalues $u+1$ on $S_0^2 V \cong \mathbf{14}$, $u-1$ on $\Lambda^2 V \cong \mathbf{10}$, and $(u^2 + \frac{5}{2}u - \frac{7}{2})/(u + \frac{3}{2})$ on $\mathbf{1}$. Serre: $[e_2, [e_2, [e_2, e_1]]] = 0$ from $(\mathfrak{so}_5)_{3\alpha_2 + \alpha_1} = 0$.

Type $C_2(\mathfrak{sp}_4, h^\vee = 3, V = \mathbb{C}^4)$. Cartan matrix $\begin{pmatrix} 2 & -2 \\ -1 & 2 \end{pmatrix}$; positive roots $\alpha_1, \alpha_2, \alpha_1 + \alpha_2, 2\alpha_1 + \alpha_2$; max height 3. The Casimir image uses the symplectic form $J: \Omega_V = P - K_J$, with $(K_J)_{ij,kl} = J_{il} J_{jk}$. The symplectic R -matrix is

$$R(u) = u \cdot \text{id} + P + \frac{K}{u - \kappa}, \quad \kappa = n+1 = 3,$$

with eigenvalues $u+1$ on $\text{Sym}^2 V \cong \mathbf{10}$, $u-1$ on $\Lambda_0^2 V \cong \mathbf{5}$, and $(u^2 - 4u - 1)/(u - 3)$ on $\mathbf{1}$. The sign of the contraction pole is *opposite* to type B : this is the R -matrix-level manifestation of Langlands duality $B_n \leftrightarrow C_n$. Serre: $[e_1, [e_1, [e_1, e_2]]] = 0$ from $(\mathfrak{sp}_4)_{3\alpha_1 + \alpha_2} = 0$.

Type $G_2(\mathfrak{g}_2, h^\vee = 4, V = \mathbb{C}^7)$. Cartan matrix $\begin{pmatrix} 2 & -1 \\ -3 & 2 \end{pmatrix}$; positive roots $\alpha_1, \alpha_2, \alpha_1 + \alpha_2, 2\alpha_1 + \alpha_2, 3\alpha_1 + \alpha_2, 3\alpha_1 + 2\alpha_2$; max height 5. The tensor product $V \otimes V \cong \mathbf{1} \oplus \mathbf{7} \oplus \mathbf{14} \oplus \mathbf{27}$ decomposes into four G_2 -irreducibles with Casimir eigenvalues $c_1 = 0, c_7 = 1/4, c_{14} = 1/2, c_{27} = 5/12$. The R -matrix involves four equivariant projectors:

$$R(u) = \sum_{\lambda \in \{\mathbf{1}, \mathbf{7}, \mathbf{14}, \mathbf{27}\}} f_\lambda(u) \cdot \Pi_\lambda, \quad (27.17)$$

with $f_{27} = u+1, f_{14} = u-1, f_7 = (u+1)(u-2)/(u+2), f_1 = (u+1)(u-4)/(u+4)$. The poles at $u = -2$ and $u = -4$ correspond to the two primitive G_2 -invariant tensors beyond id and P . The Serre relations follow from root-space vanishing: $[e_2, [e_2, e_1]] = 0$ since $\alpha_1 + 2\alpha_2 \notin \Phi(G_2)$; $[e_1, [e_1, [e_1, e_2]]] = 0$ since $4\alpha_1 + \alpha_2 \notin \Phi(G_2)$. The Jacobi collapse lemma handles the degree-5 star-sector at the longest root $3\alpha_1 + 2\alpha_2$.

Proof. All collision residues and root-space one-dimensionality follow from Theorem 27.16.1. The R -matrices are the unique $\mathfrak{g}$ -invariant rational YBE solutions with classical limit $R(u) = u \cdot \text{id} + \hbar \Omega_V / u + O(u^{-2})$: for types B/C , the Brauer algebra relations ($P^2 = \text{id}, Q^2 = NQ$ or $K^2 = -2nK$) determine all coefficients; for G_2 , $\dim \text{End}_{G_2}(V \otimes V) = 4$ and the YBE plus unitarity $R(u)R_{21}(-u) \propto \text{id}$ fix the eigenvalues uniquely. Serre relations and strictification are proved by direct root-space analysis. $\square$

Remark 27.19.5 (Comparison across rank-2 types).

Type	$h^\vee$	$\dim V_{\text{fund}}$	$ \Phi^+ $	max height	R -matrix structure
A_2	3	3	3	2	P only
B_2	3	5	4	3	P, Q
C_2	3	4	4	3	P, K_J
G_2	4	7	6	5	four projectors

The R -matrix complexity increases with $|\text{Irr}(V_{\text{fund}} \otimes V_{\text{fund}})|$: type A has 2 summands, types B/C have 3, G_2 has 4. The Langlands duality $B_2^\vee = C_2$ interchanges $Q \leftrightarrow K_J$ and reverses the contraction-pole sign. The G_2 representation $V = \mathbb{C}^7$ is the imaginary octonions; the four-projector R -matrix encodes octonionic structure constants.

The preceding sections develop the ordered bar complex at genus zero. Wrapping the topological direction $\mathbb{R}$ into S^1 lifts the theory to genus one.

27.20 THE ANNULAR BAR COMPLEX AND GENUS-ONE STRUCTURE

The strip ordered bar complex $\overline{B}^{\text{ch,ord}}(\mathcal{A})$ on $\text{FM}_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R})$ computes genus-zero data: the topological direction is $\mathbb{R}$, an interval, and the resulting chain complex classifies the genus-zero E_1 -chiral Koszul dual. Replacing the strip $\mathbb{R}$ by the circle $S^1 = \mathbb{R}/\mathbb{Z}$ wraps the topological direction and produces a genus-one analogue: the *annular bar complex*. The wrapping converts the two-sided cobar complex into a coHochschild complex, and the resulting object computes $\text{HH}_\bullet^{\text{ch}}(\mathcal{A})$, connecting the ordered sector to the modular operad at genus 1.

27.20.1 Definition of the annular bar complex

Definition 27.20.1 (Annular bar complex). Let $\mathcal{A}$ be a strongly admissible augmented E_1 -chiral algebra and $C = \overline{B}^{\text{ch,ord}}(\mathcal{A})$ its ordered bar coalgebra, with C_Δ the diagonal bicomodule (Theorem 27.7.4). The *annular bar complex* is the chain complex

$$B_\bullet^{\text{ann}}(\mathcal{A}) := C_\bullet(\overline{\text{FM}}_{r,s}^{\text{ann}}; \omega_{\text{bar}}) \cong \bigoplus_{n \geq 0} \text{cyc}^n(C, C_\Delta),$$

where $\text{cyc}^n(C, C_\Delta) := C_\Delta \widehat{\otimes}_C C^{\widehat{\otimes} n}$ is the *cyclic cotensor*: the completed tensor product that cyclically identifies the last right C -coaction with the first left C -coaction, reflecting the periodicity of the circle.

The annular configuration space $\overline{\text{FM}}_{r,s}^{\text{ann}}$ parametrises r holomorphic marked points on $\mathbb{C}$ and s ordered marked points on S^1 , with the Fulton–MacPherson compactification in the holomorphic direction. It is the geometric carrier for the genus-one ordered sector: the strip $\text{FM}_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R})$ wraps to $\text{FM}_k(\mathbb{C}) \times \text{Conf}_k^{\text{cyc}}(S^1)$, where $\text{Conf}_k^{\text{cyc}}(S^1)$ denotes cyclically ordered configurations on the circle. The compactification $\overline{\text{FM}}_{r,s}^{\text{ann}}$ is a manifold with corners whose codimension-one boundary strata encode the four components of the annular differential below.

27.20.2 The annular bar differential

THEOREM 27.20.2 (Annular bar differential;). The differential on $B_\bullet^{\text{ann}}(\mathcal{A})$ decomposes as

$$d^{\text{ann}} = d_{\text{int}} + d_{\text{res}} + d_\Delta + d_{\text{wrap}},$$

where:

- (a) d_{int} : internal differential on each tensor factor (the intrinsic differential of $\mathcal{A}$).
- (b) d_{res} : collision residue differential arising from OPE residues at interior collisions in the holomorphic direction (identical to the strip bar differential).
- (c) d_Δ : comultiplication differential at non-wrapping boundary collisions, the coface maps δ_i for $1 \leq i \leq n-1$ that split a tensor factor via the ordered coproduct.
- (d) d_{wrap} : the wrap-around differential at the seam of the annulus, given by

$$d_{\text{wrap}} \langle a_1 | \cdots | a_n \rangle = \sum_{(a_n)} (-1)^\epsilon \langle a_1 | \cdots | a_{n-1} | a'_n | a''_n \rangle + \sum_{(a_1)} (-1)^{\epsilon'} \langle a'_1 | a''_1 | a_2 | \cdots | a_n \rangle,$$

where the sums are over the ordered coproduct $\Delta(a_n) = \sum a'_n \otimes a''_n$ and $\Delta(a_1) = \sum a'_1 \otimes a''_1$, and the signs ϵ, ϵ' are the Koszul signs dictated by the suspended grading $|s^{-1}a| = |a| - 1$.

The identity $(d^{\text{ann}})^2 = 0$ follows from $\partial^2 = 0$ on the manifold with corners $\overline{\text{FM}}_{r,s}^{\text{ann}}$: each boundary face of codimension 2 appears as the common boundary of exactly two codimension-1 faces, with opposite orientations.

Proof. The proof parallels that of the strip bar differential (Construction 27.11.9). The codimension-1 boundary strata of $\overline{\text{FM}}_{r,s}^{\text{ann}}$ are of four types:

- (i) an internal bubble separates at a single tensor factor (producing d_{int});
- (ii) two or more holomorphic points collide away from the seam (producing d_{res});
- (iii) two consecutive topological points collide away from the seam, splitting a tensor factor via the ordered coproduct (producing d_{Δ});
- (iv) a topological point crosses the seam $0 \sim 1$ of S^1 , forcing the first or last tensor factor to split and re-enter at the opposite end (producing d_{wrap}).

The identity $(d^{\text{ann}})^2 = 0$ is the algebraic manifestation of $\partial^2 = 0$: every codimension-2 face of $\overline{\text{FM}}_{r,s}^{\text{ann}}$ is a common boundary of exactly two codimension-1 faces, and the orientations cancel pairwise. $\square$

Remark 27.20.3 (The wrap-around differential as the genus-one novelty). The wrap-around differential d_{wrap} is the only component without a strip analogue. Algebraically, it provides the coface maps δ_0 and δ_n that close the two-sided cobar complex into the coHochschild complex: without it the complex computes $\text{Cotor}^{C^e}(C_{\Delta}, C_{\Delta})$; with it, the result is the self-cotrace $C_{\Delta} \square_{C^e}^{\mathbf{L}} C_{\Delta} \simeq \text{coHH}_{\bullet}^{\text{ch}}(C, C_{\Delta})$.

27.20.3 Annular chiral Hochschild identification

THEOREM 27.20.4 (*Annular bar complex computes chiral Hochschild homology*;). Let $\mathcal{A}$ be a strongly admissible E_1 -chiral algebra with ordered bar coalgebra $C = \overline{B}^{\text{ch,ord}}(\mathcal{A})$ and diagonal bicomodule C_{Δ} . There is a canonical quasi-isomorphism

$$B_{\bullet}^{\text{ann}}(\mathcal{A}) \simeq \text{coHH}_{\bullet}^{\text{ch}}(C, C_{\Delta}) \simeq \text{HH}_{\bullet}^{\text{ch}}(\mathcal{A}),$$

where the second equivalence is Theorem 27.8.1.

Proof. By Definition 27.20.1, the annular bar complex is the cyclic cotensor $\bigoplus_{n \geq 0} \text{cyc}^n(C, C_{\Delta})$. The coHochschild complex of a coalgebra C with coefficients in a bicomodule M is the standard cochain complex

$$\text{coHH}_{\bullet}^{\text{ch}}(C, M) = \bigoplus_{n \geq 0} M \widehat{\otimes}_C C^{\widehat{\otimes} n}$$

with differential assembled from the coface maps $\delta_0, \dots, \delta_n$. For $M = C_{\Delta}$, this is precisely the annular bar complex: the coface maps $\delta_1, \dots, \delta_{n-1}$ produce d_{Δ} (non-wrapping boundary collisions), and the coface maps δ_0 and δ_n produce d_{wrap} (the wrap-around at the seam). The internal differential d_{int} and collision residue d_{res} are carried along as the internal structure of each tensor factor.

The second equivalence is Theorem 27.8.1, which identifies $\text{coHH}_{\bullet}^{\text{ch}}(C, C_{\Delta}) \simeq \text{HH}_{\bullet}^{\text{ch}}(\mathcal{A})$ via the bimodule/bicomodule equivalence of Theorem 27.7.3. $\square$

27.20.4 Connection to the modular operad at genus 1

Remark 27.20.5 (The annular bar complex and the modular E_1 -chiral structure). The annular bar complex provides the ordered sector's contribution to the genus-1 modular E_1 -chiral operad. The passage from strip to annulus ($\mathbb{R} \rightsquigarrow S^1$) is the topological-direction analogue of the holomorphic passage from $\mathbb{C}$ to the elliptic curve E_{τ} : both wrap an infinite direction into a compact one, and both introduce monodromy.

In the modular operad framework:

- (i) The strip bar complex $\overline{B}^{\text{ch,ord}}(\mathcal{A})$ is the genus-0 open sector, computing the E_1 Koszul dual.

- (ii) The annular bar complex $B_{\bullet}^{\text{ann}}(\mathcal{A})$ is the genus-1 open sector, computing chiral Hochschild homology.
- (iii) The genus-1 closed sector carries the curvature $d^2 = \kappa(\mathcal{A}) \cdot \omega_1$ from the Hodge bundle (Vol I, Theorem D).
- (iv) The annular closure of Conjecture 27.30.3(4) is the geometric realisation of the isomorphism $B_{\bullet}^{\text{ann}} \simeq \text{coHH}_{\bullet}^{\text{ch}}(C)$ at the configuration-space level.

The open trace formalism (Theorem 27.9.5) at genus 1 factors through the annular bar complex: the decategorified trace $\text{tr}: K_0(C_{\text{line}}) \rightarrow \text{HH}_0^{\text{ch}}(\mathcal{A})$ computes characters of line operators by wrapping them around the annulus.

27.20.5 Curvature–braiding dichotomy at genus 1

At genus 0, the curvature $\kappa(\mathcal{A})$ (measuring the failure of formality, i.e. $d^2 = \kappa \cdot \omega_g$ in the curved bar complex) and the spectral R -matrix $R(z)$ (measuring the braiding monodromy on the ordered configuration space) are independent structures: the curvature is controlled by the chiral differential, the braiding by the coassociative coproduct. At genus 1, however, they meet: the spectral braiding must be defined on the elliptic curve E_{τ} , and the quasi-periodicity of the elliptic propagator forces the two structures to interact. The nature of this interaction is controlled entirely by the lowest-pole coefficient c_0 of the λ -bracket.

Remark 27.20.6 (Convention for this subsection). Throughout this subsection and through Definition 27.23.2 we use the *raw* λ -bracket expansion $\{a_{\lambda}b\} = \sum_{n \geq 0} c_n(a, b) \lambda^n$ (so c_n is the n -th OPE mode coefficient $a_{(n)}b$) and parameterise the genus-0 classical r -matrix by $r(z) = \sum c_n/z^{n+1}$. This differs from the d log-absorbed collision-residue convention used in Theorem 27.12.3, in the Virasoro collision-residue proposition below, and in Theorem 27.16.1, where the simple-pole coefficient of r^{coll} corresponds to $a_{(1)}b$ rather than $a_{(0)}b$. The two conventions are related by the shift $n \mapsto n-1$ in the pole index. Within the present subsection we keep the raw convention because it aligns with the standard genus-1 dichotomy (Heisenberg decoupled because $c_0 = a_{(0)}b = 0$, affine entangled because $c_0 = f^{ab}{}_c J^c \neq 0$).

THEOREM 27.20.7 (Curvature–braiding dichotomy at genus 1;). Let $\mathcal{A}$ be a logarithmic E_1 -chiral algebra and write the (-1) -shifted λ -bracket on cohomology as

$$\{a_{\lambda}b\} = c_0(a, b) + c_1(a, b) \lambda + c_2(a, b) \lambda^2 + \cdots,$$

so that the genus-0 classical r -matrix has the Laurent expansion

$$r(z) = \frac{c_0}{z} + \frac{c_1}{z^2} + \frac{c_2}{z^3} + \cdots \quad (\text{formal, } z \rightarrow \infty).$$

At genus 1, the classical r -matrix on E_{τ} is obtained by replacing each rational function $1/z^{n+1}$ ($n \geq 0$) by its unique elliptic counterpart with the same local singularity at $z = 0$:

$$r^{E_{\tau}}(z) = c_0 \cdot \zeta(z|\tau) + \sum_{n \geq 1} \frac{(-1)^{n-1}}{n!} c_n \cdot \wp^{(n-1)}(z|\tau), \quad (27.18)$$

where $\wp^{(0)} := \wp$, and $\zeta(z|\tau), \wp(z|\tau)$ are the Weierstrass zeta and $\wp$ -functions with periods 1, τ . The first three terms are $c_0 \zeta + c_1 \wp - \frac{1}{2} c_2 \wp' + \cdots$; the prefactors $(-1)^{n-1}/n!$ come from the Laurent expansion $\wp^{(m)}(z) = (-1)^m (m+1)!/z^{m+2} + O(1)$ setting $m = n-1$. Then:

(a) (Quasi-periodicity.) The B -cycle monodromy of r^{E_τ} is

$$r^{E_\tau}(z + \tau) - r^{E_\tau}(z) = 2\eta_\tau \cdot c_o,$$

where $\eta_\tau = \zeta(\tau/2|\tau)$ is the quasi-period. The A -cycle monodromy is $2\eta_1 \cdot c_o$.

(b) (Decoupling: Cartan type.) If $c_o = 0$ (equivalently, $\{a_o b\} = 0$ for all $a, b \in H^\bullet(\mathcal{A}, Q)$), then $r^{E_\tau}(z)$ is a meromorphic function on E_τ (doubly periodic). The spectral braiding is independent of the B -cycle monodromy that sources the curvature $\kappa(\mathcal{A}) \cdot \omega_1$. The genus-1 E_1 -chiral bar complex splits:

$$\overline{B}^{\text{ch,ord}}(\mathcal{A})^{(1)} \simeq (\text{curved chiral differential}) \times (\text{flat coassociative coproduct with meromorphic braiding}).$$

(c) (Entanglement: Yangian type.) If $c_o \neq 0$, then $r^{E_\tau}(z)$ is quasi-periodic with non-trivial B -cycle monodromy $2\eta_\tau \cdot c_o$. The spectral braiding is a section of a flat connection on the universal cover of E_τ with holonomy c_o , and the genus-1 E_1 -chiral bar complex does *not* split. The braiding and the curvature share a common geometric source: the B -cycle monodromy of the Weierstrass zeta function.

Proof. **Step 1** (Elliptic propagator). At genus 0, the holomorphic propagator is $K^\mathbb{C}(z) = dz/z$ (the $d \log$ kernel). At genus 1, on the elliptic curve E_τ , the unique meromorphic one-form with a simple pole at $z = 0$ and prescribed quasi-periodicity is $K^{E_\tau}(z) = \zeta(z|\tau) dz$. This has the same local singularity $\zeta(z|\tau) = 1/z + O(z)$ near $z = 0$ but acquires the quasi-periodicity $\zeta(z + 1|\tau) = \zeta(z|\tau) + 2\eta_1$ and $\zeta(z + \tau|\tau) = \zeta(z|\tau) + 2\eta_\tau$.

Step 2 (Expansion of the elliptic r -matrix). The genus-0 r -matrix $r(z) = \sum_{n \geq 0} c_n/z^{n+1}$ arises from pairing the propagator dz/z with the λ -bracket coefficients. At genus 1, each rational function $1/z^{n+1}$ is replaced by its unique elliptic counterpart: $1/z \mapsto \zeta(z|\tau)$ and $1/z^{n+1} \mapsto \frac{(-1)^{n-1}}{n!} \wp^{(n-1)}(z|\tau)$ for $n \geq 1$, with $\wp^{(0)} := \wp$. These are the unique functions on $\mathbb{C} \setminus (\mathbb{Z} + \mathbb{Z}\tau)$ that match $1/z^{n+1} + O(z)$ near $z = 0$ and are doubly periodic for $n \geq 1$ (or quasi-periodic for $n = 0$). The prefactor comes from the Laurent expansion $\wp^{(m)}(z) = (-1)^m (m+1)!/z^{m+2} + O(1)$ specialised to $m = n - 1$. This yields formula (27.18).

Step 3 (Dichotomy). The quasi-periodicity is inherited entirely from $\zeta(z|\tau)$, since $\wp$ and all its derivatives are doubly periodic. Therefore the B -cycle monodromy of r^{E_τ} is $2\eta_\tau \cdot c_o$, proving (a). When $c_o = 0$, the ζ -term is absent and r^{E_τ} is meromorphic on E_τ , hence the spectral braiding defined by the annular bar differential decouples from the curved chiral differential. When $c_o \neq 0$, the non-trivial monodromy forces the braiding to be a section of a flat connection with holonomy $\exp(2\pi i \cdot c_o)$, and this flat connection is the same geometric object whose B -cycle monodromy controls the curvature $\kappa(\mathcal{A}) \cdot \omega_1$. $\square$

Remark 27.20.8 (Classification by pole structure). The dichotomy partitions all E_∞ -chiral algebras (i.e. all vertex algebras, which are local and Σ_n -equivariant) into two classes at genus 1:

Class	c_o	Monodromy	Example
Cartan (decoupled)	$= 0$	trivial	Heisenberg $\mathcal{H}_k$, free fermion
Yangian (entangled)	$\neq 0$	$2\eta_\tau \cdot c_o$	$\widehat{\mathfrak{g}}_k$ ($\mathfrak{g}$ simple), Virasoro

For the Heisenberg algebra $\mathcal{H}_k$, the OPE $J(z)J(w) \sim k/(z-w)^2$ has $c_0 = \{J_{(0)}J\} = 0$ (no simple pole in the λ -bracket: the lowest nonvanishing coefficient is $c_1 = k$). The genus-I r -matrix is $r^{E_\tau}(z) = k \cdot \wp(z|\tau)$, which is doubly periodic. For $\widehat{\mathfrak{sl}}_2$ at level k , the OPE $J^a(z)J^b(w) \sim k \kappa^{ab}/(z-w)^2 + f^{ab}{}_c J^c(w)/(z-w)$ has $c_0 = f^{ab}{}_c J^c \neq 0$, and the genus-I structure is genuinely entangled.

27.21 QUANTUM GROUPS FROM GENUS-I MONODROMY

The preceding sections develop the ordered bar complex and its R -matrix on the genus-zero configuration space $\text{Conf}_n(\mathbb{C})$. At genus I the configuration space is replaced by $\text{Conf}_n(E_\tau)$, where $E_\tau = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ is the elliptic curve with modulus τ . The fundamental group of $\text{Conf}_n(E_\tau)$ is richer than the pure braid group P_n : it contains two additional generators (the A -cycle and B -cycle monodromies), and their interaction with the braid generators supplies the quantum-group monodromy readout associated with $U_q(\mathfrak{g})$.

The genus-I lift for the affine lineage $V^k(\mathfrak{g})$ combines the Drinfeld–Kohno theorem with the one-loop collapse mechanism established in Volume II, giving a rigorous passage from the ordered bar superconnection to the KZ/KZB connections and then to the finite-dimensional quantum-group monodromy comparison.

27.21.1 The KZ connection on ordered configurations

The genus-0 starting point is as follows. Let $\mathfrak{g}$ be a simple Lie algebra and $k \in \mathbb{C} \setminus \{-h^\vee\}$ generic. Choose an orthonormal basis $\{I^a\}$ for $\mathfrak{g}$ with respect to the Killing form normalised so that $\text{tr}(I^a I^b) = \delta^{ab}$. The Casimir tensor is $\Omega = \sum_a I^a \otimes I^a \in \mathfrak{g} \otimes \mathfrak{g}$.

Definition 27.21.1 (KZ connection). On the trivial bundle over $\text{Conf}_n(\mathbb{C})$ with fibre $V_1 \otimes \cdots \otimes V_n$ (finite-dimensional $\mathfrak{g}$ -modules), the *Knizhnik–Zamolodchikov connection* is

$$\nabla_{\text{KZ}} = d - \hbar \sum_{1 \leq i < j \leq n} \Omega_{ij} d(z_i - z_j)/(z_i - z_j), \quad (27.19)$$

where $\hbar = 1/(k + h^\vee)$ and Ω_{ij} denotes the Casimir acting in the (i, j) tensor slots.

Remark 27.21.2. The connection (27.19) is a special case of the Kohno connection (27.1): for the affine algebra $V^k(\mathfrak{g})$, the collision residue $r_{ij}(z)$ extracted by the $d \log$ kernel (cf. the kernel absorbs one pole) is $r_{ij}(z) = \hbar \Omega_{ij}/z$, which has the expected simple pole. The one-loop collapse mechanism from Volume II ensures that the higher A_∞ operations m_k ($k \geq 3$) do not contribute on evaluation modules, so the full superconnection reduces to the KZ connection. The flatness $\nabla_{\text{KZ}}^2 = 0$ follows from $[\Omega_{ij}, \Omega_{ik} + \Omega_{jk}] = 0$, which is the $\mathfrak{g}$ -equivariance of the Casimir.

27.21.2 Genus-0 monodromy: the R -matrix

At genus 0, the fundamental group $\pi_1(\text{Conf}_n(\mathbb{C}))$ is the pure braid group P_n . The monodromy of ∇_{KZ} around the generator γ_{ij} (in which z_i circles z_j) gives the R -matrix:

$$R_{ij} = \text{Mon}_{\gamma_{ij}}(\nabla_{\text{KZ}}) = \mathcal{P} \exp \left(\hbar \oint_{\gamma_{ij}} \Omega_{ij} d(z_i - z_j)/(z_i - z_j) \right) = e^{2\pi i \hbar \Omega_{ij}}.$$

This is the *pure-braid monodromy*: it encodes how parallel transport twists when one point winds around another on the genus-0 surface. The Yang–Baxter equation $R_{12} R_{13} R_{23} = R_{23} R_{13} R_{12}$ follows from flatness (eq. (27.2) and its exponentiated form), as proved in Proposition 27.4.3.

27.21.3 The KZB connection on the elliptic curve

At genus 1 the base curve is E_τ and the configuration space $\text{Conf}_n(E_\tau)$ has fundamental group containing two distinguished classes of generators beyond the braid generators: the A -cycle (a point traverses the real period 1) and the B -cycle (a point traverses the imaginary period τ). The KZ connection must be replaced by the *Knizhnik–Zamolodchikov–Bernard* (KZB) connection, which encodes the genus-1 monodromy of conformal blocks.

Definition 27.21.3 (KZB connection). On the trivial bundle over $\text{Conf}_n(E_\tau)$ with fibre $V_1 \otimes \cdots \otimes V_n$, the *KZB connection* is

$$\nabla_{\text{KZB}} = d - \hbar \sum_{1 \leq i < j \leq n} \Omega_{ij} \wp_1(z_i - z_j, \tau) dz_{ij} - \frac{\hbar}{2\pi i} \sum_{i=1}^n D_i d\tau, \quad (27.20)$$

where $\wp_1(z, \tau) = \partial_z \log \theta_1(z, \tau)$ is the logarithmic derivative of the Jacobi theta function (the elliptic analogue of $1/z$), $z_{ij} = z_i - z_j$, and D_i is the modular Hamiltonian

$$D_i = \sum_{j \neq i} (\wp(z_{ij}, \tau) \Omega_{ij} + \text{lower order}),$$

with $\wp(z, \tau) = -\partial_z \wp_1(z, \tau)$ the Weierstrass $\wp$ -function.

Remark 27.21.4. The KZB connection is a genus-1 deformation of the KZ connection. In the degeneration limit $\tau \rightarrow i\infty$ (the nodal rational curve), $\wp_1(z, \tau) \rightarrow \pi \cot(\pi z) \rightarrow 1/z + O(z)$, and the KZB connection degenerates to the KZ connection. The $d\tau$ term, absent at genus 0, records the dependence of conformal blocks on the modulus τ and is the source of the modular anomaly: it measures the failure of conformal blocks to form a flat bundle over the moduli space $\mathcal{M}_{1,n}$.

Remark 27.21.5 (Bar-complex origin). In the E_1 -chiral framework, the KZB connection arises from the ordered bar complex on the elliptic curve E_τ equipped with its logarithmic chiral coassociative structure. The collision residue on $\text{Conf}_n^{\text{ord}}(E_\tau)$ is $r_{ij}^{E_\tau}(z) = \hbar \Omega_{ij} \wp_1(z, \tau)$, which replaces the genus-0 collision residue $r_{ij} = \hbar \Omega_{ij}/z$ by its elliptic regularisation. The additional $d\tau$ connection component encodes the curvature $\kappa(A) \cdot \omega_1$ from the Hodge bundle on $\overline{\mathcal{M}}_{1,n}$: the curved bar structure $d^2 = \kappa(A) \cdot \omega_1$ at genus 1 is precisely the non-flatness of the naive genus-0 connection, corrected by the Bernard term $D_i d\tau$.

27.21.4 B -cycle monodromy and the quantum group parameter

The decisive new phenomenon at genus 1 is the B -cycle monodromy.

THEOREM 27.21.6 (*Quantum-group parameter from B -cycle monodromy*;). Let $\mathfrak{g}$ be a simple Lie algebra and $k \in \mathbb{C} \setminus \{-h^\vee\}$ generic. Consider the KZB monodromy representation

$$\rho_n^{\text{KZB}} : \pi_1(\text{Conf}_n(E_\tau)) \longrightarrow \text{GL}(V_1 \otimes \cdots \otimes V_n).$$

- (i) **A -cycle monodromy.** The monodromy around the A -cycle generator α_i (in which $z_i \mapsto z_i + 1$, all other points fixed) gives the R -matrix:

$$\rho_n^{\text{KZB}}(\alpha_i) = R_i(z),$$

which is the spectral R -matrix of Construction 27.4.2, now defined via the elliptic collision residue.

- (ii) **B -cycle monodromy.** The monodromy around the B -cycle generator β_i (in which $z_i \mapsto z_i + \tau$, all other points fixed) produces the quantum group parameter:

$$\rho_n^{\text{KZB}}(\beta_i) = q^{2H_i} \cdot (\text{braiding corrections}),$$

where

$$q = e^{\pi i \hbar} = e^{\pi i / (k + h^\vee)}$$

and H_i is the Cartan action in the i -th tensor slot.

- (iii) **Quantum-group readout.** The combined A -cycle and B -cycle monodromies, together with the braid monodromies, give the braid and Cartan operators that the Drinfeld–Kohno comparison identifies with the finite-dimensional $U_q(\mathfrak{g})$ representation at the parameter $q = e^{\pi i \hbar}$.

Proof. (i) is immediate from the fact that A -cycle monodromy around $z_i \mapsto z_i + 1$ corresponds to the quasi-periodicity of $\wp_1(z, \tau)$ along the real period, which introduces the same braid-type contribution as at genus 0.

(ii). The B -cycle monodromy arises from $z_i \mapsto z_i + \tau$. The quasi-periodicity of the Jacobi theta function gives $\wp_1(z + \tau, \tau) = \wp_1(z, \tau) - 2\pi i$, so the connection form acquires a constant shift $-2\pi i \cdot \hbar \Omega_{ij}$ from each pair. The parallel transport along the B -cycle path $z_i \mapsto z_i + t\tau$ ($t \in [0, 1]$) includes both the dz contribution (from the connection one-form) and the $d\tau$ contribution (from the modular Hamiltonian D_i). On evaluation modules, the one-loop collapse ensures that only the leading Casimir term contributes, and the result is

$$\rho_n^{\text{KZB}}(\beta_i) = \exp(2\pi i \hbar \cdot H_i + \text{off-diagonal}),$$

where H_i is the Cartan element acting in the i -th slot. The full-cycle exponential $e^{2\pi i \hbar} = q^2$ determines the standard quantum-group parameter $q = e^{\pi i \hbar}$. The “braiding corrections” are conjugations by R -matrices arising from the interaction of the B -cycle path with the other points; they are controlled by the mixed A - B relations in $\pi_1(\text{Conf}_n(E_\tau))$.

(iii). The A -cycle monodromies give the R -matrix readout, the full B -cycle monodromies give the Cartan operators q^{2H} , and after choosing the standard half-monodromy convention one recovers the usual q^H operators. The identification of this package with the finite-dimensional $U_q(\mathfrak{g})$ braid representation is the external genus-1 Drinfeld–Kohno comparison recorded in Theorem 27.21.12; the calculation here supplies the parameter and the monodromy operators. $\square$

Remark 27.21.7 (Physical origin of q). The parameter $\hbar = 1/(k + h^\vee)$ has a transparent origin in the holomorphic-topological framework. At genus 0, the bar complex on $\text{FM}_n(\mathbb{C}) \times \text{Conf}_n(\mathbb{R})$ produces the Yangian $Y_\hbar(\mathfrak{g})$, a deformation over the additive parameter $\hbar = 1/(k + h^\vee)$. At genus 1, the B -cycle monodromy exponentiates the additive parameter $\hbar$ into the full-cycle factor $e^{2\pi i \hbar} = q^2$. The standard quantum-group parameter is therefore $q = e^{\pi i \hbar}$: the passage from the additive formal group $\widehat{\mathbb{G}}_a$ to the multiplicative formal group $\widehat{\mathbb{G}}_m$ is the passage from the additive Yangian readout to the multiplicative quantum-group readout. The elliptic curve E_τ provides the geometric mechanism: its B -cycle is the Wick-rotated time circle in the holomorphic-topological theory, and the monodromy around it converts the infinitesimal deformation parameter into a finite one.

Remark 27.21.8 (EF comparison). The affine normalization used here matches the standard KZ/KZB literature after one explicit bridge. In Remark ?? we fixed the *KZ normalization*

$$r^{\text{KZ}}(z) = \frac{\Omega}{(k + h^\vee)z} = \hbar \frac{\Omega}{z}, \quad \hbar = \frac{1}{k + h^\vee},$$

while the landscape census often records the same tensor in the trace-form convention as $k \Omega_{\text{tr}}/z$. These are two normalizations of the same affine monodromy datum, with $\Omega = 2h^\vee \Omega_{\text{tr}}$ and the KZ coupling $(k + h^\vee)^{-1}$ applied after the trace-form collision residue is extracted. They are not the same rational function of k . With the KZ choice, (27.19) is the usual affine KZ connection of Etingof–Frenkel–Kirillov [?EFK98, Ch. 1]. Our monodromy formula uses pure braid loops, hence gives the full-loop operator $e^{2\pi i \hbar \Omega}$; the Drinfeld–Kohno braid-generator convention uses the corresponding half-monodromy, so the standard quantum-group parameter is $q = e^{\pi i \hbar}$.

At genus 1, equation (27.20) matches Bernard’s torus KZB system [?Bernard88, §§3–4] and the ordinary elliptic KZB connection of Calaque–Enriquez–Etingof [?CEE09, Prop. 6.6]: the dz term carries the coefficient $1/(k + h^\vee)$, while the $d\tau$ term carries the additional factor $1/(2\pi i)$ forced by the theta-function heat equation. Drinfeld’s original Yangian $Y(\mathfrak{g})$ [?Drinfeld85] is recovered from our ordered bar construction after passing to degree zero and evaluation modules; the dg-shifted Yangian is a chain-level enhancement, not a different rational quantum group.

Felder’s elliptic quantum-group picture and the Etingof–Varchenko theory [?Felder94, ?EV98] are *dynamical*: the elliptic R -matrix depends on a Cartan variable $\lambda \in \mathfrak{h}^*$ and satisfies the dynamical, not ordinary, Yang–Baxter equation. The affine genus-1 surface in this chapter is therefore compared directly with Bernard/CEE. Comparison with Felder–Etingof–Varchenko requires adjoining the dynamical Cartan variable, or equivalently performing a vertex-face gauge transform. In particular, Conjecture 27.30.31 is not an identification of ordinary Belavin monodromy with the dynamical elliptic quantum group without this extra datum.

Observation 27.21.9 (Sesquilinearity forces the additive formal group). The spectral parameter λ in the λ -bracket $\{a_\lambda b\}$ carries the additive formal group law $F(\lambda, \mu) = \lambda + \mu$. Sesquilinearity $\{\partial a_\lambda b\} = -\lambda \{a_\lambda b\}$ identifies λ as the Fourier dual of translation; the Fourier dual of the additive group is the additive group. A multiplicative law $F(\lambda, \mu) = \lambda + \mu + \lambda\mu$ would require $\{\partial a_\lambda b\} = -(1 + \lambda)\{a_\lambda b\} \cdot \log(1 + \lambda)/\lambda$, which is not polynomial in λ .

Observation 27.21.10 (Endomorphism ring of $\widehat{\mathbb{G}}_a$ and the Wick rotation). Over any $\mathbb{C}$ -algebra R , $\text{End}(\widehat{\mathbb{G}}_a/R) = R$: every element $\alpha \in R$ defines an endomorphism $[\alpha]: x \mapsto \alpha x$, and these exhaust all endomorphisms since $\widehat{\mathbb{G}}_a$ has no nonlinear endomorphisms in characteristic zero. In particular, $[i] \in \text{End}(\widehat{\mathbb{G}}_a/\mathbb{C})$: the Wick rotation $\lambda \mapsto i\lambda$ (equivalently $t \mapsto it$ in the topological direction of $\mathbb{C}_z \times \mathbb{R}_t$) is an automorphism of the spectral-parameter formal group.

Remark 27.21.11 (Spectralization contracts the endomorphism ring). Over $\mathbb{F}_p$, the additive formal group has height ∞ ($[p](x) = px = 0$), not height 1. Upon spectralization (passing from chain complexes to spectra, replacing $\widehat{\mathbb{G}}_a$ by a formal group of finite height), the endomorphism ring contracts:

$$\begin{aligned} \widehat{\mathbb{G}}_a &: \text{End} = \mathbb{C} && (\text{height } \infty \text{ over } \mathbb{F}_p) \\ \widehat{\mathbb{G}}_m &: \text{End} = \mathbb{Z}_p && (\text{height } 1) \\ \widehat{E}_\tau &: \text{End} = \text{order in } \mathbb{Q}(\sqrt{-d}) && (\text{height } \leq 2) \end{aligned}$$

The ring $\mathbb{Z}_p$ does not contain i for $p \neq 2$ unless $p \equiv 1 \pmod{4}$, and even then $i \in \mathbb{Z}_p$ is a p -adic integer, not the complex Wick rotation. For a generic elliptic curve, $\text{End}(\widehat{E}_\tau) = \mathbb{Z}$, which excludes $[i]$ entirely.

The sole exception is the CM curve E_i with j -invariant $j = 1728$: here $\text{End}(\widehat{E}_i) \supseteq \mathbb{Z}[i]$, so $[i]$ is an endomorphism. This is the unique elliptic curve over $\mathbb{C}$ (up to isomorphism) whose formal group admits a Wick rotation: an arithmetic accident, not a structural feature.

The bar-cobar theory of this monograph is a theory of chain complexes over $\mathbb{C}$. Every chain complex is an $H\mathbb{C}$ -module, hence rational, hence chromatic height 0. The endomorphism ring $\text{End}(\widehat{\mathbb{G}}_a) = \mathbb{C}$ reflects this: the theory admits all constant endomorphisms, including $[i]$. Positive chromatic height enters only after spectralization, which contracts the endomorphism ring from $\mathbb{C}$ to an arithmetic object ($\mathbb{Z}_p$ or an order in a quadratic field) and generically excludes the Wick rotation (cf. the chromatic/shadow discussion in Chapter ??).

27.21.5 The Drinfeld–Kohno theorem

The identification of KZ monodromy with the quantum-group braid representation is external input. The contribution of the ordered bar complex is the reduction of the affine line to the KZ/KZB connections under one-loop collapse.

THEOREM 27.21.12 (*Drinfeld–Kohno on the affine evaluation surface; for monodromy, for ordered reduction*). Let $\mathfrak{g}$ be a simple Lie algebra, $k \in \mathbb{C} \setminus \{-h^\vee\}$ generic, and $V_1, \dots, V_n$ finite-dimensional $\mathfrak{g}$ -modules. Fix a Drinfeld associator and the standard half-monodromy convention $q = e^{\pi i/(k+h^\vee)}$.

- (i) **Genus 0.** The monodromy representation of the KZ connection (27.19) on $\text{Conf}_n(\mathbb{C})$ is isomorphic to the braid group representation obtained from the braided monoidal structure of $\text{Rep}_q(\mathfrak{g})$ via the universal R -matrix of $U_q(\mathfrak{g})$:

$$\rho_n^{\text{KZ}} \simeq \rho_n^{U_q(\mathfrak{g})}. \quad (27.21)$$

- (ii) **Genus 1.** The KZB connection (27.20) on $\text{Conf}_n(E_\tau)$ gives an elliptic braid-group monodromy representation. In the finite-dimensional affine evaluation surface, the Etingof–Schiffmann and Calaque–Enriquez–Etingof comparisons identify its trigonometric/quantum-group specialisation with the corresponding $U_q(\mathfrak{g})$ braid action, with the full B -cycle Cartan operator q^{2H} and the usual half-monodromy convention q^H . This is a completed/dynamical monodromy comparison; it is not a category- $\mathcal{O}$ equivalence and not an assertion that an elliptic braid group acts through the ordinary algebra $U_q(\mathfrak{g})$ without the Cartan and completion data.
- (iii) **Ordered-bar reduction.** For the affine lineage $V^k(\mathfrak{g})$, the one-loop collapse of the ordered bar superconnection on finite-dimensional evaluation modules reduces the bar-complex monodromy to the KZ connection at genus 0 and to the KZB connection at genus 1. Hence the external monodromy theorem applies to the ordered bar complex exactly on this evaluation surface.

Proof. (i) is the classical Drinfeld–Kohno theorem. Drinfeld constructs a formal associator $\Phi \in U(\mathfrak{g})^{\widehat{\otimes}^3}[[\hbar]]$ from iterated integrals of $d \log(z_i - z_j)$ on $\text{Conf}_3(\mathbb{C})$. The pentagon and hexagon equations for Φ identify the braid representation of the infinitesimal braid Lie algebra $\mathfrak{t}_n$ with the braid representation of $\text{Rep}_q(\mathfrak{g})$ carrying the universal $U_q(\mathfrak{g})$ R -matrix. This proves (27.21) after the standard half-monodromy normalisation.

(ii) is the elliptic monodromy comparison of Etingof–Schiffmann and Calaque–Enriquez–Etingof. The point relevant here is its scope: the elliptic KZB connection produces a monodromy representation with dynamical Cartan data; after the chosen trigonometric/quantum-group specialisation this gives the $U_q(\mathfrak{g})$ braid action on the finite-dimensional evaluation sector. The B -cycle monodromy supplies q^{2H} , and the usual quantum-group convention chooses the half-monodromy q^H .

(iii). For the affine algebra $V^k(\mathfrak{g})$, the one-loop exactness of the BV-BRST differential (Theorem ?? of Volume II) ensures that the higher A_∞ operations m_k ($k \geq 3$) vanish on evaluation modules. The full superconnection on the bar complex therefore collapses to the KZ connection, and the bar-complex monodromy ρ_n^{HT} equals ρ_n^{KZ} (the one-loop collapse statement of Volume II). The same reduction on E_τ gives the KZB connection, because the logarithmic kernel $1/z$ is replaced by $\wp_1(z, \tau)$ and the Bernard $d\tau$ term records the Hodge-bundle correction. Combining this reduction with (i) and (ii) gives the ordered-bar monodromy comparison on the affine evaluation surface. $\square$

27.21.6 The genus-1 deformation: from Yangian to quantum group

The passage from genus 0 to genus 1 is a comparison of monodromy readouts. The genus-0 ordered line algebra is the Yangian on the finite-dimensional evaluation surface; the genus-1 KZB monodromy has quantum-group braid and Cartan readouts after the completed elliptic comparison.

THEOREM 27.21.13 (Affine genus-one monodromy readout). Let $\mathfrak{g}$ be a simple Lie algebra and $k \in \mathbb{C} \setminus \{-h^\vee\}$ generic.

- (i) At genus 0, the ordered bar complex of $V^k(\mathfrak{g})$ on $\text{FM}_n(\mathbb{C}) \times \text{Conf}_n(\mathbb{R})$ produces the line-side algebra $Y_{\hbar}(\mathfrak{g})$ on finite-dimensional evaluation modules, with $\hbar = 1/(k + h^\vee)$.
- (ii) At genus 1, the ordered bar complex on $E_\tau \times \mathbb{R}$ reduces, on the same affine evaluation surface, to the KZB monodromy. After the Etingof–Schiffmann/CEE comparison this monodromy has the $U_q(\mathfrak{g})$ braid and Cartan readout, with $q = e^{\pi i \hbar}$. This is a monodromy-category statement, not an identification of the ordered Koszul-dual algebra with $U_q(\mathfrak{g})$.
- (iii) The degeneration $\tau \rightarrow i\infty$ (pinching the B -cycle) recovers the rational KZ/Yangian readout from the elliptic monodromy readout: the KZB connection degenerates to the KZ connection and the extra B -cycle Cartan monodromy becomes trivial in the nodal limit. No literal algebraic limit $\lim U_q(\mathfrak{g}) = Y_{\hbar}(\mathfrak{g})$ is asserted.
- (iv) The full B -cycle factor $e^{2\pi i \hbar} = q^2$ is the exponential of the Yangian parameter $\hbar$ under the exponential map $\widehat{\mathbb{G}}_a \rightarrow \widehat{\mathbb{G}}_m$ provided by the B -cycle of E_τ ; the standard quantum-group parameter is its square root $q = e^{\pi i \hbar}$.

Proof. Part (i) is the content of the genus-0 construction: the bar differential on $\text{FM}_n(\mathbb{C})$ encodes the chiral OPE, the E_1 coproduct on $\text{Conf}_n(\mathbb{R})$ encodes the associative composition, and the resulting line-side algebra on evaluation modules is the Yangian (see the holographic dictionary of Volume II, Corollary ??).

Part (ii) combines Theorem 27.21.6 with the Drinfeld–Kohno comparison (Theorem 27.21.12(ii)): the KZB monodromy supplies the quantum-group braid matrices and the B -cycle Cartan operators on the finite-dimensional evaluation sector.

Part (iii) follows from the degeneration $\wp_1(z, \tau) \rightarrow 1/z + O(z)$ as $\tau \rightarrow i\infty$: the KZB connection degenerates to KZ, the B -cycle shrinks to a point, and the full q^{2H} monodromy becomes trivial.

Part (iv) is a restatement: the full-cycle factor $e^{2\pi i \hbar} = q^2$ is the exponential of $\hbar$ multiplied by $2\pi i$, and the B -cycle monodromy is the geometric mechanism that implements this exponentiation. $\square$

PROPOSITION 27.21.14 (*Quantum-group convention bridge for DK/KZ readouts;*). [Type signature: (Open/line, KZ monodromy readout, levels = 1 $\rightarrow$ 4, hypothesis package = affine evaluation surface + chosen Drinfeld associator + half-monodromy convention)]. On the affine evaluation surface the additive parameter is

$$\hbar = (k + h^\vee)^{-1}.$$

The full B -cycle/self-monodromy factor is

$$q^2 = e^{2\pi i \hbar},$$

and the quantum-group braiding parameter is the framing square root

$$q = e^{\pi i \hbar} = e^{\pi i / (k + h^\vee)}. \quad (27.22)$$

With this convention, the KZ local monodromy around $z_i = z_j$ is

$$\exp(2\pi i \hbar \Omega_{ij}),$$

while the braided tensor category uses the half-braiding $P \circ R$ whose diagonal framing contribution is the square root (27.22). The modular T -matrix convention is

$$T_{ii} = \exp(2\pi i (h_i - c/24)),$$

so self-monodromy (twist/framing of one object) and mutual monodromy (double braiding of two objects) are related by the ribbon identity, not by equality of the two numbers. Converting between KZ, quantum-group, and modular T -matrix conventions therefore requires carrying the square root (27.22), the associator gauge, and the orientation of the loop around the diagonal.

Proof. Theorem 27.21.13 identifies the full B -cycle monodromy as $e^{2\pi i \hbar} = q^2$ and the standard quantum-group parameter as its half-monodromy square root $q = e^{\pi i \hbar}$. The KZ connection has residue $\hbar \Omega_{ij}$ along the diagonal $z_i = z_j$, hence a positively oriented loop has monodromy $\exp(2\pi i \hbar \Omega_{ij})$. Passing from this full local monodromy to the braided tensor category chooses the Drinfeld associator and the square-root framing convention, producing the half-braiding parameter in (27.22). The formula for T_{ii} is the standard conformal-block twist convention; the ribbon identity then separates the twist of one object from the mutual double braiding of two objects. $\square$

Conjecture 27.21.15 (*Yangian-quantum group deformation beyond the affine lineage*). The Yangian-quantum group deformation of Theorem 27.21.13 extends to non-affine chiral algebras: for any modular Koszul algebra $\mathcal{A}$ on $E_\tau \times \mathbb{R}$ whose ordered bar superconnection admits a KZB-type reduction and a strong-unitary elliptic descent datum, the genus-1 ordered bar complex is conjectured to produce a monodromy object whose trigonometric degeneration is the genus-0 ordered line algebra, with the B -cycle monodromy implementing the exponential map $\hbar \mapsto q^2 = e^{2\pi i \hbar}$ and the standard quantum parameter $q = e^{\pi i \hbar}$.

27.21.7 The $\mathfrak{sl}_2$ case and roots of unity

For $\mathfrak{g} = \mathfrak{sl}_2$, the quantum group parameter specialises to a root of unity at integer level.

COROLLARY 27.21.16 (*$U_q(\mathfrak{sl}_2)$ at roots of unity from affine $\mathfrak{sl}_2$;*). For $\mathfrak{g} = \mathfrak{sl}_2$ at positive integer level $k \in \mathbb{Z}_{>0}$:

- (i) The quantum group parameter is $q = e^{\pi i/(k+2)}$, and $q^{2(k+2)} = 1$.
- (ii) The quantum group $U_q(\mathfrak{sl}_2)$ at this root of unity has a finite-dimensional quotient with $k+1$ irreducible modules $V_0, V_1, \dots, V_k$ of dimensions $1, 2, \dots, k+1$.
- (iii) These $k+1$ modules are in bijection with the integrable highest-weight modules of $\widehat{\mathfrak{sl}}_2$ at level k . The truncation of the representation category is the genus-1 avatar of the level- k WZW fusion category.

Proof. Part (i): $h^\vee = 2$ for $\mathfrak{sl}_2$, so $\hbar = 1/(k+2)$ and $q = e^{\pi i \hbar} = e^{\pi i/(k+2)}$. For the root-of-unity property: $q^{2(k+2)} = e^{2\pi i} = 1$.

Part (ii) is a classical result: at q a root of unity, the quantum group $U_q(\mathfrak{sl}_2)$ has a large centre generated by E^{k+2} , F^{k+2} , and $K^{2(k+2)}$, and the quotient by this centre has finitely many simple modules.

Part (iii) is the Kazhdan–Lusztig equivalence: $\mathcal{O}_k^{\text{int}}(\widehat{\mathfrak{sl}}_2) \simeq \text{Rep}_q(\mathfrak{sl}_2)^{\text{fin}}$. $\square$

27.21.8 The Jones polynomial from genus-1 monodromy

The Jones polynomial emerges as a topological invariant from the genus-1 monodromy applied to the bar complex.

THEOREM 27.21.17 (*Jones polynomial from genus-1 bar-complex monodromy;*). For $\mathfrak{g} = \mathfrak{sl}_2$ at level $k \in \mathbb{Z}_{>0}$, let K be a framed knot presented as the closure of a braid $\beta \in B_n$. Then:

- (i) The bar complex of $V^k(\mathfrak{sl}_2)$, viewed as a logarithmic $\text{SC}^{ch, top}$ -algebra, produces the braid group representation $\rho_n^{\text{HT}} = \rho_n^{\text{KZ}}$ on tensor powers of the fundamental representation V .
- (ii) By the Drinfeld–Kohno theorem (Theorem 27.21.12), this representation factors through $U_q(\mathfrak{sl}_2)$ at $q = e^{\pi i/(k+2)}$.
- (iii) The Jones polynomial is recovered by the quantum trace:

$$J_K(q) = \text{tr}_q(\rho_n^{\text{HT}}(\beta)) = \text{tr}(q^{2\rho} \cdot \rho_n^{\text{KZ}}(\beta)),$$

where ρ is the half-sum of positive roots ($\rho = 1/2$ for $\mathfrak{sl}_2$) and tr_q is the categorical trace in the ribbon category $\text{Rep}_q(\mathfrak{sl}_2)$.

- (iv) The integration domain is $\text{FM}_n(\mathbb{C}) \times \text{Conf}_n(\mathbb{R})$: the $\text{FM}_n(\mathbb{C})$ factor carries the bar differential encoding the chiral OPE, and the $\text{Conf}_n(\mathbb{R})$ factor carries the E_1 coproduct implementing the topological interval-cutting. This ordered holomorphic-topological domain supplies the monodromy input; the topological link invariant is obtained only after the external Reshetikhin–Turaev ribbon trace, equivalently the E_∞ factorization-homology/CFG topological trace package, is applied.

Proof. Parts (i)–(ii) combine the Volume II one-loop collapse statement (the bar-complex monodromy equals the KZ monodromy for the affine lineage) with Theorem 27.21.12(i) (the KZ monodromy is externally identified with the quantum-group braid representation).

Part (iii) is the Reshetikhin–Turaev construction: $\text{Rep}_q(\mathfrak{sl}_2)$ is a ribbon category (the ribbon element is $v = K^{-1}u$ where $K = q^H$ and $u = \sum S(b_i)a_i$), and the quantum trace $\text{tr}_q = \text{tr}(q^{2\rho} \cdot)$ implements

the Markov closure converting a braid representation into a framed link invariant. Since $\rho_n^{\text{HT}} = \rho_n^{\text{KZ}} \simeq \rho_n^{U_q}$, the quantum trace applied to the bar-complex monodromy equals the Jones polynomial.

Part (iv) is a scope statement, not a derivation of the Reshetikhin–Turaev invariant from the raw E_1 -ordered bar. The bar complex lives on the product of holomorphic and topological configuration spaces and supplies the monodromy input. The passage from that monodromy to a topological link invariant uses the external Reshetikhin–Turaev ribbon trace, equivalently the E_∞ factorization-homology/CFG topological trace package. $\square$

Remark 27.21.18 (The three levels of the construction). The passage from chiral algebra to knot invariant has three levels, each proved:

Level	Object	Output
Genus 0, ordered bar	KZ connection	Yangian $Y_h(\mathfrak{g})$
Genus 1, B -cycle monodromy	KZB connection	Quantum group $U_q(\mathfrak{g})$
Markov closure	Quantum trace	Jones polynomial $J_K(q)$

Each level is proved for the affine lineage by the one-loop collapse mechanism. Beyond the affine lineage (for $\mathcal{W}$ -algebras obtained by Drinfeld–Sokolov reduction, where higher A_∞ operations contribute), the correspondence between bar-complex monodromy and quantum group representations remains conjectural.

27.21.9 Affine and Higher-Genus Boundary

Remark 27.21.19 (Affine-lineage boundary). The results of this section are proved for the *affine lineage*: $V^k(\mathfrak{g})$ for simple $\mathfrak{g}$ at generic level k , acting on finite-dimensional evaluation modules. The proof mechanism is the one-loop collapse mechanism from Volume II, which reduces the full bar-complex superconnection to the KZ/KZB connection, and the Drinfeld–Kohno theorem (classical at genus 0, Etingof–Schiffmann/Calaque–Enriquez–Etingof at genus 1), which identifies the KZ/KZB monodromy with the quantum group representation.

Beyond the affine lineage, two extensions remain unproved:

- (a) *$\mathcal{W}$ -algebras.* For $\mathcal{W}$ -algebras obtained by Drinfeld–Sokolov reduction, the higher A_∞ operations m_k ($k \geq 3$) do not vanish: the one-loop collapse mechanism breaks. The full superconnection contributes to the monodromy, and the genus-1 deformation should produce a *deformed quantum group* or *quantum $\mathcal{W}$ -algebra*. This is the content of Conjecture ?? in Volume II.
- (b) *Higher genus.* At genus $g \geq 2$, the configuration space $\text{Conf}_n(\Sigma_g)$ has $2g$ distinguished cycle classes, and the monodromy acquires $2g$ additional generators. The curvature $\kappa(\mathcal{A}) \cdot \omega_g$ from the Hodge bundle on $\overline{\mathcal{M}}_{g,n}$ provides genus-by-genus corrections. The algebraic object controlling the monodromy at genus g is conjecturally a *higher-genus quantum group* or *mapping-class-group representation* generalising the braid-group representations at genus 0 and 1.

27.21.10 The ordered tridegree decomposition

The symmetric bar complex carries a natural bidegree (g, n) with g the genus and n the degree. The ordered bar complex refines this to a *tridegree* that records the depth of consecutive collisions in the Fulton–MacPherson compactification.

Definition 27.21.20 (Ordered tridegree). Let A be a strongly admissible associative chiral algebra and $\overline{B}^{\text{ch,ord}}(A)$ its ordered bar complex. The *ordered tridegree* of a bar element $\alpha \in \overline{B}^{\text{ch,ord}}(A)$ is the triple $(g, n, d)^{E_1}$ where:

- (i) $g \geq 0$ is the genus (the number of handles of the underlying curve);
- (ii) $n \geq 1$ is the degree (the number of bar slots);
- (iii) $d \geq 0$ is the *ordered collision depth*: the codimension of the planted-forest boundary stratum of $\overline{\text{FM}}_n^{\text{ord}}(\mathbb{C})$ at which α is supported.

At degree n , the ordered compactification $\overline{\text{FM}}_n^{\text{ord}}(\mathbb{C})$ has exactly $n-1$ codimension-one boundary divisors $D_{i,i+1}$, $1 \leq i \leq n-1$, corresponding to consecutive collisions $z_i \rightarrow z_{i+1}$. The depth d counts the codimension in this boundary stratification: $d = 0$ is the interior (no collision), and the maximal depth at degree n is $d = n-1$ (complete consecutive collapse). In the unordered FM compactification, degree n has $\binom{n}{2}$ codimension-one divisors; the restriction to $n-1$ consecutive divisors is the geometric signature of the E_1 -structure.

THEOREM 27.21.21 (Ordered pole-depth spectrum). Let A be a strongly admissible associative chiral algebra whose OPE has pole orders $\{p_1, \dots, p_s\}$ (i.e., $a_{(n)}b \neq 0$ precisely for $n \in \{p_1-1, \dots, p_s-1\}$, with the convention that $a_{(n)}b$ contributes a pole of order $n+1$). Then the pole-depth spectrum at genus 0, degree 2 is

$$\text{Spec}(q_{\text{pole}}^{E_1}; A)|_{(0,2)} = \{ \max(p-1, 0) : p \text{ is a pole order of the OPE of } A \}.$$

Here $q_{\text{pole}}^{E_1}$ is pole/normal-jet depth, not the geometric Mok/Fulton–MacPherson boundary codimension. At degree 2 the geometric collision divisor still has codimension 1. The following table records the pole-depth spectrum for the standard examples:

Algebra	OPE poles	Pole-depth spectrum
Heisenberg H_k	$\{2\}$	$\{0, 1\}$
Affine $V^k(\mathfrak{g})$	$\{1, 2\}$	$\{0, 1\}$
Virasoro Vir_c	$\{1, 2, 4\}$	$\{0, 1, 3\}$

The pole-depth spectrum of the Virasoro algebra exhibits a gap at $q_{\text{pole}} = 2$, reflecting the absence of a cubic pole in the Virasoro OPE $T(z)T(w) \sim (c/2)(z-w)^{-4} + 2T(w)(z-w)^{-2} + \partial T(w)(z-w)^{-1}$.

Proof. At degree 2, the ordered bar differential acts by extracting the collision residue at the unique divisor $D_{1,2} = \{z_1 = z_2\}$ via the ordered logarithmic propagator $\eta = d \log(z_1 - z_2)$. A pole of order p in the OPE contributes a term $c_{JJ;p-1}^K (z_1 - z_2)^{-p}$ to the structure constants. The $d \log$ kernel absorbs one power of the pole (the collision kernel $K_A^{\text{coll}}(z)$ has pole orders one less than the OPE), producing a residue of order $p-1$ in the collision variable. This residue has pole/normal-jet depth $p-1$ along the same geometric collision divisor; it is not a statement that the degree-2 FM boundary has codimension $p-1$. The zeroth product $a_{(0)}b$ (pole of order 1) contributes at pole depth $q_{\text{pole}} = 0$, living in the interior.

For the Virasoro algebra: the quartic pole gives pole depth $q_{\text{pole}} = 3$, the double pole gives $q_{\text{pole}} = 1$, and the simple pole gives pole depth $q_{\text{pole}} = 0$. The cubic pole is absent, so $q_{\text{pole}} = 2$ does not appear. $\square$

THEOREM 27.21.22 (Ordered AOS reduction). The ordered AOS relations are the image of the Arnold–Orlik–Solomon relations under the projection to consecutive-block collision faces. Equivalently,

they are the Stasheff associahedron identities imposed on the bar differential $d_{\overline{B}^{\text{ch,ord}}}$ by $d_{\overline{B}^{\text{ch,ord}}}^2 = 0$ on the partial compactification $\overline{\text{FM}}_k^{\text{ord}}(\mathbb{C})$. At degree k , the codimension-one faces are the consecutive-block collision faces D_I with $I = \{a, \dots, b\}$ and $|I| \geq 2$; the binary part consists of $D_{i,i+1}$ ($1 \leq i \leq k-1$). The condition

$$d_{\overline{B}^{\text{ch,ord}}}^2 = 0 \iff \left(\sum_{s \geq 1} \widehat{m}_s^{\text{ch}} \right)^2 = 0 \iff \sum_{r+s+t=n} (-1)^{r+st} m_{r+1+t}^{\text{ch}} (\text{id}^{\otimes r} \otimes m_s^{\text{ch}} \otimes \text{id}^{\otimes t}) = 0 \quad (27.23)$$

with the desuspension signs fixed in Construction 27.11.9. In the strict associative case only m_1 and m_2 remain; the $n = 3$ relation is $m_2(m_2 \otimes \text{id}) - m_2(\text{id} \otimes m_2) = 0$ after unsuspending.

In the full unordered FM compactification, $d^2 = 0$ encodes the Jacobi/Borcherds identities through the Arnold relation among all $\binom{k}{2}$ pairwise divisors. In the ordered partial compactification, non-consecutive divisors are not boundary generators of the ordered bar differential. The Arnold relation is still true in the holomorphic factor and remains the flatness input for ordered-to-symmetric descent; it is not used as an extra non-consecutive face in the ordered associative differential.

Proof. By Stokes' theorem on $\overline{\text{FM}}_k^{\text{ord}}(\mathbb{C})$, the condition $d_{\overline{B}^{\text{ch,ord}}}^2 = 0$ is equivalent to the cancellation of oriented codimension-two boundary contributions for the logarithmic bar propagators. The binary part of the boundary decomposes as

$$\partial_1 \overline{\text{FM}}_k^{\text{ord}}(\mathbb{C}) = \bigcup_{i=1}^{k-1} D_{i,i+1},$$

a union of $k-1$ consecutive-collision divisors. Each divisor $D_{i,i+1}$ is isomorphic to $\overline{\text{FM}}_{k-1}^{\text{ord}}(\mathbb{C})$ (the two colliding points are replaced by their merged image). The boundary integral along $D_{i,i+1}$ computes the composition $d_{i,i+1} \circ d$, and the total relation $\sum_{i=1}^{k-1} d_{i,i+1} \circ d = 0$ is the binary shadow of the k -th Stasheff identity. Higher consecutive-block faces give the remaining summands in (27.23).

In the unordered setting, $\overline{\text{FM}}_k(\mathbb{C})$ has $\binom{k}{2}$ codimension-one divisors $D_{i,j}$ for all $i < j$, and Stokes yields $\binom{k}{2}$ terms: the Jacobi/Arnold relations. The ordered restriction to $k-1$ consecutive divisors eliminates all non-adjacent collision terms from the ordered differential. The Arnold relation $\omega_{ij} \wedge \omega_{jk} + \omega_{jk} \wedge \omega_{ki} + \omega_{ki} \wedge \omega_{ij} = 0$ still holds on the full holomorphic configuration space; after projection to the consecutive-block quotient, its non-consecutive term is outside the ordered boundary algebra, and the surviving identity is precisely the Stasheff associativity relation. $\square$

PROPOSITION 27.21.23 (Averaging and surplus). Assume the strong-unitary R -twisted descent datum of Proposition 27.4.3 has been constructed. Let $F_{\leq d}^{\text{ord}}$ and $F_{\leq d}^{\Sigma}$ denote the filtrations by boundary codimension on the ordered and symmetric compactifications. The averaging map $\text{av}: \overline{B}^{\text{ch,ord}}(A) \rightarrow \overline{B}^{\text{ch},\Sigma}(A)$ preserves this filtration:

$$\text{av}: F_{\leq d}^{\text{ord}} \overline{B}^{\text{ch,ord}}(A)_{(g,n)} \longrightarrow F_{\leq d}^{\Sigma} \overline{B}^{\text{ch},\Sigma}(A)_{(g,n)}.$$

On the associated graded, a depth- d ordered stratum maps to the R -twisted coinvariant span of its Σ_n -orbit of depth- d symmetric strata. Averaging loses ordering and monodromy data; it does not create boundary codimension. At genus 0 and fixed degree n , the kernel $\ker(\text{av}|_{(0,n)})$ is generated by the R -matrix twisted descent relations of Proposition 27.4.3. For pole-free symmetric chiral algebras the monodromy part is $R(z) = \text{id}$; the only kernel is the ordinary coinvariant relation $x - \epsilon(\sigma) \tau_{\sigma} x$. Thus the pole-free case has no *additional* R -monodromy kernel.

Proof. The averaging map is the composition $\overline{B}^{\text{ch,ord}}(A)_n \xrightarrow{\Sigma_n\text{-orbit}} \overline{B}^{\text{ch},\Sigma}(A)_n$, twisted by the R -matrix as in Proposition 27.4.3: the Σ_n -action on the ordered bar uses the R -matrix monodromy $R_{i,i+1}(z_i - z_{i+1})$ at each adjacent transposition. An element α of depth d is supported on a stratum $\partial_F \overline{\text{FM}}_n^{\text{ord}}(\mathbb{C})$ of codimension d . The ordered-to-symmetric map is finite on the open stratum and extends to the corresponding labelled Fulton–MacPherson boundary strata by relabelling and quotienting. Finite quotients preserve codimension, although several labelled strata may acquire the same image. Thus the orbit $\Sigma_n \cdot \alpha$ contributes only to the depth- d associated graded of the symmetric compactification, and the filtration $F_{\leq d}$ is preserved.

For the kernel: by the coinvariant presentation of the descended local system,

$$\ker(\text{av}|_{(0,n)}) = \left\langle \alpha - \rho_R(\sigma)\alpha : \alpha \in \overline{B}^{\text{ch,ord}}(A)_n, \sigma \in \Sigma_n \right\rangle.$$

Thus the R -dependent part of the kernel is generated by $(\rho_R(\sigma) - \epsilon(\sigma)\tau_\sigma)\alpha$. When the OPE is pole-free, $R(z) = \text{id}$ and this R -dependent part vanishes; the remaining kernel is exactly the ordinary symmetry/coinvariant span $\langle \alpha - \epsilon(\sigma)\tau_\sigma\alpha \rangle$. $\square$

PROPOSITION 27.21.24 (*Averaging, Reynolds, and R -twisted descent gate;*). [Type signature: (Open, ordered bar descent, level = 2 $\rightarrow$ 5, hypothesis package = char 0 + completed equivariance + strong unitary R + finite arity)]. The universal conductor used in this chapter is the filtered morphism

$$\text{av}_{\mathcal{A}} : \mathfrak{g}_{\mathcal{A}}^{E_i} \longrightarrow \mathfrak{g}_{\mathcal{A}}^{\text{mod}}$$

induced aritywise by the Reynolds operator

$$\text{Av}_n = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} \rho(\sigma).$$

The scalar $1/n!$ requires characteristic zero, and on completed arity n the operator is the continuous endomorphism induced by the finite group algebra action on each finite conformal-weight window and then passed to the strict inverse limit.

If the Σ_n -action is compatible with the bar differential, $\rho(\sigma)d_B = d_B\rho(\sigma)$, then $\text{Av}_n d_B = d_B \text{Av}_n$, so averaging is a chain map. If, in addition, the action is by dg Lie automorphisms of the ordered convolution algebra, then $\text{av}_{\mathcal{A}}$ is a dg Lie morphism. Without those equivariance hypotheses it is only a continuous linear projection on the underlying completed vector space.

For a strong-unitary R -twisted descent datum, define the R -twisted coinvariant complex by

$$C_{\Sigma_n, R} := C / \langle x - \rho_R(\sigma)x : \sigma \in \Sigma_n, x \in C \rangle.$$

When $\rho_R(\sigma)$ commutes with d_B , the quotient inherits the bar differential. When $\rho_R(\sigma)$ acts by dg Lie automorphisms, the quotient also inherits the convolution bracket. In degree 2 the kernel of av is the ordered antisymmetric residue, equivalently the ordered r -matrix datum:

$$\ker(\text{av}_2) = \bigwedge^2 V$$

on a finite generator window V . In higher degree, the nontrivial isotypic summands of the Σ_n -action carry the braid and associator data; Proposition 27.21.28 gives their bare tensor-power dimensions, while passage to chiral-centre cohomology is a separate theorem or conjecture in each family.

Remark 27.21.25 (Physical meaning: the soft graviton hierarchy). The ordered tridegree $(g, n, d)^{E_i}$ organises the soft graviton hierarchy of the gravity part of Volume II. The correspondence is: soft order p of a graviton theorem corresponds to degree $r = p + 2$ in the bar complex. The depth d records which OPE pole is responsible: a soft theorem at order p receives contributions from all poles whose depth $d = \max(p' - 1, 0)$ satisfies $d \leq r - 1$.

For the Virasoro algebra, the depth-3 component (from the quartic pole, i.e. the central charge c) is the first non-formal input in the transferred HPL model. The Stasheff identities organise the compatible higher operations, but the all-arity Virasoro tower uses the wheel-residue survival hypothesis; it is not a formal induction from the first ternary operation alone. The gap at depth 2 in the Virasoro spectrum (Theorem 27.21.21) is the geometric expression of the absence of a cubic pole, equivalently the vanishing of the L_n -eigenvalue at the wrong parity: $[L_m, L_n] = (m - n)L_{m+n} + \frac{c}{12}m(m^2 - 1)\delta_{m+n,0}$ jumps from the linear term ($d = 1$) to the cubic term ($d = 3$) with no quadratic intermediate.

Remark 27.21.26 (Motivic interpretation of the tridegree). The ordered tridegree refines the motivic content identified in Remark 27.4.8. The averaging map $\text{av}: \overline{B}^{\text{ch,ord}}(A) \rightarrow \overline{B}^{\text{ch},\Sigma}(A)$, when the strong-unitary descent datum exists, is a motivic projection in the following precise sense: the ordered bar complex at depth d computes periods of the mixed Hodge structure on $\overline{\text{FM}}_n^{\text{ord}}(\mathbb{C})$ that are supported on strata of codimension d .

Concretely, the three cases are:

- (i) *Depth* $d = 0$ (interior): the periods are polynomial in $2\pi i$ and the collision residues. At degree 2, these are the rational multiples of the OPE structure constants.
- (ii) *Depth* $d \geq 1$ (boundary strata): the periods are iterated integrals of the KZ connection along paths in $\text{Conf}_n^{\text{ord}}(\mathbb{C})$. At degree 3 and depth 1, the Drinfeld associator Φ_{KZ} contributes multiple zeta values $\zeta(2), \zeta(3), \dots$, periods of mixed Tate motives over $\mathbb{Z}$.
- (iii) *The symmetric image*: the averaging map av keeps the R -twisted coinvariant combinations. The scalar symmetric invariants used in this chapter (curvature κ , complementarity class C , shadow tower Q) are rational residues, periods of the trivial motive $\mathbb{Q}(0)$; the ordered iterated-integral classes carrying non-trivial mixed Tate periods are not seen by these scalar shadows.

The ordered surplus $\ker(\text{av})$ contains the iterated-integral classes discarded by the symmetric projection. The tridegree decomposition stratifies this surplus by boundary depth, and this depth filtration is compatible with the motivic weight filtration in the mixed Tate configuration-space cases. This is the precise sense in which the ordered bar complex is arithmetically richer than the symmetric bar complex: it remembers multiple-zeta periods that the scalar symmetric shadows forget.

Remark 27.21.27 (Drinfeld centre and the quantum group category). The centre appearing in the Hochschild component of this chapter is the derived chiral centre $Z_{\text{ch}}^{\text{der}}(A)$, computed by chiral Hochschild cochains under the hypotheses of Theorems 27.8.1 and 27.8.2. The Drinfeld centre of a monoidal line category is a different categorical object. For the affine $\mathfrak{sl}_2$ evaluation surface, the conjectural comparison is between the completed Drinfeld centre of the line category and the corresponding quantum-group representation category, after the Kazhdan–Lusztig completion and the half-monodromy convention $q = e^{\pi i/(k+2)}$. That comparison is not proved here and is not an algebraic statement about $Z_{\text{ch}}^{\text{der}}(A)$. The type A construction is the DK-5 comparison theorem; see [?Lorgat26I, §6].

The low-degree Yangian computations and the corresponding conjectural ordered-centre bounds concern the kernel of the averaging map on the ordered chiral centre, a cohomological object. The following proposition establishes the underlying representation-theoretic input: the dimension of $\ker(\text{av}_n)$ on the bare tensor power $V^{\otimes n}$, before passing to bar-complex cohomology.

PROPOSITION 27.21.28 (*Kernel of the Reynolds projector: general simple Lie algebras*). Let $\mathfrak{g}$ be any simple Lie algebra over $\mathbb{C}$, let V be any finite-dimensional representation of $\mathfrak{g}$ with $d = \dim V$, and let $\text{av}_n: V^{\otimes n} \rightarrow (V^{\otimes n})_{\Sigma_n}$ denote the Reynolds averaging map (projection onto the Σ_n -coinvariant quotient). Then

$$\dim \ker(\text{av}_n|_{V^{\otimes n}}) = d^n - \binom{n+d-1}{d-1}.$$

The formula depends only on $d = \dim V$, not on $\mathfrak{g}$ or on the $\mathfrak{g}$ -module structure of V .

Special cases. For $\mathfrak{g} = \mathfrak{sl}_2$ with the fundamental representation $V = \mathbb{C}^2$: $\dim \ker(\text{av}_n) = 2^n - (n+1)$. For any $\mathfrak{g}$ with d -dimensional representation V , at $n = 2$: $\dim \ker(\text{av}_2) = d^2 - d(d+1)/2 = d(d-1)/2 = \dim \wedge^2 V$.

Proof. The Reynolds projector $\text{av}_n = \frac{1}{n!} \sum_{\sigma \in \Sigma_n} \sigma$ acts on $V^{\otimes n}$ by permuting tensor factors. Its image is the Σ_n -invariant subspace $\text{Sym}^n(V)$, regardless of any Lie algebra structure on V . The dimension $\dim \text{Sym}^n(V) = \binom{n+d-1}{d-1}$ (the number of degree- n monomials in d variables) depends only on $d = \dim V$, as the stars-and-bars argument uses no algebraic structure beyond the vector space. Since $\dim V^{\otimes n} = d^n$, the kernel has dimension $d^n - \binom{n+d-1}{d-1}$.

When $\mathfrak{g} = \mathfrak{gl}_r$, with $V = \mathbb{C}^r$, Schur–Weyl duality refines this to an isotypic decomposition. The tensor power decomposes into $(\Sigma_n, \mathfrak{gl}_r)$ -bimodules:

$$V^{\otimes n} \cong \bigoplus_{\lambda \vdash n, \ell(\lambda) \leq r} S_\lambda \otimes V_\lambda(\mathfrak{gl}_r),$$

where λ runs over partitions of n with at most r rows, S_λ is the corresponding Specht module of Σ_n , and $V_\lambda(\mathfrak{gl}_r)$ is the irreducible $\mathfrak{gl}_r$ -representation of highest weight λ . The projector av_n selects the trivial isotypic component $S_{(n)} = \mathbb{C}$ and annihilates every S_λ with $\lambda \neq (n)$. The image is

$$\text{im}(\text{av}_n) \cong S_{(n)} \otimes V_{(n)}(\mathfrak{gl}_r) = \text{Sym}^n(\mathbb{C}^r),$$

and the kernel decomposes by isotypic components:

$$\ker(\text{av}_n) \cong \bigoplus_{\substack{\lambda \vdash n \\ \ell(\lambda) \leq r, \lambda \neq (n)}} S_\lambda \otimes V_\lambda(\mathfrak{gl}_r).$$

For a general simple $\mathfrak{g}$ acting on V , the Schur–Weyl decomposition involves the commutant algebra $\text{End}_{\mathfrak{g}}(V^{\otimes n})$ rather than the group algebra of $\text{GL}(V)$, and the individual summands carry different $\mathfrak{g}$ -representations with different dimensions. The total kernel dimension, however, depends only on $\dim \text{Sym}^n(V) = \binom{n+d-1}{d-1}$, which is determined by d alone. $\square$

Remark 27.21.29 (*Explicit values and conjectural ordered-centre bounds*). Table 27.2 records the kernel dimensions at low degrees for the fundamental representations of $\mathfrak{sl}_2$ through $\mathfrak{sl}_5$ (of dimensions $d = 2, 3, 4, 5$), together with the fundamental representations of $\mathfrak{so}_5$ ($d = 5$) and G_2 ($d = 7$). Since the formula depends only on $d = \dim V$, the rows for $\mathfrak{sl}_5$ and $\mathfrak{so}_5$ are identical. These are representation-theoretic upper bounds on the dimensions of the corresponding components of the ordered chiral

centre in the conjectural ordered-centre kernel: $\ker(\text{av}_n)$ on the ordered chiral centre is a subquotient of $\ker(\text{av}_n|_{V^{\otimes n}})$, obtained by passing to bar-complex cohomology (only the cocycles in the non-trivial Σ_n -isotypics survive). At degree 2 for $\mathfrak{sl}_2$: the full 1-dimensional kernel $\wedge^2 V = \mathbb{C}$ survives in the classical Yangian computation. At degree $n \geq 3$, the kernel on the chiral centre is in general strictly smaller than the representation-theoretic bound $d^n - \binom{n+d-1}{d-1}$.

	$n = 2$	$n = 3$	$n = 4$	$n = 5$	$n = 6$
$\mathfrak{sl}_2 (d=2)$	1	4	11	26	57
$\mathfrak{sl}_3 (d=3)$	3	17	66	222	701
$\mathfrak{sl}_4 (d=4)$	6	44	221	968	4,012
$\mathfrak{sl}_5, \mathfrak{so}_5 (d=5)$	10	90	555	2,999	15,415
$G_2 \text{ fund. } (d=7)$	21	259	2,191	16,345	116,725
<i>Formula</i>	$d^n - \binom{n+d-1}{d-1}$				

TABLE 27.2: Dimension of $\ker(\text{av}_n|_{V^{\otimes n}})$ for a d -dimensional representation V at degrees $n = 2, \dots, 6$ (Proposition 27.21.28). The formula depends only on $d = \dim V$.

27.22 BACKGROUND: CHIRAL ALGEBRAS AND THE E_1/E_∞ HIERARCHY

Remark 27.22.1 (The averaging kernel at genus 1: quasi-modular anomaly and Hodge curvature). Proposition 27.21.23 characterises $\ker(\text{av})$ at genus 0: it is generated by the R -matrix monodromy, carrying the full mixed Tate content of the configuration-space integrals. At genus 1, a new mechanism enters.

The genus-1 bar propagator on E_τ involves the Weierstrass $\wp$ -function and its derivatives (weight 1 after d log absorption; cf. Theorem 27.23.1). The Laurent expansion of $\wp$ near $z = 0$ generates a fan of Eisenstein corrections $G_{2k}(\tau)$, of which G_2 is distinguished: it is quasi-modular, not modular. Under $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}(2, \mathbb{Z})$,

$$G_2(\gamma \cdot \tau) = (c\tau + d)^2 G_2(\tau) - 2\pi i c(c\tau + d).$$

The anomalous term $-2\pi i c(c\tau + d)$ is the shadow of the Legendre relation $\eta_1\tau - \eta_\tau = \pi i$ and is the source of the bar curvature $d^2 = \kappa(\mathcal{A}) \cdot \omega_1$ on $\overline{\mathcal{M}}_{1,n}$ (Theorem D, Remark 27.23.3).

The passage to the non-holomorphic completion $\widehat{G}_2(\tau) = G_2(\tau) - \pi/\text{Im } \tau$ restores modularity: $\widehat{G}_2$ transforms as a true weight-2 modular form. The difference $G_2 - \widehat{G}_2 = \pi/\text{Im } \tau$ is the anomaly that the symmetric bar complex absorbs into $\kappa(\mathcal{A}) \cdot \omega_1$. In the ordered bar complex, this anomaly is visible as explicit quasi-modular coefficients in the elliptic r -matrix; the averaging map av projects these coefficients to their modular completions, absorbing the anomaly into the Hodge curvature of the chiral differential.

This gives the following conditional structural picture for $\ker(\text{av})$ at genus 1.

- (i) *Rational component* (inherited from genus 0): the R -matrix monodromy on $\text{Conf}_n^{\text{ord}}(E_\tau)$ contributes elements to $\ker(\text{av})$ by the same mechanism as Proposition 27.21.23. These carry the elliptic multiple zeta values of Enriquez.
- (ii) *Quasi-modular component* (new at genus 1): the G_2 -anomaly terms in the ordered elliptic r -matrix are annihilated by av , since the symmetric bar complex sees only the completed $\widehat{G}_2$. The resulting

kernel elements are weighted by $\kappa(\mathcal{A})$: when $\kappa(\mathcal{A}) = 0$ (uncurved, e.g. affine Kac–Moody at critical level $k = -h^\vee$), the curvature $d^2 = 0$ and the quasi-modular anomaly contributes nothing to the bar differential, so the kernel reduces to the genus-0 rational component. When $\kappa(\mathcal{A}) \neq 0$, the anomaly is nontrivial and scales linearly with $\kappa(\mathcal{A})$.

- (iii) *Interaction*: the two components are not independent. The genus-1 free energy $F_1 = \kappa(\mathcal{A})/24$ measures the leading Hodge class λ_1 on $\overline{\mathcal{M}}_{1,1}$. The $1/24$ is the residue of the η -function ($\eta(\tau) = q^{1/24} \prod_{n \geq 1} (1 - q^n)$), which is itself the square root of $1/G_2$ at leading order. The rational and quasi-modular components of $\ker(\text{av})$ are entangled through this η -function bridge: the ordered bar complex sees the full q -expansion of the propagator $E_2^*(\tau)/12$ (quasi-modular, weight 2), while the symmetric bar complex retains only the scalar $\kappa(\mathcal{A})/24$ after integration over $\overline{\mathcal{M}}_{1,1}$.

The genus-0 kernel $\ker(\text{av}|_{(0,n)})$ is a representation of the Grothendieck–Teichmüller group $\widehat{GT}$ (Remark 27.4.8). At genus 1, the conjectural extension is that $\ker(\text{av}|_{(1,n)})$ carries an action of the *elliptic* Grothendieck–Teichmüller group $\widehat{GT}^{\text{ell}}$ of Enriquez, with the quasi-modular anomaly defining the cocycle by which $\widehat{GT}^{\text{ell}}$ extends $\widehat{GT}$. The curvature $\kappa(\mathcal{A}) \cdot \omega_1$ enters as the scalar by which this cocycle acts on the chiral differential: $\widehat{GT}^{\text{ell}}$ permutes the quasi-modular completions of the elliptic associators, and the failure of the completion to commute with the $\widehat{GT}$ -action is measured by $\kappa(\mathcal{A})$.

27.23 CURVATURE–BRAIDING ENTANGLEMENT AT GENUS ONE

The dichotomy of §27.20 partitions chiral algebras according to whether curvature and braiding decouple at genus 1. The sharp form of this dichotomy isolates the mechanism that forces entanglement and identifies the central open question to which the entire annular bar theory points.

THEOREM 27.23.1 (*Elliptic spectral dichotomy, genus-1 specialisation*;). Let $\mathcal{A}$ be a logarithmic E_1 -chiral algebra with (-1) -shifted λ -bracket $\{a \lambda b\} = \sum_{n \geq 0} c_n(a, b) \lambda^n$ on $H^\bullet(\mathcal{A}, Q)$. At genus 1, the ordered r -matrix on the elliptic curve $E_\tau = \mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ takes the form

$$r_1(z; \tau) = c_0 \cdot \zeta(z | \tau) + \sum_{n \geq 1} \frac{(-1)^{n-1}}{n!} c_n \cdot \wp^{(n-1)}(z | \tau),$$

with $\wp^{(0)} := \wp$, where ζ and $\wp$ are the Weierstrass functions with periods $(1, \tau)$. The first two explicit terms are $c_0 \zeta + c_1 \wp$; the next is $-\frac{1}{2} c_2 \wp'$. The coefficient $c_0 = a_{(0)} b$ is the Coisson bracket (zeroth product) and $c_1 = a_{(1)} b$ is the conformal pairing. We use the raw λ -bracket convention here; it is shifted by one pole index from the d log-absorbed collision-residue convention.

The B -cycle monodromy is

$$r_1(z + \tau; \tau) - r_1(z; \tau) = 2\eta_\tau \cdot c_0, \quad (27.24)$$

with $\eta_\tau = \zeta(\frac{\tau}{2} | \tau)$ the quasi-period. The A -cycle monodromy is $2\eta_1 \cdot c_0$, where $\eta_1 = \zeta(\frac{1}{2} | \tau)$. The Legendre relation $\eta_1 \tau - \eta_\tau = \pi i$ constrains the two monodromies.

Proof. By Theorem 27.20.7, the genus-1 r -matrix is obtained from the genus-0 Laurent expansion $r(z) = \sum c_n/z^{n+1}$ by replacing each rational function $1/z^{n+1}$ with its unique elliptic counterpart on E_τ : $1/z \mapsto \zeta(z | \tau)$ for $n = 0$, and $1/z^{n+1} \mapsto \frac{(-1)^{n-1}}{n!} \wp^{(n-1)}(z | \tau)$ for $n \geq 1$, with $\wp^{(0)} := \wp$. These are uniquely determined by matching the local singularity $1/z^{n+1} + O(z)$ near $z = 0$ and requiring double periodicity for $n \geq 1$ (or quasi-periodicity for $n = 0$). The monodromy (27.24) follows from $\zeta(z + \tau | \tau) = \zeta(z | \tau) + 2\eta_\tau$ and the double periodicity of $\wp$ and all its derivatives. $\square$

Definition 27.23.2 (Decoupled vs. entangled genus-1 structure). Let $\mathcal{A}$ be a logarithmic E_1 -chiral algebra with $r_1(z; \tau)$ as in Theorem 27.23.1.

- (i) $\mathcal{A}$ is *decoupled at genus 1* if $c_0 = 0$: the Coisson bracket vanishes, r_1 is doubly periodic on E_τ , and the curvature $\kappa(\mathcal{A}) \cdot \omega_1$ and the spectral braiding are independent structures belonging to different components of the E_1 -chiral coalgebra.
- (ii) $\mathcal{A}$ is *entangled at genus 1* if $c_0 \neq 0$: r_1 is quasi-periodic with B -cycle monodromy $2\eta_\tau \cdot c_0$, and the braiding and the curvature share a common geometric source, the quasi-periodicity of the Weierstrass zeta function, which is the same mechanism that produces $\kappa(\mathcal{A}) \cdot \omega_1$ from the Hodge bundle on $\overline{\mathcal{M}}_{1,n}$.

Algebra	c_0	Genus-one class	Mechanism
Heisenberg $\mathcal{H}_k$	0	Decoupled	No simple pole; $r_1 = k \wp(z \tau)$
Free fermion ψ	0	Decoupled	$\{- (0) -\} = 0$; $r_1 = \wp(z \tau)$
Lattice V_Λ (abelian)	0	Decoupled	Abelian Lie bracket
Affine $\widehat{\mathfrak{g}}_k$	$\neq 0$	Entangled	$c_0 = f^{ab}{}_c J^c$; KZB monodromy
Virasoro Vir_c	$\neq 0$	Entangled	$c_0 = 2T$; $r_1 = \frac{c}{2} \wp'(z) + 2T \zeta(z)$
$\mathcal{W}_N$ ($N \geq 2$)	$\neq 0$	Entangled	DS reduction inherits $c_0 \neq 0$ from $\widehat{\mathfrak{sl}}_N$

Remark 27.23.3 (The Eisenstein fan). The Laurent expansion of $\wp$ and its derivatives near $z = 0$ on E_τ takes the form

$$\wp^{(n)}(z | \tau) = \frac{(-1)^n (n+1)!}{z^{n+2}} + \sum_{k \geq 1} \frac{(2k+n+1)!}{(2k)! (n+1)!} G_{2k+n+2}(\tau) z^{2k},$$

where $G_{2k}(\tau) = \sum'_{(m,n) \in \mathbb{Z}^2} (m\tau + n)^{-2k}$ are the Eisenstein series. Each OPE pole of order $2k$ in the λ -bracket thus generates a $G_{2k}(\tau)$ correction to the elliptic r -matrix, producing a fan of modular corrections indexed by the pole spectrum.

The G_2 correction occupies a distinguished position: it is *quasi-modular*, transforming under $\text{SL}(2, \mathbb{Z})$ with the anomalous shift

$$G_2(-1/\tau) = \tau^2 G_2(\tau) - 2\pi i \tau.$$

This anomaly is the shadow of the Legendre relation $\eta_1 \tau - \eta_\tau = \pi i$, and it manifests in the bar complex as the curvature $d^2 = \kappa(\mathcal{A}) \cdot \omega_1$ of the curved $\mathcal{A}_\infty$ -chiral structure at genus 1. More precisely: the non-holomorphic completion $\widehat{G}_2(\tau) = G_2(\tau) - \pi/\text{Im } \tau$ is modular, and the passage from G_2 to $\widehat{G}_2$ is the modular gauge transformation that renders the chiral differential well-defined on $\overline{\mathcal{M}}_{1,n}$. Whether the analogous completion can be performed simultaneously on the coassociative coproduct (disentangling the braiding from the curvature when $c_0 \neq 0$) is the subject of the following question.

Question 27.23.4 (Central genus-1 entanglement). Does the genus-1 coupling between the bar curvature $d^2 = \kappa(\mathcal{A}) \cdot \omega_1$ and the spectral braiding monodromy $2\eta_\tau \cdot c_0$ represent genuine entanglement of the chiral and coassociative structures, or can a modular gauge twist $r_1(z; \tau) \mapsto r_1(z; \tau) + \phi(z; \tau)$ disentangle them?

More precisely: for $\mathcal{A}$ with $c_0 \neq 0$, does there exist a doubly-periodic correction $\phi(z; \tau)$, meromorphic in z and modular in τ , such that

$$\widetilde{r}_1(z; \tau) := r_1(z; \tau) + \phi(z; \tau)$$

is doubly periodic in z and the annular bar differential d^{ann} computed from $\widetilde{r}_1$ remains a differential ($d^{\text{ann}} \circ d^{\text{ann}} = \kappa \cdot \omega_1$, not something worse)?

The obstruction lies in the Legendre relation. The quasi-period η_τ satisfies $\eta_1 \tau - \eta_\tau = \pi i$, which constrains the $\mathcal{A}$ - and $\mathcal{B}$ -cycle monodromies simultaneously. Any correction ϕ that kills the $\mathcal{B}$ -cycle monodromy $2\eta_\tau \cdot c_0$ must introduce an $\mathcal{A}$ -cycle defect of magnitude $2\pi i \cdot c_0/\tau$, and this defect couples to the modular parameter through the $\text{SL}(2, \mathbb{Z})$ action. The question reduces to whether the resulting cocycle in $H^1(\text{SL}(2, \mathbb{Z}), \mathcal{O}^{\text{mer}}(E_\tau) \otimes \text{End}(\mathcal{A}))$ is trivial.

For $c_0 = 0$ the answer is trivially yes: no correction is needed. For $c_0 \neq 0$, the conjectural answer is no: the G_2 quasi-modularity anomaly is intrinsic, and the entanglement between the chiral differential and the coassociative coproduct at genus 1 is a genuine feature of the theory, not a coordinate artifact. But a proof (or a counterexample at some specific algebra) remains open.

The main line of computations treats the families that drive the theory. The remaining standard families (free fields and lattice algebras) provide complementary tests.

27.24 THE $\beta\gamma$ AND bc ORDERED BAR COMPLEXES

The $\beta\gamma$ system $\mathcal{F}_{\beta\gamma}$ has generators β, γ of conformal weights $(1, 0)$ with $\beta(z) \gamma(w) \sim 1/(z-w)$. The bc ghost system $\mathcal{F}_{bc}$ has generators b, c of weights $(\lambda, 1-\lambda)$ with $b(z) c(w) \sim 1/(z-w)$. Both are E_∞ -chiral (tier (ii): vertex algebras with poles).

THEOREM 27.24.1 (*Free-field ordered bar complexes;*). Let $\mathcal{F}$ denote either $\mathcal{F}_{\beta\gamma}$ or $\mathcal{F}_{bc}$, with generators a, a' and OPE $a(z) a'(w) \sim 1/(z-w)$.

- (a) *Collision residue.* The $d \log$ kernel absorbs the simple OPE pole completely, so the pole-valued binary collision residue is

$$r_{\mathcal{F}}^{\text{coll}}(z) = 0.$$

The regular contact operator retained by the ordered bar transfer is

$$\Theta := a \otimes a' - a' \otimes a, \quad \Theta^2 = 0.$$

- (b) *Bar differential.* Every adjacent collision inserts $a_{(0)} a' = \pm 1$, which the augmentation kills. Hence $d = 0$ in the reduced complex.
- (c) *Contact transport.* The collision-residue connection has trivial monodromy, $R^{\text{coll}} = \text{id}$. If the regular contact operator is retained as a constant nilpotent transport, its exponential is

$$R = \exp(2\pi i \Theta) = \text{id} + 2\pi i \Theta,$$

terminating at linear order because $\Theta^2 = 0$; this is contact transport, not a pole-residue r -matrix.

- (d) *Koszul duals.* Duality exchanges statistics:

$$\mathcal{F}_{\beta\gamma}^{\text{l,ord}} \simeq \bigwedge^\bullet (s \beta^* \oplus s \gamma^*), \quad \mathcal{F}_{bc}^{\text{l,ord}} \simeq \text{Sym}^\bullet (s b^* \oplus s c^*).$$

Both are class C with shadow depth $r_{\text{max}} = 4$ (Volume I, Theorem ??), and $K(bc)_\lambda = c_{bc}(\lambda) + c_{\beta\gamma}(\lambda) = 0$.

Proof. Nilpotency: $\Theta^2 = 0$ because $a_{(0)}a' = 1$ is scalar (central), so expanding $(a \otimes a' - a' \otimes a)^2$ and using $a'_{(0)}a = -1$ gives cancellation. Bar differential: in the reduced complex every raw simple-pole contraction ± 1 lies in $\mathbb{C} \cdot 1$, which the augmentation kills, and the pole-valued residue is zero because the simple pole is absorbed by the $d \log$ kernel. Contact transport terminates at linear order because $\Theta^2 = 0$. Koszul dual: the antisymmetric $\Theta_{\beta\gamma}$ (bosonic generators) dualizes to $\wedge$; Θ_{bc} (fermionic generators) dualizes to Sym . $\square$

Remark 27.24.2 (Contrast with Heisenberg). The Heisenberg R -matrix $R(z) = \exp(k\hbar/z)$ (Theorem 27.12.3) is an infinite power series; the free-field collision-residue monodromy is trivial, while the regular contact transport terminates at linear order. This dichotomy reflects the composite-closed support-packet classification: the Heisenberg packet is binary and scalar (class G), whereas the $\beta\gamma$ generator pole is simple but its closed contact envelope is finite and nilpotent (class C).

THEOREM 27.24.3 (Wakimoto bar complex descent;). For $\mathfrak{g}$ simple of rank r and $k \neq -h^\vee$, the Wakimoto module $\mathcal{M}_{\text{Wak}} = \bigotimes_{\alpha \in \Delta_+} (\beta\gamma)_\alpha \otimes \mathcal{H}_{\mathfrak{h}}$ satisfies, under the exactness, PBW-preservation, and BRST-lift hypotheses of Theorem 27.30.7,

$$H^\bullet(\overline{B}^{\text{ch}}(\mathcal{M}_{\text{Wak}}), d_{\overline{B}^{\text{ch}}} + Q_{\text{DS}}) \simeq \overline{B}^{\text{ch}}(\widehat{\mathfrak{g}}_k),$$

and at the Koszul dual level, $Y_h^{\text{dg}}(\mathfrak{g}) \simeq H^\bullet(\bigotimes_\alpha \mathcal{F}_{\beta\gamma, \alpha}^{\text{l, ord}} \otimes Y(\mathfrak{u}(1))^{\otimes r}, Q_{\text{DS}}^\dagger)$.

Proof. Under the stated hypotheses, Q_{DS} lifts to the bar coalgebra and is compatible with the PBW filtration. The resulting spectral sequence has $E_1 = H^\bullet(\overline{B}^{\text{ch}}(\mathcal{M}_{\text{Wak}}), d_{\overline{B}^{\text{ch}}})$ and $d_1 = Q_{\text{DS}}$. Its convergence is part of the hypothesis package, and its abutment is the reduced bar model. Theorem 27.30.7 ensures Koszul duality and DS commute. $\square$

System	R -matrix	Depth	Class	$\mathcal{A}_{\text{line}}^{\text{l, ord}}$	E_∞

TABLE 27.3: Ordered bar complex data for the standard families. All entries are E_∞ -chiral; the R -matrix is derived from the local OPE in every case.

Remark 27.24.4 (The Wakimoto escalation). Shadow depth escalates through the Wakimoto chain: $\mathcal{H}_k \otimes \beta\gamma^{\otimes |\Delta_+|}$ (depths 2, 4) $\xrightarrow{Q_{\text{DS}}} \widehat{\mathfrak{g}}_k$ (depth 3) $\xrightarrow{Q_{\text{DS}}} \text{Vir}_c$ (depth ∞). The second reduction manufactures the quartic pole via Sugawara, escalating from class L to class M.

27.25 LATTICE VERTEX ALGEBRAS

Let Λ be an even lattice of rank d with bilinear form $\langle \cdot, \cdot \rangle$ and let $\varepsilon: \Lambda \times \Lambda \rightarrow \mathbb{C}^\times$ be a normalized bimultiplicative 2-cocycle. The lattice vertex algebra V_Λ^ε has vertex operators $Y(e^\alpha, z)$ for $\alpha \in \Lambda$ with OPE

$$Y(e^\alpha, z) Y(e^\beta, w) \sim \varepsilon(\alpha, \beta) (z - w)^{\langle \alpha, \beta \rangle} Y(e^{\alpha+\beta}, w) + \dots$$

The E_1/E_∞ character of V_Λ^ε depends on the symmetry of the cocycle, as established in §?? of the lattice foundations chapter.

27.25.0.1 SYMMETRIC COCYCLE: E_∞ -CHIRAL

THEOREM 27.25.1 (*Ordered bar complex with symmetric cocycle;*). Let ε be a symmetric cocycle satisfying the Borchers symmetry $\varepsilon(\alpha, \beta) = (-1)^{\langle \alpha, \beta \rangle} \varepsilon(\beta, \alpha)$. Then V_Λ^ε is E_∞ -chiral, and the ordered bar complex $\overline{B}^{\text{ch}}(V_\Lambda^\varepsilon)$ has:

- (1) **Collision residue.** The collision residue kernel on the diagonal α -sector is:

$$r(z) = \frac{1}{z} \sum_{\alpha \in \Lambda} \langle \alpha, \alpha \rangle (e^\alpha \otimes e^{-\alpha}). \quad (27.25)$$

This is the *diagonal* residue: only the Heisenberg-type contributions $\alpha \otimes (-\alpha)$ survive, weighted by the norm $\langle \alpha, \alpha \rangle$.

- (2) **R-matrix.** Since ε is symmetric, the R-matrix is determined by the local OPE (tier (ii) of the three-tier picture). The ordered-to-unordered descent $\overline{B}^{\text{ch}} \rightarrow \tilde{B}$ is the R-matrix-twisted Σ_n -quotient, with twist $R(z)$ derived from the OPE monodromy:

$$R_{\alpha, \beta}(z) = (-1)^{\langle \alpha, \beta \rangle} e^{\pi i \langle \alpha, \beta \rangle},$$

the standard lattice braiding phase. This is *not* independent input: it is the monodromy of the flat connection on $\text{Conf}_2(\mathbb{C})$ determined by the OPE poles, confirming the E_∞ character.

Proof. The OPE $Y(e^\alpha, z) Y(e^\beta, w) \sim \varepsilon(\alpha, \beta) (z - w)^{\langle \alpha, \beta \rangle} Y(e^{\alpha+\beta}, w) + \dots$ has a pole of order $-\langle \alpha, \beta \rangle$ at $z = w$. After $d \log$ absorption, the collision residue extracts the order-1 coefficient: $\text{Res}_{z=w} [(z - w)^{-m} d \log(z - w)] = \delta_{m,1}$. For the diagonal sector $\beta = -\alpha$, the pole order is $-\langle \alpha, -\alpha \rangle = \langle \alpha, \alpha \rangle$, which is always even for an even lattice. The non-diagonal residue at order 1 gives (27.25).

For the R-matrix: the connection is $\nabla = d - r(z) d(z_1 - z_2)$, and the monodromy around $z_1 = z_2$ is $\exp(2\pi i \cdot r)$. On the lattice sector (e^α, e^β) , this is $(-1)^{\langle \alpha, \beta \rangle} e^{\pi i \langle \alpha, \beta \rangle}$, matching the standard lattice braiding. The Borchers symmetry of ε ensures this monodromy is *derived from* the local OPE, confirming E_∞ . $\square$

27.25.0.2 NON-SYMMETRIC COCYCLE: GENUINELY E_1 -CHIRAL

THEOREM 27.25.2 (*Ordered bar complex with non-symmetric cocycle;*). Let ε be a non-symmetric cocycle: there exist $\alpha, \beta \in \Lambda$ with $\varepsilon(\alpha, \beta)/\varepsilon(\beta, \alpha) \neq (-1)^{\langle \alpha, \beta \rangle}$. Then V_Λ^ε is genuinely E_1 -chiral (nonlocal), and the ordered bar complex $\overline{B}^{\text{ch}}(V_\Lambda^\varepsilon)$ has:

- (1) **Differential.** In bar degree 2:

$$d([e^{\alpha_1} | e^{\alpha_2}]) = \varepsilon(\alpha_1, \alpha_2) \delta_{\langle \alpha_1, \alpha_2 \rangle, -1} [e^{\alpha_1 + \alpha_2}].$$

The cocycle $\varepsilon(\alpha_1, \alpha_2)$ appears with its value at the *specific ordered pair* (α_1, α_2) . For a non-symmetric cocycle, the coefficients $\varepsilon(\alpha, \beta) \neq (-1)^{\langle \alpha, \beta \rangle} \varepsilon(\beta, \alpha)$, so permuting the pair changes the differential. No Σ_2 -quotient is possible.

- (2) **R-matrix as independent input.** The R-matrix $R_{\alpha, \beta}$ is part of the defining data of the E_1 -chiral algebra, not derivable from a local OPE. The ratio

$$\frac{\varepsilon(\alpha, \beta)}{\varepsilon(\beta, \alpha)}$$

measures the asymmetry of the cocycle and enters the R-matrix directly. When this ratio is not $(-1)^{\langle \alpha, \beta \rangle}$, the braiding is genuinely nonlocal: it cannot be obtained as the monodromy of any connection on $\text{Conf}_2(\mathbb{C})$ determined by a local OPE. This is tier (iii) of the three-tier picture.

Proof. The differential follows from the ordered lattice OPE and the ordered bar construction: adjacent collisions in the ordered bar complex use the d log kernel, selecting simple poles ($\langle \alpha_i, \alpha_{i+1} \rangle = -1$) with coefficient $\varepsilon(\alpha_i, \alpha_{i+1})$ at the specific ordered pair.

For the R-matrix claim: the Borchers symmetry $\varepsilon(\alpha, \beta) = (-1)^{\langle \alpha, \beta \rangle} \varepsilon(\beta, \alpha)$ is precisely the condition for the Σ_2 -action on the ordered bar complex to be compatible with the differential. When this fails, the descent $\overline{B}^{\text{ch}} \rightarrow \mathbf{B}$ requires independent braiding data, and the algebra is genuinely E_1 . $\square$

27.25.0.3 KOSZUL DUAL OF LATTICE ALGEBRAS

THEOREM 27.25.3 (*Ordered Koszul dual of lattice algebras;*). The ordered Koszul dual of V_Λ^ε depends on the lattice:

- (i) For a self-dual even lattice $\Lambda = \Lambda^*$ with symmetric cocycle, the Koszul dual $(V_\Lambda^\varepsilon)^\dagger$ is again a lattice vertex algebra $(V_\Lambda^{\varepsilon^{-1}})^\dagger$ with inverse cocycle (Theorem ??).
- (ii) For a non-self-dual lattice or non-symmetric cocycle, the ordered Koszul dual carries strictly more structure: the ordered bar complex has independent generators in each ordering, and the dual algebra reflects this asymmetry.
- (iii) In all cases, the lattice grading is preserved: the Koszul dual decomposes as $\bigoplus_{\gamma \in \Lambda} (V_\Lambda^\varepsilon)_\gamma^\dagger$ with the differential preserving total lattice degree.

Proof. Part (i) follows from Theorem ?? and its proof: the bar complex coproduct has structure constants $\varepsilon(\alpha, \beta)^{-1}$, and linear duality recovers the lattice algebra with inverse cocycle. Self-duality $\Lambda = \Lambda^*$ ensures the dual lives on the same lattice.

Part (ii): for a non-symmetric cocycle, the ordered bar complex in degree 2 has generators $[e^\alpha \mid e^\beta]$ and $[e^\beta \mid e^\alpha]$ that are *independent* (no Σ_2 -identification). Their duals generate the Koszul dual algebra with product reflecting the asymmetric cocycle values.

Part (iii): the bar differential preserves the total lattice degree $\gamma = \sum_i \alpha_i \in \Lambda$ (Theorem ??(i)), so the Koszul dual inherits the same decomposition. $\square$

Remark 27.25.4 (*The three-tier picture for lattice algebras*). Lattice vertex algebras provide the cleanest illustration of the three-tier picture:

- (i) *Pole-free commutative* ($R = \tau$): degenerate case where $\langle \alpha, \beta \rangle = 0$ for all α, β (the lattice is trivial or the restriction to a sublattice with vanishing pairing).
- (ii) *E_∞ with poles* ($R \neq \tau$, derived from locality): symmetric cocycle, OPE with poles from $\langle \alpha, \beta \rangle < 0$. The R-matrix is the standard lattice braiding, determined by the OPE monodromy.

- (iii) *Genuinely* E_1 ($R \neq \tau$, independent input): non-symmetric cocycle. The R -matrix is part of the defining data. The descent from ordered to unordered configurations requires this independent braiding datum.

The lattice family thus realizes all three tiers explicitly, with the cocycle symmetry as the single discrete parameter controlling the E_∞/E_1 transition.

27.26 EVALUATION MODULES AND THE LINE CATEGORY

The ordered bar complex and the Yangian $Y_\hbar(\mathfrak{g})$ classify the line operators of the corresponding holomorphic-topological theory. This section develops the representation-theoretic side: evaluation modules, the Drinfeld polynomial classification, tensor products and their braiding, and the identification of the resulting module category with the line category $\mathcal{C}_{\text{line}}$.

Throughout, $\mathfrak{g}$ denotes a finite-dimensional simple Lie algebra over $\mathbb{C}$ of rank r , with Cartan matrix (a_{ij}) , simple roots $\alpha_1, \dots, \alpha_r$, fundamental weights $\omega_1, \dots, \omega_r$, and normalised Killing form $(\cdot, \cdot)$ for which $(\alpha, \alpha) = 2$ for long roots. We write $\Omega \in \mathfrak{g} \otimes \mathfrak{g}$ for the quadratic Casimir element and $P \in \text{End}(V \otimes W)$ for the permutation operator $v \otimes w \mapsto w \otimes v$.

27.26.1 The Yangian $Y_\hbar(\mathfrak{g})$ and the evaluation homomorphism

Definition 27.26.1 (Drinfeld Yangian). The Yangian $Y_\hbar(\mathfrak{g})$ is the associative $\mathbb{C}[[\hbar]]$ -algebra generated by $\{J_o^a, J_1^a \mid a = 1, \dots, \dim \mathfrak{g}\}$ subject to:

- (i) J_o^a generate a copy of $U(\mathfrak{g})$;
- (ii) $[J_o^a, J_1^b] = f^{ab}{}_c J_1^c$;
- (iii) Drinfeld's ternary relation: $[J_1^a, [J_o^b, J_1^c]] - [J_o^a, [J_1^b, J_1^c]] = \hbar^2 A_{def}^{abc} \{J_o^d, J_o^e, J_o^f\}$,
where A_{def}^{abc} is the totally symmetric tensor of [Drinfeld-Yangians] and $\{x, y, z\} = \frac{1}{24} \sum_{\sigma \in S_3} x_{\sigma(1)} y_{\sigma(2)} z_{\sigma(3)}$.

The coproduct is $\Delta(J_o^a) = J_o^a \otimes 1 + 1 \otimes J_o^a$, $\Delta(J_1^a) = J_1^a \otimes 1 + 1 \otimes J_1^a + \frac{\hbar}{2} f^a{}_{bc} J_o^b \otimes J_o^c$.

Construction 27.26.2 (Evaluation homomorphism). For each $a \in \mathbb{C}$, there is a surjective algebra homomorphism

$$\text{ev}_a: Y_\hbar(\mathfrak{g}) \longrightarrow U(\mathfrak{g}), \quad J_o^a \mapsto J^a, \quad J_1^a \mapsto a J^a.$$

The evaluation map is an algebra homomorphism because $[J^a, a J^b] = a f^{ab}{}_c J^c = a f^{ab}{}_c J_o^c$, and the ternary relation reduces to the Jacobi identity in $U(\mathfrak{g})$.

Definition 27.26.3 (Evaluation module). Let (ρ, V) be a finite-dimensional $\mathfrak{g}$ -representation and $a \in \mathbb{C}$. The *evaluation module* V_a is the $Y_\hbar(\mathfrak{g})$ -module obtained by pulling back along ev_a :

$$V_a := \text{ev}_a^*(V).$$

Concretely, $V_a = V$ as a vector space, with

$$T^a(u) \cdot v = v + \frac{\hbar \rho(\Omega_{(1)}) \otimes \Omega_{(2)}}{u - a} \cdot v = v + \frac{\hbar}{u - a} \sum_\alpha \rho(J^\alpha) v \otimes J_\alpha,$$

where $\Omega = \sum_\alpha J^\alpha \otimes J_\alpha$ is the Casimir tensor and the transfer matrix $T(u) = 1 + \hbar \sum_{n \geq 0} J_n u^{-n-1}$.

27.26.2 *Explicit evaluation modules for $\mathfrak{sl}_2$*

COMPUTATION 27.26.4 (*$\mathfrak{sl}_2$ evaluation module; $\cdot$*). Let $\mathfrak{g} = \mathfrak{sl}_2$ with standard basis e, f, h and $[h, e] = 2e$, $[h, f] = -2f$, $[e, f] = h$. The fundamental representation is $V = \mathbb{C}^2$ with basis v_+, v_- and

$$\rho(e) = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \rho(f) = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \rho(h) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The Casimir tensor is $\Omega = \frac{1}{2}h \otimes h + e \otimes f + f \otimes e$, so $\rho(\Omega) \in \text{End}(\mathbb{C}^2)$ is $\rho(\Omega) = \frac{1}{2}C_2(\text{fund}) \cdot \text{id} = \frac{3}{4} \cdot \text{id}$ (half the quadratic Casimir eigenvalue).

The evaluation module $V_a = \mathbb{C}^2$ has

$$J_0^a \cdot v_{\pm} = \rho(J^a) v_{\pm}, \quad J_1^a \cdot v_{\pm} = a \rho(J^a) v_{\pm}.$$

The transfer matrix in the fundamental representation is

$$T(u) = \text{id}_2 + \frac{\hbar}{u-a} \begin{pmatrix} \frac{1}{2}h & f \\ e & -\frac{1}{2}h \end{pmatrix}, \quad (27.26)$$

where the matrix entries are $\mathfrak{sl}_2$ -generators acting via ρ in the quantum space and via the fundamental in the auxiliary space.

Proof. The evaluation homomorphism sends each Yangian generator to its $\mathfrak{sl}_2$ -action scaled by the spectral parameter, so the displayed formulas for J_0 and J_1 are immediate from $J_n^a \mapsto a^n \rho(J^a)$. With the chosen matrices,

$$\rho(\Omega) = \frac{1}{2}\rho(h)^2 + \rho(e)\rho(f) + \rho(f)\rho(e) = \frac{3}{4} \text{id}_{\mathbb{C}^2},$$

which is the stated fundamental Casimir value. Substituting this into the general transfer-matrix action

$$T^a(u) \cdot v = v + \frac{\hbar}{u-a} \sum_{\alpha} \rho(J^{\alpha}) v \otimes J_{\alpha}$$

yields (27.26). □

THEOREM 27.26.5 (*R -matrix on $V_a \otimes V_b$ for $\mathfrak{sl}_2$; $\cdot$*). The R -matrix governing the braiding of $V_a \otimes V_b$ is

$$R(a-b) = (a-b) \text{id} + \hbar P \in \text{End}(\mathbb{C}^2 \otimes \mathbb{C}^2), \quad (27.27)$$

where P is the permutation operator $v \otimes w \mapsto w \otimes v$. Equivalently, in the normalised form $\check{R}(u) = P R(u)$:

$$\check{R}(u) = u P + \hbar \text{id}.$$

This is the Yang R -matrix.

Proof. The intertwining equation $\Delta^{\text{op}}(x) R = R \Delta(x)$ for all $x \in Y_{\hbar}(\mathfrak{sl}_2)$, evaluated on $V_a \otimes V_b$, uniquely determines R up to scalar. For $x = J_0^a$: $[\rho^{(1)}(J^a) + \rho^{(2)}(J^a), R] = 0$, so R commutes with the diagonal $\mathfrak{sl}_2$ -action. By Schur's lemma applied to the decomposition $\mathbb{C}^2 \otimes \mathbb{C}^2 = \text{Sym}^2 \oplus \wedge^2$, $R = \alpha \Pi_{\text{sym}} + \beta \Pi_{\text{alt}}$ for scalars α, β . Writing $\Pi_{\text{sym}} = \frac{1}{2}(\text{id} + P)$ and $\Pi_{\text{alt}} = \frac{1}{2}(\text{id} - P)$:

$$R = \frac{\alpha+\beta}{2} \text{id} + \frac{\alpha-\beta}{2} P.$$

Evaluating the intertwining equation for $x = J_1^a$ with $\Delta(J_1^a) = J_1^a \otimes 1 + 1 \otimes J_1^a + \frac{\hbar}{2} f^a_{bc} J_0^b \otimes J_0^c$ yields $\alpha - \beta = \hbar$ and $\alpha + \beta = a - b$. Hence $R = (a - b) \text{id} + \hbar P$. $\square$

COROLLARY 27.26.6 (*Clebsch–Gordan decomposition and non-semisimplicity*;). The tensor product $V_a \otimes V_b$ of fundamental $\mathfrak{sl}_2$ -evaluation modules is:

- (a) **Semisimple** when $a - b \notin \{0, \pm\hbar\}$: the R -matrix (27.27) is invertible, and $V_a \otimes V_b \simeq W_{3,a+b} \oplus W_{1,a+b}$, where $W_{d,c}$ denotes the evaluation module of dimension d at the averaged spectral parameter.
- (b) **Non-semisimple** when $a - b = \pm\hbar$: $R(a - b) = \pm\hbar \text{id} + \hbar P$ is not scalar but remains invertible. The tensor product is reducible but indecomposable: $V_a \otimes V_b$ has a two-step filtration with Jordan–Hölder factors W_3 and W_1 , but the extension does not split.
- (c) **Singular** when $a = b$: $R(0) = \hbar P$ has eigenvalues $\pm\hbar$, and the tensor product $V_a \otimes V_a$ degenerates: the braiding becomes the graded permutation, and the intertwiner is no longer generic. The image of the bar complex at this point reflects the coalescence singularity of the ordered configuration space.

Proof. The eigenvalues of $R(u) = u \text{id} + \hbar P$ on the Sym^2 and $\wedge^2$ summands are $u + \hbar$ and $u - \hbar$, respectively. Part (a): when $u = a - b \neq 0, \pm\hbar$, both eigenvalues are nonzero and the corresponding projectors split the tensor product. Part (b): when $u = \pm\hbar$, one eigenvalue is $2\hbar$ or 0 and the other is 0 or $-2\hbar$; the zero eigenvalue signals a non-split extension. Part (c) is $u = 0$. $\square$

27.26.3 Evaluation modules for $\mathfrak{sl}_3$

COMPUTATION 27.26.7 ($\mathfrak{sl}_3$ fundamental evaluation module;). Let $\mathfrak{g} = \mathfrak{sl}_3$ with standard Chevalley generators e_i, f_i, h_i ($i = 1, 2$). The fundamental representation $V = \mathbb{C}^3$ has basis v_1, v_2, v_3 with weight vectors of weights $\omega_1, \omega_1 - \alpha_1, \omega_1 - \alpha_1 - \alpha_2$. The evaluation module $V_a = \mathbb{C}^3$ has

$$J_0^{e_i} = E_i, \quad J_0^{f_i} = F_i, \quad J_0^{h_i} = H_i, \quad J_1^{e_i} = a E_i, \quad J_1^{f_i} = a F_i, \quad J_1^{h_i} = a H_i,$$

where E_i, F_i, H_i are the standard 3×3 matrices representing e_i, f_i, h_i .

The R -matrix on $V_a \otimes V_b$ in the fundamental takes the universal Yang form:

$$R(u) = u \text{id} + \hbar P \in \text{End}(\mathbb{C}^3 \otimes \mathbb{C}^3),$$

where $u = a - b$. Under $\mathfrak{sl}_3$, $\mathbb{C}^3 \otimes \mathbb{C}^3 \simeq \text{Sym}^2(\mathbb{C}^3) \oplus \wedge^2(\mathbb{C}^3)$ (dimensions $6 + 3$), and the eigenvalues of $R(u)$ are $u + \hbar$ on Sym^2 and $u - \hbar$ on $\wedge^2$, exactly as for $\mathfrak{sl}_2$.

Proof. Applying the evaluation map to the defining representation of $\mathfrak{sl}_3$ gives the displayed formulas for the level-0 and level-1 generators. The decomposition $\mathbb{C}^3 \otimes \mathbb{C}^3 = \text{Sym}^2(\mathbb{C}^3) \oplus \wedge^2(\mathbb{C}^3)$ is the standard $\mathfrak{sl}_3$ tensor-product splitting. Theorem 27.27.2 gives $R(u) = u \text{id} + \hbar P$ on the fundamental tensor square. Since P acts by $+1$ on the symmetric summand and by -1 on the alternating summand, the two eigenvalues are $u + \hbar$ and $u - \hbar$. $\square$

COMPUTATION 27.26.8 ($\mathfrak{sl}_3$ adjoint evaluation module;). The adjoint representation $W = \mathfrak{sl}_3$ has $\dim W = 8$. The evaluation module W_a is the pullback of the adjoint $\mathfrak{sl}_3$ -module along ev_a . Since $\mathbb{C}^3 \otimes (\mathbb{C}^3)^* \simeq \mathfrak{sl}_3 \oplus \mathbb{C}$, one has

$$W_a \simeq (V_a \otimes V_a^*)/\mathbb{C},$$

where V_a^* is the contragredient evaluation module at the same spectral parameter. The R -matrix on $V_a \otimes W_b$ (fundamental $\otimes$ adjoint) is determined by the Yangian intertwining equation and decomposes into three eigenvalues on the three $\mathfrak{sl}_3$ -irreducible summands of $\mathbb{C}^3 \otimes \mathfrak{sl}_3$:

$$\mathbb{C}^3 \otimes \mathfrak{sl}_3 \simeq V(2\omega_1 + \omega_2) \oplus V(\omega_1) \oplus V(\omega_2),$$

with eigenvalues $u + 2\hbar, u - \hbar, u + \hbar$ respectively, where $u = a - b$.

Proof. The identification $W_a \simeq (V_a \otimes V_a^*)/\mathbb{C}$ is the usual realization of the adjoint representation as the traceless part of $\text{End}(\mathbb{C}^3)$, transported through the evaluation map. The tensor-product decomposition $\mathbb{C}^3 \otimes \mathfrak{sl}_3 \cong V(2\omega_1 + \omega_2) \oplus V(\omega_1) \oplus V(\omega_2)$ is the standard Littlewood–Richardson decomposition $\mathbf{3} \otimes \mathbf{8} = \mathbf{15} \oplus \mathbf{3} \oplus \mathbf{6}^*$. Proposition 27.27.1 implies that the Yangian R -matrix acts by scalars on these three irreducible summands. Using the fusion realization of W_a from the fundamental and dual fundamental evaluation modules, those scalars are fixed by the fundamental Yang R -matrix of Computation 27.26.7; the three channels pick up the shifts $+2\hbar, -\hbar$, and $+\hbar$, which gives the stated eigenvalues. $\square$

27.26.4 Drinfeld polynomials and the classification of finite-dimensional modules

THEOREM 27.26.9 (*Drinfeld classification*;). For $\mathfrak{g}$ a finite-dimensional simple Lie algebra of rank r , the isomorphism classes of irreducible finite-dimensional $Y_\hbar(\mathfrak{g})$ -modules are in bijection with r -tuples of monic polynomials $(P_1(u), \dots, P_r(u)) \in \mathbb{C}[u]^r$, called the *Drinfeld polynomials*.

The bijection sends an irreducible module L to the r -tuple where $P_i(u)$ records the eigenvalues of the level-1 generating series associated to the i -th simple root on a highest-weight vector of L :

$$T_i(u) \cdot v_+ = \frac{P_i(u - \hbar)}{P_i(u)} v_+.$$

PROPOSITION 27.26.10 (*Evaluation modules as single-root Drinfeld polynomials*;). Let $V(\omega_i)$ be the i -th fundamental representation of $\mathfrak{g}$ and $a \in \mathbb{C}$. The evaluation module $V(\omega_i)_a$ has Drinfeld polynomials

$$P_j(u) = \begin{cases} u - a & \text{if } j = i, \\ 1 & \text{if } j \neq i. \end{cases}$$

More generally, the evaluation of an irreducible $\mathfrak{g}$ -module $V(\lambda)$ with highest weight $\lambda = \sum_i m_i \omega_i$ at points $a_1, \dots, a_N \in \mathbb{C}$ produces the tensor product evaluation module $V(\lambda_1)_{a_1} \otimes \dots \otimes V(\lambda_N)_{a_N}$, whose Drinfeld polynomials are

$$P_j(u) = \prod_{k=1}^N (u - a_k)^{m_j^{(k)}},$$

where $m_j^{(k)}$ is the multiplicity of ω_j in λ_k .

Proof. By definition, ev_a sends $J_1^a \mapsto a J^a$, so the generating series $T_i(u)$ acts on the highest-weight vector v_+ of $V(\omega_i)_a$ as a rational function of u . In the normalisation where $P_i(u) = u - a$, one obtains $T_i(u) \cdot v_+ = (u - a - \hbar)/(u - a) \cdot v_+$ and $T_j(u) \cdot v_+ = v_+$ for $j \neq i$, matching the classification. The general formula follows from the tensor product rule for Drinfeld polynomials: the P_j of a tensor product is the product of the P_j 's of the factors. $\square$

Example 27.26.11 (Drinfeld polynomials for evaluation chains). For $\mathfrak{g} = \mathfrak{sl}_2$, rank $r = 1$, and an evaluation chain at points $a_1, \dots, a_n \in \mathbb{C}$ in the fundamental representation:

$$P(u) = \prod_{k=1}^n (u - a_k).$$

The module $V_{a_1} \otimes \dots \otimes V_{a_n}$ is irreducible if and only if $a_i - a_j \notin \mathbb{Z}\hbar$ for all $i \neq j$ (the non-resonance condition). When $a_i - a_j \in \mathbb{Z}\hbar$ for some pair, the tensor product is reducible and the irreducible subquotients are classified by combinatorial data (segments in the sense of Zelevinsky).

27.26.5 The line category

The line operators of a holomorphic-topological theory on $\mathbb{C}_z \times \mathbb{R}_t$ are operators supported on lines $\{z = z_0\} \times \mathbb{R}_t$. These form a category $\mathcal{C}_{\text{line}}$, and the ordered bar complex identifies it with the module category of the E_1 -chiral Koszul dual.

THEOREM 27.26.12 (Line category as finite-dimensional modules;). Let $\mathcal{A}$ be a strongly admissible E_1 -chiral algebra with ordered bar coalgebra $C = \overline{B}^{\text{ch,ord}}(\mathcal{A})$ and E_1 -chiral Koszul dual $\mathcal{A}_{\text{line}}^!$. Then:

- (i) The line category is

$$\mathcal{C}_{\text{line}} \simeq \mathcal{A}_{\text{line}}^! \text{-mod}^{\text{fd}},$$

the category of finite-dimensional modules over the E_1 -chiral Koszul dual.

- (ii) On the chirally Koszul locus (where the bar–cobar equivalence holds and $\mathcal{A}_{\text{line}}^!$ is formal), for $\mathcal{A}$ in the affine lineage (i.e., $\mathcal{A} = \hat{\mathfrak{g}}_k$ for simple $\mathfrak{g}$ at non-critical level),

$$\mathcal{A}_{\text{line}}^! \simeq Y_{\hbar}(\mathfrak{g})$$

and accordingly

$$\mathcal{C}_{\text{line}} \simeq Y_{\hbar}(\mathfrak{g})\text{-mod}^{\text{fd}}.$$

- (iii) The evaluation modules V_a of Definition 27.26.3 are the line operators obtained by inserting a Wilson line in representation V at position $z = a$. The spectral parameter a is the holomorphic position on $\mathbb{C}_z$.

Proof. Part (i) is the content of the one-sided module/comodule duality (Hypothesis 27.2.3(I)) combined with the ordered bar–cobar equivalence: left C -comodules are equivalently right $\mathcal{A}_{\text{line}}^!$ -modules. Part (ii) follows from the identification of $\mathcal{A}_{\text{line}}^!$ with the dg-shifted Yangian (Vol. II comparison theorem ??). Part (iii) is the physical interpretation: a Wilson line in representation ρ at position $z = a$ defines a line operator whose endomorphism algebra is $\text{ev}_a^* \rho$, and the intertwining between different Wilson lines is governed by the R -matrix. $\square$

Remark 27.26.13 (Finite-dimensional surface, category $\mathcal{O}$, and RTT). Theorem 27.26.12 is a finite-dimensional evaluation-surface statement. It identifies the line category with modules over the ordered Koszul dual after the finite-type continuous dual has been taken; for affine inputs this gives $Y_{\hbar}(\mathfrak{g})\text{-mod}^{\text{fd}}$. It does not identify the BGG/category- $\mathcal{O}$ category, the Kazhdan–Lusztig WZW category, or a completed RTT representation category. The RTT presentation is an algebra presentation of the same Yangian on this surface, and Drinfeld polynomial classification applies to finite-dimensional irreducible Yangian modules. Passing to category $\mathcal{O}$, admissible affine modules, or completions is extra representation-theoretic input, not a consequence of the ordered bar–cobar counit.

27.26.6 *Tensor products and the braided monoidal structure*

THEOREM 27.26.14 (*Braiding from the R -matrix;*). The tensor product of evaluation modules $V_a \otimes W_b$, with V, W finite-dimensional $\mathfrak{g}$ -representations, is a $Y_h(\mathfrak{g})$ -module via the coproduct Δ . The braiding isomorphism

$$\sigma_{V_a, W_b}: V_a \otimes W_b \xrightarrow{\sim} W_b \otimes V_a$$

is given by $\sigma_{V_a, W_b} = P \circ R_{V, W}(a - b)$, where $R_{V, W}(u) \in \text{End}(V \otimes W)((u^{-1}))$ is the universal R -matrix of $Y_h(\mathfrak{g})$ evaluated in $V \otimes W$.

When $a = b$, the R -matrix $R_{V, W}(0)$ degenerates: its kernel is nontrivial whenever $V \otimes W$ is not multiplicity-free. This singularity reflects the coalescence of two line operators at the same point, corresponding to the boundary stratum $z_1 = z_2$ in $\overline{\text{FM}}_2^{\text{ord}}(\mathbb{C})$.

Proof. The coproduct Δ of $Y_h(\mathfrak{g})$ defines the tensor product module structure. The universal R -matrix satisfies the intertwining equation $\Delta^{\text{op}}(x) R = R \Delta(x)$, which means $R_{V, W}(a - b)$ intertwines the two orderings of the tensor product. The braiding axioms (Yang–Baxter equation) follow from the quantum group structure. The coalescence statement follows from the fact that $R_{V, W}(u)$ has a pole at $u = 0$ of order determined by the Casimir eigenvalue in the tensor product, and the bar differential at the boundary stratum $\partial \overline{\text{FM}}_2$ imposes exactly the residue of this pole. $\square$

27.26.7 *The Grothendieck ring*

THEOREM 27.26.15 (*Grothendieck ring of Yangian modules;*). The Grothendieck ring of finite-dimensional $Y_h(\mathfrak{g})$ -modules is

$$K_0(Y_h(\mathfrak{g})\text{-mod}^{\text{fd}}) \simeq K_0(\text{Rep}(\mathfrak{g}))[u],$$

the polynomial extension of the representation ring of $\mathfrak{g}$. The isomorphism sends the class of $V(\lambda)_a$ to $[V(\lambda)] \cdot u^{\deg P_\lambda}$, and the product is the convolution of Drinfeld polynomials.

Remark 27.26.16 (*Generators of the Grothendieck ring*). The Grothendieck ring is generated as a $\mathbb{Z}[u]$ -algebra by the classes $[V(\omega_i)_a]$ ($i = 1, \dots, r, a \in \mathbb{C}$). The Drinfeld polynomial classification (Theorem 27.26.9) establishes the bijection between irreducible classes and r -tuples of monic polynomials. The ring structure reflects the fact that the tensor product of evaluation modules, while not generically irreducible as a $Y_h(\mathfrak{g})$ -module, becomes irreducible in the Grothendieck group.

Remark 27.26.17 (*Relation to the open trace formalism*). The ordered open trace formalism of Theorem 27.9.5 acquires concrete content on the Yangian locus. The diagonal bicomodule C_Δ parametrises the identity line operator; evaluation modules V_a are line operators at position a ; the interval composition $\square_C^{\mathbb{R}}$ is the sequential fusion of line operators along $\mathbb{R}_t$; and the ordered pair-of-pants μ_P is the OPE of line operators at the same holomorphic position. The Grothendieck ring K_0 of the line category is the natural receptacle for the decategorified open trace.

27.27 EXPLICIT R -MATRICES FOR THE STANDARD FAMILIES

The R -matrix is the monodromy of the Kohno connection $\nabla = d - \sum_{i < j} r_{ij}(z_{ij}) dz_{ij}$. For the Yangian $Y(\mathfrak{g})$ of a simple Lie algebra, the rational R -matrix on $V = \mathbb{C}^N$ takes a closed form: the Yang R -matrix for type A , and the Zamolodchikov–Zamolodchikov R -matrix for types B, C, D , and the exceptionals. In every case, the classical limit recovers $r(u) = \Omega/u$ with $\Omega = \sum_a I^a \otimes I_a$ the Casimir tensor. All R -matrices below are derived from the local OPE via Construction 27.4.2; they are *not* independent input.

PROPOSITION 27.27.1 (*Eigenvalue decomposition;*). Let $V \otimes V = \bigoplus_{\lambda} V_{\lambda}$ be the $\mathfrak{g}$ -irreducible decomposition. Then $R(u)|_{V_{\lambda}} = f_{\lambda}(u) \cdot \text{id}_{V_{\lambda}}$ with $f_{\lambda}(u)$ rational, $f_{\lambda}(u) \sim u$ as $u \rightarrow \infty$. For type A , f_{λ} is linear; for types $B/C/D$ and the exceptionals, additional primitive invariants introduce rational corrections.

Proof. The universal R -matrix intertwines the diagonal $\mathfrak{g}$ -action on $V \otimes V$, so each irreducible summand V_{λ} is $R(u)$ -stable. Schur's lemma therefore implies that the restriction of $R(u)$ to V_{λ} is scalar, say $f_{\lambda}(u) \cdot \text{id}_{V_{\lambda}}$. The rationality of f_{λ} comes from the RTT presentation of the Yangian, where $R(u)$ is a rational function of the spectral parameter, and the normalization of the universal R -matrix gives $R(u) = u \cdot \text{id} + O(1)$ as $u \rightarrow \infty$, hence $f_{\lambda}(u) \sim u$. For type A , only the permutation operator appears, so the eigenvalue functions are linear; the other types acquire extra invariant tensors, which produce the stated rational corrections. $\square$

THEOREM 27.27.2 (*Yang R -matrix for $\mathfrak{sl}_N$;*). For all $\mathfrak{sl}_N$, the rational R -matrix on $V = \mathbb{C}^N$ is

$$R(u) = u \cdot \text{id}_{V \otimes V} + P,$$

where $P(v \otimes w) = w \otimes v$ is the permutation. The eigenvalues are $u+1$ on $\text{Sym}^2(\mathbb{C}^N)$ and $u-1$ on $\wedge^2(\mathbb{C}^N)$. In the standard basis of $\mathbb{C}^2 \otimes \mathbb{C}^2$:

$$R(u) = \begin{pmatrix} u+1 & 0 & 0 & 0 \\ 0 & u & 1 & 0 \\ 0 & 1 & u & 0 \\ 0 & 0 & 0 & u+1 \end{pmatrix}.$$

Proof. P has eigenvalue $+1$ on symmetric and -1 on alternating tensors. The YBE holds in $\text{End}(V^{\otimes 3})$ for any V , using only $P_{ij}^2 = \text{id}$ and $P_{12}P_{13}P_{23} = P_{23}P_{13}P_{12}$. The classical limit $r(u) = P/u = \Omega/u$ satisfies the CYBE (27.2). $\square$

Remark 27.27.3 (*Type- A universality*). For $\mathfrak{sl}_N$, the centraliser $\text{End}_{\mathfrak{sl}_N}(V \otimes V)$ is two-dimensional (spanned by id and P), so the R -matrix is linear in u . Types $B/C/D$ and the exceptionals have larger centralisers, necessitating rational corrections.

The orthogonal and symplectic R -matrices for B_2 and C_2 , and the four-projector R -matrix for G_2 , are recorded in Theorem 27.19.4 (equations (27.16)–(27.17)) with full eigenvalue decompositions and proofs.

Remark 27.27.4 (*The universal classical r -matrix*). For every simple $\mathfrak{g}$ and every finite-dimensional V , $r(u) = \Omega/u$ with $\Omega = \sum_a I^a \otimes I_a \in \mathfrak{g} \otimes \mathfrak{g} \hookrightarrow \text{End}(V)^{\otimes 2}$. The CYBE follows from the Jacobi identity: $[\Omega_{12}, \Omega_{13}] + [\Omega_{12}, \Omega_{23}] + [\Omega_{13}, \Omega_{23}] = 0$ is the Jacobi identity in $\mathfrak{g}^{\otimes 3}$. Quantum corrections: type A has none; types $B/C/D$ have one rational correction from the trace/symplectic contraction; the exceptionals have multiple.

27.28 ROSETTA STONE: THE E_1 ORDERED BAR COMPLEX ACROSS THE LANDSCAPE

The ordered bar complex $\overline{B}^{\text{ch,ord}}(A)$ carries two layers of data: the collision residue $r^{\text{coll}}(z)$, which records the chiral differential of the E_1 -chiral coalgebra, and the R -matrix $R(z)$, which governs the

passage from ordered to unordered configurations. The following table collects this data for all standard families.

Every entry is an E_∞ -chiral algebra (a vertex algebra in the sense of Beilinson–Drinfeld: the chiral product is defined on *unordered* configuration spaces with Σ_n -equivariant factorization structure). The ordered bar complex $\overline{B}^{\text{ch,ord}}(A)$ retains the ordering as auxiliary order data; the descent to the symmetric bar $B^\Sigma(A)$ is the strong-unitary R -matrix-twisted quotient of Proposition 27.4. None of the families below is E_1 -chiral in the sense of the E_1 core of Volume II: genuinely E_1 -chiral algebras (nonlocal, ordered configurations as primitive data) are the Etingof–Kazhdan quantum vertex algebras, which lie outside the Beilinson–Drinfeld framework.

THEOREM 27.28.1 (*E_1 ordered bar landscape*;). Let A be a strongly admissible augmented associative chiral algebra from the standard landscape. The ordered bar complex $\overline{B}^{\text{ch,ord}}(A)$ has the following invariants, where $r^{\text{coll}}(z)$ denotes the collision residue (the OPE kernel after the $d \log$ bar propagator absorbs one pole order), $\Omega_{\mathcal{H}} = J \otimes J$ on the rank-one Heisenberg current window, $R(z)$ is the spectral R -matrix on $\text{Conf}_2^{\text{ord}}(\mathbb{C})$, $r_{\max}$ is the shadow depth, $A_{\text{line}}^!$ is the ordered Koszul dual governing the line category, and “formal” means the transferred A_∞ operations m_k vanish on cohomology for all k above the shadow depth:

Family	Class	OPE poles	Collision residue $r^{\text{coll}}(z)$	R -matrix $R(z)$	$r_{\max}$	$A_{\text{line}}^!$	Formal?
$\mathcal{H}_k$	G	2	$k\Omega_{\mathcal{H}}/z$	$e^{k\hbar/z}$	2	$Y(\mathbf{u}(1))^{\dagger}$	yes
V_Λ (even)	G	2	$\text{diag}(\lambda_i)/z$	$\text{diag}(e^{\lambda_i\hbar/z})$	2	$Y(\mathbf{u}(1)^{\oplus \text{rk } \Lambda})^{\dagger}$	yes
$\widehat{\mathfrak{g}}_k$ ($\mathfrak{sl}_2$)	L	2	$k\Omega_{\text{tr}}/z^{\frac{1}{2}}$	$uI + \hbar P$	3	$Y_{\hbar}(\mathfrak{sl}_2)$	yes
$\widehat{\mathfrak{g}}_k$ ($\mathfrak{sl}_3$)	L	2	$k\Omega_{\text{tr}}/z^{\frac{1}{2}}$	Yang (9×9)	3	$Y_{\hbar}(\mathfrak{sl}_3)$	yes
$\widehat{\mathfrak{g}}_k$ (general)	L	2	$k\Omega_{\text{tr}}/z^{\frac{1}{2}}$	Yang ($\dim \mathfrak{g}^2$)	3	$Y_{\hbar}(\mathfrak{g})$	yes
$\beta\gamma$	C	1	o	id (contact: $I + 2\pi i \Theta$)	4	bc	yes
bc	C	1	o	id (contact: $I + 2\pi i \Theta_{bc}$)	4	$\beta\gamma$	yes
Vir_c	M	4	$\frac{c/2}{z^3} + \frac{2T}{z}$	[class M]	∞	$Y^{\text{dg}}(\text{Vir}_c)$	no
$\mathcal{W}_3$	M	6	degree 5 in $1/z$	[class M]	∞	$Y^{\text{dg}}(\mathcal{W}_3)$	no
$\mathcal{W}_N$	M	$2N$	degree $2N-1$ in $1/z$	[class M]	∞	$Y^{\text{dg}}(\mathcal{W}_N)$	no

[†]The Koszul dual algebra $\mathcal{H}_k^! = \text{Sym}^{\text{ch}}(V^*)$ is categorically distinct from $\mathcal{H}_{-k}$ but both have $\kappa = -k$ and the line category $\mathcal{C}_{\text{line}} \simeq \mathcal{H}_{-k}\text{-mod}$ is equivalent. Similarly, $V_\Lambda^!$ and V_Λ^* share the same modular characteristic but differ as chiral algebras.

[‡]The KZ/Yangian normalization of the same affine monodromy datum is $r^{\text{KZ}}(z) = \Omega/((k + \hbar^\vee)z)$.

Proof. The table assembles data from three sources.

OPE pole orders. The maximal OPE pole order on generators is standard: $J(z)J(w) \sim k/(z-w)^2$ for Heisenberg; $J^a(z)J^b(w) \sim k\delta^{ab}/(z-w)^2 + f^{ab}_c J^c/(z-w)$ for affine Kac–Moody;

$\beta(z)\gamma(w) \sim 1/(z-w)$ and $b(z)c(w) \sim 1/(z-w)$ for the free-field systems; $T(z)T(w) \sim (c/2)/(z-w)^4 + 2T/(z-w)^2 + \partial T/(z-w)$ for Virasoro; and $W_s(z)W_s(w)$ has poles up to order $2s$ for the spin- s generator of $\mathcal{W}_N$, giving maximal pole $2N$ at the top spin.

Collision residues. The d log bar kernel absorbs one pole order (the d log absorption principle; see Section 7.1.17): the collision residue $r^{\text{coll}}(z)$ from an OPE pole of order d has pole of order $d-1$. For Heisenberg: double-pole $k/(z-w)^2$ gives $r_{\mathcal{H}}^{\text{coll}} = k\Omega_{\mathcal{H}}/z$, whose rank-one coefficient is k/z . For affine $\widehat{\mathfrak{g}}_k$: the trace-form Casimir $\Omega_{\text{tr}} = \sum_a t^a \otimes t_a$ produces $r^{\text{coll}} = k\Omega_{\text{tr}}/z$; the KZ/Yangian normalization rewrites the same monodromy datum as $\Omega/((k+h^\vee)z)$ with $\Omega = 2h^\vee\Omega_{\text{tr}}$. For $\beta\gamma/bc$: the simple-pole OPE $1/(z-w)$ is absorbed completely, so $r^{\text{coll}} = 0$; the nilpotent operator Θ is a regular contact class, not a pole-valued collision residue. For Virasoro: quartic pole gives $(c/2)/z^3 + 2T/z$ (the $\partial T/(z-w)$ term of the OPE is absorbed completely, producing no pole in the collision residue).

R-matrices. The R -matrix is the monodromy of the connection $\nabla = d - r^{\text{coll}}(z) dz$ on $\text{Conf}_2^{\text{ord}}(\mathbb{C})$. For abelian algebras $(\mathcal{H}_k, V_\Lambda)$: the connection is scalar and $R(z) = \exp(k\hbar/z)$ (Volume II, Corollary ??). For affine $\widehat{\mathfrak{g}}_k$ at $\mathfrak{g} = \mathfrak{sl}_2$: the 4×4 Yang R -matrix $R(u) = uI + P$ (up to normalisation), where P is the permutation and $u = \hbar/z$ is the spectral parameter. For $\beta\gamma/bc$: the collision-residue monodromy is the identity. If the regular contact class Θ is retained as a constant nilpotent transport, $\exp(2\pi i \Theta) = I + 2\pi i \Theta$ because $\Theta^2 = 0$. For class **M**: the triple-pole collision residue produces an R -matrix that is not expressible in closed form as a finite product of elementary functions.

Shadow depth and formality. The shadow depth r_{max} is the highest degree at which the transferred A_∞ operation m_k is non-vanishing on cohomology. Class **G**: $m_{k \geq 3} = 0$ (abelian OPE, clean Lagrangian intersection), so $r_{\text{max}} = 2$ and the A_∞ -chiral structure is formal. Class **L**: $m_3 \neq 0$ from the Lie bracket but $m_{k \geq 4} = 0$ on cohomology (Jacobi closes the obstruction), so $r_{\text{max}} = 3$ and the structure is formal. Class **C**: $m_4 \neq 0$ from the contact term but the tower terminates at $r_{\text{max}} = 4$ by rank-one abelian rigidity, so the structure is formal. Class **M**: $m_k \neq 0$ for all $k \geq 3$ on cohomology (the quartic pole manufactures a propagating obstruction), so $r_{\text{max}} = \infty$ and the A_∞ -chiral structure is *non-formal*.

Ordered Koszul duals. For affine $\widehat{\mathfrak{g}}_k$: under the ordered PBW, completion, and Drinfeld–Kohno comparison hypotheses, the ordered line-operator companion is the Yangian $Y_{\hbar}(\mathfrak{g})$ (Volume II, Theorem ??); this is not a bare identification with the strict symmetric chiral Koszul dual. For Virasoro and $\mathcal{W}_N$: the ordered bar-dual lies on the completed infinite-generator surface; under the Volume II E₁ hypotheses its finite windows are represented by the dg-shifted Yangian Y^{dg} . For $\beta\gamma/bc$: the Koszul duality exchanges statistics ($bc^! = \beta\gamma, \beta\gamma^! = bc$), so the line-side algebra is the dual free-field system.

All entries are chirally Koszul (bar cohomology concentrated), as established by PBW universality (Volume I) and the one-loop exactness criterion (Volume II, Theorem ??). $\square$

Remark 27.28.2 (CY-2 [2]-shift and the $\widetilde{\mathcal{M}}_{2,4}$ anomaly cocycle on the K_3 input). The landscape Theorem 27.28.1 covers the four standard chain-level classes **G/L/C/M** of genus-zero affine input. The K_3 input of Remark 27.17.13 sits off the table because its carrier is a Calabi–Yau surface rather than a curve, and two separate refinements must be installed before the ordered bar complex can be assembled. First, the cohomology of $K_3 \times E$ carries a [2]-shift relative to the curve case: the CoHA inputs $\text{CoHA}_{K_3 \times E}$ sit in the CY-2 derived category $D_{\text{CY-2}}^b(K_3 \times E)$, so the shuffle presentation of the realised positive Hall object acquires a cohomological shift that is invisible on the curve lineage of this chapter. The [2]-shift feeds directly into the degree assignment of the ordered bar complex: each CoHA generator contributes two additional units of cohomological degree, so the shadow depth r_{max} of the K_3 input is shifted by +2 relative to the naive affine reading. Second, the automorphic symmetry acting on the K_3 Fock lattice is not

$\mathcal{M}_{24}$ but the projective $\widetilde{\mathcal{M}}_{24}$ cover induced by the H^3 anomaly cocycle (generalised-Mathieu-moonshine 't Hooft anomaly, Gaberdiel–Persson–Ronellenfisch–Volpato 2013)

$$[\omega] \in H^3(\mathcal{M}_{24}, U(1)) \supseteq \mathbb{Z}/12,$$

and the relevant cocycle $[\omega]$ has order exactly 6 in this cyclic subgroup. The factor-of-6 is the same order that governs the sixfold symmetry of the Igusa form Δ_5 under the Fricke involution of Remark 27.29.6, and the two are related by the standard comparison between anomaly-twisted and untwisted sectors of the $\mathcal{M}_{24}$ -action on the K_3 Fock space. Both refinements lie outside the reach of the landscape table above but are forced on the K_3 /BKM extension; the fourth taxonomic slot of Remark 27.17.13 acquires this double structural input.

Remark 27.28.3 (The $\mathbf{G}/\mathbf{L}/\mathbf{C}/\mathbf{M}$ classification). The four classes are determined by the OPE pole structure on generators:

- (i) Class **G** (Gaussian): double-pole OPE with scalar residues. The bar complex is cogenerated in degree 2, the R -matrix is scalar-valued (abelian braiding), and the Lagrangian self-intersection $\mathfrak{S}_b = L \times_X L$ is clean. Archetype: $\mathcal{H}_k$.
- (ii) Class **L** (Lie): double-pole OPE with non-scalar (Lie-bracket) residues. The Lie bracket creates a transverse intersection defect at codimension 1, but the Jacobi identity kills all higher defects. The R -matrix is the Yang R -matrix: matrix-valued, satisfying the Yang–Baxter equation with spectral parameter. Archetype: $\widehat{\mathfrak{g}}_k$.
- (iii) Class **C** (Contact): simple-pole OPE on generators. The composite-field OPE reaches pole order 3, producing a quartic contact invariant. Rank-one abelian rigidity forces the quintic obstruction to vanish. The pole-valued collision-residue monodromy is the identity; the regular contact transport is a unipotent perturbation of the identity ($\Theta^2 = 0$ forces $R_{\text{contact}} = I + 2\pi i \Theta$). Archetype: $\beta\gamma$.
- (iv) Class **M** (Modular): quartic or higher poles on generators. The R -matrix is not expressible in closed form. The shadow obstruction tower does not terminate: the composite-field exchange generates new obstructions at every degree. Non-formality is visible already at genus 0: infinitely many $\mathcal{A}_\infty$ operations $m_n \neq 0$ on $\widetilde{\mathcal{M}}_{0,n+1}$, driven by the self-referential OPE $T_{(1)}T = 2T$. At genus $g \geq 1$, this infinite cascade interacts with the curvature $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ to produce the genuinely modular content of the tower. Archetype: Vir_c .

Remark 27.28.4 (Formality, non-formality, and the E_1/E_∞ distinction). A critical conceptual point: non-formality *does not* imply E_1 . All ten families in Theorem 27.28.1 are E_∞ -chiral (local vertex algebras with Σ_n -equivariant factorization structure), including the non-formal families Vir_c , $\mathcal{W}_3$, and $\mathcal{W}_N$. Having OPE poles does not break E_∞ ; having non-vanishing higher $\mathcal{A}_\infty$ operations does not break E_∞ . The poles are singularities of a *local* product, and the non-formality measures structural complexity *within* the E_∞ world.

The three-tier picture is:

- (a) *Pole-free commutative*: $R(z) = \tau$ (the Koszul-signed flip). This is the subclass where the chiral product extends across the diagonal without singularities.
- (b) *Vertex algebras with poles* (all families in the table above): $R(z) \neq \tau$, but $R(z)$ is *derived* from the local OPE via analytic continuation. Both (a) and (b) are E_∞ -chiral.
- (c) *Genuinely E_1 -chiral* (Etingof–Kazhdan quantum vertex algebras, Yangians as independent algebras, quantum groups): $R(z) \neq \tau$ and $R(z)$ is *independent input*, not derivable from a local symmetric structure. Only (c) is genuinely E_1 .

Tiers (a) and (b) are both E_∞ . The ordered bar complex is a computational tool for E_∞ -chiral algebras; it does not make them E_1 .

Remark 27.28.5 (Pole escalation: DS reduction transports $\mathbf{L} \rightarrow \mathbf{M}$). Principal Drinfeld–Sokolov reduction sends $V_k(\mathfrak{g}) \mapsto \mathcal{W}_N(\mathfrak{g})$. On the ordered bar complex, this transports class $\mathbf{L}$ to class $\mathbf{M}$: the affine double-pole OPE $J^a(z)J^b(w) \sim k\delta^{ab}/(z-w)^2 + \cdots$ becomes the Virasoro quartic-pole OPE $T(z)T(w) \sim (c/2)/(z-w)^4 + \cdots$ via the Sugawara construction. The shadow depth escalates from $r_{\max} = 3$ (finite, formal) to $r_{\max} = \infty$ (infinite, non-formal). The affine ordered datum and the principal DS reduction land in the Virasoro/W shadow tower. This does not turn the ordinary Drinfeld–Yangian $Y_h(\mathfrak{g})$ into a Yangian of Vir_c . A dg-shifted Virasoro/W object, if used, is a separate ordered derived construction with its own generators and differential.

This pole escalation is the ordered-bar avatar of the *single-line dichotomy* of Volume I: double poles produce a linear (tree-level) bar differential, while quartic poles produce a quadratic (one-loop) bar differential whose iterations generate the infinite tower. The mechanism is the Sugawara pole: $T = \frac{1}{2(k+h^\vee)} \sum_a :J^a J_a:$ is a normally ordered composite, and the OPE of composites escalates pole orders. Theorem 27.30.7 ensures that this pole escalation is compatible with the ordered bar–cobar equivalence.

Remark 27.28.6 ($\mathcal{W}_{1+\infty}$ as a class $\mathbf{M}$ chiral quantum group). The $\mathcal{W}$ -algebra $\mathcal{W}_{1+\infty}[\mathcal{Y}]$ (Schiffmann–Vasserot, Maulik–Okounkov) is a class $\mathbf{M}$ algebra whose Hall origin passes through three typed steps: the Jordan–quiver CoHA is the positive half $Y^+(\widehat{\mathfrak{gl}}_1)$, the Drinfeld double gives the full affine Yangian, and the Miura/vacuum evaluation gives the $\mathcal{W}_{1+\infty}[\mathcal{Y}]$ vertex algebra. This chain provides all three structures of the chiral bialgebra equivalence (Theorem 27.29.3): the R -matrix from the stable-envelope construction, the $\mathcal{A}_\infty$ -structure from the CoHA multiplication (which is E_1 -associative: the preferred direction on short exact sequences gives the ordering), and the chiral coproduct from the Hall comultiplication. The shadow obstruction tower is infinite (class $\mathbf{M}$: the irregular KZ connection has Stokes data), and the ordered chiral homology carries richer data than the symmetric shadow. This is the bridge between Vol I (chiral quantum group equivalence) and Vol III (CoHA as the E_1 -sector of the CY engine).

Remark 27.28.7 (Genuinely E_1 -chiral algebras: ordered $\neq$ symmetric). Every family in the Rosetta stone table above is E_∞ -chiral: the ordered bar complex carries a nontrivial R -matrix, but this R -matrix is derived from the E_∞ -chiral OPE (tier (b) of Definition 1.4.8). The averaging map $\text{av}: \overline{B}^{\text{ord}} \rightarrow \overline{B}^\Sigma$ is a descent map only after the strong-unitary R -twisted Σ_n -datum has been fixed (Proposition 27.4.5(ii)). The descended invariant complex is the Beilinson–Drinfeld symmetric bar. The raw ordered complex may still contain a non-invariant kernel; no quasi-isomorphism is asserted unless that kernel is acyclic. In the pole-free case this reduces to the ordinary Reynolds/coinvariant descent of Proposition 27.4.5(i).

For genuinely E_1 -chiral algebras (tier (c): the Yangian $Y_h(\mathfrak{g})$, Etingof–Kazhdan quantum vertex algebras), there is no symmetric bar without extra descent data. The R -matrix is independent input, the factorisation $\mathcal{D}$ -module $\mathcal{F}_n^{\text{ord}}$ is not automatically Σ_n -equivariant, and the ordered theory retains braid-monodromic data. In KZ-type examples the first associator class $\Phi_{\text{KZ}} \in \exp(\hat{\mathfrak{t}}_3)$ occurs at three points and carries GRT_1 -dependent information; a chosen symmetric descent projects to the invariant shadow and forgets the non-invariant representative. The Yangian evaluation surface is therefore a first test case for genuinely ordered data, not a proof that all ordered kernels are nonzero in every degree.

27.29 THE CHIRAL BIALGEBRA EQUIVALENCE ON THE ORDERED KOSZUL LOCUS

The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ is a single object from which three readouts are recovered, after a Drinfeld associator and an R -twisted descent gauge have been fixed: the vertex R -matrix

$S(z)$ (regularised KZ holonomy of the pole-valued collision residue, together with the regular contact class in class **C**), the chiral A_∞ -structure maps m_k^{ch} (higher associativity from boundary strata of associahedra), and the chiral coproduct Δ^{ch} (coalgebra data from deconcatenation transported through the bar–cobar counit). Without these fixed gauges, the ordered bar determines a braid-monodromic local system, not a symmetric chiral bialgebra structure.

Definition 27.29.1 (E₁-chiral algebra with compatible chiral coproduct). An E₁-chiral algebra with compatible chiral coproduct is a triple $(\mathcal{A}, Y, \Delta^{\text{ch}})$ where $(\mathcal{A}, Y)$ is a chiral algebra and

$$\Delta^{\text{ch}}: \mathcal{A} \longrightarrow (\mathcal{A} \hat{\otimes} \mathcal{A})((z))$$

is a chiral coproduct satisfying:

- (i) (Coassociativity up to associator.) The two iterated coproducts agree up to conjugation by the Drinfeld associator Φ :

$$(\Delta^{\text{ch}} \otimes \text{id}) \circ \Delta^{\text{ch}} = \Phi \cdot (\text{id} \otimes \Delta^{\text{ch}}) \circ \Delta^{\text{ch}} \cdot \Phi^{-1}.$$

- (ii) (OPE compatibility.) The coproduct intertwines the vertex operation, as in equation (27.28).

- (iii) (Counit.) There exists a counit $\varepsilon: \mathcal{A} \rightarrow \mathbb{C}$ with $(\varepsilon \otimes \text{id}) \circ \Delta^{\text{ch}} = \text{id} = (\text{id} \otimes \varepsilon) \circ \Delta^{\text{ch}}$.

The associated vertex R -matrix is recovered from the coproduct by equation (27.30).

Definition 27.29.2 (Ordered Koszul locus;). Let $\text{ChirAlg}_X^{\text{E}_1, \text{ft}, \text{aug}}$ denote the chosen finite-type augmented presentation of E₁-chiral algebras on X . The *ordered Koszul locus*

$$\text{Kosz}_{\text{E}_1}^{\text{ord}}(X) \subset \text{ChirAlg}_X^{\text{E}_1, \text{ft}, \text{aug}}$$

is the full subcategory of those $\mathcal{A}$ for which the ordered bar–cobar counit

$$\epsilon_{\mathcal{A}}^{\text{ord}}: \Omega(\overline{B}^{\text{ord}}(\mathcal{A})) \longrightarrow \mathcal{A}$$

is a quasi-isomorphism in the chosen complete E₁-chiral category. This is the ordered condition used in this section. It is not the symmetric Koszul locus $\text{Kosz}(X)$ of Definition 3.1.7, whose bar object is the $\Sigma_\bullet$ -equivariant Ran bar. If an E_∞-chiral algebra lies in $\text{Kosz}(X)$ and the ordered forgetful presentation preserves the bar–cobar counit, then its ordered underlying E₁-chiral algebra lies in $\text{Kosz}_{\text{E}_1}^{\text{ord}}(X)$; genuinely E₁-chiral inputs must satisfy the ordered counit condition directly.

THEOREM 27.29.3 (Chiral bialgebra equivalence on the ordered Koszul locus). Let $\mathcal{A}$ be a finite-type strongly admissible E₁-chiral algebra on the ordered Koszul locus $\text{Kosz}_{\text{E}_1}^{\text{ord}}(X)$. Fix a Drinfeld associator $\Phi \in \exp(\hat{\mathfrak{t}}_3)$ and a strong-unitary R -twisted descent datum as in Proposition 27.4.3. Then the following three compatible structures are equivalent descriptions of the same ordered bar coalgebra:

- (I) E₁-chiral algebra with vertex R -matrix $S(z)$ satisfying S -locality, the quantum Yang–Baxter equation, unitarity, shift condition, and hexagon axiom (the Etingof–Kazhdan axioms);
- (II) A_∞ -algebra in the chiral endomorphism operad $\text{End}_{\mathcal{A}}^{\text{ch}}$, with structure maps $m_k^{\text{ch}}: \mathcal{A}^{\otimes k} \rightarrow \mathcal{A}((\lambda_1)) \cdots ((\lambda_{k-1}))$ satisfying the Stasheff identities;
- (III) E₁-chiral algebra with compatible chiral coproduct $\Delta^{\text{ch}}: \mathcal{A} \rightarrow (\mathcal{A} \hat{\otimes} \mathcal{A})((z))$, coassociative up to conjugation by Φ .

The equivalences form a triangle:

$$\begin{array}{ccc}
 \text{(I)} & \xrightleftharpoons[\alpha^{-1}]{\alpha} & \text{(II)} \\
 & \searrow \gamma \quad \swarrow \beta^{-1} & \\
 & \text{(III)} &
 \end{array}$$

where α restricts the OPE to the real Stasheff associahedra $K_n \hookrightarrow \overline{\text{FM}}_n^{\text{ord}}(\mathbb{C})$, β applies the cobar functor to the deconcatenation coproduct on $\overline{B}^{\text{ord}}(\mathcal{A})$, and γ extracts the R -matrix as $S(z) = \sigma \circ \Delta^{\text{ch}} \circ (\Delta^{\text{ch,op}})^{-1}$ (the chiral Drinfeld formula). The statement is an ordered Koszul-locus statement: the ordered bar-cobar counit $\Omega(\overline{B}^{\text{ord}}(\mathcal{A})) \rightarrow \mathcal{A}$ and the chosen associator/descent gauges are part of the data.

Proof. **(I) $\rightarrow$ (II).** The Stasheff associahedron K_n is isomorphic to the real FM compactification $\overline{\text{FM}}_n^{\text{ord}}(\mathbb{R})$ (Sinha). The chiral A_∞ -maps are the integrals

$$m_k^{\text{ch}}(a_1, \dots, a_k) = \int_{K_k} Y(a_1, z_1) \cdots Y(a_k, z_k) \omega_k,$$

where ω_k is the canonical volume form induced by the bar propagator. The Stasheff identity follows from Stokes' theorem on K_{n+1} : the codimension-1 boundary decomposes into facets $K_{r+1} \times K_{s+1}$ recording consecutive collisions, and $\int_{K_{n+1}} d\omega = 0$ yields $\sum (-1)^e m_i^{\text{ch}} \circ_p m_j^{\text{ch}} = 0$. The inverse α^{-1} recovers $S(z)$ as the degree-2 KZ holonomy.

(II) $\rightarrow$ (III). The A_∞ -maps determine the bar differential $d_{\overline{B}^{\text{ord}}} = \sum_{k \geq 1} \hat{m}_k^{\text{ch}}$ (coderivation extension). The deconcatenation coproduct Δ on $T^c(s^{-1}\vec{\mathcal{A}})$ is a dg coalgebra map; applying the cobar functor Ω to Δ produces the chiral coproduct Δ^{ch} on $\mathcal{A}$ via $\mathcal{A} \simeq \Omega(\overline{B}^{\text{ord}}(\mathcal{A}))$ (the ordered Koszul-locus condition of Definition 27.29.2). Strict coassociativity of deconcatenation becomes coassociativity-up-to- Φ after passage through the formality quasi-isomorphism underlying Ω . The inverse β^{-1} reads off m_k^{ch} as the tensor-degree- k component of $d_{\overline{B}^{\text{ord}}}$.

(III) $\rightarrow$ (I). The chiral Drinfeld formula $S(z) = \sigma \circ \Delta^{\text{ch}} \circ (\Delta^{\text{ch,op}})^{-1}$ defines the vertex R -matrix once the Drinfeld–Kohno or Etingof–Kazhdan quantization datum has been supplied: source Lie bialgebra, $\hbar$ -adic/pro-nilpotent topology, associator, and QUE/quasi-Hopf target. The pentagon for Φ gives the braid coherence; the QYBE is the hexagon consequence for the induced braiding. Coassociativity alone recovers the classical CYBE at the infinitesimal residue level and does not quantize it. $\square$

Remark 27.29.4 (Bialgebra, not Hopf: the antipode does not lift). The equivalence of Theorem 27.29.3 produces three compatible descriptions of a *chiral bialgebra*: R -matrix, chiral A_∞ -algebra, and chiral coproduct with counit. It does not produce an antipode. The classical formula $S(T(u)) = T(u)^{-1}$ does not lift to a vertex-algebraic map on the spectral parameter; the precise content is Proposition 27.29.19, which exhibits two independent structural obstructions. The first is an OPE-locality obstruction: the quartic pole of $S(T)$ with itself agrees with the Virasoro value $c/2$ only at the two isolated points $\Psi \in \{1, 2\}$. The second is a Hopf-axiom obstruction: the residual of $m_z \circ (S \otimes \text{id}) \circ \Delta_z$ on T contains a term $z \cdot J$ that survives at every value of Ψ , reflecting the z -dependence of the spectral coproduct. The two obstructions vanish on disjoint loci (OPE on $\Psi \in \{1, 2\}$, Hopf nowhere), so they are not two symptoms of a single defect but two genuinely independent structural failures. We therefore reserve the

name “chiral bialgebra equivalence” for this statement; the phrase “chiral quantum group” continues to denote the underlying structural package, with the understanding that no Hopf antipode exists at the vertex-algebraic level.

Remark 27.29.5 (Associator class: cohomological vs. cochain canonicity). The choice of Drinfeld associator $\Phi \in \exp(\hat{\mathfrak{t}}_3)$ is not canonical: the group $\text{GRT}_1(\mathbb{Q})$ acts transitively on the set of admissible associators, so Theorem 27.29.3 produces a $\text{GRT}_1(\mathbb{Q})$ -torsor of equivalences rather than a single canonical one. The invariant actually used below is narrower: for the verified $\mathfrak{sl}_2$ and affine Kac–Moody checks, the bar-side H° shadow (κ , the shadow tower, and the cohomology class of the ordered Maurer–Cartan datum) is unchanged after replacing Φ by a $\text{GRT}_1(\mathbb{Q})$ -transport. For a general simple $\mathfrak{g}$ this associator-independence is a comparison hypothesis in the ordered Koszul/descent package, not a formal consequence of the GRT_1 action. It does not prove GRT_1 -triviality of categorical modular data, the Drinfeld centre, the line category, or any root-of-unity BKM S -matrix. At the cochain level, different associator representatives produce coproducts related by the supplied gauge transformation inside the chosen descent datum; the representatives are homotopic in that datum but are not equal. The statement of Theorem 27.29.3 is therefore canonical only after passing to the specified H° bar-shadow quotient and remains non-canonical up to $\text{GRT}_1(\mathbb{Q})$ at the cochain/coproduct level. Throughout the chapter a stronger chain-level claim requires fixing a specific associator class.

Remark 27.29.6 (Automorphic normalization and the compact Hall recognition problem; Open). The established automorphic input is the Borcherds product normalisation. In theta normalisation the weight-5 form Δ_5 has leading coefficient 64; the monic product is $D_5 = 64^{-1}\Delta_5$, and

$$\Phi_{10}^{\text{un}} = \Delta_5^2, \quad \Phi_{10}^{\text{OP}} = D_5^2 = 4096^{-1}\Delta_5^2.$$

The coefficient 64 and its square are checked, in this convention, by `igusa-cusp-form/compute/verify_square_root.py` and `calabi-yau-quantum-groups/compute/lib/borcherds_denominator_phi10_engine.py`; they establish the scalar automorphic face.

The compact Hall statement requires a separately defined deformation complex for the completed Hall–Drinfeld double, together with the Fricke action, orientation data, and a comparison map from its cohomology to the Borcherds-product line. The recognition target is a one-dimensional image generated by Δ_5 . Establishing that target, its injectivity range, and its relation to the Mukai integer $2c_+ = 8$ is an open theorem obligation. This formulation keeps the automorphic denominator, the Hall object, and the chiral conductor as three typed layers joined by explicit comparison maps.

COROLLARY 27.29.7 (*The ordered bar encodes all three structures*). The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$, together with the chosen associator and strong-unitary descent gauge of Theorem 27.29.3, is the universal chain-level datum: the vertex R -matrix is the regularised holonomy of the degree-2 KZ-normalized collision datum $r^{\text{KZ}}(z)$ (and, in class **C**, of the regular contact operator left after the pole-valued residue vanishes), the A_∞ -maps are the bar differential components $d_{\overline{B}}|_{\text{degree } k}$, and the chiral coproduct is the cobar-dual of the deconcatenation. No additional operation on $\mathcal{A}$ is needed; without the associator/descent gauge the same bar coalgebra determines only the ordered braid-monodromic object.

Proof. Theorem 27.29.3 provides three readouts of the same ordered bar coalgebra. Arrow α identifies the degree-2 KZ-normalized collision datum, after regularised holonomy and the chosen descent gauge, with the vertex R -matrix. Arrow β identifies the higher components of the bar differential with the

transferred A_∞ operations. Arrow γ identifies the deconcatenation coproduct, after cobar dualization, with the chiral coproduct. Since these are all functorial projections of $\overline{B}^{\text{ord}}(\mathcal{A})$ once the associator and descent gauge have been fixed, no further product or coproduct on $\mathcal{A}$ is required. $\square$

Remark 27.29.8 (Key formulas of the equivalence). The three equivalences involve the following explicit formulas. The OPE compatibility axiom:

$$\Delta^{\text{ch}}(Y(a, z) b) = Y^{(2)}(\Delta^{\text{ch}}(a), z) \cdot \Delta^{\text{ch}}(b), \quad (27.28)$$

where $Y^{(2)}$ is the tensorwise vertex operation. The coproduct from the bar complex:

$$\Delta^{\text{ch}}: \mathcal{A} \simeq \Omega(\overline{B}^{\text{ord}}(\mathcal{A})) \xrightarrow{\Omega(\Delta)} \Omega(\overline{B}^{\text{ord}}(\mathcal{A}) \otimes \overline{B}^{\text{ord}}(\mathcal{A})) \rightarrow (\mathcal{A} \hat{\otimes} \mathcal{A})((z)). \quad (27.29)$$

The R -matrix from the coproduct (the chiral Drinfeld formula):

$$S(z) := \sigma \circ \Delta^{\text{ch}} \circ (\Delta^{\text{ch,op}})^{-1}. \quad (27.30)$$

Example 27.29.9 (Etingof–Kazhdan quantum VOA as a chiral bialgebra). QYBE, unitarity, shift, hexagon. The quantum Yang–Baxter equation on $V_{\text{EK}}^{\otimes 3}$ reduces on $V^{\otimes 3}$ to (27.50), as in the classical Yangian case; the extension to V_{EK} follows from the universal property of $\mathcal{R}(z)$. Unitarity $S_{12}(z) \cdot (\sigma \circ S_{12}(-z) \circ \sigma) = \text{id}$ follows from Drinfeld–Jimbo unitarity. The shift condition

$$[D \otimes \text{id} + \text{id} \otimes D, S(z)] = \partial_z S(z)$$

follows from the translation-covariance of the Drinfeld coproduct. The hexagon follows from the pentagon relation for Φ (from the Stasheff boundary of $\overline{\text{FM}}_4^{\text{ord}}(\mathbb{C}) = K_4$) combined with the QYBE for S , by the standard argument of Drinfeld [EK96] lifted to the vertex-algebraic setting.

Part B: the ordered chiral center of the EK quantum VOA. We compute the ordered chiral Hochschild cohomology $\text{HH}_{\text{ch}}^{*, \text{ord}}(V_{\text{EK}}, V_{\text{EK}})$ at low degrees on the formal disk D , paralleling the classical Yangian computation but now using the *full* vertex R -matrix $S(z)$ rather than the Yang R -matrix on $V \otimes V$ alone.

Degree 2: the KZ connection with the full vertex R -matrix. At degree 2, the KZ connection on $C_2^{\text{ord}}(\mathbb{C})$ with coefficients in $\text{End}(V_{\text{EK}}^{\otimes 2})$ is

$$\nabla_{\text{KZ}}^S = d + \frac{\hbar \Omega}{z} dz + \frac{\hbar^2}{z^2} \left(\Omega^{(2)} + \frac{1}{2} \Omega^2 \right) dz + O(z^{-3}), \quad (27.31)$$

where $z = z_1 - z_2$. The connection (27.31) is obtained from $S(z)$ via the general formula $\nabla = d + (\partial_z \log S(z)) dz$ (logarithmic derivative of the vertex R -matrix).

For the classical $V_k(\mathfrak{sl}_2)$ (trivial braiding $S(z) = \text{id}$), the flat sections are $\Phi(z) = z^{\Omega/(k+2)}$ with algebraic monodromy. For the EK quantum VOA ($S(z) \neq \text{id}$), the flat sections acquire quantum corrections:

$$\Phi^S(z) = z^{\hbar \Omega} \left(I + \frac{\hbar^2 \Omega^{(2)}}{z} + O(z^{-2}) \right).$$

The kernel $\ker(\text{av})$. The ordered chiral centre computation parallels the classical Yangian case; the result is identical on cohomology. On $V \otimes V$: $\ker(\text{av}_2)|_{V \otimes V} \cong \wedge^2 V = \mathbb{C}$, the same one-dimensional space as in that classical computation. The quantum corrections from $S(z)$ shift the subleading terms

of the flat sections but do not alter the $\ker(\text{av}_2)$ dimension. The scalar shadow surviving av_2 is $\kappa = 3(k+2)/4$ (equation (??)), identical to the classical value. At degree 3, the kernel $\ker(\text{av}_3) \cong \Lambda^3(\mathfrak{g}) = \mathbb{C}$ carries the quantum-corrected Drinfeld associator

$$\Phi_{\text{KZ}}^S - 1 = \hbar^2 \zeta(2) [\Omega_{12}, \Omega_{23}] + O(\hbar^3),$$

whose leading term agrees with the classical KZ associator.

Part C: S -locality as an A_∞ relation. The braided VOA axioms of the EK quantum VOA are equivalent to the chiral A_∞ relations for V_{EK} through the chiral bialgebra equivalence (Theorem 27.29.3, (I) $\Leftrightarrow$ (II)). In the ordered bar complex $\overline{B}^{\text{ord}}(V_{\text{EK}}) = T^c(\mathcal{S}^{-1}\overline{V}_{\text{EK}})$, the S -locality axiom (??) governs the reordering of two insertions: the braid group $\pi_1(C_2^{\text{ord}}(\mathbb{C})) = \mathbb{Z}$ acts on degree-2 bar chains by $\sigma_1 \cdot [a|b] = S(z) \cdot [b|a]$. The S -locality axiom is the $n = 2$ Stasheff relation, the hexagon is the $n = 3$ relation, and the QYBE is the $n = 4$ relation (from the pentagon for Φ on $K_4 = \overline{\text{FM}}_4^{\text{ord}}(\mathbb{R})$).

Summary. The EK quantum VOA $(V_{\text{EK}}, Y, S(z))$ provides the first concrete instance of all three structures of the chiral bialgebra equivalence (Theorem 27.29.3) exhibited simultaneously on a single algebra satisfying all axioms. The ordered chiral center carries the full quantum R -matrix $S(z)$, together with the classical r -matrix $r^{\text{KZ}}(z) = \Omega/((k + \hbar^\vee)z)$, and the kernel $\ker(\text{av}_2) \neq 0$ demonstrates that the ordered theory is strictly richer than the symmetric Beilinson–Drinfeld chiral homology even at the quantum level.

Example 27.29.10 (Heisenberg: trivial case). For the Heisenberg algebra $\mathcal{H}_k$ (class G), all three structures are trivial: $S(z) = \text{id}$ (the braiding is symmetric); $m_k^{\text{ch}} = 0$ for $k \geq 3$ (the algebra is strictly associative in the chiral sense); $\Delta^{\text{ch}}(J) = J \otimes 1 + 1 \otimes J$ is cocommutative and strictly coassociative (Φ acts trivially). The ordered and symmetric data coincide.

THEOREM 27.29.11 ($\mathcal{W}_{1+\infty}[\Psi]$ as a chiral quantum group). In its completed positive-energy/Yangian presentation, the algebra $\mathcal{W}_{1+\infty}[\Psi]$ carries a chiral quantum group datum in the sense of Theorem 27.29.3: an R -matrix, a chiral coproduct, and an A_∞ structure, all explicit and obtained from the Jordan-quiver CoHA only after the positive-half and double/evaluation arrows are crossed:

$$\mathcal{H}_{\text{Jor}} \cong Y^+(\widehat{\mathfrak{gl}}_1) \hookrightarrow D(\mathcal{H}_{\text{Jor}}) \cong Y(\widehat{\mathfrak{gl}}_1) \longrightarrow U(\mathcal{W}_{1+\infty}[\Psi]).$$

The CoHA itself is the positive half, not $\mathcal{W}_{1+\infty}$. The raw direct-sum class $\mathbf{M}$ bar complex is not the ambient of this theorem. The precise content is as follows.

- (I) (R -matrix.) The Maulik–Okounkov R -matrix [M019] of quantum toroidal $\mathfrak{gl}_1$, restricted to the positive-half CoHA, is *scalar*:

$$R(z) = g(z) = \frac{(z - h_1)(z - h_2)(z - h_3)}{(z + h_1)(z + h_2)(z + h_3)}, \quad h_1 + h_2 + h_3 = 0, \quad (27.32)$$

where h_1, h_2, h_3 are the equivariant parameters of $\mathbb{C}^3$ subject to the Calabi–Yau constraint. The classical limit is $r(z) = \Psi/z$ (class G , level prefix Ψ).

- (II) (Chiral coproduct at all spins.) The Drinfeld coproduct on $Y(\widehat{\mathfrak{gl}}_1)$ gives an explicit spectral coproduct $\Delta_z: \mathcal{W}_{1+\infty}[\Psi] \rightarrow (\mathcal{W}_{1+\infty}[\Psi] \hat{\otimes} \mathcal{W}_{1+\infty}[\Psi])((z))$ satisfying strict coassociativity, the spectral counit, and OPE compatibility at all spins. The transfer matrix $T(u) = 1 + \sum_{n \geq 1} \psi_n u^{-n}$ is scalar ($\mathfrak{gl}_1$ has rank 1), and

$$\Delta_z(T(u)) = T(u) \otimes T(u - z). \quad (27.33)$$

The general spin- n formula is

$$\Delta_z(\psi_n) = \psi_n \otimes 1 + \sum_{k=0}^{n-1} \sum_{m=1}^{n-k} \binom{n-k-1}{m-1} z^{n-k-m} \psi_k \otimes \psi_m, \quad (27.34)$$

where $\psi_0 = 1$.

(III) (A_∞ structure.) The chiral A_∞ -operations m_k^{ch} are extracted from the ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{W}_{1+\infty}) = T^c(\mathcal{S}^{-1}\overline{\mathcal{W}}_{1+\infty})$ via the functor α of Theorem 27.29.3, with input the R -matrix (27.32).

With this R -matrix and the fixed associator/descent gauge, Theorem 27.29.3 identifies the three structures as the same ordered-bar datum on the ordered Koszul locus. The OPE compatibility axiom (27.28) is satisfied at all spins simultaneously by the coderivation property on the completed ordered Koszul-locus bar complex and, on the positive-half CoHA comparison surface, by the JKL vertex bialgebra theorem.

Proof. The argument proceeds in seven steps.

Step 1 (CoHA identification; Schiffmann–Vasserot [?SV13], Schiffmann–Mellit–Minets–Vasserot [?SMMV23]). The critical CoHA of the Jordan quiver is

$$\mathcal{H}_{\text{Jor}} = \bigoplus_{n \geq 0} H_{\text{BM},*}^{GL_n}(\mathcal{M}_n^{\text{nil}}, \varphi_W), \quad W = \text{Tr}(x[y, z]),$$

where $\mathcal{M}_n^{\text{nil}}$ is the nilpotent locus in the representation variety of the Jordan quiver and φ_W denotes the vanishing-cycle twist. Schiffmann–Vasserot [?SV13] proved $\mathcal{H}_{\text{Jor}} \cong Y^+(\widehat{\mathfrak{gl}}_1)$ by matching generators and relations. This is the positive half only; the $\mathcal{W}_{1+\infty}$ vertex algebra appears after Drinfeld doubling and Miura/vacuum evaluation. The critical refinement is [?SMMV23]. Kontsevich–Soibelman [?KS11] established the general CoHA framework (see also Joyce [?Joyce18]).

Step 2 (Bialgebra and Drinfeld double; Yang–Zhao [?YZ18a]). The CoHA carries a bialgebra coproduct $\Delta_{\text{CoHA}}: \mathcal{H}_{\text{Jor}} \rightarrow \mathcal{H}_{\text{Jor}} \otimes \mathcal{H}_{\text{Jor}}$ from restriction to Levi subalgebras $GL_{n_1} \times GL_{n_2} \hookrightarrow GL_n$. Yang–Zhao proved that the Drinfeld double is the full affine Yangian: $D(\mathcal{H}_{\text{Jor}}) \cong Y(\widehat{\mathfrak{gl}}_1)$.

Step 3 (Yangian– $\mathcal{W}$ -algebra identification; Procházka–Rapčák [?PR19]). The quantum Miura transform gives an isomorphism of filtered associative algebras

$$Y(\widehat{\mathfrak{gl}}_1) \cong U(\mathcal{W}_{1+\infty}[\Psi]),$$

intertwining the Yangian filtration with the conformal filtration. The ψ -generators map to $\mathcal{W}_{1+\infty}$ fields via a triangular change of basis: $\psi_1 = J$, $\psi_n = W_n + P_n(J, W_2, \dots, W_{n-1})$ for $n \geq 2$, where $W_2 = T$ (stress tensor), $W_3 = W$ (spin-3 current), and P_n is a nonlinear polynomial in lower-spin fields with coefficients depending on Ψ .

Step 4 (Drinfeld coproduct at all spins). The transfer matrix $T(u) = 1 + \sum_{n \geq 1} \psi_n u^{-n}$ is a scalar formal power series in u^{-1} ($\widehat{\mathfrak{gl}}_1$ has rank 1). The Drinfeld coproduct (27.33) is the product of two such series. The expansion (27.34) follows from $(u-z)^{-m} = u^{-m} \sum_{j \geq 0} \binom{m+j-1}{j} (z/u)^j$ applied to $T(u) \otimes T(u-z)$

and collecting the coefficient of u^{-n} , giving the spin-1, 2, and 3 expansions displayed below. Through spin 3:

$$\begin{aligned}\Delta_z(\psi_1) &= \psi_1 \otimes 1 + 1 \otimes \psi_1, \\ \Delta_z(\psi_2) &= \psi_2 \otimes 1 + 1 \otimes \psi_2 + \psi_1 \otimes \psi_1 + z(1 \otimes \psi_1), \\ \Delta_z(\psi_3) &= \psi_3 \otimes 1 + 1 \otimes \psi_3 + \psi_1 \otimes \psi_2 + \psi_2 \otimes \psi_1 \\ &\quad + z(\psi_1 \otimes \psi_1 + 2 \cdot 1 \otimes \psi_2) + z^2(1 \otimes \psi_1).\end{aligned}$$

In the $\mathcal{W}_{1+\infty}$ field basis (via the Miura substitution $\psi_1 = J$, $\psi_2 = T + J^2/(2\Psi)$ of step 3):

$$\begin{aligned}\Delta_z(J) &= J \otimes 1 + 1 \otimes J, \\ \Delta_z(T) &= T \otimes 1 + 1 \otimes T + \frac{\Psi-1}{\Psi} J \otimes J + z(1 \otimes J).\end{aligned}\tag{27.35}$$

The coefficient $(\Psi - 1)/\Psi$ in (27.35) arises from the Miura inversion $T = \psi_2 - J^2/(2\Psi)$: the $\psi_1 \otimes \psi_1$ cross-term in $\Delta_z(\psi_2)$ has coefficient 1, and subtracting $(1/(2\Psi)) \Delta_z(J)^2 = (J^2/(2\Psi)) \otimes 1 + (1/\Psi) J \otimes J + 1 \otimes J^2/(2\Psi)$ replaces the coefficient by $1 - 1/\Psi = (\Psi - 1)/\Psi$. At $\Psi = 1$ (free boson) the cross-term vanishes; in the classical limit $\Psi \rightarrow \infty$ it tends to 1. The Heisenberg OPE $J(z)J(w) \sim \Psi/(z-w)^2$ gives $r(z) = \Psi/z$ (class G , level prefix Ψ). The general formula (27.34) gives $\Delta_z(\psi_n)$ at every spin in closed form; the coproduct on the $\mathcal{W}_{1+\infty}$ field basis $\{J, T, W, W_4, \dots\}$ is obtained by inverting the Miura transform, and the computation is triangular and algorithmic at each spin.

Step 5 (R -matrix from Maulik–Okounkov; vertex bialgebra structure; Maulik–Okounkov [?M019], Jindal–Kaubrys–Latyntsev [?JKL26]). The critical CoHA of any quiver with potential carries a vertex coproduct forming a vertex bialgebra ([?JKL26], Theorems A and C). The R -matrix is

$$R(z) = \frac{\Psi(\sigma^* \text{Ext}^\vee, z)}{\Psi(\text{Ext}, z)},$$

where Ψ on the right denotes the motivic exponential and Ext is the Ext^1 -bundle on the stack of quiver representations. The Maulik–Okounkov R -matrix [?M019] restricted to the CoHA gives $R_{\text{CoHA}} = q^{\alpha \cdot \beta}$ ($q = e^{\pi i \Psi}$) with classical limit $r(z) = \Psi/z$.

Step 6 (OPE compatibility at all spins: two independent arguments). The vertex bialgebra axiom (27.28) requires $\Delta_z(Y(a, w)b) = Y^{(2)}(\Delta_z(a), w) \Delta_z(b)$ as an identity of vertex operators. This is stronger than an identity in the underlying associative algebra. We give two independent proofs that this holds at all spins simultaneously.

Argument A (coderivation on the ordered Koszul locus). The algebra $\mathcal{W}_{1+\infty}[\Psi]$ at generic Ψ lies on the ordered Koszul locus (Definition 27.29.2: the bar-cobar adjunction $\Omega(\overline{B}^{\text{ord}}(\mathcal{W}_{1+\infty}[\Psi])) \xrightarrow{\sim} \mathcal{W}_{1+\infty}[\Psi]$ is an equivalence). By the direction (II) $\rightarrow$ (III) of Theorem 27.29.3, the bar construction produces a chiral coproduct on $\mathcal{W}_{1+\infty}[\Psi]$ from the deconcatenation coproduct Δ on $\overline{B}^{\text{ord}}(\mathcal{W}_{1+\infty}[\Psi]) = T^c(s^{-1}\overline{\mathcal{W}}_{1+\infty}[\Psi])$ via the cobar dualization (27.29). The bar differential $d_{\overline{B}^{\text{ord}}}$ is a coderivation with respect to Δ :

$$\Delta \circ d_{\overline{B}^{\text{ord}}} = (d_{\overline{B}^{\text{ord}}} \otimes \text{id} + \text{id} \otimes d_{\overline{B}^{\text{ord}}}) \circ \Delta.\tag{27.36}$$

This identity holds at *all arities simultaneously* as a structural property of the cofree tensor coalgebra. Under the cobar functor Ω , the coderivation property (27.36) dualizes to the OPE compatibility axiom (27.28): the bar differential encodes the vertex operation $Y(a, w)$, and the deconcatenation encodes the coproduct Δ_z (see the proof of Theorem 27.29.3, direction (II) $\rightarrow$ (III)).

It remains to identify this bar-cobar coproduct with the Drinfeld coproduct of step 4. The bar-cobar coproduct is determined by the vertex algebra structure of $\mathcal{W}_{1+\infty}[\Psi]$; the Drinfeld coproduct is determined by the generating-series formula (27.33). Both satisfy coassociativity and the counit axiom. On the ordered Koszul locus, the coproduct compatible with a given vertex R -matrix is unique (Theorem 27.29.3: the functors α, β, γ form an equivalence triangle). The bar-cobar coproduct is compatible with the Maulik–Okounkov R -matrix (by construction via α and γ^{-1}). The Drinfeld coproduct is compatible with the same R -matrix (the Yangian R -matrix of step 5 restricts to the MO R -matrix). By uniqueness, the two coproducts coincide. Therefore the Drinfeld coproduct satisfies OPE compatibility at all spins.

Argument B (JKL vertex bialgebra on the CoHA). Jindal–Kaubrys–Latyntsev [JKL26] construct a vertex coproduct on the critical CoHA of any quiver with potential, satisfying the vertex bialgebra axiom (27.28) (their Theorems A and C). For the Jordan quiver, the CoHA is $\mathcal{H}_{\text{Jor}} \cong Y^+(\widehat{\mathfrak{gl}}_1)$ (step 1), and the JKL vertex coproduct recovers the Drinfeld coproduct on the Yangian (their Theorem B). Since the JKL vertex bialgebra axiom is exactly the OPE compatibility axiom (27.28), this gives a second proof at all spins simultaneously.

RTT triviality (corroboration, not proof). For $\mathfrak{gl}_1$, the Maulik–Okounkov R -matrix is scalar: $R(z) = g(z)$ of (27.32). The RTT relation

$$R(u - v) T_1(u) T_2(v) = T_2(v) T_1(u) R(u - v) \quad (27.37)$$

is trivially satisfied because a scalar commutes through all operators. This confirms that the Drinfeld coproduct is compatible with the R -matrix at the *associative algebra* level; arguments A and B upgrade this to the full vertex algebra compatibility. For $Y(\widehat{\mathfrak{gl}}_N)$ with $N \geq 2$, the R -matrix is no longer scalar, and OPE compatibility at each truncation is a separate question (Remark 27.29.18).

Step 7 (Full axiom check). The spectral coproduct (27.33) satisfies all axioms of Definition 27.29.1:

- (a) *Strict coassociativity.* $(\Delta_{z_1} \otimes \text{id}) \circ \Delta_{z_2}(T(u)) = T(u) \otimes T(u - z_2) \otimes T(u - z_1 - z_2)$ and $(\text{id} \otimes \Delta_{z_2}) \circ \Delta_{z_1}(T(u)) = T(u) \otimes T(u - z_1) \otimes T(u - z_1 - z_2)$. For $\mathfrak{gl}_1$ the Drinfeld associator acts trivially (the algebra is abelian), so Δ_z is *strictly* coassociative.
- (b) *Counit.* $\varepsilon(\psi_n) = 0$ for $n \geq 1$, $\varepsilon(1) = 1$ gives $(\varepsilon \otimes \text{id}) \circ \Delta_z(T(u)) = T(u - z)$ and $(\text{id} \otimes \varepsilon) \circ \Delta_z(T(u)) = T(u)$.
- (c) *OPE compatibility at all spins.* By step 6: the coderivation property on the bar complex of $\mathcal{W}_{1+\infty}[\Psi]$ (argument A) gives the vertex bialgebra axiom (27.28) at all spins via the Koszul-locus equivalence (Theorem 27.29.3), and the JKL vertex bialgebra theorem on the CoHA (argument B) provides an independent proof. RTT triviality for $\mathfrak{gl}_1$ corroborates the result at the associative algebra level.

No constant coproduct exists for $c \neq 0$: the conformal anomaly $T(z)T(w) \sim (c/2)/(z-w)^4 + \dots$ obstructs any z -independent ansatz $\Delta(T) = T \otimes 1 + 1 \otimes T + X$ because the quartic pole on the left maps to $(c/2 + c/2)/(z-w)^4$ while the right retains $c/2$. The spectral parameter in (27.33) absorbs this obstruction through the shift $u \mapsto u - z$.

The structures (I)–(III) are the three readouts of Theorem 27.29.3: the R -matrix is given by step 5, the coproduct by steps 4 and 6, and the A_∞ structure is extracted, after fixing the same gauge, from $\overline{B}^{\text{ord}}(\mathcal{W}_{1+\infty})$ via the functor α with input the R -matrix from step 5. $\square$

Remark 27.29.12 (Structural features of the spectral coproduct). The coproduct of Theorem 27.29.11 has the following convention-independent features:

- (1) $\Delta_z(J) = J \otimes 1 + 1 \otimes J$ is cocommutative with no z -dependence (Heisenberg is abelian, confirming class G).
- (2) $\Delta_z(\psi_2)$ has a noncocommutative cross-term $\psi_1 \otimes \psi_1$ at order z^0 and a spectral tail $z(1 \otimes \psi_1)$ from the shift $u \mapsto u - z$. In the $\mathcal{W}_{1+\infty}$ basis, $\Delta_z(T)$ acquires a correction $(\Psi - 1)/\Psi \cdot (J \otimes J)$ from the Miura inversion $T = \psi_2 - J^2/(2\Psi)$.
- (3) $\Delta_z(\psi_3)$ has cross-terms $\psi_1 \otimes \psi_2 + \psi_2 \otimes \psi_1$, a spectral tail through z^2 , and the z^1 coefficient involves both $\psi_1 \otimes \psi_1$ and $1 \otimes \psi_2$. In the $\mathcal{W}_{1+\infty}$ basis, $\Delta_z(W)$ mixes all three spins with coefficients polynomial in Ψ .
- (4) The general formula (27.34) gives $\Delta_z(\psi_n)$ at every spin in closed form. The coproduct on the $\mathcal{W}_{1+\infty}$ field basis $\{J, T, W, W_4, \dots\}$ is obtained by inverting the Miura transform; the computation is triangular and algorithmic at each spin.

Remark 27.29.13 (Effective central charge and intertwining in the Miura basis). The coproduct (27.35) in the $\mathcal{W}_{1+\infty}$ field basis has cross-term coefficient $(\Psi - 1)/\Psi$ (not $1/\Psi$), as derived in step 4.

Remark 27.29.14 (Independent proof via the cohomological Hall algebra). The equivalence (I) $\leftrightarrow$ (II) $\leftrightarrow$ (III) has a second comparison surface for algebras arising as critical CoHAs of quivers with potential, using the framework of Kontsevich–Soibelman [KS11], Schiffmann–Vasserot [SV13], Yang–Zhao [YZ18a], and Jindal–Kaubrys–Latyntsev [JKL26]. The logic is orthogonal to the bar-cobar adjunction above: rather than constructing the triangle abstractly from the ordered bar complex, one exhibits the CoHA-side R -matrix and vertex coproduct on a single geometric object and then asks which double, completion, and vertex-algebra evaluation identify that object with the required full Yangian or $\mathcal{W}$ -algebra target.

Step 1: simultaneous existence of (I) and (III) on the CoHA. Let (Q, W) be a quiver with potential. The critical CoHA

$$\mathcal{H}_{Q,W} = \bigoplus_{d \in \mathbb{Z}_{\geq 0}^{Q_0}} H_{\text{BM},*}^{G_d}(\mathcal{M}_d^{\text{nil}}, \varphi_W)$$

carries two structures of independent geometric origin:

- (a) *Vertex coproduct* Δ_{CoHA} , from restriction to Levi subalgebras $G_{d_1} \times G_{d_2} \hookrightarrow G_d$; and
- (b) *R -matrix* $R(z)$, from the Maulik–Okounkov stable envelope construction [M019] on the Nakajima variety associated to Q .

Jindal–Kaubrys–Latyntsev [JKL26] prove that these two structures satisfy the vertex bialgebra axiom (their Theorems A and C):

$$\Delta_{\text{CoHA},z}(Y(a, w) b) = Y^{(2)}(\Delta_{\text{CoHA},z}(a), w) \Delta_{\text{CoHA},z}(b),$$

which is the OPE compatibility axiom (27.28). The R -matrix satisfies the QYBE and unitarity by the stable envelope formalism [M019]; the quasi-coassociativity of Δ_{CoHA} follows from the associativity of the Hall product on the Drinfeld double [YZ18a]. This establishes the CoHA-side instance of (I) and (III): the R -matrix and the coproduct coexist on $\mathcal{H}_{Q,W}$ and satisfy the quasi-triangularity relation $R(z) \Delta^{\text{ch}} = \Delta^{\text{ch,op}} R(z)$. It is not, by itself, an identification with a full Yangian or finite $\mathcal{W}_N$ vertex algebra.

Step 2: extraction of (II) from the CoHA vertex bialgebra. The CoHA $\mathcal{H}_{Q,W}$, equipped with its R -matrix, is an E_1 -chiral algebra in the sense of Definition 3.11.4. The functor α of the equivalence triangle (??) extracts the chiral A_∞ operations $\{m_k^{\text{ch}}\}$ by restricting the OPE to the associahedra $K_k \hookrightarrow \overline{\text{FM}}_k^{\text{ord}}(\mathbb{C})$ as in (??). The Stasheff identities follow from Stokes' theorem on K_{k+1} as before; the convergence of the integrals is guaranteed by S -locality of the R -matrix. This gives (I) $\rightarrow$ (II) on the CoHA.

The reverse direction (II) $\rightarrow$ (I) is the degree-2 holonomy recovery of the R -matrix from m_2^{ch} , which depends only on the formal structure of the Stasheff associahedra and not on the CoHA origin.

Step 3: the comparison triangle on the CoHA surface. By the JKL vertex bialgebra theorem, the CoHA simultaneously carries the CoHA analogues of (I), (II), and (III). To identify this with the triangle of Theorem 27.29.3, one must add the Drinfeld-double, completion, and vertex-algebra evaluation maps that carry the positive-half Hall object to the chosen target. On the Koszul locus:

- (i) (I) determines (III): given an R -matrix satisfying the QYBE and S -locality, the quasi-triangular coproduct is unique up to gauge equivalence by the Drinfeld reconstruction [?Drinfeld90] (spectral parameter version: Etingof–Kazhdan [?EK96]). The JKL coproduct on the CoHA is the unique one compatible with the MO R -matrix when the Drinfeld reconstruction hypotheses are imposed.
- (ii) (III) determines (I): the Drinfeld formula (27.30) recovers $S(z)$ from Δ^{ch} , independently of the CoHA construction.
- (iii) (I) $\leftrightarrow$ (II): the extraction of A_∞ operations from the R -matrix is the Stasheff–FM construction (direction α), whose inverse recovers the R -matrix as holonomy (direction α^{-1}). Neither direction uses the CoHA.

The triangle coherence $\alpha \circ \gamma \circ \beta = \text{id}$ then follows on the target surface from the uniqueness of each vertex, not from the positive-half CoHA statement alone.

Independence from the bar-cobar proof. The argument above differs from the proof of Theorem 27.29.3 in two respects. First, the equivalence (I) $\leftrightarrow$ (III) is checked on the geometric CoHA construction (stable envelopes for the R -matrix, Levi restriction for the coproduct, JKL for the vertex bialgebra axiom), before any passage through the ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ and the cobar dualization (27.29). Second, the uniqueness of the coproduct given the R -matrix is deduced from the Drinfeld reconstruction theorem for quasi-triangular vertex bialgebras, rather than from the bar-cobar adjunction on the ordered Koszul locus. The functor α (extraction of A_∞ operations from the R -matrix via associahedron integrals) is shared between the two proofs, but it enters as an a posteriori observation in the CoHA argument, not as the engine of the construction.

CoHA domain. The CoHA proof applies to associative Hall algebras arising as critical CoHAs of quivers with potential; the chiral object appears only after the comparison to a vertex-algebra target. For the Jordan quiver, $\mathcal{H}_{\text{Jor}} \cong Y^+(\widehat{\mathfrak{gl}}_1)$ [?SV13], and the equivalence specializes to the chiral quantum group structure on $\mathcal{W}_{1+\infty}[\Psi]$ only after the Drinfeld double and Miura/vacuum evaluation (Theorem 27.29.11). For quivers of type $\widehat{A}_{N-1}$, the CoHA is $Y^+(\widehat{\mathfrak{sl}}_N)$, and the JKL coproduct recovers the Drinfeld coproduct on the affine Yangian [?JKL26] on that positive-half comparison surface. This is a quiver-origin statement; it is not the rank- N Jordan-quiver substitute for the $\mathfrak{gl}_N$ positive half. Beyond quiver-origin algebras, and before the double/completion/evaluation arrows are supplied, the CoHA argument does not directly apply; the bar-cobar proof of Theorem 27.29.3 remains the primary route for general E_1 -chiral algebras on the ordered Koszul locus.

Remark 27.29.15 (Effective central charge and intertwining in the Miura basis). The coproduct (27.35) in the $\mathcal{W}_{1+\infty}$ field basis has cross-term coefficient $(\Psi - 1)/\Psi$ (not $1/\Psi$), as derived in step 4. This coefficient controls two structural invariants of the image $\Delta_z(T)$ in $V \otimes V$:

- (1) *Effective central charge.* The image $\Delta_z(T_n)$ generates a Virasoro subalgebra in the tensor product mode algebra with effective central charge

$$c_{\text{eff}}(\Psi) = 2 + 2(\Psi - 1)^2.$$

At $\Psi = 1$ (free boson): $c_{\text{eff}} = 2$ (two decoupled copies, the cross-term vanishes). At $\Psi = 2$: $c_{\text{eff}} = 4$. The quadratic growth $c_{\text{eff}} \sim 2\Psi^2$ at large Ψ reflects the quadratic Miura nonlinearity $\psi_2 = T + J^2/(2\Psi)$. The formula is independent of the spectral parameter z (the z -dependent terms in $\Delta_z(T)$ do not contribute to the vacuum expectation value of the commutator $[\Delta_z(T_2), \Delta_z(T_{-2})]$).

- (2) *Intertwining with $\Delta_z(J)$.* The commutator $[\Delta_z(T_n), \Delta_z(J_m)] = -\Psi \cdot m \cdot \Delta_z(J_{n+m})$ has intertwining factor Ψ (not 1). The extra factor $\Psi - 1$ beyond the original algebra relation $[T_n, J_m] = -m J_{n+m}$ arises from the cross-term $(\Psi - 1)/\Psi \cdot (J \otimes J)_n$ commuting with $\Delta_z(J_m) = J_m^L + J_m^R$: the left and right Heisenberg commutators each contribute $-((\Psi - 1)/\Psi) \cdot \Psi \cdot m = -(\Psi - 1)m$. At $\Psi = 1$: factor 1 (algebra homomorphism).

Both features are consequences of the Miura nonlinearity: the Drinfeld coproduct is an algebra homomorphism of the Yangian $Y(\widehat{\mathfrak{gl}}_1)$ (preserving the ψ -generator relations), but when expressed in the $\mathcal{W}_{1+\infty}$ field basis via the nonlinear Miura inversion $T = \psi_2 - J^2/(2\Psi)$, the image acquires Ψ -dependent structural invariants that are absent in the ψ -basis.

Remark 27.29.16 (Descent to $\mathcal{W}_N$). Drinfeld–Sokolov reduction gives $\pi_N: \mathcal{W}_{1+\infty}[\Psi] \rightarrow \mathcal{W}_N$ for each $N \geq 2$. Since the spectral coproduct of Theorem 27.29.11 is defined on the full $\mathcal{W}_{1+\infty}$, it descends to $\mathcal{W}_N$ provided $\pi_N \otimes \pi_N$ intertwines Δ_z with a coproduct on $\mathcal{W}_N$. For $\mathcal{W}_{1+\infty}$ itself, OPE compatibility holds at all spins by the GL_1 triviality argument (step 6 of the proof); for finite N , the intertwining $(\pi_N \otimes \pi_N) \circ \Delta_z = \Delta_z^{(N)} \circ \pi_N$ follows from the compatibility of the Miura transform with truncation (Remark 27.29.18). The tower $\cdots \rightarrow \mathcal{W}_{N+1} \rightarrow \mathcal{W}_N \rightarrow \cdots \rightarrow \mathcal{W}_2 = \text{Vir}_c$ is a projective system of algebras with spectral coproducts. At $N = 2$: class $\mathcal{M}$, $\kappa = c/2$, irregular KZ connection. At $N = 3$: $\kappa(\mathcal{W}_3) = 5c/6$ (where $H_3 - 1 = 5/6$). The Gaiotto–Rapčák Y -algebras $Y_{N_1, N_2, N_3}[\Psi]$ [gaiotto-rapchak] are truncations of $\mathcal{W}_{1+\infty}$; the S_3 -triality is a symmetry of the spectral coproduct, corresponding to three Hecke correspondences on spiked-instanton moduli (Rapčák–Soibelman–Yang–Zhao [RSYZ20]). The $\mathcal{D}$ -module $\mathcal{F}_n^{\text{ord}}(\mathcal{W}_{1+\infty})$ has irregular singularities of unbounded Poincaré rank (spin- s contributes pole order $2s - 1$ after d -log absorption), providing the boundary algebra of higher-spin holographic gravity.

Remark 27.29.17 (GRZ comparison;). Theorem 27.29.11 has three comparison surfaces in the type- $\mathcal{A}$ literature. The cited type- $\mathcal{A}$ results are external; the identification with the ordered $\mathcal{W}_{1+\infty}$ chiral quantum group of this manuscript is conditional on the hypothesis package of Theorem 27.29.11.

- (1) *Corner truncations.* Gaiotto–Rapčák identify the corner algebras $Y_{N_1, N_2, N_3}[\Psi]$ as truncations of $\mathcal{W}_{1+\infty}$ along the curve $\sum_i N_i/\lambda_i = 1$ and prove generic free strong generation [gaiotto-rapchak, Theorem 3.1 and eq. 3.35]. This matches Remark 27.29.16: our spectral coproduct is constructed on the ordered $\mathcal{W}_{1+\infty}$ object and only then descends to finite truncations.

- (2) *DDCA and affine-Yangian coproducts.* Gaiotto–Rapčák–Zhou construct coproducts on the finite-rank DDCA / matrix-extended $\mathcal{W}_\infty$ / affine-Yangian side [GRZ25, §§5–7]. For type $\mathcal{A}$, this is consistent

with the Drinfeld coproduct of Theorem 27.29.11: both sides work with the same Yangian mode algebra, and both organize truncation data at finite rank before passing to the large-rank $\mathcal{W}_{1+\infty}$ limit. The statement proved here is different in nature: the coproduct is recovered from deconcatenation on the ordered bar coalgebra $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$, and step 6 proves OPE compatibility by a coderivation argument on the ordered bar side.

(3) *Independent CoHA route.* For quiver-origin algebras there is a second comparison route. Jindal–Kaubrys–Latyntsev construct a vertex coproduct on critical CoHAs and recover the deformed Drinfeld coproduct for ADE Yangians after restriction to the Yangian generators [?JKL26]. This matches Remark 27.29.14: the CoHA vertex coproduct is the positive-half comparison surface. Identifying it with the ordered E_1 -chiral coproduct on a full Yangian or finite $\mathcal{W}_N$ target still requires the Drinfeld double, completion, and Miura/Drinfeld–Sokolov evaluation hypotheses.

Convention check. Our spectral parameter z is the Drinfeld/Yangian shift parameter. The OPE coordinate enters only after the factorization-envelope or ordered-bar reconstruction, and the braided E_2 structure appears later at the derived-center stage, not on the primitive bar coalgebra.

Spectral-parameter firewall. This convention does not license erasure of spectral parameters from associative Yangians or from topological Drinfeld-centre language. The associative Yangian $Y(\mathfrak{g})$ has evaluation modules $V(u)$, and the universal R -matrix on $V(u) \otimes W(v)$ gives the rational matrix $R_{V,W}(u-v)$ [?ChariPressley94, Ch. 12]. What is independent of the collision coordinate is the primitive topological bar deconcatenation coproduct before the evaluation-module shift is chosen. The chiral bar differential is different: it is meromorphic in the Ran collision coordinate, and this meromorphic dependence is the datum carried by the ordered factorisation reconstruction.

Remark 27.29.18 (RTT, CoHA, and coproduct compatibility). Three comments on the proof of Theorem 27.29.11.

(1) *Why RTT alone does not suffice.* The RTT relation (27.37) is a constraint on the *associative algebra* structure (mode commutators). The vertex bialgebra axiom (27.28) is a constraint on the *vertex algebra* structure (all n -products $a_{(n)}b$, including the regular products for $n < 0$). For $\mathfrak{gl}_1$ the RTT relation is trivially satisfied because the R -matrix is scalar; this confirms associative-algebra compatibility but does not, by itself, establish the full vertex-algebra compatibility. The construction in step 6 closes this gap by the coderivation property on the ordered Koszul-locus bar complex; the JKL vertex bialgebra theorem gives the matching comparison on the positive-half CoHA surface.

(2) *Truncation to $\mathcal{W}_N$.* Theorem 27.29.35 resolves this question as a conditional Koszul-locus statement: for the truncations $\mathcal{W}_N$ at finite $N \geq 2$, the R -matrix of $Y(\widehat{\mathfrak{gl}}_N)$ is Yang’s rational R -matrix $R(u) = uI + \Psi P$ (no longer scalar), and the OPE compatibility at each truncation level is constructed by the coderivation argument (argument A). The CoHA route (argument B) gives an independent comparison only after a quiver-origin positive-half CoHA has been identified with the required Y^+ , then transported through the Drinfeld double, completion, and Miura/Drinfeld–Sokolov evaluation. JKL’s general-quiver vertex bialgebra theorem does not by itself produce a rank- N Jordan-quiver identification with $Y^+(\widehat{\mathfrak{gl}}_N)$.

(3) *Antipode and Drinfeld double.* The Schiffmann–Mellit–Minets–Vasserot isomorphism [?SMMV23] identifies the Jordan-quiver CoHA with the positive half of the affine Yangian, $\mathcal{H}_{\text{Jor}} \cong Y^+(\widehat{\mathfrak{gl}}_1)$; the $\mathcal{W}_{1+\infty}[\Psi]$ fields appear only after Drinfeld doubling and Miura/vacuum evaluation. The Drinfeld double $D(\mathcal{H}_{\text{Jor}}) \cong Y(\widehat{\mathfrak{gl}}_1)$ (Yang–Zhao [?YZ18a]) provides the full algebra with antipode $S(T(u)) = T(u)^{-1}$. Proposition 27.29.19 below resolves the question of whether this lifts to a vertex Hopf algebra

structure: the Yangian antipode gives explicit formulas $S(J) = -J$ and $S(T) = -T + \frac{\Psi-1}{\Psi} :JJ:$ on $\mathcal{W}_{1+\infty}$, but two independent obstructions prevent it from satisfying the vertex Hopf algebra axiom.

PROPOSITION 27.29.19 (*Yangian antipode on $\mathcal{W}_{1+\infty}$: explicit formula and vertex Hopf obstruction*). Let $\mathcal{W}_{1+\infty}[\Psi]$ carry the chiral quantum group structure of Theorem 27.29.11, with spectral coproduct $\Delta_z(T(u)) = T(u) \otimes T(u-z)$ and Miura identification $\psi_1 = J, \psi_2 = T + J^2/(2\Psi)$.

- (i) (Explicit antipode.) The Yangian antipode $S(T(u)) = T(u)^{-1}$, with $T(u)^{-1} = 1 + \sum_{n \geq 1} \sigma_n u^{-n}$ and

$$\sigma_n = -\psi_n - \sum_{k=1}^{n-1} \psi_k \sigma_{n-k}, \quad (27.38)$$

induces a well-defined linear map $S: \mathcal{W}_{1+\infty} \rightarrow \mathcal{W}_{1+\infty}$ via the Miura transform. At spins 1 and 2:

$$S(J) = -J, \quad S(T) = -T + \frac{\Psi-1}{\Psi} :JJ:.$$

The map S is an involution: $S^2 = \text{id}$.

- (ii) (OPE obstruction.) The map S does not preserve the Virasoro OPE at generic Ψ . The quartic pole of $S(T)$ with itself is

$$S(T)_{(3)} S(T) = \frac{c}{2} + 2(\Psi-1)(\Psi-2), \quad (27.39)$$

which equals $T_{(3)} T = c/2$ only at $\Psi \in \{1, 2\}$ ($c = 1$ free boson, $c = -2$ bc ghost).

The four OPE contributions are: $T_{(3)} T = c/2$; $T_{(3)} (:JJ:) = \Psi$ (Wick theorem, J primary of weight 1); $(:JJ:)_{(3)} T = \Psi$ (skew-symmetry); $(:JJ:)_{(3)} (:JJ:) = 2\Psi^2$ (Sugawara scaling).

- (iii) (Hopf axiom obstruction.) The vertex Hopf algebra axiom $m_z \circ (S \otimes \text{id}) \circ \Delta_z = \iota \circ \varepsilon$ fails on T with residual

$$m_z \circ (S \otimes \text{id}) \circ \Delta_z(T) = -\frac{\Psi-1}{z^2} + zJ. \quad (27.40)$$

The $-(\Psi-1)/z^2$ term arises from the OPE singularity $Y(J, z)J \sim \Psi/z^2$; the $z \cdot J$ term arises from the spectral dependence $z \cdot (1 \otimes J)$ in $\Delta_z(T)$. The $z \cdot J$ term persists at all Ψ , including $\Psi = 1$: the spectral coproduct Δ_z is z -dependent and cannot admit a z -independent antipode satisfying the classical Hopf axiom.

Proof. Part (i): the recurrence (27.38) follows from $T(u)T(u)^{-1} = 1$ by extracting the coefficient of u^{-n} . The Miura inversion giving $S(J) = -\psi_1 = -J$ and $S(T) = S(\psi_2 - J^2/(2\Psi)) = (\psi_1^2 - \psi_2) - S(J)^2/(2\Psi) = -T + (\Psi-1)/\Psi \cdot :JJ:$ uses the commutativity of the ψ_i (rank 1). The involutivity $S^2 = \text{id}$ is the identity $S^2(T) = -S(T) + (\Psi-1)/\Psi \cdot S(J)^2 = T - (\Psi-1)/\Psi \cdot J^2 + (\Psi-1)/\Psi \cdot J^2 = T$.

Part (ii): write $\alpha = (\Psi-1)/\Psi$ and $S(T) = -T + \alpha :JJ:$. By bilinearity of the (3)-product,

$$S(T)_{(3)} S(T) = T_{(3)} T - \alpha T_{(3)} (:JJ:) - \alpha (:JJ:)_{(3)} T + \alpha^2 (:JJ:)_{(3)} (:JJ:).$$

The individual (3)-products are computed by the Wick theorem (non-linear lambda-bracket formula):

- $T_{(3)} (:JJ:) = \Psi$: from the lambda-bracket $\{T_\lambda :JJ:\} = (\Psi/6)\lambda^3 + 2:JJ:\lambda + \partial(:JJ:)$, reading off the $\lambda^3/3!$ coefficient.
- $(:JJ:)_{(3)} T = \Psi$: by skew-symmetry and $T_{(n)} (:JJ:) = 0$ for $n \geq 4$.
- $(:JJ:)_{(3)} (:JJ:) = 2\Psi^2$: the Sugawara tensor $T_{\text{Sug}} = :JJ:/(2\Psi)$ satisfies Virasoro at $c = 1$, so $(:JJ:)_{(3)} (:JJ:) = (2\Psi)^2 \cdot (1/2) = 2\Psi^2$.

Substituting: $S(T)_{(3)} S(T) = c/2 - 2\alpha\Psi + 2\alpha^2\Psi^2 = c/2 + 2(\Psi - 1)(\Psi - 2)$.

Part (iii): the spectral coproduct gives four terms $\Delta_z(T) = T \otimes 1 + 1 \otimes T + \alpha J \otimes J + z(1 \otimes J)$. Applying $S \otimes \text{id}$ and composing with $m_z(a \otimes b) = Y(a, z)b$:

$$\begin{aligned} & Y(S(T), z) \cdot 1 + Y(1, z) \cdot T + \alpha Y(-J, z) \cdot J + z \cdot Y(1, z) \cdot J \\ &= S(T) + T + \alpha(-\Psi/z^2 - :JJ: + O(z)) + z \cdot J \\ &= (-T + \alpha :JJ:) + T - \alpha\Psi/z^2 - \alpha :JJ: + zJ \\ &= -(\Psi - 1)/z^2 + zJ. \end{aligned}$$

Since $\varepsilon(T) = 0$ (positive conformal weight), the right-hand side of the Hopf axiom is zero, and the obstruction is the nonzero expression above.

Independence of the two obstructions. The OPE obstruction (27.39) vanishes on the locus $\Psi \in \{1, 2\}$, while the Hopf-axiom obstruction (27.40) contains the $z \cdot J$ tail for every value of Ψ . Substituting $\Psi = 1$ into (ii) and (iii): $S(T)_{(3)} S(T) - c/2 = 2(0)(-1) = 0$, while $m_z \circ (S \otimes \text{id}) \circ \Delta_z(T) = z \cdot J \neq 0$. The OPE locus and the Hopf locus are therefore disjoint, so the two obstructions are independent: neither reduces to the other, and lifting the antipode requires resolving both simultaneously. The $z \cdot J$ tail encodes the spectral covariance of Δ_z , which has no counterpart in the classical Yangian antipode; it is this covariance, not the OPE singularity, that is the genuinely chiral obstruction. $\square$

LEMMA 27.29.20 (*Miura inversion of the spectral coproduct at spin 2*). Let $\psi_1 = J$ and $\psi_2 = T + J^2/(2\Psi)$ be the Miura identification of Procházka–Rapčák [?PR19]. The spectral coproduct $\Delta_z(T) = \Delta_z(\psi_2) - (1/(2\Psi)) \Delta_z(J)^2$ equals

$$\Delta_z(T) = T \otimes 1 + 1 \otimes T + \frac{\Psi-1}{\Psi} J \otimes J + z(1 \otimes J). \quad (27.41)$$

Proof. The Drinfeld formula $\Delta_z(T(u)) = T(u) \otimes T(u - z)$ gives, at the u^{-2} coefficient,

$$\Delta_z(\psi_2) = \psi_2 \otimes 1 + 1 \otimes \psi_2 + \psi_1 \otimes \psi_1 + z(1 \otimes \psi_1).$$

Since Δ_z is an algebra homomorphism and $J = \psi_1$ is primitive,

$$\begin{aligned} \Delta_z(J)^2 &= (J \otimes 1 + 1 \otimes J)^2 \\ &= J^2 \otimes 1 + 2J \otimes J + 1 \otimes J^2. \end{aligned}$$

Substituting $T = \psi_2 - J^2/(2\Psi)$:

$$\begin{aligned} \Delta_z(T) &= \Delta_z(\psi_2) - \frac{1}{2\Psi} \Delta_z(J)^2 \\ &= \left[(T + \frac{J^2}{2\Psi}) \otimes 1 + 1 \otimes (T + \frac{J^2}{2\Psi}) + J \otimes J + z(1 \otimes J) \right] \\ &\quad - \frac{1}{2\Psi} \left[J^2 \otimes 1 + 2J \otimes J + 1 \otimes J^2 \right] \\ &= T \otimes 1 + 1 \otimes T + \left(1 - \frac{1}{\Psi}\right) J \otimes J + z(1 \otimes J). \end{aligned}$$

Since $1 - 1/\Psi = (\Psi - 1)/\Psi$, this is (27.41). The $J^2/(2\Psi)$ terms cancel between the Miura substitution and the $\Delta_z(J)^2$ correction. At $\Psi = 1$ (free boson, $c = 1$) the $J \otimes J$ cross-term vanishes and $\Delta_z(T) = T \otimes 1 + 1 \otimes T + z(1 \otimes J)$; in the classical limit $\Psi \rightarrow \infty$ the coefficient tends to 1. $\square$

27.29.1 *The spin-3 coproduct, Miura universality, and the conformal anomaly*

PROPOSITION 27.29.21 (*Spin-3 Miura coproduct*). The spectral coproduct on the spin-3 field W of $\mathcal{W}_{1+\infty}[\Psi]$ is

$$\begin{aligned} \Delta_z(W) = & W \otimes 1 + 1 \otimes W + \frac{\Psi-1}{\Psi} (J \otimes T + T \otimes J) \\ & + \frac{1-\Psi}{2\Psi^2} (J \otimes :J^2: + :J^2: \otimes J) + \frac{\Psi-1}{\Psi} z J \otimes J + 2z (1 \otimes T) + z^2 (1 \otimes J). \end{aligned} \quad (27.42)$$

The coefficient $(\Psi - 1)/\Psi$ on the primary cross-terms $J \otimes T + T \otimes J$ is the same as the coefficient on $J \otimes J$ in $\Delta_z(T)$ (27.41). A new composite correction $(1 - \Psi)/(2\Psi^2)$ appears on $J \otimes :J^2: + :J^2: \otimes J$, with opposite sign and suppressed by $1/(2\Psi)$. At $\Psi = 1$ (free boson): all cross-terms vanish. At $\Psi \rightarrow \infty$: primary coefficients tend to 1, composite corrections to 0.

Proof. The Miura transform gives $\psi_3 = W + (1/\Psi):JT: + (1/(6\Psi^2)):J^3: + (1/(2\Psi))J''$. The Drinfeld formula at u^{-3} gives $\Delta_z(\psi_3) = \psi_3 \otimes 1 + 1 \otimes \psi_3 + \psi_1 \otimes \psi_2 + \psi_2 \otimes \psi_1 + z(\psi_1 \otimes \psi_1 + 2 \cdot 1 \otimes \psi_2) + z^2(1 \otimes \psi_1)$. Substituting $W = \psi_3 - (1/\Psi):JT: - \dots$ and using the multiplicativity of Δ_z on the Miura correction terms gives (27.42) after cancellation. The primary coefficient $(\Psi - 1)/\Psi = 1 - 1/\Psi$ arises as 1 (from $\psi_1 \otimes \psi_2$) minus $1/\Psi$ (from $\Delta_z(:JT:)$). $\square$

LEMMA 27.29.22 (*Miura triangularity under the Drinfeld coproduct*). Work in the Open quadrant, in the ordered associative chiral/Yangian presentation, in the Beilinson level $4 \rightarrow 5$ operator-to-coproduct lane. Assume the generic Ψ package consisting of the Procházka–Rapčák triangular Miura basis

$$\psi_n = W_n + P_n(J, W_2, \dots, W_{n-1}) \quad (P_n \in F_{\leq n-1}^W)$$

and the Drinfeld spectral coproduct $\Delta_z(T(u)) = T(u) \otimes T(u - z)$. Let $F_{\leq p}^W$ be the normally ordered filtration by largest primary W -spin appearing in a monomial, with $J = W_1$ and the unit in $F_{\leq 0}^W$. Then

$$\Delta_z(F_{\leq p}^W) \subset F_{\leq p}^W \widehat{\otimes} F_{\leq p}^W.$$

Consequently, for $s \geq 3$, every lower Miura monomial of W -spin $\leq s - 2$ in the inversion of ψ_s has spectral coproduct with no component in $J \otimes W_{s-1}$ or $W_{s-1} \otimes J$.

Proof. The triangular Miura theorem gives the associated-graded identity $\text{gr}^W \psi_n = W_n$. Its inverse is therefore also triangular: $W_n = \psi_n + Q_n(\psi_1, \dots, \psi_{n-1})$, with Q_n of W -spin at most $n - 1$. The Drinfeld formula for the u^{-n} coefficient,

$$\Delta_z(\psi_n) = \psi_n \otimes 1 + \sum_{k=0}^{n-1} \sum_{m=1}^{n-k} \binom{n-k-1}{m-1} z^{n-k-m} \psi_k \otimes \psi_m,$$

has tensor indices $k, m \leq n$. After triangular expansion from the ψ -basis to the primary basis, each tensor factor has W -spin at most n . Hence $\Delta_z(\psi_n) \in F_{\leq n}^W \widehat{\otimes} F_{\leq n}^W$, and the same statement for W_n follows from the triangular inverse and multiplicativity of Δ_z .

The filtration is defined by the largest primary spin in a normal monomial. Multiplication by powers of $J = W_1$ does not increase that largest spin, and normal-ordering contractions with J produce derivatives or lower composites, not a new primary W_r with larger r . Thus, for a representative lower sector $M_{s,k} = :J^k W_{s-k}: with $k \geq 2$,$

$$\Delta_z(M_{s,k}) \in \sum_{a=0}^k :J^a F_{\leq s-k}^W \widehat{\otimes} J^{k-a} F_{\leq s-k}^W:,$$

up to derivative and lower normal-ordering terms in the same filtration. Since $s - k \leq s - 2$, no tensor factor can contain the target primary W_{s-1} .

The first nontrivial displayed case is spin 3. The composite term in Proposition 27.29.21 is

$$\frac{1 - \Psi}{2\Psi^2} (J \otimes :J^2: + :J^2: \otimes J),$$

which has W -spin 1 on both sides and therefore cannot contribute to the $J \otimes T$ or $T \otimes J$ channel. At spin 4, the lower representatives $:J^2 T:$ and $:T T:$ remain in $F_{\leq 2}^W$ after applying Δ_z , so they cannot produce $J \otimes W_3$. At spins 5 and 6, the maximal lower primary spins are respectively 3 and 4, below the targets W_4 and W_5 . This proves the required non-contribution of all lower sectors. $\square$

THEOREM 27.29.23 (*Miura cross-term universality*). For all $s \geq 2$, the spectral coproduct on the spin- s primary generator W_s of $\mathcal{W}_{1+\infty}[\Psi]$ satisfies

$$\Delta_z(W_s) = W_s \otimes 1 + 1 \otimes W_s + \frac{\Psi - 1}{\Psi} (J \otimes W_{s-1} + W_{s-1} \otimes J) + (\text{lower-spin and composite corrections}) + (\text{spectral tail in } z).$$

The coefficient $(\Psi - 1)/\Psi$ of the primary cross-term $J \otimes W_{s-1} + W_{s-1} \otimes J$ is independent of the spin s .

Proof. The case $s = 2$ is Lemma 27.29.20. For $s \geq 3$ the spin-uniform argument has three steps.

Step 1: the Miura coefficient of $:J \cdot W_{s-1}:$ in ψ_s is $1/\Psi$ at every spin. The quantum Miura factorisation (Procházka–Rapčák [?PR19]) writes the transfer matrix as a product of Miura fields: $T(u) = \prod_{i \geq 1} (1 + \Lambda_i/u)$, with $\psi_s = e_s(\Lambda_1, \Lambda_2, \dots)$ the s -th elementary symmetric function. Each Λ_i decomposes as $\Lambda_i = \sigma_i + J_i/\Psi$, where σ_i is the primary (non- J) contribution from the i -th Miura slot. Expanding e_s and collecting the sector with exactly one J -insertion and $(s - 1)$ primary slots:

$$e_s(\Lambda_1, \dots) \supset \frac{1}{\Psi} \sum_i J_i \cdot \prod_{j \neq i}^{s-1 \text{ slots}} \sigma_j = \frac{1}{\Psi} :J \cdot W_{s-1}:,$$

where the last identification uses the fact that the $(s - 1)$ -slot primary block is W_{s-1} by the triangular structure of the Miura transform (Step 3 of the proof of Theorem 27.29.11). Each such term carries the same factor $1/\Psi$ from the single J/Ψ slot. The remaining sectors have $k \geq 2$ distinguished J -insertions with W -spin $\leq s - 2$:

$$\psi_s = W_s + \frac{1}{\Psi} :J \cdot W_{s-1}: + (\text{terms of } W\text{-spin} \leq s - 2). \quad (27.43)$$

Step 2: the Drinfeld formula contributes $+1$ to $\psi_1 \otimes \psi_{s-1}$. The general coproduct formula (27.34) gives the z^0 coefficient of $\psi_1 \otimes \psi_{s-1}$ as $\binom{s-2}{s-2} = 1$, and the z^0 coefficient of $\psi_{s-1} \otimes \psi_1$ as $\binom{0}{0} = 1$. Both are identically 1 for all $s \geq 2$.

Step 3: assembly and non-contribution of lower sectors. Inverting (27.43):

$$W_s = \psi_s - \frac{1}{\Psi} :J \cdot W_{s-1}: + (\text{terms of } W\text{-spin} \leq s - 2).$$

Applying Δ_z and extracting the coefficient of $J \otimes W_{s-1}$:

- (i) From $\Delta_z(\psi_s)$: the $\psi_1 \otimes \psi_{s-1}$ term contributes $+1 \cdot J \otimes W_{s-1}$, since $\psi_1 = J$ and $\psi_{s-1} = W_{s-1} +$ composites of spin $\leq s - 2$, which do not produce W_{s-1} in the right tensor factor.

- (ii) From $-(1/\Psi) \Delta_z(:J \cdot W_{s-1}:)$: the leading piece $(J \otimes 1)(1 \otimes W_{s-1}) = J \otimes W_{s-1}$ contributes $-1/\Psi$.
- (iii) From the Miura sectors with $k \geq 2$ J -insertions: their W -spin is $\leq s - 2$. By Lemma 27.29.22, the tensor support of these sectors is contained in W -spin $\leq s - 2$ on each side after applying Δ_z . They therefore contribute zero to the $J \otimes W_{s-1}$ channel.

The total coefficient is $1 - 1/\Psi = (\Psi - 1)/\Psi$. The argument for $W_{s-1} \otimes J$ is symmetric. The three ingredients are each spin-independent: the Drinfeld binomial coefficient $\binom{s-2}{s-2} = 1$ is tautological, the single-slot Miura factor $1/\Psi$ is structural (one J/Ψ slot), and the non-contribution of higher J -sectors follows from W -spin filtration. Limiting cases: at $\Psi = 1$ (free boson) the coefficient vanishes; at $\Psi \rightarrow \infty$ it tends to 1. The identity has been computed at spins 2–6 in the rational function field $\mathbb{Q}(\Psi)$ via `miura_universality_proof_engine.py` (symbolic channel-level abstraction $\prod_i(\sigma_i + J_i/\Psi)$, spin-uniform by construction); full-algebraic coproduct cross-checked at $s \in \{2, 3, 4\}$ by `miura_coproduct_universal_engine.py`. $\square$

Remark 27.29.24 (Primary cross-term only). Theorem 27.29.23 asserts the universal coefficient $(\Psi - 1)/\Psi$ only on the *primary* cross-term $J \otimes W_{s-1} + W_{s-1} \otimes J$. The composite cross-terms, for example $J \otimes :J \cdot W_{s-2}: , :J^2: \otimes W_{s-2}$, and the higher J -insertion sectors, carry spin-dependent coefficients. At spin 3 the unique composite correction $(1 - \Psi)/(2\Psi^2)$ on $J \otimes :J^2: + :J^2: \otimes J$ is established in Proposition 27.29.21 above. For $s \geq 4$ no closed form for the composite corrections is established in this volume.

Remark 27.29.25 (Attribution for the triangular Miura basis). The identification used in Step 1 of the proof, namely that the $(s - 1)$ -slot primary block of the single- J Miura sector equals W_{s-1} modulo lower-spin composites, is the general- s form of the triangular change of basis $\psi_n = W_n + P_n(J, W_2, \dots, W_{n-1})$ of Procházka–Rapčák [?PR19]; see also Step 3 of the proof of Theorem 27.29.11 for the statement at the level of the filtered isomorphism $Y(\widehat{\mathfrak{gl}}_1) \cong U(\mathcal{W}_{1+\infty}[\Psi])$. The triangular structure is explicit through ψ_3 in this volume; the general- s statement is cited from [?PR19] rather than independently derived here. Lemma 27.29.22 separates this imported triangular basis from the filtration consequence used in the coproduct proof: once the triangular basis and Drinfeld coproduct are assumed, preservation of W -spin under Δ_z is proved in this volume.

Remark 27.29.26 (The conformal anomaly forces the spectral parameter). The quartic pole $T(z)T(w) \sim (c/2)/(z-w)^4 + \dots$ obstructs constant coproducts for $c \neq 0$: the primitive ansatz $\Delta(T) = T \otimes 1 + 1 \otimes T + X$ produces quartic pole $c/(z-w)^4$ (each copy contributes $c/2$), but the coproduct must reproduce $c/2$. The obstruction equals $c/2 = \kappa(\text{Vir}_c)$. At $c = 0$ (Heisenberg): vanishes, constant coproduct exists. At $c \neq 0$: the spectral parameter in $\Delta_z(T(u)) = T(u) \otimes T(u - z)$ absorbs the mismatch through $u \mapsto u - z$.

Remark 27.29.27 (Stokes ray count for $\mathcal{W}_N$). The $\mathcal{W}_N$ KZ connection at degree 2 has Poincaré rank $2N - 2$ (from the W_N – W_N OPE pole $2N$, d-log absorption to $2N - 1$) and, in the generic anti-Stokes / Stokes-sector convention of Boalch and Jimbo–Miwa–Ueno, $2r = 4N - 4$ Stokes rays. $\mathcal{W}_2$: 4 rays. $\mathcal{W}_3$: 8 rays. Linear growth in N .

Remark 27.29.28 (The antipode does not lift). The Yangian antipode $S(T(u)) = T(u)^{-1}$ does not lift to a vertex-algebraic antipode on $\mathcal{W}_{1+\infty}[\Psi]$. Two independent obstructions: (1) $S(T)_{(3)}S(T) = c/2 + 2(\Psi - 1)(\Psi - 2) \neq c/2$ at generic Ψ ; (2) the Hopf axiom residual $z \cdot J$ persists at all Ψ . Both vanish only at $\Psi \in \{1, 2\}$. Source: the Miura nonlinearity $T = \psi_2 - J^2/(2\Psi)$.

Remark 27.29.29 (Shadow tower as perturbative Gromov–Witten). At $\kappa = \Psi$ (the level of $\mathcal{W}_{1+\infty}$), the shadow tower $\{F_g\}$ produces the perturbative constant-map Gromov–Witten free energies $F_g^{\text{GW, const}}(\mathbb{C}^3)$. The MacMahon function $M(q) = \prod_{n \geq 1} (1 - q^n)^{-n}$ lives on the Donaldson–Thomas side; the bridge is the MNOP/DT-GW correspondence under $q = -e^{ig_s}$. For $\mathbb{C}^3$ (no compact curves), this identifies the scalar constant-map sector in the MNOP normalisation; it is not a chain-level or physical Gromov–Witten partition function without the corresponding comparison datum.

27.29.2 The chiral quantum group structure on $\mathcal{W}_N$ for $N \geq 2$

Theorem 27.29.11 established the chiral quantum group structure on $\mathcal{W}_{1+\infty}[\Psi]$ via the scalar Maulik–Okounkov R -matrix. For the truncations $\mathcal{W}_N = \mathcal{W}_{1+\infty}/\mathcal{I}_N$ (generators of spins $1, 2, \dots, N$) the R -matrix is no longer scalar: it is Yang’s rational R -matrix on $\mathbb{C}^N \otimes \mathbb{C}^N$, and the RTT relation is a non-trivial matrix identity.

The general theorem is best understood by first computing everything at $N = 2$, where $\mathcal{W}_2 = \text{Vir}_c$ with $c = 1 - 6(\Psi - 1)^2/\Psi$ and the affine Yangian $Y(\widehat{\mathfrak{gl}}_2)$ has a 2×2 transfer matrix. At $N = 2$ every matrix is small enough to write in full, and the general pattern becomes visible.

Example 27.29.30 (The $N = 2$ chiral quantum group: $Y(\widehat{\mathfrak{gl}}_2)$ and Virasoro). *Transfer matrix.* The 2×2 transfer matrix is

$$T(u) = I_2 + T^{(1)}u^{-1} + T^{(2)}u^{-2} + \dots = \begin{pmatrix} t_{11}(u) & t_{12}(u) \\ t_{21}(u) & t_{22}(u) \end{pmatrix},$$

where each entry $t_{ij}(u) = \delta_{ij} + \sum_{r \geq 1} t_{ij}^{(r)} u^{-r}$. At degree 1 the four generators are $t_{11}^{(1)}, t_{12}^{(1)}, t_{21}^{(1)}, t_{22}^{(1)}$. The quantum Miura factorisation (27.48) gives

$$T(u) = \begin{pmatrix} u + \Lambda_1^{(1)} & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & u + \Lambda_2^{(1)} \end{pmatrix} + \text{lower order},$$

where $\Lambda_1^{(1)}, \Lambda_2^{(1)}$ are the Miura fields of Procházka–Rapčák [PR19].

Yang’s R -matrix at $N = 2$. The R -matrix is $R(u) = u I_4 + \Psi P$ on $\mathbb{C}^2 \otimes \mathbb{C}^2$, where P is the permutation $P(e_i \otimes e_j) = e_j \otimes e_i$. In the standard basis $\{e_1 \otimes e_1, e_1 \otimes e_2, e_2 \otimes e_1, e_2 \otimes e_2\}$:

$$R(u) = \begin{pmatrix} u + \Psi & 0 & 0 & 0 \\ 0 & u & \Psi & 0 \\ 0 & \Psi & u & 0 \\ 0 & 0 & 0 & u + \Psi \end{pmatrix}.$$

At $\Psi = 0$: $R(u) = u I_4$ (no interaction). The eigenvalues of $R(u)$ are $u + \Psi$ (symmetric, multiplicity 3) and $u - \Psi$ (antisymmetric, multiplicity 1). The unitarity relation $R(u) R(-u) = (\Psi^2 - u^2) I_4$ follows by direct 4×4 multiplication. The classical r -matrix is $r(z) = \Psi P/z$, with $r|_{\Psi=0} = 0$.

RTT relation: explicit commutation relations. The RTT relation $R_{12}(u - v) T_1(u) T_2(v) = T_2(v) T_1(u) R_{12}(u - v)$ at $N = 2$ encodes the following quadratic relations among the generators.

Writing $R_{ij,kl}(u) = u \delta_{ik} \delta_{jl} + \Psi \delta_{il} \delta_{jk}$ for the matrix entries (that is, $R = u I + \Psi P$), the RTT relation in component form reads:

$$\sum_{k,l=1}^2 R_{ab,kl}(u-v) t_{ka'}(u) t_{lb'}(v) = \sum_{k,l=1}^2 t_{bk}(v) t_{al}(u) R_{lk,a'b'}(u-v)$$

for all $1 \leq a, b, a', b' \leq 2$. The key relations extracted at degree 1 are:

$$\begin{aligned} (u-v) [t_{ij}(u), t_{kl}(v)] &= \Psi (t_{kj}(u) t_{il}(v) - t_{kl}(v) t_{ij}(u)), \\ [t_{11}^{(1)}, t_{12}^{(1)}] &= \Psi t_{12}^{(1)}, \\ [t_{11}^{(1)}, t_{21}^{(1)}] &= -\Psi t_{21}^{(1)}, \\ [t_{12}^{(1)}, t_{21}^{(1)}] &= \Psi (t_{11}^{(1)} - t_{22}^{(1)}). \end{aligned}$$

These are the standard $Y(\mathfrak{gl}_2)$ relations (Molev [?Molev07], §1.4). For $N = 1$ all four generators collapse to ψ_1 and the RTT is trivially satisfied (scalar R -matrix).

Quantum determinant at $N = 2$. The quantum determinant (27.53) specialises at $N = 2$ to

$$\text{qdet } T(u) = t_{11}(u) t_{22}(u - \Psi) - t_{12}(u) t_{21}(u - \Psi).$$

The Ψ -shift $u \mapsto u - \Psi$ in the second column is the quantum correction: at $\Psi = 0$ this reduces to the classical determinant. Centrality: $\text{qdet } T(u)$ commutes with all $t_{ij}(v)$ (Molev [?Molev07], Theorem 1.11.2; computed numerically at $\Psi = 1$ by `glN_affine_yangian_chiral_qg_engine.py`).

Drinfeld coproduct at $N = 2$. The matrix Drinfeld formula $\Delta_z(T(u)) = T(u) \cdot T(u - z)$ gives explicit 2×2 matrix multiplication:

$$\Delta_z \begin{pmatrix} t_{11}(u) & t_{12}(u) \\ t_{21}(u) & t_{22}(u) \end{pmatrix} = \begin{pmatrix} t_{11}(u) & t_{12}(u) \\ t_{21}(u) & t_{22}(u) \end{pmatrix} \otimes \begin{pmatrix} t_{11}(u-z) & t_{12}(u-z) \\ t_{21}(u-z) & t_{22}(u-z) \end{pmatrix},$$

where the product is matrix multiplication in $\mathbb{C}^2$ with the tensor product in the algebra. In components:

$$\Delta_z(t_{11}(u)) = t_{11}(u) \otimes t_{11}(u-z) + t_{12}(u) \otimes t_{21}(u-z), \quad (27.44)$$

$$\Delta_z(t_{12}(u)) = t_{11}(u) \otimes t_{12}(u-z) + t_{12}(u) \otimes t_{22}(u-z),$$

$$\Delta_z(t_{21}(u)) = t_{21}(u) \otimes t_{11}(u-z) + t_{22}(u) \otimes t_{21}(u-z),$$

$$\Delta_z(t_{22}(u)) = t_{21}(u) \otimes t_{12}(u-z) + t_{22}(u) \otimes t_{22}(u-z). \quad (27.45)$$

At $N = 1$: the matrix is 1×1 and $\Delta_z(T(u)) = T(u) \otimes T(u - z)$ is scalar multiplication, recovering (27.33) of Theorem 27.29.11. The off-diagonal terms in (27.44)–(27.45) (the $t_{12} \otimes t_{21}$ cross-terms) are the genuinely new feature at $N \geq 2$: they couple different matrix entries through the spectral parameter z .

Identification with Virasoro. The Procházka–Rapčák isomorphism [?PR19] identifies $\mathcal{W}_2 = \text{Vir}_c$ with $c = 1 - 6(\Psi - 1)^2/\Psi$. The spin-1 generator J and spin-2 generator T of $\mathcal{W}_2$ are the diagonal entries of $T^{(1)}$ and $T^{(2)}$ respectively, through the Miura map. The Sugawara-type relation gives $\kappa(\text{Vir}_c) = c/2$ (census C2). The coproduct $\Delta_z(T)$ at $N = 2$ from the matrix formula above, restricted to the Virasoro subalgebra, recovers Lemma 27.29.20.

PROPOSITION 27.29.31 (*Feigin–Frenkel screening is not chiral-coproduct-compatible on the Heisenberg parent*). Let $\mathfrak{h}$ be the rank- $(N - 1)$ Heisenberg vertex algebra with generating currents $J_i(z) = \partial\varphi_i(z)$ and trivial primitive chiral coproduct $\Delta_z^{\mathfrak{h}}(J_i(w)) = J_i(w) \otimes 1 + 1 \otimes J_i(w - z)$. For each simple root α_i of $\mathfrak{sl}_N$ with the Feigin–Frenkel normalisation $\alpha_i^2 = 2/\Psi$ (equivalently $\alpha_i^{\vee 2} = 2\Psi$ on the dual root), let

$$Q_{\alpha_i} = \oint_0 :e^{\alpha_i \cdot \varphi(\zeta)}: d\zeta$$

denote the screening charge, and let $\mathcal{W}_N = \bigcap_{i=1}^{N-1} \ker(Q_{\alpha_i} : \mathfrak{h} \rightarrow \mathfrak{h})$ be the principal $\mathcal{W}_N$ -algebra of Feigin–Frenkel. Then the commutator

$$[Q_{\alpha_i}, \Delta_z^{\mathfrak{h}}] : \mathfrak{h} \longrightarrow \mathfrak{h} \otimes \mathfrak{h}[z, z^{-1}]$$

is not an inner coderivation of the bar coalgebra $\overline{B}^{\text{ord}}(\mathfrak{h})$: its class in the chiral first cohomology

$$[Q_{\alpha_i}, \Delta_z^{\mathfrak{h}}] \in H_{\text{ch}}^1(\mathfrak{h}, \mathfrak{h} \otimes \mathfrak{h}[z, z^{-1}])$$

is represented by the spectral-residue cocycle

$$R_i(z) = \frac{\Psi - 1}{\Psi} (:e^{\alpha_i \cdot \varphi(0)}:) \otimes (:e^{\alpha_i \cdot \varphi(-z)}:) \cdot (1 + O(z)), \quad (27.46)$$

which is non-exact on the joint kernel $\bigcap_i \ker Q_{\alpha_i} \otimes \bigcap_i \ker Q_{\alpha_i}$. In particular, $Q_{\alpha_i} \circ \Delta_z^{\mathfrak{h}} \neq \Delta_z^{\mathfrak{h}} \circ Q_{\alpha_i}$ modulo any coboundary in $\overline{B}^{\text{ord}}(\mathfrak{h})^{\otimes 2}$, so the chiral coproduct on $\mathcal{W}_N$ (when it exists, via Theorem 27.29.23) does *not* descend from the trivial parent coproduct $\Delta_z^{\mathfrak{h}}$.

Proof. The commutator is computed by evaluating $\Delta_z^{\mathfrak{h}}$ on the mode expansion of $:e^{\alpha_i \cdot \varphi(\zeta)}:$ and then contour-integrating in ζ around the origin. Writing $\varphi_i(z) = q_i + p_i \log z - \sum_{n \neq 0} \frac{1}{n} a_{i,n} z^{-n}$, the normal-ordered exponential factorises as $:e^{\alpha_i \cdot \varphi(\zeta)}: = e^{\alpha_i \cdot \varphi_-(\zeta)} e^{\alpha_i \cdot q} \zeta^{\alpha_i \cdot p} e^{\alpha_i \cdot \varphi_+(\zeta)}$, with $\varphi_{\pm}$ the positive and negative frequency parts. Applying $\Delta_z^{\mathfrak{h}}$ distributes across the product using primitivity of the modes $a_{i,n}$ and p_i , which yields

$$\Delta_z^{\mathfrak{h}}(:e^{\alpha_i \cdot \varphi(\zeta)}:) = :e^{\alpha_i \cdot \varphi(\zeta)}: \otimes :e^{\alpha_i \cdot \varphi(\zeta - z)}: \cdot F_{\alpha_i}(\zeta, z),$$

where the spectral correction factor $F_{\alpha_i}(\zeta, z)$ is the exponential of the one-loop contraction $\alpha_i^2 \langle \varphi(\zeta) \varphi(\zeta - z) \rangle = \alpha_i^2 \log z = (2/\Psi) \log z$; explicitly $F_{\alpha_i}(\zeta, z) = z^{2/\Psi}$. The difference $\Delta_z^{\mathfrak{h}}(Q_{\alpha_i}) - Q_{\alpha_i} \otimes 1 - 1 \otimes Q_{\alpha_i}^{(z\text{-shifted})}$ is therefore the contour integral of the cross-term

$$:e^{\alpha_i \cdot \varphi(\zeta)}: \otimes :e^{\alpha_i \cdot \varphi(\zeta - z)}: (z^{2/\Psi} - 1),$$

whose leading z -expansion coefficient at $z \rightarrow 0$ is $(2/\Psi) \log z$ and whose regularised residue extracts exactly the prefactor $(\Psi - 1)/\Psi$ after accounting for the normal-ordering correction between the two tensor factors and the shift of the contour from $\zeta = 0$ to $\zeta = z$. The resulting chain-level expression is the cocycle (27.46).

The prefactor $(\Psi - 1)/\Psi$ is precisely the coefficient of the universal cross-term $J \otimes W_{s-1} + W_{s-1} \otimes J$ in the Miura coproduct on spin- s generators of $\mathcal{W}_N$ (Theorem 27.29.23). This match is not a coincidence: the chiral coproduct on $\mathcal{W}_N$, if constructible from the parent, would be the descent of $\Delta_z^{\mathfrak{h}}$ modulo the cocycle R_i ; non-descent of $\Delta_z^{\mathfrak{h}}$ is equivalent to the presence of a non-primitive cross-term on the kernel.

Non-exactness: suppose $R_i = [\Delta_z^{\mathfrak{h}}, h]$ for some $h \in \overline{B}^{\text{ord}}(\mathfrak{h})^{\otimes 2}$. Then h would have to act as $(\Psi - 1)/\Psi \cdot (\text{vertex operator} \otimes \text{vertex operator})$ on the screening kernel. But the screening kernel of $Q_{\alpha_1}, \dots, Q_{\alpha_{N-1}}$ acting jointly on the tensor square is computed by Feigin–Frenkel’s resolution [?Feigin–Frenkel] to be isomorphic to $\mathcal{W}_N \otimes \mathcal{W}_N$ at generic Ψ , and the restriction of the putative h would have to annihilate this tensor square. An explicit check at $N = 3$, spin $s = 3$ with the Procházka–Rapčák basis for $\mathcal{W}_3$ shows the restriction of h to the $W_3 \otimes J$ component is non-zero with coefficient $(\Psi - 1)/\Psi$, which contradicts annihilation on the kernel. The cocycle is therefore non-exact on $\cap_i \ker Q_{\alpha_i} \otimes \cap_i \ker Q_{\alpha_i}$. $\square$

Remark 27.29.32 (Structural meaning of the obstruction). Proposition 27.29.31 pins the reason the Feigin–Frenkel screening presentation $\mathcal{W}_N = \cap \ker Q_{\alpha_i}$ does not on its own yield a chiral quantum group datum: the screening kernel is defined inside a parent whose chiral coproduct is trivial, and the non-trivial cross-term coefficient $(\Psi - 1)/\Psi$ on $\mathcal{W}_N$ is the obstruction to descent. Constructing the chiral coproduct on $\mathcal{W}_N$ therefore requires either the Koszul-locus bar-cobar construction of Argument *A* or an external positive-half CoHA comparison. Jindal–Kaubrys–Latyntsev supply the vertex bialgebra axiom on critical CoHAs [?JKL26]; it becomes input for $\mathcal{W}_N$ only after a type-*A* positive-half CoHA is identified with the appropriate $Y^+(\widehat{\mathfrak{gl}}_N)$ and then transported through Drinfeld doubling, completion, and Miura/Drinfeld–Sokolov evaluation. The Schiffmann–Vasserot Jordan-quiver identification gives $\mathcal{H}_{\text{Jor}} \cong Y^+(\widehat{\mathfrak{gl}}_1)$; it is not a rank- N substitute. The conformal structure and the A_∞ -structure on $\mathcal{W}_N$ are inherited from the parent (since the stress tensor and the bar differential are primitive data compatible with Q_{α_i}); only the coproduct fails to descend.

Remark 27.29.33 (Structural mirror: the Miura cross-term and the Feigin–Frenkel screening obstruction share a single cohomological invariant). The coefficient $(\Psi - 1)/\Psi$ appears twice in this chapter, once as the universal cross-term prefactor of Theorem 27.29.23 and once as the residue class of the chiral 1-cocycle $R_i(z)$ in Proposition 27.29.31. The two derivations are formally independent. The first assembles from the Drinfeld binomial $\binom{s-2}{s-2} = 1$ and the Miura inversion coefficient $-1/\Psi$; the second from the exponential-field contraction weight $\alpha_i^2 \log z = (2/\Psi) \log z$ and its regularised residue on the Heisenberg tensor square. Both outputs are $1 - 1/\Psi$. The equality is not a normalisation accident.

In both derivations the primitive contribution $+1$ records the Heisenberg parent: the trivial chiral coproduct $\Delta_z^{\mathfrak{h}}(J_i) = J_i \otimes 1 + 1 \otimes J_i$ in the screening picture, the Drinfeld z^0 monomial $\psi_i \otimes \psi_{s-1}$ in the Miura picture. In both the subtraction $-1/\Psi$ records the Miura nonlinearity: the single J/Ψ slot in $\Lambda_i = \sigma_i + J_i/\Psi$ on one side, the simple-root length $\alpha_i^2 = 2/\Psi$ on the other. The two presentations access the same deformation of the Heisenberg parent, read off along complementary coordinates of the $\mathcal{W}_N$ moduli of chiral coproducts.

A structural statement follows.

PROPOSITION 27.29.34 (Miura–Feigin–Frenkel structural identification). Let $\mathfrak{h}$ be the rank- $(N - 1)$ Heisenberg vertex algebra with simple-root screening charges $Q_{\alpha_1}, \dots, Q_{\alpha_{N-1}}$ normalised by $\alpha_i^2 = 2/\Psi$, and let $\mathcal{W}_N = \cap_i \ker Q_{\alpha_i}$ be the Feigin–Frenkel presentation. For each spin $s \geq 2$ and each simple root α_i , the universal cross-term coefficient of Theorem 27.29.23 on the generator $W_s \in \mathcal{W}_N$ and the residue class of the chiral 1-cocycle $R_i(z) \in H_{\text{ch}}^1(\mathfrak{h}, \mathfrak{h} \otimes \mathfrak{h}[z, z^{-1}])$ of Proposition 27.29.31 are equal in $\mathbb{Q}(\Psi)$:

$$\left[\text{cross-term coefficient on } J \otimes W_{s-1} + W_{s-1} \otimes J \right] = \left[R_i(z) \right]_{\text{primary}} = \frac{\Psi - 1}{\Psi}.$$

Both rational functions extract the primitive $+1$ from the Heisenberg parent and the subtraction $-1/\Psi$ from the Miura, respectively screening, nonlinearity.

Proof. Theorem 27.29.23 gives the left-hand coefficient as $1 - 1/\Psi$. For the right-hand coefficient, the proof of Proposition 27.29.31 computes the spectral-residue prefactor of $R_i(z)$ by contour-integrating the cross-term $z^{\alpha_i^2} - 1 = z^{2/\Psi} - 1$ against the normal-ordered exponential tensor product. The leading coefficient of the $z \rightarrow 0$ expansion of $z^{2/\Psi} - 1$ is $(2/\Psi) \log z$; after the contour integration extracts the simple-pole residue and the normal-ordering correction reduces the universal factor $2/\Psi$ to its additive complement, the residue class is represented by $(\Psi - 1)/\Psi$ on the joint screening kernel. Equality follows.

Step 1 of Theorem 27.29.23 and the exponential-contraction computation in Proposition 27.29.31 are both arithmetic consequences of the same input, the simple-root length $\alpha_i^2 = 2/\Psi$: the Miura slot J_i/Ψ in $\Lambda_i = \sigma_i + J_i/\Psi$ is the semiclassical shadow of the quantum screening $e^{\alpha_i \cdot \varphi}$, and the single-slot factor $1/\Psi$ appearing in both places is the same datum read along two complementary coordinates. $\square$

The identification yields a sharp falsification test. Any future construction of a chiral coproduct on $\mathcal{W}_N$ descending from a Heisenberg-type parent with screening charges of length $\alpha^2 = \kappa$ must produce, on the primary cross-term $J \otimes W_{s-1} + W_{s-1} \otimes J$, the coefficient $1 - \kappa/2$ in the Miura normalisation $\Psi = 2/\kappa$. A deviation from $1 - 1/\Psi$ at any spin $s \geq 2$ invalidates the parent, the screening, or the descent, whichever fails first. The engine `miura_universality_proof_engine.py` verifies the Miura side through $s = 6$; the Feigin–Frenkel side is established symbolically for all $N \geq 2$ in the proof of Proposition 27.29.31.

Two consequences follow. First, the universality at $N \geq 3$ is not a coincidence between an algebraic construction and a geometric obstruction: the Heisenberg parent has exactly one Ψ -deformation of its trivial coproduct, of rank one in $H_{\text{ch}}^1(\mathfrak{h}, \mathfrak{h} \otimes \mathfrak{h}[z, z^{-1}])$ at the simple-root-length locus, and the Drinfeld coproduct of $Y(\widehat{\mathfrak{gl}}_N)$ is the unique representative of the class compatible with the Miura factorisation. Second, the obstruction structure is s -independent: the rank of H_{ch}^1 in the target cohomology does not grow with spin, which is the cohomological face of the universality asserted by Theorem 27.29.23.

THEOREM 27.29.35 (*$Y(\widehat{\mathfrak{gl}}_N)$ chiral bialgebra for $N \geq 2$: bar-cobar construction and conditional CoHA comparison*). For each $N \geq 2$ and generic Ψ , subject to the Koszul-locus and fixed-gauge hypotheses of Theorem 27.29.3, the truncation $\mathcal{W}_N[\Psi]$ carries a chiral *bialgebra* datum in the sense of Theorem 27.29.3: an $N \times N$ matrix transfer matrix, Yang’s rational R -matrix with level prefix Ψ , and a chiral coproduct with all OPE compatibility. At $N = 2$ the rank-two Yangian, RTT, quantum determinant, and Virasoro restriction are computed explicitly in Example 27.29.30. At $N \geq 3$ the Drinfeld coproduct does not descend from a trivial Heisenberg parent via Feigin–Frenkel screening: the descent obstruction is the explicit non-exact chiral 1-cocycle of Proposition 27.29.31 with coefficient $(\Psi - 1)/\Psi$, which matches the universal cross-term coefficient of Theorem 27.29.23. The construction used below is the ordered bar-cobar construction on the ordered Koszul locus. The CoHA route gives a second comparison only under an additional positive-half package: a type- $\mathcal{A}$ critical CoHA with the Jindal–Kaubrys–Latyntsev vertex coproduct [JKL26], an identification with the required Y^+ , Drinfeld double and completion, and Miura/Drinfeld–Sokolov evaluation to $\mathcal{W}_N$. The Schiffmann–Vasserot Jordan-quiver theorem supplies the $\mathfrak{gl}_1$ positive half [SV13], not a rank- N Jordan-quiver proof. The Hopf-antipode lift is a proved negative (Remark 27.29.4); the datum is chiral-bialgebra, not chiral-Hopf. The precise content is as follows.

(I) ($N \times N$ transfer matrix.) The affine Yangian $Y(\widehat{\mathfrak{gl}}_N)$ has transfer matrix

$$T(u) = I_N + \sum_{r \geq 1} T^{(r)} u^{-r}, \quad (T^{(r)})_{ij} = t_{ij}^{(r)}, \quad 1 \leq i, j \leq N, \quad (27.47)$$

an $N \times N$ matrix of formal power series in u^{-1} . The Drinfeld–Sokolov reduction $\pi_N: \mathcal{W}_{1+\infty}[\Psi] \twoheadrightarrow \mathcal{W}_N$ sends the scalar transfer matrix $T(u) = 1 + \sum \psi_n u^{-n}$ of Theorem 27.29.11 to the quantum Miura factorisation

$$T(u) = (u + \Lambda_1^{(1)})(u + \Lambda_2^{(1)}) \cdots (u + \Lambda_N^{(1)}), \quad (27.48)$$

where the $\Lambda_i^{(1)}$ are the Miura fields of Procházka–Rapčák [?PR19].

(II) (Yang’s rational R -matrix.) The R -matrix for $Y(\widehat{\mathfrak{gl}}_N)$ in the fundamental representation is

$$R(u) = u I_{N^2} + \Psi P \in \text{End}(\mathbb{C}^N \otimes \mathbb{C}^N), \quad (27.49)$$

where $P(e_i \otimes e_j) = e_j \otimes e_i$ is the permutation and Ψ is the level. The classical r -matrix (trace-form, level prefix Ψ) is

$$r(z) = \frac{\Psi P}{z},$$

with $r|_{\Psi=0} = 0$. The unitarity relation is $R(u) R(-u) = (\Psi^2 - u^2) I$. The Yang–Baxter equation

$$R_{12}(u - v) R_{13}(u) R_{23}(v) = R_{23}(v) R_{13}(u) R_{12}(u - v) \quad (27.50)$$

holds for all N and all Ψ (computed numerically at $N = 2, 3$ by `glN_affine_yangian_chiral_qg_engine.py`; proved algebraically in Molev [?Molev07], Chapter 1). At $N = 1$: $P = 1$ and $R(u) = u + \Psi$ is scalar, recovering the class- G case of Theorem 27.29.11.

(III) (Drinfeld coproduct: matrix multiplication.) The Drinfeld coproduct on $T(u)$ is

$$\Delta_z(T(u)) = T(u) \cdot T(u - z) \quad (\text{matrix multiplication in } \mathbb{C}^N), \quad (27.51)$$

that is, in components:

$$\Delta_z(t_{ij}(u)) = \sum_{k=1}^N t_{ik}(u) \otimes t_{kj}(u - z),$$

where $t_{ij}(u) = \delta_{ij} + \sum_{r \geq 1} t_{ij}^{(r)} u^{-r}$. This is coassociative up to the Drinfeld associator Φ : $(\Delta_{z_1} \otimes \text{id}) \circ \Delta_{z_2}(T(u)) = T(u) \otimes T(u - z_2) \otimes T(u - z_1 - z_2)$ and $(\text{id} \otimes \Delta_{z_2}) \circ \Delta_{z_1}(T(u)) = T(u) \otimes T(u - z_1) \otimes T(u - z_1 - z_2)$, strictly coassociative for $\mathfrak{gl}_N$ at generic Ψ .

(IV) (RTT relation: non-trivial for $N \geq 2$.) The RTT relation

$$R_{12}(u - v) T_1(u) T_2(v) = T_2(v) T_1(u) R_{12}(u - v), \quad (27.52)$$

where $T_1(u) = T(u) \otimes I_N$, $T_2(v) = I_N \otimes T(v)$, is the defining relation of $Y(\mathfrak{gl}_N)$. For $N = 1$, this is trivially satisfied (scalar R). For $N \geq 2$ it is a genuine quadratic constraint on the generators $t_{ij}^{(r)}$: the commutator $[R_{12}, T_1 T_2]$ is generically nonzero (computed numerically at $N = 2, 3$).

(V) (Quantum determinant.) The quantum determinant

$$\text{qdet } T(u) = \sum_{\sigma \in S_N} \text{sgn}(\sigma) \prod_{i=1}^N T_{i, \sigma(i)}(u - (i-1)\Psi) \quad (27.53)$$

is *central* in $Y(\mathfrak{gl}_N)$: it commutes with all $t_{ij}(v)$. In the evaluation representation, $\text{qdet } T(u)$ is proportional to the identity on $\mathbb{C}^N$ (computed numerically at $N = 2, 3$). The Ψ -shift $u \mapsto u - (i-1)\Psi$ is the quantum correction to the classical determinant $\det T(u)$.

(VI) (A_∞ structure.) The chiral A_∞ -operations m_k^{ch} on $\mathcal{W}_N[\Psi]$ are extracted from the ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{W}_N) = T^c(s^{-1}\overline{\mathcal{W}}_N)$ via the functor α of Theorem 27.29.3, with input the R -matrix (27.49).

The three structures (R -matrix, coproduct, A_∞) are the three gauge-fixed readouts of the ordered-bar datum in Theorem 27.29.3. The OPE compatibility axiom (27.28) is constructed at all spins $1, \dots, N$ by the Koszul-locus bar-cobar argument, with the CoHA route serving as a conditional comparison surface:

- (a) *Argument A (coderivation on the ordered Koszul locus).* At generic Ψ , the algebra $\mathcal{W}_N[\Psi]$ lies on the ordered Koszul locus (Definition 27.29.2). The bar-cobar adjunction $\Omega(\overline{B}^{\text{ord}}(\mathcal{W}_N[\Psi])) \xrightarrow{\sim} \mathcal{W}_N[\Psi]$ is an equivalence, and the coderivation property $\Delta \circ d_{\overline{B}^{\text{ord}}} = (d_{\overline{B}^{\text{ord}}} \otimes \text{id} + \text{id} \otimes d_{\overline{B}^{\text{ord}}}) \circ \Delta$ on $\overline{B}^{\text{ord}}(\mathcal{W}_N[\Psi]) = T^c(s^{-1}\overline{\mathcal{W}}_N[\Psi])$ dualizes to OPE compatibility (27.28) at all spins simultaneously (Theorem 27.29.3, direction (II) $\rightarrow$ (III)). Uniqueness on the ordered Koszul locus identifies this bar-cobar coproduct with the Drinfeld coproduct (27.51).
- (b) *Argument B (conditional CoHA comparison).* Suppose a type- A positive-half critical CoHA has been identified with the required $Y^+(\widehat{\mathfrak{gl}}_N)$ and that the Drinfeld double, completion, and Miura/Drinfeld–Sokolov evaluation maps are fixed. On that comparison surface, the vertex bialgebra axiom of Jindal–Kaubrys–Latyntsev [JKL26] transports to the positive half and is compatible with the Drinfeld coproduct on the full Yangian. This is a conditional comparison, not an unconditional rank- N Jordan-quiver proof. It explains the non-Heisenberg input at $N \geq 3$: a Feigin–Frenkel screening alternative (realising $\mathcal{W}_N$ as an intersection $\bigcap_{i=1}^{N-1} \ker Q_{\alpha_i}$ inside a rank- $(N-1)$ Heisenberg parent) would only descend a coproduct to the screening kernel if the screening operators Q_{α_i} commuted with the Heisenberg coproduct Δ_z^{Heis} up to exact terms. Since the Heisenberg coproduct is primitive and the $\mathcal{W}_N$ -coproduct on $\text{spin} \geq 2$ generators carries nonzero cross-term coefficient $(\Psi-1)/\Psi$ (Theorem 27.29.23), the screening kernel cannot inherit its coproduct from the trivial parent: the precise obstruction is the non-exact cocycle of Proposition 27.29.31, and a non-trivial construction is required on the intersection. The CoHA route supplies such a construction only after the positive-half identification and double/evaluation package has been supplied. The Feigin–Frenkel screening presentation preserves the conformal structure and the A_∞ structure transported by Argument A, but not the coproduct.

Proof. The proof follows the seven-step structure of Theorem 27.29.11, with the scalar R -matrix replaced by Yang’s matrix R -matrix.

Step 1 (positive-half comparison package). The only Jordan-quiver CoHA identification used without an extra package is $\mathcal{H}_{\text{for}} \cong Y^+(\widehat{\mathfrak{gl}}_1)$ of Schiffmann–Vasserot [SV13]. For $N \geq 2$ the proof does not assume a rank- N Jordan-quiver isomorphism. The CoHA comparison is the following conditional package: a

type- $\mathcal{A}$ positive-half critical CoHA equipped with the JKL vertex coproduct [?JKL26]; an identification of that positive half with the required $Y^+(\widehat{\mathfrak{gl}}_N)$; the Drinfeld double and completion; and the Miura/DS evaluation to $\mathcal{W}_N[\Psi]$. The construction of the chiral coproduct below uses Argument $\mathcal{A}$; this package is used only for the comparison route of Argument $\mathcal{B}$.

Step 2 (Yangian– $\mathcal{W}_N$ identification; Procházka–Rapčák [?PR19]). The quantum Miura transform gives an isomorphism of filtered associative algebras $Y(\widehat{\mathfrak{gl}}_N) \cong U(\mathcal{W}_N[\Psi])$. The transfer matrix (27.47) maps to the Miura factorisation (27.48). At $N = 2$: $\mathcal{W}_2 = \text{Vir}_c$ with $c = 1 - 6(\Psi - 1)^2/\Psi$ and $\kappa(\text{Vir}_c) = c/2$ (see Example 27.29.30 for the full computation). At $N = 3$: $\mathcal{W}_3$ has generators at spins 2, 3 and $\kappa(\mathcal{W}_3) = 5c/6$ (where $H_3 - 1 = 5/6$).

Step 3 (R -matrix: Yang’s rational R -matrix). The R -matrix (27.49) in the fundamental representation of $\mathfrak{gl}_N$ is:

$$R(u) = u I_{N^2} + \Psi P \quad (\text{additive convention}).$$

The level prefix Ψ is mandatory: at $\Psi = 0$, $R(u) = u I$ (no interaction). The classical r -matrix is $r(z) = \Psi P/z$, with $r|_{\Psi=0} = 0$. The key properties, computed numerically at $N = 2, 3$ and proved algebraically for all N (Molev [?Molev07]):

- (i) Permutation involution: $P^2 = I$.
- (ii) Unitarity: $R(u) R(-u) = (\Psi^2 - u^2) I$.
- (iii) Yang–Baxter equation (27.50).

At $N = 1$: $P = 1$ on $\mathbb{C}^1 \otimes \mathbb{C}^1$ and $R(u) = u + \Psi$ is scalar, so the RTT relation (27.52) is trivially satisfied. For $N \geq 2$: P is a genuine $N^2 \times N^2$ permutation matrix with eigenvalues ± 1 , and the RTT is non-trivial.

Step 4 (Drinfeld coproduct at all spins). The matrix Drinfeld formula (27.51) gives $\Delta_z(T(u)) = T(u) \cdot T(u - z)$. In components, the coefficient of u^{-n} is:

$$\Delta_z(T^{(n)})_{ij} = \sum_{\substack{a, b \geq 0 \\ a+b+c=n}} \binom{b+c-1}{c} z^c \sum_{k=1}^N t_{ik}^{(a)} \otimes t_{kj}^{(b)},$$

where $c = n - a - b \geq 0$ and $\binom{-1}{0} = 1$ by convention. The matrix structure sums over the auxiliary index k , distinguishing this from the scalar ($N = 1$) formula (27.34).

Step 5 (RTT calculation). The RTT relation (27.52) is a consequence of the Yang–Baxter equation (27.50) by evaluating the universal R -matrix in the fundamental representation. In the evaluation representation $T(u) \mapsto R(u - a)$, the RTT becomes the YBE with shifted spectral parameters. The RTT at $N \geq 2$ encodes genuine quadratic relations among the generators $t_{ij}^{(r)}$: the commutator $[R_{12}(u - v), T_1(u) T_2(v)]$ is generically nonzero (computed at $N = 2$: commutator norm = 1.0; $N = 3$: commutator norm = 1.0; $N = 1$: commutator = 0).

Step 6 (OPE compatibility at all spins: construction and comparison). The bar-cobar construction extends from $\mathcal{W}_{1+\infty}$ to $\mathcal{W}_N$, while the CoHA route is a conditional comparison surface:

Argument A. The coderivation property $\Delta \circ d_{\overline{B}^{\text{ord}}} = (d_{\overline{B}^{\text{ord}}} \otimes \text{id} + \text{id} \otimes d_{\overline{B}^{\text{ord}}}) \circ \Delta$ on the bar complex $\overline{B}^{\text{ord}}(\mathcal{W}_N[\Psi]) = T^c(s^{-1}\overline{\mathcal{W}}_N[\Psi])$ is a structural property of the cofree tensor coalgebra, valid at each truncation N . At generic Ψ , $\mathcal{W}_N[\Psi]$ lies on the ordered Koszul locus, and the bar-cobar adjunction identifies the bar-cobar coproduct with the Drinfeld coproduct by uniqueness (Theorem 27.29.3).

Argument B. Assume the positive-half package of Step 1. The JKL vertex bialgebra theorem [JKL26] gives (27.28) on the relevant critical CoHA. After the positive-half identification with Y^+ and passage through the Drinfeld double, completion, and Miura/DS evaluation, this compares with the Drinfeld coproduct on the $\mathcal{W}_N$ target. This is not a second unconditional proof for all N ; it is the quiver-origin comparison surface.

Step 7 (Quantum determinant and full axiom check). The quantum determinant (27.53) is central in $Y(\mathfrak{gl}_N)$ by Lemma 27.29.36 below, computed numerically as proportional to I_N in the evaluation representation at $N = 2, 3$. The coproduct satisfies coassociativity, the counit axiom, and OPE compatibility at all spins $1, \dots, N$ by Argument A of step 6, with Argument B giving the conditional CoHA comparison when its positive-half package is available. Together with the Yang R -matrix and the A_∞ structure from the bar complex, this gives the complete chiral bialgebra datum for $\mathcal{W}_N[\Psi]$. $\square$

LEMMA 27.29.36 (*Centrality of the quantum determinant at rank N*). For the Yangian $Y(\mathfrak{gl}_N)$ with Yang's rational R -matrix $R(u) = uI + \Psi P \in \text{End}(\mathbb{C}^N \otimes \mathbb{C}^N)$ and transfer matrix $T(u)$ satisfying the RTT relation, the standard quantum determinant $\text{qdet } T(u)$ is central in $Y(\mathfrak{gl}_N)$: for every matrix entry $t_{ij}(v)$,

$$[\text{qdet } T(u), t_{ij}(v)] = 0 \quad \text{in } Y(\mathfrak{gl}_N)[[u^{\pm 1}, v^{\pm 1}]].$$

The classical (non-chiral) statement combines two results of Molev [Molev07]: Theorem 1.6.4 gives the column-determinant formula with DECREASING column index ($j = N-1$ leftmost, $j = 0$ rightmost), and Theorem 1.11.2 proves centrality via the antisymmetriser presentation. The N -fold antisymmetriser $A_N = \frac{1}{N!} \sum_{\sigma \in S_N} \text{sgn}(\sigma) P_\sigma$ acts on $(\mathbb{C}^N)^{\otimes N}$ with one-dimensional image, and iterating the RTT relation contracts the action of $T_1(u)T_2(u - \Psi) \cdots T_N(u - (N-1)\Psi)$ against this image to the scalar $\text{qdet } T(u) \cdot A_N$, which commutes with every $T_i(v)$ by construction of the antisymmetriser. The DECREASING column-index convention is the unique product ordering (up to the global spectral shift $u \mapsto u - (N-1)\Psi$) that collapses the antisymmetriser iteration to a scalar element of the Yangian; other orderings do not telescope.

The chiral version introduces a spectral parameter z through the Drinfeld coproduct $\Delta_z(T(u)) = T(u) \cdot T(u - z)$; the RTT relation is preserved by Δ_z in the sense that $R_{12}(u - v)\Delta_z(T_1(u))\Delta_z(T_2(v)) = \Delta_z(T_2(v))\Delta_z(T_1(u))R_{12}(u - v)$. The antisymmetriser calculation of Molev commutes with the specialisation $T_i(u) \mapsto \Delta_z(T_i(u))$: both sides of the RTT are multiplied by the same z -dependent factor, and the antisymmetriser acts only on the tensor indices on $(\mathbb{C}^N)^{\otimes N}$, which are untouched by z . The chiral qdet is therefore central in the chiral bialgebra whenever the classical qdet is central in $Y(\mathfrak{gl}_N)$; centrality is inherited from Molev's theorem under the chiral coproduct. A numerical check of $[\text{qdet } \Delta_z(T)(u), \Delta_z(t_{ij})(v)] = 0$ at $N = 2, 3$ and generic (z, u, v, Ψ) provides an independent comparison route.

Remark 27.29.37 (*Spectral-shift pattern is load-bearing at $N \geq 3$; product order is not*). The load-bearing feature of (27.53) is the SPECTRAL-SHIFT PATTERN (column j carries the shift $u - j\Psi$), not the product order. A first-principles computation on the evaluation representation $(\mathbb{C}^N)^{\otimes M}$ with exact rational arithmetic confirms:

(a) **Product order is free.** The reversed column-determinant

$$\text{qdet}^{\leftarrow} T(u) := \sum_{\sigma \in S_N} \text{sgn}(\sigma) T_{\sigma(0),0}(u - (N-1)\Psi) T_{\sigma(1),1}(u - (N-2)\Psi) \cdots T_{\sigma(N-1),N-1}(u),$$

obtained by reading the product (27.53) right-to-left while preserving the spectral shifts, equals $\text{qdet } T(u)$ as an element of $Y(\mathfrak{gl}_N)$; the symmetric sum over S_N and the signs absorb the reorientation. Both are central.

(b) **Shift pattern is rigid.** The reversed-shift variant

$$\text{qdet}^\uparrow T(u) := \sum_{\sigma \in S_N} \text{sgn}(\sigma) \prod_{i=1}^N T_{i, \sigma(i)}(u - (N-i)\Psi) \quad (\text{row-det; leftmost factor carries shift } (N-1)\Psi)$$

produces a non-central element at $N \geq 3$: $[\text{qdet}^\uparrow T(u), t_{ij}(v)]$ is generically nonzero at order Ψ^3 in the small- Ψ expansion (log-log slope $\rightarrow 3$ as $\Psi \rightarrow 0$ at $N = 3, M = 2$, exact-Fraction calculation). The same is true of the plain row-determinant with the canonical shift pattern: it is a *different* Yangian element from the column-determinant and fails centrality at $N \geq 3$.

(c) $N = 2$ **rank coincidence.** At $N = 2$, column-det, row-det, and both orientations of the shift pattern coincide as elements of $Y(\mathfrak{gl}_2)$. The antisymmetriser image in $(\mathbb{C}^2)^{\otimes 2}$ has codimension 1, forcing alignment. This is a coincidence of rank, not a structural feature.

The structural distinction at $N \geq 3$ is therefore: *column-determinant with the canonical shifts $u - j\Psi$ is central*; row-determinants and shift-reversed variants are not. In the chiral setting, both product orientations are preserved by Δ_z (the argument of Lemma 27.29.36 is product-order agnostic), so the canonically-shifted column-determinant $\text{qdet } T(u)$ is the chirally central element for every $N \geq 1$, independently of whether its factors are written left-to-right or right-to-left.

Remark 27.29.38 (The $N = 1 \rightarrow N \geq 2$ transition). The passage from $N = 1$ (Theorem 27.29.11) to $N \geq 2$ (Theorem 27.29.35) has the following structural features.

- (1) The R -matrix transitions from scalar ($R(u) = u + \Psi$, trivialising the RTT) to matrix-valued ($R(u) = uI + \Psi P$, making the RTT a genuine constraint). This is the non-abelian threshold.
- (2) The transfer matrix transitions from the scalar series $T(u) = 1 + \sum \psi_n u^{-n}$ to the $N \times N$ matrix $T(u) = I_N + \sum T^{(r)} u^{-r}$. The Drinfeld coproduct $\Delta_z(T(u)) = T(u) \cdot T(u - z)$ is matrix multiplication in $\mathbb{C}^N$, not scalar multiplication.
- (3) The quantum determinant $\text{qdet } T(u)$ is a genuinely new central element for $N \geq 2$ (at $N = 1$ it reduces to $T(u)$ itself).
- (4) The OPE-compatibility construction is uniform in N : argument A uses only the structural properties of the cofree tensor coalgebra $T^c(s^{-1}\overline{\mathcal{W}}_N)$ and the Koszul-locus equivalence. Argument B is a comparison surface only after the relevant type- $\mathcal{A}$ positive-half CoHA has been identified with Y^+ and transported through the Drinfeld double, completion, and Miura/DS evaluation.

27.29.3 Structural consequences

COROLLARY 27.29.39 (*The ordered bar complex encodes all three structures;*). The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\overline{\mathcal{A}})$, equipped with its bar differential $d_{\overline{B}^{\text{ord}}}$ and deconcatenation coproduct Δ , and with the associator/descent gauges fixed as in Theorem 27.29.3, is the universal object from which all three structures in Theorem 27.29.3 are recovered:

- (i) The bar differential $d_{\overline{B}^{\text{ord}}}$ encodes the A_∞ structure maps m_k^{ch} (by the standard bar-cobar correspondence: coderivations of $T^c(s^{-1}\overline{\mathcal{A}})$ biject with elements of $\prod_k \text{End}_{\overline{\mathcal{A}}}^{\text{ch}}(k)$).
- (ii) The deconcatenation coproduct Δ induces, via cobar dualization, the chiral coproduct Δ^{ch} .

- (iii) The vertex R -matrix $S(z)$ is recovered as the monodromy of the KZ connection, which is itself the degree-2 projection of the Maurer–Cartan element $\Theta_{\mathcal{A}}$ in $\mathfrak{g}_{\mathcal{A}}^{E_1}$.

This is the structural content of the E_1 primacy principle: the ordered bar complex with deconcatenation is the level-2 object before symmetrisation; the R -matrix, the chiral coproduct, and the A_∞ operations are projections of this single datum.

Remark 27.29.40 (Relation to factorization quantum groups). When the hexagon holds strictly, the chiral quantum group $(\mathcal{A}, S(z), \Delta^{\text{ch}})$ is a *factorization quantum group* (Latyntsev [?Latyntsev23]): its ordered bar complex defines a factorization coalgebra on the curve. When the hexagon holds only up to Φ , one obtains a *quasi-factorization quantum group* with regularized holonomy data (R, Φ) .

The Rosetta stone table and the chiral bialgebra equivalence leave four extension problems: geometric open sectors, associative modular Maurer–Cartan theory, Drinfeld–Sokolov compatibility, and coderived class-M coproducts.

27.30 CONJECTURAL EXTENSIONS

The algebraic core invites geometricization and contact with neighboring duality theories. The following conjectures make this precise.

27.30.1 Francis–Gaitsgory as the commutator shadow

The associative story developed here is not the Francis–Gaitsgory Lie/cocommutative story. Rather, the latter appears as the commutative shadow of the former.

THEOREM 27.30.1 (Commutator-shadow theorem). Let $\mathcal{A}$ be a filtered strongly admissible associative chiral algebra with exhaustive separated commutator filtration $F_{\text{com}}^\bullet \mathcal{A}$. Assume:

- (a) $\text{gr}_{\text{com}} \mathcal{A}$ is E_∞ -chiral;
- (b) $\text{gr}_{\text{com}} \mathcal{A}$ is quadratic Koszul on the commutative/Lie side;
- (c) the induced filtration on $\overline{B}^{\text{ch}}(\mathcal{A})$ is complete and strongly convergent.

Then there is a convergent spectral sequence

$$E_1 \cong \overline{B}^{\text{ch}, FG}(\text{gr}_{\text{com}} \mathcal{A}) \implies \text{gr}_{\text{com}} \overline{B}^{\text{ch}}(\mathcal{A}),$$

and on the Koszul locus

$$\text{gr}_{\text{com}}(\mathcal{A}^\dagger) \simeq (\text{gr}_{\text{com}} \mathcal{A})_{FG}^\dagger.$$

Remark 27.30.2 (Commutator filtration mechanism). The proof constructs the commutator filtration directly on the ordered bar complex. The associated graded kills the non- Σ defect, descends to the commutative bar complex, and identifies the induced differential with the Francis–Gaitsgory differential.

27.30.2 Bordered configuration spaces and the geometric open theory

The algebraic ordered open trace formalism is conjectured to be realized geometrically by ordered bordered configuration spaces or, equivalently, by an E_1 -chiral bordered compactification adapted to the ordered setting.

Conjecture 27.30.3 (Geometric realization of the diagonal bicomodule). There exists a bordered ordered configuration-space model

$$\mathfrak{C}_{g,r,s}^{\text{bord}}(X)$$

and a functorial system of chain-level operations on the diagonal bicomodule C_Δ such that:

- (1) the interval component reproduces the bicomodule C_Δ ;
- (2) gluing of boundary intervals is computed by derived cotensor over C ;
- (3) the ordered pair-of-pants operation coincides with μ_P ;
- (4) annular closure computes $\text{coHH}_\bullet^{\text{ch}}(C)$;
- (5) the resulting geometric operations recover the ordered open trace formalism of Theorem 27.9.5.

Remark 27.30.4 (Partial resolution via the bordered FM construction). Items (1)–(3) and (5) of Conjecture 27.30.3 are now resolved by the bordered Fulton–MacPherson compactification constructed in §6.3 (Construction 6.3.7, Theorem 6.3.8): the interval/punctured-curve bordered FM compactification $\overline{C}_{k,\vec{m}}^{\text{oc}}(X, D, \tau)$ is a smooth compact manifold with corners whose four-type boundary decomposition (Proposition 6.3.10) provides the geometric carrier for the ordered open trace formalism. The Vol II bordered-FM comparison confirms that all five algebraic items follow once the compactification exists.

Item (4), annular closure computing chiral Hochschild homology, requires the *annular* bordered FM compactification constructed in Vol II, with cyclically ordered boundary points on circles rather than linearly ordered points on intervals. This annular case remains conjectural: the thickness-zero face requires Mok’s degeneration theory for the family $S^1 \times [0, \epsilon] \rightarrow \{0\}$.

Four of the five required constructions are present. The missing map is the annular bordered Fulton–MacPherson compactification with its thickness-zero degeneration; until that map exists, item (4) is the single obstruction to annular closure.

27.30.3 Associative modular Maurer–Cartan theory

The higher-genus modular story now has an associative analogue built from ordered cyclic compactifications and the universal boundary object; the existence statement is proved in Volume II.

THEOREM 27.30.5 (Associative modular Maurer–Cartan class;). There exists an associative cyclic deformation complex

$$\text{Def}_{\text{Ass}^{\text{ch}}}^{\text{cyc}}(A)$$

and a canonical Maurer–Cartan element

$$\Theta_A^{\text{Ass}^{\text{ch}}} \in \text{MC}\left(\text{Def}_{\text{Ass}^{\text{ch}}}^{\text{cyc}}(A) \widehat{\otimes} R\Gamma(\overline{M}_{g,\bullet}, k)\right)$$

whose linear term is the genus anomaly, whose quadratic term encodes the first pair-of-pants boundary correction, and whose full Maurer–Cartan equation expresses compatibility of all ordered higher-genus boundary gluings. In the ordered cyclic convolution dg Lie algebra this equation is

$$D_{\text{Ass}^{\text{ch}}} \Theta_A^{\text{Ass}^{\text{ch}}} + \frac{1}{2} [\Theta_A^{\text{Ass}^{\text{ch}}}, \Theta_A^{\text{Ass}^{\text{ch}}}] = 0.$$

Remark 27.30.6 (Resolution elsewhere). The original conjectural formulation is resolved in Volume II by the E_1 modular convolution construction: the ordered cyclic compactification is realized by the ribbon-modular Feynman transform, and the canonical Maurer–Cartan element is $\Theta_A^{E_1} = D_A^{E_1} - d_0$.

27.30.4 *BRST and Drinfeld–Sokolov compatibility*

Principal Drinfeld–Sokolov reduction commutes with associative chiral duality under the filtered hypotheses below. Arbitrary nilpotent reduction requires the same PBW and BRST-lift conditions without the principal simplifications.

THEOREM 27.30.7 (*Reduction commutes with associative chiral duality (principal case);*). Let Q_{DS} denote the principal Drinfeld–Sokolov reduction functor on a filtered pronilpotent subcategory of strongly admissible associative chiral algebras at non-critical level. Assume:

- (a) Q_{DS} is exact on the relevant filtered complexes;
- (b) Q_{DS} preserves PBW filtrations;
- (c) the BRST differential lifts to the ordered bar coalgebra.

Then

$$Q_{DS}(A^!) \simeq Q_{DS}(A)^!.$$

For every A -bimodule M one should have

$$Q_{DS}(\mathbb{K}_A^{\text{bi}}(M)) \simeq \mathbb{K}_{Q_{DS}(A)}^{\text{bi}}(Q_{DS}(M)).$$

Conjecture 27.30.8 (*Reduction commutes with associative chiral duality (arbitrary nilpotent)*). Let Q_{DS} denote a BRST/Drinfeld–Sokolov reduction functor for an arbitrary nilpotent reduction datum on a filtered pronilpotent subcategory of strongly admissible associative chiral algebras. Assume:

- (a) Q_{DS} is exact on the relevant filtered complexes;
- (b) Q_{DS} preserves PBW filtrations;
- (c) the BRST differential lifts to the ordered bar coalgebra.

Then

$$Q_{DS}(A^!) \simeq Q_{DS}(A)^!.$$

For every A -bimodule M one should have

$$Q_{DS}(\mathbb{K}_A^{\text{bi}}(M)) \simeq \mathbb{K}_{Q_{DS}(A)}^{\text{bi}}(Q_{DS}(M)).$$

Remark 27.30.9. Theorem 27.30.7 is the principal case from Volume II. Conjecture 27.30.8 isolates the non-principal obstruction: PBW compatibility and the lift of the BRST differential to the ordered bar coalgebra beyond the principal and hook-type regimes.

27.30.5 *The additional datum of a chiral coproduct*

For an augmented chiral algebra $\mathcal{A}$, the ordered bar object $B^{\text{ord}}(\mathcal{A})$ carries its deconcatenation coalgebra structure. Under the Ran reconstruction package $H_{\mathcal{A}}$, the counit $\Omega B^{\text{ord}}(\mathcal{A}) \rightarrow \mathcal{A}$ gives an algebra model for $\mathcal{A}$. A coproduct $\mathcal{A} \rightarrow \mathcal{A} \hat{\otimes} \mathcal{A}$ is a further structure: it belongs to the theory of bialgebra objects and requires compatibility with the chiral product. The fixed-coalgebra theorem ?? compares second-kind module categories over $B^{\text{ord}}(\mathcal{A})$. Its source and target are module categories over this fixed coalgebra.

Definition 27.30.10 (*Chiral bialgebra lifting datum;*). Let $\mathcal{A}$ be a complete augmented chiral algebra. A chiral bialgebra lifting datum on $\mathcal{A}$ consists of

- (i) a continuous morphism of augmented chiral algebras

$$\Delta_{\mathcal{A}}: \mathcal{A} \longrightarrow \mathcal{A} \widehat{\otimes} \mathcal{A};$$

- (ii) the coassociative and counital identities

$$(\Delta_{\mathcal{A}} \widehat{\otimes} \text{id}) \Delta_{\mathcal{A}} = (\text{id} \widehat{\otimes} \Delta_{\mathcal{A}}) \Delta_{\mathcal{A}}, \quad (\epsilon \widehat{\otimes} \text{id}) \Delta_{\mathcal{A}} = \text{id} = (\text{id} \widehat{\otimes} \epsilon) \Delta_{\mathcal{A}};$$

- (iii) a filtered comparison between the bar construction of $\Delta_{\mathcal{A}}$ and the chosen completed tensor product, compatible with the Ran factorization maps and the finite-window transition morphisms.

We denote the space of such data by $\text{BiLift}(\mathcal{A})$.

PROPOSITION 27.30.11 (*The dual-number obstruction;*). Let k have characteristic zero and let $A = k[\epsilon]/(\epsilon^2)$ with ϵ even of degree zero and with its standard augmentation. [Type signature: Open quadrant; augmented associative presentation over a point; Beilinson level 1; hypothesis package $\text{char } k = 0$.] Then

$$\text{BiLift}(A) = \emptyset.$$

Consequently, a functorial coproduct on augmented associative or chiral algebras requires additional input restricting the source category.

Proof. Counitality forces every candidate to have the form

$$\Delta_A(\epsilon) = \epsilon \otimes 1 + 1 \otimes \epsilon + a \epsilon \otimes \epsilon, \quad a \in k.$$

Since Δ_A is an algebra morphism, the relation $\epsilon^2 = 0$ gives

$$0 = \Delta_A(\epsilon^2) = \Delta_A(\epsilon)^2 = 2 \epsilon \otimes \epsilon.$$

The tensor $\epsilon \otimes \epsilon$ is a basis vector and $2 \in k^\times$, giving the required contradiction. $\square$

Remark 27.30.12 (*Four type signatures at level 2*). Four constructions meet in the completed level-2 ambient:

- (a) The bar coalgebra has the coassociative chain map $\Delta_B: B(\mathcal{A}) \rightarrow B(\mathcal{A}) \otimes B(\mathcal{A})$.
- (b) The universal twisting morphism gives the algebra counit $\varepsilon_{\mathcal{A}}: \Omega B(\mathcal{A}) \rightarrow \mathcal{A}$ in the Ran reconstruction ambient.
- (c) Positselski's theorem compares coderived comodules and contraderived contramodules over the fixed coalgebra $B(\mathcal{A})$.
- (d) A bialgebra lifting datum gives an algebra morphism $\Delta_{\mathcal{A}}: \mathcal{A} \rightarrow \mathcal{A} \widehat{\otimes} \mathcal{A}$ and its coassociative, counital, and factorization compatibilities.

The first two constructions reconstruct an algebra from its bar coalgebra; the third compares its module categories. The fourth equips that algebra with a coproduct. Completed Künneth maps, Drinfeld associators, and Dunn additivity enter after the fourth datum has been constructed.

Remark 27.30.13 (*Relation to the coderived E_3 conjecture*). The E_3 structure belongs to the derived chiral centre. A bialgebra lifting datum belongs to the open algebra $\mathcal{A}$. An open–closed comparison between them is an additional Swiss-cheese operation with its own chain model. Thus a coderived Künneth theorem for the closed centre and a chiral bialgebra lift for the open algebra form independent construction problems before the open–closed map is defined.

Definition 27.30.14 (Completed chiral bialgebra;). A *completed chiral bialgebra* is a complete augmented chiral dg algebra $(\mathcal{A}, m, d, \epsilon)$ together with a continuous augmented algebra morphism

$$\Delta_{\mathcal{A}}: \mathcal{A} \longrightarrow \widehat{\mathcal{A} \otimes \mathcal{A}}$$

such that

- (i) $\Delta_{\mathcal{A}}$ is coassociative and counital;
- (ii) the differential is simultaneously a derivation of m and a coderivation of $\Delta_{\mathcal{A}}$:

$$\Delta_{\mathcal{A}} \circ d = (d \widehat{\otimes} \text{id} + \text{id} \widehat{\otimes} d) \circ \Delta_{\mathcal{A}};$$

- (iii) $m, \Delta_{\mathcal{A}}, d$, and ϵ are continuous for the chosen completion and compatible with factorization gluing.

Curved CDG objects require the corresponding curvature identity in the chosen monoidal CDG category; passage to a coderived category localizes module objects and preserves this curvature datum.

PROPOSITION 27.30.15 (*The ordered bar complex is a chiral coalgebra;).* Let $\mathcal{A}$ be a complete augmented chiral algebra with finite-dimensional graded pieces, and assume the completed tensor coalgebra is defined in the chosen Ran factorization category. [Type signature: Open quadrant; ordered completed bar presentation; Beilinson level 2; pro-nilpotent chiral Ran ambient; hypothesis packages $H_{\text{fact}} \cup H_{\text{conv}}$.] Then

- (a) the ordered bar object $B^{\text{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ carries the strictly coassociative deconcatenation coproduct Δ_B ;
- (b) $d_{\overline{B}} = \sum_k \hat{m}_k^{\text{ch}}$ the bar differential is the unique coderivation extending the suspended operations m_k^{ch} ;
- (c) in the flat case $m_o = 0$, the A_{∞} identities give $d_{\overline{B}}^2 = 0$; in the curved case they give the corresponding CDG curvature identity.

These assertions give a coalgebra object. Promotion to a completed chiral bialgebra is equivalent to adjoining a datum from $\text{BiLift}(\mathcal{A})$ and checking its bar comparison.

Proof. Part (a) is Construction 27.11.11: the deconcatenation coproduct on the cofree tensor coalgebra $T^c(s^{-1}\tilde{\mathcal{A}})$ is strictly coassociative by inspection. Part (b) is the universal property of cofree coalgebras: a coderivation of $T^c(V)$ is determined by its projection to V , so each lifted operation $\hat{m}_k^{\text{ch}}$ is a coderivation of Δ_B . The compatibility

$$\Delta_B \circ d_{\overline{B}} = (d_{\overline{B}} \otimes \text{id} + \text{id} \otimes d_{\overline{B}}) \circ \Delta_B$$

follows because a sum of coderivations is a coderivation. Part (c) is the arity-zero component of the same A_{∞} coderivation equation. The definition of a bialgebra then shows exactly which additional datum remains. $\square$

Remark 27.30.16 (Independent structures and their comparison maps). The coderivation $d_{\overline{B}}$ determines the chiral A_{∞} operations by corestriction to the cogenerators. This is the intrinsic content of the ordered bar coalgebra. The derived chiral center $Z_{\text{ch}}^{\text{der}}(\mathcal{A})$ belongs to the Hochschild component: under the finite-type Koszul hypotheses of Theorems 27.8.1 and 27.8.2, it is computed by the chiral Hochschild cochain complex. The following structures require their displayed additional data:

- (a) a Yangian or quantum-group coproduct requires $\text{BiLift}(\mathcal{A})$;

- (b) an RTT presentation requires an R -matrix satisfying the Yang–Baxter equation and $R\Delta(a) = \Delta^{\text{op}}(a)R$;
- (c) an E_3 enhancement requires the brace operations of Conjecture 28.13.32;
- (d) the symmetric bar requires an equivariant comparison from the ordered configuration model to Σ_n -coinvariants.

Comparison among these structures is itself a theorem with source, target, and compatibility hypotheses.

27.30.6 The $\mathcal{W}_3$ ordered bar complex via DS transport

The principal DS reduction $V_k(\mathfrak{sl}_3) \twoheadrightarrow \mathcal{W}_3^k$ transports the ordered bar complex of $\widehat{\mathfrak{sl}}_{3,k}$ to the ordered bar complex of $\mathcal{W}_3$. The DS–KD intertwining theorem (Theorem 27.30.7; for the symmetric bar, Theorem 36.10.1) guarantees that the functor $H^\circ(Q_{\text{DS}})$ commutes with the ordered bar construction at chain level:

$$\overline{B}_{\text{ord}}^{\text{ch}}(\mathcal{W}_3^k) \simeq H_{\text{DS}}^\circ(\overline{B}_{\text{ord}}^{\text{ch}}(V_k(\mathfrak{sl}_3))). \quad (27.54)$$

This subsection records the explicit structure of the left-hand side.

THEOREM 27.30.17 (*Ordered bar complex of $\mathcal{W}_3$ via DS transport;*). Let $k \neq -3$ be non-critical. The ordered bar complex $\overline{B}_{\text{ord}}^{\text{ch}}(\mathcal{W}_3^k)$ has the following structure.

- (i) **Generators.** The complex is cogenerated by T (spin 2, from the Sugawara tensor) and W (spin 3, from the cubic Casimir), both obtained as $H^\circ(Q_{\text{DS}})$ -images of $\mathfrak{sl}_3$ currents.
- (ii) **Pole structure.** The collision residues are:
 - T - T channel: poles up to order 3 in the collision residue (from the quartic Virasoro OPE $T_{(3)}T = c/2$; the d log kernel absorbs one pole).
 - T - W channel: poles up to order 2 (from $T_{(2)}W = {}_3W$).
 - W - W channel: poles up to order 4 (from the quintic OPE pole $W_{(4)}W = c/3$; the d log kernel absorbs one).
- (iii) **A_∞ operations.** The transferred operations $m_k^{\mathcal{W}_3}$ on the cohomology $H^\bullet(\overline{B}_{\text{ord}}^{\text{ch}}(\mathcal{W}_3^k))$ satisfy:
 - m_2 is the ordered binary product (collision residue at D_{ij});
 - $m_3 \neq 0$ in the T -sector, inherited from the Virasoro quartic pole;
 - $m_k \neq 0$ for all $k \geq 3$ (class M: infinite tower).
- (iv) **Curvature.** The bar curvature decomposes by channel:

$$m_o^{\mathcal{W}_3} = \kappa_T |o\rangle + \kappa_W |o\rangle = \frac{c}{2} |o\rangle + \frac{c}{3} |o\rangle = \frac{5c}{6} |o\rangle,$$

which is the DS projection of the $\widehat{\mathfrak{sl}}_{3,k}$ curvature $m_o = (k+3)\kappa/6$.

- (v) **Complementarity.** The Koszul involution is $c \mapsto 100 - c$, and the Koszul conductor is

$$K_3 = 2(3-1)(2 \cdot 9 + 2 \cdot 3 + 1) = 100.$$

The companion fixed central charge is $c^* = K_3/2 = 50$; algebraic same-family Koszul self-duality is conditional on DS/bar transport. The full Koszul conductor $K(\mathcal{W}_3) = K_3 \cdot (H_3 - 1) = 100 \cdot 5/6 = 250/3$ controls the complementarity sum $\kappa(\mathcal{W}_3^k) + \kappa(\mathcal{W}_3^{k'}) = 250/3$.

Proof. Part (i). The principal DS reduction $V_k(\widehat{\mathfrak{sl}}_3) \rightarrow \mathcal{W}_3^k$ sends the 8 current generators J^a ($a = 1, \dots, 8$) of $\widehat{\mathfrak{sl}}_{3,k}$ to two generators: the stress tensor T (via the Sugawara construction) and the spin-3 field W (via the cubic Casimir). The remaining 6 currents lie in $\text{im}(Q_{\text{DS}})$ and are killed by the projection $H^0(Q_{\text{DS}})$. By equation (27.54), the ordered bar complex of $\mathcal{W}_3$ is cogenerated by the images of those $\widehat{\mathfrak{sl}}_3$ bar elements that survive DS projection.

Part (ii). The pole orders in the ordered bar differential are one less than the corresponding OPE pole orders (the $d \log$ kernel absorbs one power). The $\mathcal{W}_3$ OPE has: $T(z)T(w) \sim c/2 \cdot (z-w)^{-4} + \dots$ (quartic pole), $T(z)W(w) \sim {}_3W(w)(z-w)^{-2} + \dots$ (cubic pole), and

$$W(z)W(w) \sim \frac{c/3}{(z-w)^6} + \frac{2T}{(z-w)^4} + \frac{\partial T}{(z-w)^3} + \frac{\beta\Lambda + \frac{3}{10}\partial^2 T}{(z-w)^2} + \dots$$

where $\Lambda = (TT) - \frac{3}{10}\partial^2 T$ is the quasi-primary of weight 4 and $\beta = 16/(22 + 5c)$. The $d \log$ absorption gives collision residues with poles of order 3, 2, and 4 in the respective channels (since $W_{(5)}W = 0$ and the leading nonzero term is $W_{(4)}W = c/3$, the sextic pole produces a quintic-order n -product, and the $d \log$ kernel reduces the collision residue pole by one to order 4).

Part (iii). The Virasoro subalgebra $\text{Vir}_c \hookrightarrow \mathcal{W}_3^k$ (generated by T) is autonomous: its OPE closes on itself. The quartic pole $T_{(3)}T = c/2$ forces $m_3 \neq 0$ on the T -sector by the single-line class M theorem (Theorem ??): the critical discriminant $\Delta_T = 40/(5c + 22) \neq 0$ ensures that the shadow tower is infinite. The operations m_k for $k \geq 4$ are then generated by the resolvent tree formula (Theorem 12.3.2): each m_k is a sum over planar binary trees with k leaves,

$$m_k^{\mathcal{W}_3} = \sum_{T \in \text{PBT}(k)} m_2^{(T)} \circ h_{\text{DS}}^{(\text{edges}(T))}, \quad (27.55)$$

where $m_2^{(T)}$ denotes the iterated binary product along the tree T , and h_{DS} is the DS contracting homotopy inserted on each internal edge. The number of planar binary trees with k leaves is the Catalan number C_{k-1} , so m_k receives C_{k-1} contributions. The homotopy h_{DS} is the composition of the standard SDR homotopy for $\widehat{\mathfrak{sl}}_3 \rightarrow \mathcal{W}_3$ with the homotopy transfer data (Construction 12.3.1): the infinite tower $\{m_k\}_{k \geq 3}$ is generated from the single quadratic product m_2 on $\widehat{\mathfrak{sl}}_3$ by iterated composition with h_{DS} .

The W -line also has $m_{2k} \neq 0$ for all $k \geq 2$ (but $m_{2k+1} = 0$ by the $\mathbb{Z}_2$ parity $W \mapsto -W$); the nonvanishing of m_4^W follows from $\Delta_W = 20480/[3(5c+22)^3] \neq 0$ (Computation ??).

Part (iv). The curvature decomposition $\kappa(\mathcal{W}_3) = \kappa_T + \kappa_W = c/2 + c/3 = 5c/6$ follows by direct computation (Computation ??, Step 4): the DS projection of the $\widehat{\mathfrak{sl}}_3$ curvature $m_o = (k+3)\kappa/6$ onto the T - and W -channels produces exactly $c/2$ and $c/3$ respectively.

Part (v). The Koszul involution is $k \mapsto k' = -k - 2h^\vee = -k - 6$, which sends $c(k) = 2 - 24(k+2)^2/(k+3)$ to $c' = 100 - c$. Hence $c + c' = 100 = K_3$. The self-dual point is $c = c'$, i.e., $c = 50$. The complementarity sum $\kappa(\mathcal{W}_3^k) + \kappa(\mathcal{W}_3^{k'}) = 5c/6 + 5(100-c)/6 = 250/3$ is k -independent. $\square$

THEOREM 27.30.18 (*Class M persistence under DS transport;*). Let $\mathcal{W}_N = \mathcal{W}^k(\widehat{\mathfrak{sl}}_N, f_{\text{prin}})$ be a principal $\mathcal{W}$ -algebra at non-critical level. Then:

- (i) The ordered bar complex $\overline{B}_{\text{ord}}^{\text{ch}}(\mathcal{W}_N)$ contains the Virasoro T -line obstruction package. It is class M after the T -line non-cancellation hypothesis of Theorem 27.15.4 is imposed.
- (ii) The non-formality is forced by the Virasoro sub-sector: the stress tensor T generates an autonomous Virasoro subalgebra $\text{Vir}_{c(k)} \hookrightarrow \mathcal{W}_N^k$, and the quartic pole $T_{(3)}T = c/2$ gives the

first obstruction away from the corresponding specialization locus. The higher operations are the specialized Virasoro T -line classes.

- (iii) DS reduction preserves Koszulness and creates the wheel tower: $V_k(\mathfrak{sl}_N)$ is class L (double-pole OPE, finite Lie transfer), while $\mathcal{W}_N^k$ is the conditional class M candidate (quartic-and-higher poles, with all-order non-formality conditional on the T -line specialization). The Sugawara construction escalates the pole depth: the affine double-pole OPE $J^a(z)J^b(w) \sim k\delta^{ab}/(z-w)^2 + f_c^{ab}J^c(w)/(z-w)$ produces, upon taking normal-ordered products in the DS construction, the Virasoro quartic-pole OPE and the W -channel poles of order $\leq 2s$ for each strong generator of spin s .
- (iv) The Koszul conductor and self-dual central charge for $\mathcal{W}_N$ are:

$$K_N = 2(N-1)(2N^2+2N+1), \quad c^* = K_N/2 = (N-1)(2N^2+2N+1).$$

For $N = 2$: $K_2 = 26$, $c^* = 13$ (Virasoro). For $N = 3$: $K_3 = 100$, $c^* = 50$. For $N = 4$: $K_4 = 246$, $c^* = 123$.

Proof. Part (i). Each principal $\mathcal{W}_N$ contains a Virasoro subalgebra $\text{Vir}_{c(k)}$ generated by the stress tensor. The T -channel shadow obstruction tower is the Virasoro shadow obstruction tower, which is class M by the single-line dichotomy: $\Delta_T = 40/(5c+22) \neq 0$ for $c \neq -22/5$.

Part (ii). The quartic pole $T(z)T(w) \sim c/2 \cdot (z-w)^{-4}$ in the Virasoro sub-sector gives a cubic-order collision residue (after d log absorption). This is the source of $m_3 \neq 0$: the homotopy transfer formula produces $m_3 = p \circ m_2(h \circ m_2 \otimes \text{id}) + (-1)^{|a|} p \circ m_2(\text{id} \otimes h \circ m_2)$ with both Catalan trees contributing nonzero terms. The resolvent tree formula then generates all m_k for $k \geq 4$ from m_2 and the contracting homotopy.

Part (iii). The affine algebra $V_k(\mathfrak{sl}_N)$ has a double-pole OPE, so its collision residue has poles of order 1. The bar complex is formal: $m_k = 0$ for $k \geq 3$ on cohomology (class L). The DS reduction introduces the Sugawara construction $T = \frac{1}{2(k+h^\vee)}(J^a J^a)$, which creates a quartic pole $T(z)T(w) \sim c/2 \cdot (z-w)^{-4}$ from the double-pole affine OPE. This is pole-order escalation via normal ordering: two double poles compose (through the Sugawara quadratic) to produce a quartic pole. For higher-spin generators $W^{(s)}$, the $W^{(s)}W^{(s)}$ OPE has poles up to order $2s$, produced by the same mechanism applied to the degree- s Casimir invariants. The Koszulness is preserved because $H^0(Q_{\text{DS}})$ is exact on the relevant filtered complexes (Theorem 27.30.7, hypothesis (a)), but the formality is destroyed because the homotopy transfer data $(p, \iota, h_{\text{DS}})$ generate nonzero m_k for $k \geq 3$ from the new higher-order poles.

Part (iv). The DS central charge is $c(k) = (N-1)[1 - N(N+1)(N-1)/(k+N)]$ (Freudenthal-de Vries), and the Koszul involution $k \mapsto -k - 2N$ sends $c \mapsto K_N - c$. The value of K_N is read off: $c(k) + c(-k-2N) = 2(N-1)(2N^2+2N+1)$. The self-dual point is $c = c^* = K_N/2$. $\square$

Remark 27.30.19 (The resolvent tree formula for $\mathcal{W}_3$). The resolvent tree formula (27.55) makes explicit the mechanism by which DS reduction generates the infinite A_∞ tower from a single quadratic product. The affine algebra $V_k(\mathfrak{sl}_3)$ has m_2 as its only nontrivial operation (the bar complex is formal: class L). Applying the SDR data $(p, \iota, h_{\text{DS}})$ to the homotopy transfer theorem produces:

$$m_3^{\mathcal{W}_3}(a, b, c) = p m_2(h_{\text{DS}} m_2(\iota a, \iota b), \iota c) + (-1)^{|a|} p m_2(\iota a, h_{\text{DS}} m_2(\iota b, \iota c)),$$

where $\iota: \mathcal{W}_3 \hookrightarrow V_k(\mathfrak{sl}_3)$ is the inclusion (via the Miura embedding) and $p: V_k(\mathfrak{sl}_3) \rightarrow \mathcal{W}_3$ is the DS projection. At degree k , the number of contributing trees is the Catalan number C_{k-1} : for m_3 , $C_2 = 2$

(the two planar binary trees with 3 leaves); for m_4 , $C_3 = 5$; for m_5 , $C_4 = 14$. Each tree contributes a term of the form $m_2 \circ (h_{\text{DS}} \circ m_2)^{\circ(k-2)}$, iterated along the tree topology.

The key structural point: the affine binary residue is finite-depth, but the homotopy h_{DS} is non-trivial on the Sugawara sector: it mediates the passage from affine currents to the stress tensor and higher-spin fields, and this non-trivial mediation is what generates the infinite cascade. *DS reduction preserves Koszulness and creates the wheel tower: this is the transport from class L to class M.*

Remark 27.30.20 (The W -channel parity rule on the ordered bar complex). The $\mathbb{Z}_2$ symmetry $W \mapsto -W$ of the $\mathcal{W}_3$ OPE descends to the ordered bar complex: on the W -line (deformation direction x_W with $x_T = 0$), all odd-degree operations vanish ($m_{2k+1}^W = 0$), while even-degree operations are generically nonzero ($m_{2k}^W \neq 0$ for $k \geq 1$). The first nonzero higher operation on the W -line is m_4^W , with shadow coefficient $S_4^W = 2560/[c(5c+22)^3]$ (Computation ??). This parity constraint is inherited from the $\mathbb{Z}_2$ automorphism of the DS reduction: the principal embedding $\mathfrak{sl}_2 \hookrightarrow \mathfrak{sl}_3$ determines a $\mathbb{Z}_2$ that acts by -1 on the cubic Casimir and hence on W .

27.30.7 Comparison with shifted and factorization quantum groups

Three mathematical traditions converge on the same combinatorial-algebraic object: the ordered bar complex $\overline{B}^{\text{ch,ord}}(A)$ on $\text{FM}_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R})$. Ordered associative chiral Koszul duality supplies the physical column; shifted quantum groups of Finkelberg–Tsybaliuk and the Coulomb-branch construction of Braverman–Finkelberg–Nakajima supply the algebraic-geometric column; Latyntsev’s factorization quantum groups and the Maulik–Okounkov stable-envelope construction supply the spectral and stable-envelope columns, synthesized for 3d $\mathcal{N} = 4$ theories by Costello–Okounkov–Zhang–Zhou.

THE THREE-LANGUAGE SPINE

Datum	Physical (this work)	Spectral (Latyntsev)	Geometric (COZZ)
R -matrix	OPE exchange	factorisation isomorphism	stable envelope
YBE	Ward identity	factorisation axiom	braid relation
Strictification	root multiplicity 1	by construction	by construction

In each column the R -matrix, the Yang–Baxter equation, and the strictification mechanism arise from the internal logic of the framework:

- **Physical column.** The R -matrix is the regularised holonomy of the derived additive KZ connection on $\text{Conf}_n^{\text{ord}}(\mathbb{A}^1)$, with connection one-form built from OPE residues (Theorem ??). The Yang–Baxter equation is the Ward identity for the flat connection: $\mathbb{D}_n^2 = 0$. Strictification requires that the spectral Drinfeld obstruction class vanish, which holds for all simple Lie algebras because every root has multiplicity one by Vol II’s root-sector scalar strictification criterion.
- **Spectral column.** Latyntsev defines factorisation quantum groups as factorisation algebras on the spectral curve, with the R -matrix encoded as a factorisation isomorphism (the structure map for disjoint-support factorisation). The Yang–Baxter equation is the coherence axiom for threefold factorisation. Strictification is built in: the factorisation structure is strict by definition.
- **Geometric column.** Costello–Okounkov–Zhang–Zhou identify the R -matrix with the Maulik–Okounkov stable envelope for the Nakajima quiver variety or the BFN Coulomb branch. The Yang–Baxter equation is the braid relation for stable envelopes (which follows from uniqueness of the stable envelope under the Maulik–Okounkov axioms). Strictification is again automatic: stable envelopes are ordinary matrices; no A_∞ data enters.

THE COMMON OBJECT

All three languages attach algebraic data to the same configuration-space carrier:

$$\overline{B}^{\text{ch,ord}}(A) \text{ on } \text{FM}_k(\mathbb{C}) \times \text{Conf}_k^<(\mathbb{R}).$$

The holomorphic factor $\text{FM}_k(\mathbb{C})$ carries the chiral differential (OPE residues), while the topological factor $\text{Conf}_k^<(\mathbb{R})$ carries the coassociative coproduct (ordered deconcatenation). What differs among the three traditions is which of these two factors is taken as primary input and which is derived.

SHIFTED QUANTUM GROUPS

Finkelberg–Tsybaliuk define, for a simple Lie algebra $\mathfrak{g}$ and a pair of coweights (μ, ν) , the *shifted quantum group* $Q_\mu^\nu(\mathfrak{g})$ by explicit generators (Drinfeld–Cartan generators, shifted Chevalley generators) and shifted Serre relations. The unshifted specialisation recovers the Yangian:

$$Q_o^\circ(\mathfrak{g}) \simeq Y_h(\mathfrak{g}).$$

THEOREM 27.30.21 (*Unshifted identification;*). On the chirally Koszul locus, the line-side algebra $A_{\text{line}}^!$ produced by ordered associative chiral Koszul duality of $\widehat{\mathfrak{g}}_k$ is isomorphic to the Yangian $Y_h(\mathfrak{g})$:

$$A_{\text{line}}^!(\widehat{\mathfrak{g}}_k) \simeq Y_h(\mathfrak{g}) \simeq Q_o^\circ(\mathfrak{g}).$$

Proof. This is the content of the Yangian recognition theorem (Theorem ??, recorded from Volume II). The RTT presentation of $Y_h(\mathfrak{g})$ is read off from the regularised holonomy of the derived additive KZ connection (Theorem ??). The identification $Y_h(\mathfrak{g}) \simeq Q_o^\circ(\mathfrak{g})$ is the Levendorskiĭ–Drinfeld theorem. $\square$

Remark 27.30.22 (*Shift parameters as boundary conditions*). The shift parameters (μ, ν) in $Q_\mu^\nu(\mathfrak{g})$ correspond, in the 3d holomorphic-topological picture, to the choice of boundary conditions at the two ends of the topological interval $\mathbb{R}$. Different choices of boundary condition produce different shifted quantum groups; the unshifted case $(\mu, \nu) = (o, o)$ corresponds to Neumann boundary conditions on both sides. The algebraic manifestation is that the shift modifies the Serre relations, which on the bar-complex side corresponds to modifying the augmentation datum of the ordered bar coalgebra.

FACTORIZATION QUANTUM GROUPS

Latyntsev constructs factorisation quantum groups as factorisation algebras on the formal spectral curve $\widehat{\mathbb{A}}_\mu^1$, working at the derived/ ∞ -categorical level throughout.

THEOREM 27.30.23 (*Factorisation identification under strictification;*). On the chirally Koszul locus for a simple Lie algebra $\mathfrak{g}$, assume a bar-horizontal strictification satisfying the root-sector package of Theorem 27.17.8. the dg-shifted Yangian $Y_h^{\text{dg}}(\mathfrak{g})$ produced by ordered chiral Koszul duality, after bar-horizontal strictification, yields a strict spectral factorisation quantum group.

Proof. Vol II’s quasi-factorisation theorem shows that every residue-bounded complete dg-shifted Yangian with a bar-horizontal strictification produces a spectral quasi-factorisation quantum group. The spectral Drinfeld obstruction class controls the passage from quasi to strict. Under the root-sector scalar strictification criterion, this class vanishes filtration by filtration, yielding a strict factorisation quantum group. $\square$

Remark 27.30.24 (Factorisation quantum group definition). Latyntsev's construction operates at the ∞ -categorical level from the outset, producing factorisation quantum groups as E_1 -algebra objects in ind-coherent sheaves on the Ran space of the spectral curve. Its definition does not require choosing a strictification: the factorisation isomorphisms are part of the defining data. The E_1 -chiral bar complex $\overline{B}^{\text{ord}}(\mathcal{A})$ produces the same object once strictification is carried out; for simple Lie algebras this is a theorem only under the root-sector strictification package. The Kac–Moody regime with root multiplicities > 1 is where the strictification mechanism fails and Latyntsev's a priori construction must be used as the primary definition.

COULOMB BRANCH ALGEBRAS AND STABLE ENVELOPES

Braverman–Finkelberg–Nakajima (BFN) define the Coulomb branch algebra $\mathcal{A}_C(G, N)$ as the equivariant Borel–Moore homology of the BFN moduli space $\mathcal{R}_{G,N}$. Maulik–Okounkov construct R -matrices from stable envelopes of Nakajima quiver varieties; the Costello–Okounkov–Zhang–Zhou synthesis extends this to 3d $N = 4$ gauge theories.

PROPOSITION 27.30.25 (R -matrix comparison;). For $\mathfrak{g}$ simple and $\widehat{\mathfrak{g}}_k$ at non-critical generic level, the R -matrix $R(z)$ produced by the regularised holonomy of the derived additive KZ connection coincides with the Maulik–Okounkov stable envelope on evaluation modules.

Proof. On evaluation modules, both R -matrices satisfy the same Yang–Baxter equation with the same spectral dependence and the same classical limit $r(z)$ (the rational r -matrix of $\mathfrak{g}$). The uniqueness theorem for trigonometric/rational R -matrices with prescribed classical limit and spectral dependence (the Drinfeld uniqueness argument) gives the identification. $\square$

Remark 27.30.26 (Beyond the affine lineage). The comparison with stable envelopes agrees on evaluation modules of the Yangian. The full comparison for non-evaluation modules, and the extension to shifted quantum groups (where the stable envelope is for the BFN Coulomb branch rather than the Nakajima variety), remains conjectural in general.

Conjecture 27.30.27 (Full three-language equivalence). For any 3d $N = 4$ gauge theory with gauge group G and matter representation N :

- (a) the ordered chiral Koszul dual of the boundary chiral algebra $\mathcal{A}_\partial(G, N)$ is isomorphic, after bar-horizontal strictification, to a factorisation quantum group in Latyntsev's sense;
- (b) this factorisation quantum group, evaluated on the unshifted Ran space, recovers the Yangian of the Coulomb branch;
- (c) the R -matrix from ordered-to-unordered descent agrees with the Maulik–Okounkov stable envelope for $\mathcal{M}_C(G, N)$.

Remark 27.30.28 (Affine case and remaining extension). Parts (a) and (b) of Conjecture 27.30.27 are conditional in the standard affine case $\mathcal{A} = \widehat{\mathfrak{g}}_k$ with $\mathfrak{g}$ simple (Theorems 27.30.21 and 27.30.23). Part (c) is proved on evaluation modules (Proposition 27.30.25). The full conjecture extends these identifications to arbitrary gauge theories and all module categories.

27.30.8 Boundary questions from ordered chiral homology

The ordered chiral homology theory (§26.2, §26.2.1) and the chiral bialgebra equivalence (Theorem 27.29.3) open five further problems.

THEOREM 27.30.29 (*E₃ identification for affine Kac–Moody*). Let $\mathfrak{g}$ be a simple finite-dimensional Lie algebra and $V_k(\mathfrak{g})$ the affine Kac–Moody vertex algebra at level k . Fix a formality rigidification Φ and the corresponding cofibrant chain operad model $C_*^\Phi(E_3)$. Writing $\lambda = k + \hbar^\vee$, the formal-disk global sections of the chiral E_3 model for the derived chiral centre $Z_{\text{ch}}^{\text{der}}(V_k(\mathfrak{g}))$ and the Costello–Francis–Gwilliam perturbative Chern–Simons E_3 -algebra $\mathcal{A}^\lambda$ determine the same MC class in the filtered deformation groupoid of cofibrant $C_*^\Phi(E_3)$ -algebra models over $\lambda H^3(\mathfrak{g})[[\lambda]]$.

Proof. The deformation spaces agree (both one-dimensional at each order in λ for simple $\mathfrak{g}$), the associated graded algebras match (both $C^*(\mathfrak{g})$), and the formal disk global sections match at the level of P_3 -brackets (Theorem 28.13.58(ii)). For simple $\mathfrak{g}$, $H^3(\mathfrak{g}) \cong \mathbb{C}$ is one-dimensional, so at each order $p \geq 1$ in λ the space of E_3 -deformations extending the lower orders is one-dimensional. The matching of P_3 -brackets on the formal disk fixes the scalar at each order, forcing the two MC classes to agree. The gauge equivalence is constructed order by order and passes to the λ -adic limit. $\square$

Conjecture 27.30.30 (*CY-to-chiral trace comparison*;). Let Y be a Calabi–Yau surface and let

$$\Phi = \text{Sp}_{\Sigma_3, E}^{\text{ch}} \circ \Phi_3^{\text{FA}} : D_{\text{CY-3}}^b(Y \times E) \longrightarrow \text{ChirAlg}_E$$

denote the proposed two-stage CY-to-chiral comparison. Choose an object $\mathcal{E}$ and an equivalence $\theta : \Phi(\mathcal{E}) \simeq \mathcal{A}$. Assume the package $H_{\Phi\text{-tr}}$: proper trace-class completions on both sides, vanishing-cycle and orientation data for the compact CoHA, compatibility of θ with the two trace maps, and convergence of the ordered-bar supertrace. The expected comparison is

$$\text{STr}_{\overline{B}^{\text{ord}}(A)}^{\text{ch}}(\text{id}) = \text{STr}_{\mathcal{E}}^{\text{aut}}(\text{id}).$$

The left side is curve-local; the right side belongs to the compact global Hall realization. A proof must construct the trace-preserving comparison itself. The finite Rees hCS–Hall maps furnish bounded comparison classes and supply evidence in finite windows. This conjecture is logically separate from the line-side square-root convention of Remark 27.16.6 and from the automorphic recognition problem of Remark 27.29.6.

Conjecture 27.30.31 (*Trigonometric and elliptic ordered chiral homology*). The rational Yang R -matrix $R(u) = 1 + \hbar r(u)/u + O(\hbar^2)$ treated in this chapter extends to two richer settings: the trigonometric R -matrix (quantum affine algebras) and the elliptic Belavin kernel, and after adjoining the Cartan dynamical variable the Felder–Etingof–Varchenko dynamical R -matrix, producing ordered chiral homology with higher-order Stokes phenomena, theta-function monodromy, and flat sections valued in elliptic hypergeometric integrals. The regular/irregular dichotomy of Theorem 26.2.19 should extend to a trichotomy (regular, irregular-rational, irregular-elliptic) correlated with the three types of quantum groups.

Conjecture 27.30.32 (*Higher-genus ordered chiral homology*). The genus-0 ordered chiral homology of §26.2 extends to genus $g \geq 1$ via a period-corrected differential whose degree-2 coefficients involve the $(g \times g)$ -matrix $(\text{Im } \Omega)^{-1}$ of the Siegel period matrix. The ordered chiral chain complex at genus g should define a flat connection over $\overline{\mathcal{M}}_g$ compatible with $\kappa_1 = c_1(\mathbb{E})$, and the resulting system of conformal blocks should satisfy factorisation at the boundary divisors of $\overline{\mathcal{M}}_g$.

PROPOSITION 27.30.33 (*Critical level: monodromy trivialises, Koszulness fails, center jumps*). At the critical level $k = -\hbar^\vee$ for $V_{-\hbar^\vee}(\mathfrak{sl}_2)$ ($\hbar^\vee = 2$, so $k = -2$):

- (i) $\kappa = 3(k+2)/4 = 0$: the bar complex is uncurved.
- (ii) In the trace-form convention, $r(z) = k \Omega_{\text{tr}}/z = -2 \Omega/z$ is finite and nonzero. The monodromy eigenvalues $\exp(2\pi i k \lambda_f)$ are $\exp(-4\pi i) = 1$ on $\text{Sym}^2 V$ and $\exp(6\pi i) = 1$ on $\wedge^2 V$: ALL monodromy is trivial.
- (iii) The degree-2 ordered chiral homology jumps: $\dim H^0 = 4$ (all of $V \otimes V$ is invariant), and $\chi = -4$ forces $\dim H^1 = 8$ (total dimension 12, triple the generic 4).
- (iv) Koszulness fails: $H^*(\overline{B}^{\text{ord}}(V_{-2}(\mathfrak{sl}_2)))$ is not concentrated in degree 1 but spreads to $\Omega^*(\text{Op}_{\mathfrak{sl}_2}(D))$, the de Rham algebra of $\mathfrak{sl}_2$ -opers on the formal disk (Feigin–Frenkel).
- (v) The spectral sequence mechanism: the bar differential $d_k = d_{\text{crit}} + (k+2)\delta$. At $\lambda = k+2 = 0$, the d_1 page vanishes and the full de Rham algebra survives as bar cohomology. At generic $\lambda \neq 0$, the $d_1 = \lambda[\delta]$ contracts the de Rham complex to $\mathbb{C}^3$ (Koszul concentration).

Proof. Part (i): direct substitution. Part (ii): on $V \otimes V = \text{Sym}^2 V \oplus \wedge^2 V$ the quadratic Casimir of $\mathfrak{sl}_2$ acts with eigenvalues $c_2 = j(j+1)$, giving $c_2 = 2$ on the spin-1 piece $\text{Sym}^2 V$ and $c_2 = 0$ on the spin-0 piece $\wedge^2 V$; multiplied by $k = -2$ these give -4 and 0 , both integers, so $\exp(2\pi i \cdot k c_2) = 1$ on every eigenspace. Part (iii): trivial monodromy gives $H^0 = V \otimes V$ (all flat sections are global), so $\dim H^0 = \dim(V \otimes V) = 4$. The Euler characteristic $\chi_{\text{ord},2} = \dim H_{\text{ord},2}^0 - \dim H_{\text{ord},2}^1$ of the degree-2 ordered chiral homology is an invariant of the underlying graded vector space, independent of the choice of differential in the bicomplex $d_k = d_{\text{crit}} + (k+2)\delta$; at generic k one has $\dim H_{\text{ord},2}^0 = 0$ and $\dim H_{\text{ord},2}^1 = 4$, giving $\chi_{\text{ord},2} = -4$. Hence at $k = -2$, $\dim H_{\text{ord},2}^1 = \dim H_{\text{ord},2}^0 - \chi_{\text{ord},2} = 4 - (-4) = 8$ (total dimension 12 = $3 \cdot 4$, triple the generic 4). Part (iv): the Feigin–Frenkel theorem identifies the center $Z(V_{-h^\vee}(\mathfrak{g})) \cong \text{Fun}(\text{Op}_{\mathfrak{g}^\vee}(D))$; at the bar-complex level, this center is H^0 of the bar complex, which is infinite-dimensional. Part (v): the bicomplex structure $d_k = d_{\text{crit}} + \lambda \delta$ with $\lambda = k + h^\vee$ gives a spectral sequence whose E_1 page is $H^*(d_{\text{crit}})$ with differential $d_1 = \lambda[\delta]$. At $\lambda = 0$, $d_1 = 0$ and $E_2 = E_1 = H^*(d_{\text{crit}}) \cong \Omega^*(\text{Op}_{\mathfrak{g}^\vee}(D))$. At $\lambda \neq 0$, d_1 is an isomorphism on the contractible part, leaving the Koszul residue in degree 1. $\square$

Remark 27.30.34 (Shadow stratum vs bar Koszulness at critical level). Under the quadrichotomy classification of the shadow tower (Theorem ?? of Chapter ??) the critical-level affine KM algebra $V_{-h^\vee}(\mathfrak{g})$ sits on the discriminant locus $\{\kappa = 0\} = \{\Delta = 0, \alpha = 0\}$ on the universal vacuum line: the principal-line Riccati polynomial $Q_c(t) = (2\kappa)^2$ collapses identically to zero, which is the *class G* stratum of the shadow tower. The shadow classification therefore records critical level as shadow-depth-2 truncated, same as Heisenberg. The full bar complex is *not* Koszul, however: it is quasi-isomorphic to the de Rham algebra $\Omega^*(\text{Op}_{\mathfrak{g}^\vee}(D))$, which is spread over all degrees, not concentrated in degree 1. Hence shadow truncation depth and bar Koszulness are *different* invariants: the former is a discriminantal quadratic classification on a finite-dimensional parameter space, the latter is a cohomological concentration statement on the infinite-dimensional bar complex. At integrable level $k \in \mathbb{Z}_{>0}$ and at generic k the two agree (class L, bar Koszul); at critical level they diverge (shadow class G, bar non-Koszul). This divergence is a genuine feature of the critical locus, not a mislabelling.

Remark 27.30.35 (Three-level contrast).

	Generic k	Integrable $k \in \mathbb{Z}_{>0}$	Critical $k = -2$
Koszul	yes	yes	no
H^0 (degree 2)	0	0	4
H^1 (degree 2)	4	4	8
Monodromy	infinite	finite nontrivial	trivial
Center	$\mathbb{C}$	$\mathbb{C}^{k+1}$	$\mathbb{C}[S_2]$ (infinite)
κ	$3(k+2)/4$	$3(k+2)/4$	0

Integrable and critical are opposite extremes: integrable has finite but nontrivial monodromy with finite center; critical has trivial monodromy with infinite center. The ordered chiral homology detects both extremes through the coinvariant operator and its trace. At critical level, $K_{-h^\vee, \mathfrak{g}}^{\text{coll}}(z) = -h^\vee \Omega_{\text{tr}}/z$ has the homotopy coinvariant $q_2(K_{-h^\vee, \mathfrak{g}}^{\text{coll}})$, while $\tau_{-h^\vee, \mathfrak{g}}^{\text{res}} q_2(K_{-h^\vee, \mathfrak{g}}^{\text{coll}}) = -\dim(\mathfrak{g})/2$ and $\kappa = -\dim(\mathfrak{g})/2 + \dim(\mathfrak{g})/2 = 0$.

Remark 27.30.36 ($N = 3$ explicit calculation). The 9×9 Yang R -matrix $R(u) = u I_9 + \Psi P$ for $\mathfrak{gl}_3$ satisfies the YBE at 9 random complex parameter sets (relative error $< 10^{-14}$). All 81 RTT component relations at degree 1: $[t_{ij}^{(1)}, t_{kl}^{(1)}] = \Psi(\delta_{il} t_{kj}^{(1)} - \delta_{kj} t_{il}^{(1)})$. The quantum determinant (six-term S_3 column determinant with *decreasing* column index ordering) is central at $\Psi = 1, 0.5, 2$ (53 compute tests).

COMPUTATION 27.30.37 (*Finite DS–Miura coproduct window at $\mathcal{W}_3$*). Work in the Open quadrant, in the ordered associative chiral/Yangian presentation, in the Beilinson level $4 \rightarrow 5$ operator-to-coproduct lane. The hypothesis package is: generic Ψ , the principal Drinfeld–Sokolov projection π_3 for $\mathfrak{sl}_3$, the RTT coproduct on matrix generators, and the two-boson Miura stress tensor

$$x = \psi_1, \quad y = \psi_2, \quad e_1 = x + y, \quad e_2 = :xy:, \quad T_M = e_2 - \frac{e_1^2}{2\Psi}.$$

In the z^0 , degree-2 Cartan/Sugawara window,

$$\begin{aligned} & (\pi_3 \otimes \pi_3) \Delta_{z,0}^{\text{RTT}}(T_M) - T_M \otimes 1 - 1 \otimes T_M \\ &= \frac{\Psi - 1}{\Psi} (x \otimes y + y \otimes x) - \frac{1}{\Psi} (x \otimes x + y \otimes y). \end{aligned} \tag{27.56}$$

The same tensor is obtained by applying the primitive two-boson Miura coproduct to T_M .

Proof. On the RTT side, the component coproduct for the degree-1 matrix entries has diagonal contributions $t_{ii}^{(1)} \otimes 1 + 1 \otimes t_{ii}^{(1)}$ and off-diagonal terms of the form $t_{ij}^{(1)} \otimes t_{ji}^{(1)}$. The principal DS projection sends the two diagonal Gauss/Cartan entries to x, y and kills the six root terms

$$t_{12}^{(1)} \otimes t_{21}^{(1)}, \quad t_{21}^{(1)} \otimes t_{12}^{(1)}, \quad t_{13}^{(1)} \otimes t_{31}^{(1)}, \quad t_{31}^{(1)} \otimes t_{13}^{(1)}, \quad t_{23}^{(1)} \otimes t_{32}^{(1)}, \quad t_{32}^{(1)} \otimes t_{23}^{(1)}.$$

Thus the projected RTT computation gives

$$\Delta(e_2) - e_2 \otimes 1 - 1 \otimes e_2 = x \otimes y + y \otimes x$$

and

$$\Delta(e_1^2) - e_1^2 \otimes 1 - 1 \otimes e_1^2 = 2(x \otimes x + x \otimes y + y \otimes x + y \otimes y).$$

Substituting $T_M = e_2 - e_1^2/(2\mathbb{Y})$ gives (27.56).

The Miura side is independent: x and y are primitive free-field currents, so multiplicativity gives the two displayed formulae for e_2 and e_1^2 directly. The two routes therefore agree term by term in the $\{x, y\}$ -tensor basis. The computation is implemented by `ds_w3_degree2_rtt_miura_witness` in `ds_coproduct_intertwining_engine.py`; the decorated test `test_ds_w3_degree2_rtt_miura_hz_iv` checks the RTT source terms, the killed off-diagonal list, and the primitive Miura expansion without calling the shared $\Delta_z(\psi_n)$ formula. $\square$

Remark 27.30.38 (DS coproduct intertwining at $\mathcal{W}_3$: degree-1 vs. degree- ≥ 2). The full chain-level identity

$$(\pi_3 \otimes \pi_3) \circ \Delta_z^{\mathfrak{sl}_3} = \Delta_z^{\mathcal{W}_3} \circ \pi_3$$

is the expected Drinfeld–Sokolov coproduct compatibility, but it is not proved by the degree-1 Cartan tests. At degree 1 the comparison is *tautological*: both sides use the same Drinfeld primitive formula for $\Delta_z(J)$ and the same universal $\Delta_z(\psi_n)$ expansion. Those tests verify convention consistency only.

The first non-tautological window proved here is Computation 27.30.37: the projected $\mathfrak{sl}_3$ RTT computation and the primitive two-boson Miura computation agree term by term on the z^0 , degree-2 Cartan/Sugawara sector. This does not yet prove the full spin-3 DS-HPL coproduct identity. The spin-3 sector, where the cubic primary and gravitational HPL₃ corrections enter, remains the load-bearing non-tautological obligation for the full compatibility theorem. The spectral coassociativity tests use *shifted* parameters: $(\Delta_{z_1} \otimes \text{id}) \circ \Delta_{z_1+z_2} = (\text{id} \otimes \Delta_{z_2}) \circ \Delta_{z_1}$, reflecting $T(u) \cdot T(u - z_1) \cdot T(u - z_1 - z_2)$.

Remark 27.30.39 (Explicit kernel basis at $d = 3$). For the adjoint representation of $\mathfrak{sl}_2$ ($d = 3$): $\ker(\text{av}_2) = \Lambda^2(\mathfrak{sl}_2)$ with basis $e \otimes f - f \otimes e, e \otimes h - h \otimes e, f \otimes h - h \otimes f$ (dimension 3). At $n = 3$: $\ker(\text{av}_3) = 17 = 1 + 16$, where 1 is the volume form $e \wedge h \wedge f$ and 16 is the standard-representation complement (51 compute tests).

Remark 27.30.40 (Quantum determinant column ordering). The central quantum determinant $\text{qdet } T(u)$ uses the column determinant with *decreasing* column index: $j = N - 1$ is the leftmost factor, $j = 0$ the rightmost. At $N = 2$ both orderings coincidentally agree; at $N \geq 3$ only the decreasing-index ordering is central (74 compute tests,).

Remark 27.30.41 (KZB heat equation prefactor). The genus- g heat equation $\partial_{\Omega_{ab}} \Theta = c_{ab} \partial_{z_a} \partial_{z_b} \Theta$ has prefactor $c_{ab} = 1/(4\pi i)$ for $a = b$ (diagonal) and $c_{ab} = 1/(2\pi i)$ for $a \neq b$ (off-diagonal). The factor of 2 arises from the symmetric matrix chain rule: $\partial/\partial\Omega_{aa}$ as an independent variable contributes $(1/2) \partial/\partial(\text{matrix entry})$. Numerical evaluation gives agreement at machine precision ($< 10^{-14}$) across 5 generic points in the upper half-plane.

Remark 27.30.42 (Bernard heat identity for the Weierstrass ζ). The Jacobi odd theta $\theta_1(z, \tau)$ on the torus of periods $(1, \tau)$ satisfies the Bernard heat equation (Bernard, Nucl. Phys. B 303 (1988), eq. (2.15))

$$4\pi i \partial_\tau \theta_1(z, \tau) = \partial_z^2 \theta_1(z, \tau). \quad (27.57)$$

The Weierstrass zeta $\zeta(z, \tau) = \theta_1'(z, \tau)/\theta_1(z, \tau) + 2\eta_1(\tau)z$ with quasi-period $\eta_1(\tau) = (\pi^2/6) E_2(\tau)$ inherits from (27.57) the identity

$$4\pi i \partial_\tau \zeta(z, \tau) = -\wp'(z, \tau) + 2(\zeta'(z, \tau) - 2\eta_1(\tau)z)(-\wp(z, \tau) - 2\eta_1(\tau)) + 8\pi i \eta_1'(\tau)z. \quad (27.58)$$

The derivation is two lines of z -differentiation of $\log \theta_1$ combined with (27.57) and $\zeta' = -\wp$. The quasi-period drift term $8\pi i \eta'_1(\tau) z$ is forced by the τ -dependence of $\eta_1(\tau)$ and closes against the Halphen–Ramanujan system

$$\partial_\tau E_2 = \frac{1}{12}(E_2^2 - E_4), \quad \partial_\tau E_4 = \frac{1}{3}(E_2 E_4 - E_6), \quad \partial_\tau E_6 = \frac{1}{2}(E_2 E_6 - E_4^2),$$

originally due to Ramanujan (1916, Trans. Camb. Phil. Soc. 22, §2) and Halphen (Traité des fonctions elliptiques et de leurs applications, Gauthier-Villars 1886, Ch. II). On the Cartan sector of the Knizhnik–Zamolodchikov–Bernard connection with connection forms $A_z = \zeta(z_{ij}, \tau) \Omega / (k + h^\vee)$ and $A_\tau = \wp(z_{ij}, \tau) \Omega / (k + h^\vee)$, the naive scalar flatness $\partial_\tau \zeta = \partial_z \wp = \wp'$ fails by exactly the three corrections in (27.58): the heat-equation prefactor $1/(4\pi i)$, the nonlinear $\zeta \wp$ cross-term, and the quasi-period drift. After those three corrections are installed, scalar flatness is equivalent at leading order in $\hbar$ to the Halphen–Ramanujan closure via $\eta_1(\tau) = (\pi^2/6)E_2(\tau)$. Chain-level flatness of the full KZB connection on the n -point configuration space requires in addition the elliptic classical Yang–Baxter equation with dynamical shift (Felder, ICM 1994), and is established in the standard references (Felder, [?Felder94]; Etingof–Frenkel–Kirillov, [?EFK98], Ch. 5; Calaque, Enriquez, Etingof, *Universal KZB equations: the elliptic case*, Prog. Math. 269 (2010)). Identity (27.58) itself follows numerically at machine precision in the companion engine `verify_bernard_heat_identity_zeta` across five generic points in the upper half-plane; the two-point matrix commutator $[A_z, A_\tau] = 0$ is trivial because Ω self-commutes and so the two-point case is structurally uninformative at the matrix level.

Remark 27.30.43 ($n \geq 3$ KZB flatness: Felder dynamical shift + Halphen–Ramanujan). At three or more points on E_τ , the Cartan-sector affine Kac–Moody r -matrix $r_{\mathfrak{g}_k}^{(1)}(z, \tau) = \Omega \zeta_\tau(z) / (k + h^\vee)$ appearing in the KZB connection (27.20) fails to satisfy the ordinary classical Yang–Baxter equation on the full tensor space $V^{\otimes 3}$: the cross-pair commutators $[\Omega_{12}, \Omega_{13}]$, $[\Omega_{12}, \Omega_{23}]$, $[\Omega_{13}, \Omega_{23}]$ combine with the three $\zeta_\tau(z_{ij})$ into a residual that vanishes identically only in the Cartan-diagonal sector. Felder (ICM 1994, [?Felder94]) showed that the correct object closing 3-point KZB flatness is the *dynamical* elliptic R -matrix $r(z, \lambda, \tau)$ with $\lambda \in \mathfrak{h}^*$ the Cartan dynamical variable, satisfying the modified *dynamical* CYBE

$$[r_{12}(z_{12}, \lambda), r_{13}(z_{13}, \lambda + \hbar \Omega^{(2)})] + [r_{12}(z_{12}, \lambda), r_{23}(z_{23}, \lambda)] + [r_{13}(z_{13}, \lambda + \hbar \Omega^{(1)}), r_{23}(z_{23}, \lambda)] = 0$$

(Etingof–Varchenko [?EV98]). The rearrangement of the $\zeta_\tau(z_{12})\zeta_\tau(z_{13})$ products required by the dynamical-CYBE identity uses the theta-prime-normalised Szegő/prime-form (Fay trisecant) specialisation on the torus,

$$\wp(a, \tau) - \wp(b, \tau) = - \frac{\wp_1(a+b, \tau) \wp_1(a-b, \tau)}{\wp_1(a, \tau)^2 \wp_1(b, \tau)^2} \wp'_1(0, \tau)^2$$

(Fay 1973, Cor. 2.5; Mumford *Tata Lectures on Theta I*, Ch. I §5). The τ -derivative closure at each pair uses the full Bernard identity (27.58); the τ -derivative closure of the quasi-period $\eta_1(\tau) = (\pi^2/6)E_2(\tau)$ uses the Halphen–Ramanujan system

$$\partial_\tau E_2 = \frac{1}{12}(E_2^2 - E_4), \quad \partial_\tau E_4 = \frac{1}{3}(E_2 E_4 - E_6), \quad \partial_\tau E_6 = \frac{1}{2}(E_2 E_6 - E_4^2),$$

which forms a closed algebraic-differential system in the ring $\mathbb{C}[E_2, E_4, E_6]$.

Putting it all together. Chain-level n -point KZB flatness (the statement $[\nabla_z^{\text{KZB}}, \nabla_{z'}^{\text{KZB}}] = 0$, $[\nabla_z^{\text{KZB}}, \nabla_\tau^{\text{KZB}}] = 0$ for all pairs on $\text{Conf}_n(E_\tau)$ at $n \geq 3$) is proved at leading order in $\hbar$

in Felder [?Felder94]; the full dynamical/quantum closure on the universal KZB bundle over $\overline{\mathcal{M}}_{1,n}$ is [?CEE09, Thm. 1 + Thm. 5] (Calaque–Enriquez–Etingof, *Universal KZB equations: the elliptic case*, Progress in Mathematics 269, 2010). Neither result is established as a theorem body in Vol I; its use here is attribution-level. The non-dynamical Belavin obstruction at $n \geq 3$ is witnessed numerically by the xfail test `test_cybe_generic_points` at `compute/tests/test_theorem_genus1_seven_faces_engine.py` (residual ~ 1 at generic (z_{12}, z_{13}) ; not a numerical precision issue). The Cartan-diagonal 2-point restriction is trivially flat at the matrix level because Ω self-commutes (§27.30.42); the genuine 2-point content is the scalar Bernard identity (27.58).

27.31 APPENDIX: SIGNS AND CONVENTIONS

All formulas above are invariant under the usual choice of suspension conventions, provided one keeps the same convention simultaneously in the ordered bar complex, the shuffle map, and the twisting differential. For clarity we summarize the minimal sign content.

- (1) Reversal in Theorem 27.5.1 uses the standard desuspended Koszul sign

$$(-1)^{\sum_{i < j} (|a_i|+1)(|a_j|+1)}.$$

- (2) The left twisting term in Definition 27.6.1 carries the sign needed to move the coderivation on C past the first coalgebra leg before applying the left $\mathcal{A}$ -action.
 (3) The right twisting term carries the additional sign needed to move the twisting cochain across the middle bimodule factor.
 (4) The ordered bar differential uses the desuspension convention

$$b_1(s^{-1}a) = -s^{-1}(d_{\mathcal{A}}a), \quad b_2^{(n)}(s^{-1}a \otimes s^{-1}b) = (-1)^{|a|}s^{-1}(a_{(n)}b),$$

and extends these maps as coderivations of $T^c(s^{-1}\bar{A})$. On the i -th adjacent pair the resulting prefix sign is

$$(-1)^{\sum_{q < i} (|a_q|-1)+|a_i|}.$$

With this convention $d_{\overline{B}}^2 = 0$ is exactly the desuspended Stasheff identity.

- (5) In the strongly admissible regime the filtration is complete and bounded below, so all spectral sequence and homotopy-transfer arguments used in the proofs converge.

27.32 APPENDIX: ORDERED BOUNDARY CALCULUS

The ordered boundary calculus consists of the following constructions, identifications, and computations.

- (1) Ordered chiral shuffle theorem (Theorem 27.3.3).
 (2) Opposite-duality and anti-involution transport (Theorem 27.5.1, Corollary 27.5.2).
 (3) Enveloping duality (Corollary 27.5.5).
 (4) Two-sided twisted bicomodule and its dg structure (Definition 27.6.1, Lemma 27.6.2).
 (5) Identification of the tangent ordered bar complex with the twisted bicomodule (Theorem 27.6.5).
 (6) PBW-complete bimodule/bicomodule equivalence (Theorem 27.7.3).
 (7) Diagonal correspondence (Theorem 27.7.4).

- (8) Composition unit theorem (Corollary 27.7.5).
- (9) Tensor–cotensor gluing (Corollary 27.7.6).
- (10) chiral Hochschild/coHochschild homology and cohomology equivalence (Theorems 27.8.1 and 27.8.2).
- (11) Infinitesimal annular variation (Proposition 27.6.7).
- (12) Ordered genus-zero open trace formalism (Theorem 27.9.5).
- (13) Calabi–Yau transport to an ordered Frobenius structure (Theorem 27.9.8).
- (14) E_1 -chiral double bar of $\hat{\mathfrak{sl}}_{2,k}$ (Proposition 27.14.1).
- (15) Central extension invisible to the E_1 -chiral double bar (Theorem 27.14.1).
- (16) Double Koszul duality is involutive (Theorem 27.14.2).
- (17) Non-redundancy of the two colours (Corollary 27.14.3).
- (18) Heisenberg ordered bar complex: trivial differential, deconcatenation coproduct, collision residue $r_{\mathcal{H}}^{\text{coll}}(z) = k\Omega_{\mathcal{H}}/z$, R -matrix $R(z) = e^{kh/z}$ (Theorems 27.12.1 and 27.12.3).
- (19) Abelian Yangian $Y(\mathfrak{u}(1))$ as ordered Koszul dual of $\mathcal{H}_k$ (Theorem 27.12.5).
- (20) Formality of $\overline{B}^{\text{ch}}(\mathcal{H}_k)$: class G, shadow depth 2, $m_k = 0$ for $k \geq 3$ (Theorem 27.12.6).
- (21) Conditional universal Kac–Moody Yangian criterion: for every simple $\mathfrak{g}$ and non-critical $k \neq -h^\vee$, $A_{\text{line}}^{\text{l,ord}}(\widehat{\mathfrak{g}}_k) \simeq Y_h(\mathfrak{g})$ at $\hbar = 1/(k + h^\vee)$ under the root-sector strictification and R -twisted descent packages; trace-form collision residue $k\Omega_{\text{tr}}/z$ and KZ-normalized $r^{\text{KZ}}(z) = \Omega/((k + h^\vee)z)$; CYBE from Jacobi; root-sector strictification criterion; curvature $\kappa(Y_h(\mathfrak{g})) = -\dim(\mathfrak{g}) \cdot (k + h^\vee)/(2h^\vee)$ (Theorem 27.16.1, Table 27.1).
- (22) $\mathcal{W}_3$ ordered bar complex via DS transport: generators, pole structure, A_∞ operations (class M), curvature $5c/6$, complementarity $K_3 = 100$, self-dual at $c^* = 50$ (Theorem 27.30.17).
- (23) Class M persistence under DS transport for all $\mathcal{W}_N$: Koszulness preserved, wheel tower created on the universal T -line, $K_N = 2(N-1)(2N^2+2N+1)$ (Theorem 27.30.18).
- (24) $\beta\gamma$ ordered bar complex: pole-valued collision residue $r^{\text{coll}} = 0$; regular contact operator $\Theta = \beta \otimes \gamma - \gamma \otimes \beta$ with $\Theta^2 = 0$; contact transport $R_{\text{contact}} = \text{id} + 2\pi i \Theta$ (terminating at linear order); Koszul dual a 4-dimensional exterior algebra (class C, shadow depth 4) (Theorems 27.24.1, 27.24.1, and 27.24.1).
- (25) bc ghost ordered bar complex: pole-valued collision residue $r^{\text{coll}} = 0$; regular contact operator $\Theta_{bc} = b \otimes c - c \otimes b$ with $\Theta_{bc}^2 = 0$; contact transport $R_{\text{contact}} = \text{id} + 2\pi i \Theta_{bc}$; Koszul dual a symmetric algebra (class C, shadow depth 4, complementarity $K = 0$) (Theorem 27.24.1).
- (26) Conditional Wakimoto bar complex descent: under the DS exactness, PBW-preservation, and BRST-lift hypotheses, reduction of the free-field ordered bar complex gives the affine ordered bar model; the dg Yangian $Y_h^{\text{dg}}(\mathfrak{g})$ is the corresponding free-field Yangian reduction (Theorem 27.24.3).
- (27) Lattice vertex algebras: collision residue diagonal in α -sector, R -matrix from OPE monodromy for symmetric cocycles (E_∞), independent braiding for non-symmetric cocycles (genuinely E_1), Koszul dual with inverse cocycle for self-dual lattices (Theorems 27.25.1, 27.25.2, and 27.25.3).
- (28) Root-space one-dimensionality for simple Lie algebras (Theorem 27.17.3).
- (29) Jacobi collapse for star sectors (Lemma 27.17.4).
- (30) Dynkin coefficient via the beta integral: the universal BCH coefficient $1/n = \int_0^1 (1-t)^{n-1} dt$ (Theorem 27.17.6).

- (31) Root-sector spectral Drinfeld strictification for simple Lie algebras: after root-sector localization and coefficient comparison, the spectral Drinfeld class vanishes at every filtration, so the dg-shifted Yangian $Y_h^{\text{dg}}(\mathfrak{g})$ carries a strict filtered algebra structure (Theorem 27.17.8).
- (32) Evaluation homomorphism $\text{ev}_a : Y_h(\mathfrak{g}) \rightarrow U(\mathfrak{g})$ for all simple types (Construction 27.26.2).
- (33) $\mathfrak{sl}_2$ R -matrix on evaluation modules: $R(u) = u \text{ id} + \hbar P$ (Yang R -matrix), Clebsch–Gordan decomposition and non-semisimplicity at resonance (Theorem 27.26.5, Corollary 27.26.6).
- (34) $\mathfrak{sl}_3$ evaluation modules: fundamental and adjoint (Computations 27.26.7 and 27.26.8).
- (35) Drinfeld polynomial classification of evaluation modules (Proposition 27.26.10).
- (36) Line category $\mathcal{C}_{\text{line}} \simeq Y_h(\mathfrak{g})\text{-mod}^{\text{fd}}$ on the affine Koszul locus (Theorem 27.26.12).
- (37) Braided monoidal structure on evaluation modules from the universal R -matrix, including coalescence singularity at $a = b$ (Theorem 27.26.14).
- (38) Quantum-group parameter and braid/Cartan readout from genus-1 B -cycle monodromy of the KZB connection, with $q = e^{\pi i \hbar}$ (Theorem 27.21.6).
- (39) Drinfeld–Kohno comparison on the affine evaluation surface: KZ monodromy equals the quantum-group braid representation externally, and the ordered bar complex reduces to KZ/KZB under one-loop collapse (Theorem 27.21.12).
- (40) Affine genus-1 monodromy readout: the genus-0 Yangian evaluation surface and the genus-1 KZB quantum-group readout are related by the B -cycle exponential map $\widehat{\mathbb{G}}_a \rightarrow \widehat{\mathbb{G}}_m$ (Theorem 27.21.13).
- (41) $U_q(\mathfrak{sl}_2)$ at roots of unity from affine $\widehat{\mathfrak{sl}}_2$ at integer level; Kazhdan–Lusztig equivalence (Corollary 27.21.16).
- (42) Jones polynomial from genus-1 bar-complex monodromy via the Reshetikhin–Turaev quantum trace (Theorem 27.21.17).
- (43) Annular bar complex: wrapping $\mathbb{R} \rightarrow S^1$ produces the cyclic cotensor complex $B_{\bullet}^{\text{ann}}(\mathcal{A})$ with four-component differential $d^{\text{ann}} = d_{\text{int}} + d_{\text{res}} + d_{\Delta} + d_{\text{wrap}}$ (Definition 27.20.1, Theorem 27.20.2).
- (44) Annular bar complex computes chiral Hochschild homology: $B_{\bullet}^{\text{ann}}(\mathcal{A}) \simeq \text{HH}_{\bullet}^{\text{ch}}(\mathcal{A})$ (Theorem 27.20.4).
- (45) Curvature–braiding dichotomy at genus 1: the lowest λ -bracket coefficient c_0 controls whether the genus-1 E_1 -chiral bar complex decouples ($c_0 = 0$, Cartan type) or entangles ($c_0 \neq 0$, Yangian type) via elliptic quasi-periodicity (Theorem 27.20.7).

The diagonal is the boundary; the bar coalgebra is the ambient ordered phase space; the annulus is the self-cotensor of the diagonal. Under this identification, associative chiral duality produces open traces, centres, and bordered genus operations from the same cotensor calculus.

Remark 27.32.1 (Non-commutative Euler product). The commutative sewing lift $S_{\mathcal{H}}(u) = \prod_p (1 - p^{-u})^{-1} (1 - p^{-u-1})^{-1}$ (Theorem ??) factors the Heisenberg sewing determinant over primes via the unordered divisor function σ_{-1} . The E_1 -ordered bar complex replaces unordered by ordered factorizations; the analogous ordered sewing lift should involve composition-weighted divisor sums and factor in the ring of non-commutative formal Dirichlet series.

E_n KOSZUL DUALITY AND HIGHER-DIMENSIONAL BAR COMPLEXES

Remark 28.0.1 (Six structural anchors for this chapter). The chapter is read against six anchors that pin scope, prevent operadic conflatons, and route the reader to the comparison theorems.

- (A) *five E_1 -chiral notions.* Throughout this chapter, “ E_1 -chiral algebra” refers to notions (A)/(B) of Warning 3.11.11 (strict Ass^{ch} or A_∞ in End_A^{ch}). The factorization-algebra notion (E) on $\text{Ran}^{\text{ord}}(X)$ is the $\mathcal{D}$ -module reading of (B) and is used wherever configuration spaces enter; the Etingof–Kazhdan quantum-vertex notion (C) appears only on the Koszul locus through the chiral quantum-group equivalence (Theorem 27.29.3).
- (B) $\text{SC}^{\text{ch},\text{top}} \neq E_3$. The Swiss-cheese operad is two-coloured with directionality (no open-to-closed maps); Dunn additivity does *not* apply to coloured operads. “Topologization to E_3 ” means Sugawara at non-critical level after holomorphic translation has been killed by a BRST primitive. For class **L** the cohomological statement is Theorem 28.13.4, and the original-complex lift is conditional in the separate class- L theorem ???. For class **M** the ordinary direct-sum complex is not the proved surface; the usable construction is the weight-completed or coderived one, represented here by the finite-rung criterion of Theorem ???.
- (C) *topologization scope.* The chapter constructs the E_2^{hol} structure on the closed sector and notes the topologization route from $E_2^{\text{hol}} \rightarrow E_2^{\text{top}}$ (cohomological in general; original-complex chain-level for class **L** only under Theorem ???’s higher-brace coherence condition). Every reference to E_3^{top} *on the original complex* is scope-restricted to the cases where an explicit original-complex theorem is invoked or its stated coherence package is assumed: class **L** at non-critical level under HBC_L , class **G** by commutativity, and class **C** through FMS bosonization. Class **M** is used here only on the completed or coderived surfaces.
- (D) *Drinfeld center is the right adjoint to forgetful, not an averaging.* Categorized passage from E_1 -Cat to E_2 -Cat is by the Drinfeld center $Z: E_1\text{-Cat} \rightarrow E_2\text{-Cat}$, which is the right adjoint to the monoidal-forgetful $U: E_2\text{-Cat} \rightarrow E_1\text{-Cat}$. It is *not* the averaging map av of Chapter 26 (averaging is the Σ_n -coinvariant projection on convolution complexes; it destroys ordered data, while the Drinfeld center constructs an E_2 structure from E_1 data).
- (E) *Climax Theorem and Koszul Reflection.* The chapter culminates in the Climax Theorem (Chapter ???), which identifies the bar differential with $\text{KZ}^*(\nabla^{\text{Arnold}})$, and the Koszul Reflection Theorem (Theorem 17.1.2 in Chapter 17), which upgrades the bar–cobar adjunction to an $(\infty, 2)$ -equivalence at properad level. The E_3 -identification at chain-level (Chapter ???) exhibits the explicit associator-dependence (GRT_1 torsor) of the chain-level identification.
- (F) *E_n circle (algebraic-geometric).* The chain $E_3 \rightarrow E_2 \rightarrow E_1 \rightarrow E_2 \rightarrow E_3$ is realised in this chapter as an *algebraic-geometric* circle of functorial operations: bar (descent in colour), Drinfeld center (categorized $E_1 \rightarrow E_2$), and Deligne lift (chain-level $E_2 \rightarrow E_3$). The physical reading of the same

circle as bulk/boundary/defect for 3d HT theories is recorded in Vol II's holography chapters; nothing in this chapter appeals to a physical interpretation.

For topological E_n algebras, the bar-cobar adjunction uses a closed $(n-1)$ -form and the Totaro relations on configuration spaces of real n -manifolds. Chiral Koszul duality on a curve uses the meromorphic propagator $d \log(z - w)$, $\mathcal{D}$ -module factorization on the Ran space, and residue operations at algebraic diagonals. The two constructions have the same boundary-stratum pattern; they are not the same functor. At $n = 2$ the topological little-disks theory is the oriented-surface shadow obtained after forgetting the holomorphic and $\mathcal{D}$ -module structure. The passage from $n = 1$ (associative/ A_∞) through $n = 2$ (oriented surfaces, with a holomorphic lift on curves) to $n = 3$ (Chern–Simons and Vassiliev-type configuration integrals) gives a family of related bar-cobar constructions, not a single theorem with dimension as a parameter.

The chapter culminates in the chiral center theorem (§28.10), which identifies the chiral Hochschild cochain complex as the operadic center of an $SC^{\text{ch}, \text{top}}$ -algebra, and in the topologization theorem (§28.13), which upgrades the resulting E_2 center on BRST cohomology to E_3 via the Sugawara conformal vector. The topologization proof is made constructive by an explicit antighost contraction $G(z)$ representing $T_{\text{Sug}} = [Q, G]$ in BRST cohomology in the 3d holomorphic Chern–Simons BV complex (Construction 28.13.17). For affine Kac–Moody at non-critical level, the original-complex lift is not an automatic consequence of Dunn additivity; it uses the separate class- L chain theorem (Theorem ??) and the coherence criterion isolated in Proposition 28.13.30. For class M algebras (Virasoro, $\mathcal{W}_N$), where the ordinary complex sees the infinite shadow tower, the completed and coderived surfaces are the available path (Conjecture 28.13.32).

Throughout this monograph, the bar differential has been built from configuration spaces of points on a *curve*: the propagator $\eta_{ij} = d \log(z_i - z_j)$ is a meromorphic 1-form, its singularities are controlled by Arnold relations, and the bar-cobar adjunction lives over the chiral operad. This chapter asks a different question: what remains true when one leaves the Beilinson–Drinfeld curve setting and passes to genuine little-disks factorization on real n -manifolds? Then the propagator becomes a closed $(n - 1)$ -form, collision strata are governed by *Totaro relations*, and the bar-cobar adjunction governs E_n -algebras.

Two axes must be kept separate. Inside chiral geometry on a fixed curve one has the hierarchy $E_\infty\text{-chiral} \subset P_\infty\text{-chiral} \subset E_1\text{-chiral}$, so the passage from Heisenberg to Yangian changes commutativity and locality, not manifold dimension. Here $E_\infty\text{-chiral}$ means local factorization with full symmetric-group invariance: Heisenberg, affine Kac–Moody, Virasoro, and the other standard local chiral algebras remain $E_\infty\text{-chiral}$ even though their OPEs have poles. By contrast, $E_1\text{-chiral}$ records ordered, nonlocal data such as Yangians and Etingof–Kazhdan quantum vertex algebras. The topological ladder is instead indexed by real manifold dimension: $n = 1$ is the classical associative/ A_∞ bar-cobar theory on intervals or circles, $n = 2$ is the oriented-surface setting whose meromorphic lift gives the genus-0 local shadow of the chiral bar complex on a complex curve, and $n = 3$ interfaces with Chern–Simons theory and Vassiliev invariants (Chapter I). At $n = 2$ the bar complex governs E_2 -algebras (the natural algebraic structure on braided monoidal categories) and connects to Kontsevich's formality theorem for the little 2-disks operad.

THEOREM 28.0.2 (*Bridge theorem: E_n bar-cobar and the chiral E_1 engine;*). The chiral bar-cobar adjunction of this monograph (Theorem 14.1.103) has a genus-0 oriented-surface shadow governed by the $n = 2$ chapter of E_n Koszul duality. The full chiral adjunction is not obtained by specializing the topological E_n functor. Precisely:

- (i) The E_n bar complex on an oriented real n -manifold $\mathcal{M}$ is built from configuration spaces $C_k(\mathcal{M})$ with propagator a closed $(n-1)$ -form and collision relations governed by the Totaro presentation (Theorem 28.1.3). At $n = 2$, this specializes to the Arnold presentation on $C_k(\mathbb{C})$. The holomorphic propagator $\eta_{ij} = d \log(z_i - z_j)$ is a meromorphic lift of the angular topological generator; after taking the underlying topological factorization algebra it gives the genus-0 oriented surface shadow of the chiral bar complex on a complex curve.
- (ii) The E_1 bar-cobar adjunction of this monograph (operating on ordered, nonlocal chiral algebras with possibly non-commutative OPE, including Yangians and Etingof–Kazhdan quantum vertex algebras) is *not* the topological E_n bar-cobar at $n = 1$ (which governs ordinary associative algebras on intervals) and is not obtained from E_2 by merely dropping commutativity. It is a curve-based associative chiral structure on ordered Ran/configuration spaces, with meromorphic OPE residues and braid or R -matrix data. The topological ladder and the chirality hierarchy are orthogonal axes.
- (iii) The formality hierarchy organizes how much of the bar-cobar adjunction reduces to cohomological data:

n	Formality	Source
∞	E_∞ formal	local commutative shadow
2	E_2 formal	Kontsevich [?Kon99], Tamarkin
1	E_1 <i>non-formal</i> in general	obstructed by A_∞ Massey products

The genus-0 topological shadow of an E_∞ -chiral algebra may be compared with the formal homology operad of E_2 . This comparison does not prove formality of the full chiral bar complex: the $\mathcal{D}$ -module, residue, and genus terms are extra data. For E_1 -chiral algebras the transferred A_∞ structure is genuinely non-formal; higher operations m_k for $k \geq 3$ carry ordered homotopical content.

Proof. Part (i) is the content of Remark 28.1.4: the Arnold generators on $C_k(\mathbb{C})$ are the Totaro generators at $n = 2$. The residue of $d \log(z_i - z_j)$ on the small linking circle is the S^1 linking integral. This proves the topological shadow comparison; the $\mathcal{D}$ -module and global curve data remain extra chiral structure.

Part (ii): the chiral hierarchy E_∞ -chiral $\subset$ P_∞ -chiral $\subset$ E_1 -chiral on a fixed curve changes the commutativity constraint on the OPE, not the manifold dimension. An E_1 -chiral algebra on a complex curve is a non-symmetric chiral algebra over ordered Ran/configuration spaces. Only after forgetting holomorphic and $\mathcal{D}$ -module structure and imposing local constancy does it have a topological surface shadow; it is not an E_1 -algebra in the topological sense, which would be an A_∞ -algebra on an interval.

Part (iii): E_2 formality is Kontsevich’s theorem [?Kon99] for the little 2-disks operad; E_∞ formality is tautological; E_1 non-formality is witnessed by non-trivial Massey products in the bar cohomology of non-formal A_∞ -algebras (e.g., the commutative algebra $\mathbb{C}[x]/x^3$), which survive as higher operations m_k on the transferred structure. The chiral statement uses the $n = 2$ topological realization together with the holomorphic lift of the propagator; it is not a formal consequence of the bare E_2 adjunction. $\square$

PROPOSITION 28.0.3 (Formality hierarchy as MC obstruction truncation). The formality hierarchy $E_\infty \supset E_2 \supset E_1$ is measured by truncation of the MC obstruction tower under the stated transfer hypotheses:

- (i) E_∞ -formality: the full modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ is formal; all higher brackets $\ell_n^{(g)} = 0$ for $n \geq 3$.

- (ii) E_2 -formality: the genus-0 convolution algebra $\mathfrak{g}_{\mathcal{A}}^{(o)}$ is formal; the shadow obstruction tower terminates at degree 2 (chiral Koszulness, Theorem 14.1.59).
- (iii) E_1 -formality: the ordered convolution algebra $\mathfrak{g}_{\mathcal{A}}^{E_1}$ carries a formal A_∞ -model; the associative shadow obstruction tower terminates. The ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A})$ on ordered configuration spaces $\text{FM}_n^{\text{ord}}(\mathbb{C})$ carries the associative shadow obstruction tower $(\Theta_{\mathcal{A}}^{E_1})^{\leq r}$; formality of the ordered convolution algebra is the vanishing of the transferred A_∞ -operations m_n^{tr} for $n \geq 3$ (Chapter 26). Passing from $\overline{B}^{\text{ord}}(\mathcal{A})$ to the symmetric shadow $\overline{B}^\Sigma(\mathcal{A})$, and from $\mathfrak{g}_{\mathcal{A}}^{E_1}$ to $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$, by R -twisted Σ_n -coinvariants is lossy: it forgets ordered braid data.

Proof. Each formality level kills the obstruction classes $o_{r+1}(\mathcal{A})$ in the cyclic deformation complex above the corresponding degree threshold (Proposition ?? for degrees 2, 3, 4). Under chiral Koszulness and the complete transfer hypotheses, the E_2 case reads shadow-tower termination at degree 2 on the chiral Hochschild side; the E_1 case is the ordered associative analogue via $\overline{B}^{\text{ord}}(\mathcal{A})$ (Chapter 26). $\square$

Convention 28.0.4 (Two axes in this chapter). In this chapter, bare E_n always denotes little-disks/topological factorization on real n -manifolds. The earlier hierarchy E_∞ -chiral/ P_∞ -chiral/ E_1 -chiral remains curve-based. Hence the chiral bar complex on a complex curve belongs to the topological ladder at $n = 2$, while the $n = 1$ case is the classical associative/ A_∞ bar construction.

28.1 HIGHER-DIMENSIONAL CONFIGURATION SPACES

Definition 28.1.1 (Configuration space of $\mathbb{R}^n$). For a smooth oriented n -manifold M , the *ordered configuration space of k points* is

$$C_k(M) = \{(x_1, \dots, x_k) \in M^k \mid x_i \neq x_j \text{ for } i \neq j\}.$$

For $M = \mathbb{R}^n$, the space $C_k(\mathbb{R}^n)$ is a smooth manifold of real dimension nk , and its cohomology admits an explicit generators-and-relations presentation due to Arnold ($n = 2$, i.e., $\mathbb{R}^n = \mathbb{C}$) and Totaro (general n).

THEOREM 28.1.2 (Arnold presentation [?Arnold69]; $\mathbb{C} \cong \mathbb{R}^2$). The cohomology ring $H^*(C_k(\mathbb{C}); \mathbb{Q})$ is the graded-commutative algebra generated by classes $\eta_{ij} \in H^1$, $1 \leq i < j \leq k$, subject to the *Arnold relations*:

$$\eta_{ij} \wedge \eta_{jk} + \eta_{jk} \wedge \eta_{ki} + \eta_{ki} \wedge \eta_{ij} = 0 \quad (i < j < k).$$

This is the Orlik–Solomon algebra OS_k (Theorem 6.6.6).

THEOREM 28.1.3 (Totaro presentation, general n [?Totaro96, ?Coh76];). For $n \geq 2$, the cohomology ring $H^*(C_k(\mathbb{R}^n); \mathbb{Q})$ is the graded-commutative algebra generated by classes $\alpha_{ij} \in H^{n-1}$, $1 \leq i \neq j \leq k$, subject to the relations:

- (i) (Symmetry) $\alpha_{ij} = (-1)^n \alpha_{ji}$;
- (ii) (Totaro relations) $\alpha_{ij} \cdot \alpha_{jk} + \alpha_{jk} \cdot \alpha_{ki} + \alpha_{ki} \cdot \alpha_{ij} = 0$ for distinct i, j, k ;
- (iii) (Degree) $\alpha_{ij}^2 = 0$ when n is odd; when n is even, α_{ij}^2 is determined by the Euler class.

At $n = 2$, after identifying $\mathbb{R}^2 \cong \mathbb{C}$ and choosing the oriented generator of $H^1(C_2(\mathbb{R}^2))$, one recovers Arnold’s three-term relation on $C_k(\mathbb{C})$. By contrast, $n = 1$ is the degree-0 associative setting of ordered points on a line, not the chiral curve case.

Proof. See Totaro [?Totaro96], Theorem 1; also Cohen [?Coh76], Theorem A for the formality statement. The key geometric input is that projection maps $C_k(\mathbb{R}^n) \rightarrow C_2(\mathbb{R}^n)$ induce pullbacks of the fundamental class of S^{n-1} (the linking sphere), and all relations among these pullbacks are generated by the three-term relation (ii). $\square$

Remark 28.1.4 (Arnold as Totaro at $n = 2$). In the E_n hierarchy, n is the *real* dimension. The classical Arnold generators on $C_k(\mathbb{C})$ are Totaro generators at $n = 2$; our chiral bar complex uses $n = 2$:

E_n -level	Manifold	Bar complex
$n = 1$	interval/circle	associative bar (classical)
$n = 2$	surface/curve	chiral bar (this monograph)
$n = 3$	3-manifold	Chern–Simons bar
general n	n -manifold	E_n bar

Main Theorems A, B, C are the holomorphic refinement of the $n = 2$ chapter of E_n Koszul duality.

28.1.1 Fulton–MacPherson compactification in dimension n

Definition 28.1.5 (FM compactification of $C_k(\mathbb{R}^n)$). The *Fulton–MacPherson compactification* $\overline{C}_k(\mathbb{R}^n)$ is the real oriented blowup of $(\mathbb{R}^n)^k$ along all partial diagonals, ordered by reverse inclusion. Equivalently (Axelrod–Singer, Kontsevich), it is the closure of the image of the map

$$C_k(\mathbb{R}^n) \hookrightarrow (\mathbb{R}^n)^k \times \prod_{i < j} S^{n-1} \times \prod_{|S| \geq 2} [0, \infty]$$

recording positions, relative directions $\theta_{ij} = (x_i - x_j)/|x_i - x_j| \in S^{n-1}$, and relative distances. The result is a smooth manifold with corners whose boundary strata are indexed by nested partitions of $\{1, \dots, k\}$, the same combinatorial data as the Stasheff associahedron ($n = 1$) or the FM operad ($n \geq 2$).

PROPOSITION 28.1.6 (Boundary strata and operadic structure;). The codimension-1 boundary strata of $\overline{C}_k(\mathbb{R}^n)$ are indexed by subsets $S \subset \{1, \dots, k\}$ with $|S| \geq 2$, and are diffeomorphic to

$$\partial_S \overline{C}_k(\mathbb{R}^n) \cong \overline{C}_{k-|S|+1}(\mathbb{R}^n) \times \overline{C}_{|S|}(\mathbb{R}^n).$$

This factorization equips $\{\overline{C}_k(\mathbb{R}^n)\}_{k \geq 0}$ with the structure of a topological operad, the *Fulton–MacPherson operad* FM_n , which is a model for the E_n operad (i.e., weakly equivalent to the little n -disks operad).

Proof. The operadic structure is due to Getzler–Jones [?GJ] and Salvatore; the equivalence $\text{FM}_n \simeq E_n$ is proved by Salvatore–Longoni [?SalvatoreLongoni05] for $n \geq 2$ and follows from Stasheff’s theorem for $n = 1$. $\square$

28.2 THE E_n PROPAGATOR

Definition 28.2.1 (E_n propagator;). An E_n *propagator* on an oriented n -manifold M is a smooth closed $(n-1)$ -form

$$G \in \Omega^{n-1}(M \times M \setminus \Delta)$$

satisfying the following properties:

- (i) (Poincaré dual of diagonal) G represents the Poincaré dual of the diagonal $\Delta \subset M \times M$ in the sense that for any closed form $\eta \in \Omega^*(M)$,

$$\int_{M \times M} G \wedge \pi_2^* \eta = \int_M \eta,$$

where $\pi_2: M \times M \rightarrow M$ is the second projection.

- (ii) (Singularity) Near the diagonal Δ , in geodesic coordinates,

$$G \sim \frac{1}{\text{vol}(S^{n-1})} \frac{r_1 dr_2 \wedge \cdots \wedge dr_n - r_2 dr_1 \wedge dr_3 \wedge \cdots \wedge dr_n + \cdots}{|r|^n} + \text{smooth},$$

where $r = x_1 - x_2$ and $\text{vol}(S^{n-1}) = 2\pi^{n/2}/\Gamma(n/2)$.

- (iii) (Symmetry) Under the involution $\sigma: (x_1, x_2) \mapsto (x_2, x_1)$, $\sigma^* G = (-1)^n G$.

Example 28.2.2 ($n = 2$: the chiral propagator on a complex curve). For $M = \mathbb{C}$ (real dimension 2, but complex dimension 1, the chiral case), the propagator is $\eta_{12} = d \log(z_1 - z_2)$, a meromorphic lift of the topological angular propagator. The normalized form $(2\pi i)^{-1} \eta_{12}$ has residue 1 on a small circle around the diagonal. It is closed away from $z_1 = z_2$, represents the local Poincaré dual class after forgetting holomorphic structure, and satisfies $\sigma^* \eta_{12} = d \log(z_2 - z_1) = d \log(-(z_1 - z_2)) = d \log(-1) + d \log(z_1 - z_2) = \eta_{12}$, since $d \log(-1) = 0$ (differential of a constant). Residues along $z_1 = z_2$ extract OPE data.

Example 28.2.3 ($n = 2$: the E_2 propagator on $\mathbb{R}^2$). For $M = \mathbb{R}^2$, the propagator is

$$G = \frac{1}{2\pi} \frac{(x_1 - x_2) dy_1 - (y_1 - y_2) dx_1}{(x_1 - x_2)^2 + (y_1 - y_2)^2} = \frac{1}{2\pi} d \arg(z_1 - z_2),$$

a closed 1-form on $C_2(\mathbb{R}^2)$. This is the angular form (winding number kernel): integration over a small circle $S^1 \subset \mathbb{R}^2$ around x_2 gives 1. Note that $G = (1/2\pi) d \arg(z_1 - z_2)$ is exactly the *Kontsevich propagator* on $S^1 \subset \mathbb{C}$ (Proposition ??). The E_2 propagator on a surface and the chiral propagator on a complex curve represent the same local S^1 linking class after forgetting holomorphic data: the former is real-valued and topological, the latter is meromorphic and algebraic.

Example 28.2.4 ($n = 3$: the Chern–Simons propagator). For $M = \mathbb{R}^3$, the propagator is

$$G = \frac{1}{4\pi} \frac{\epsilon_{abc} r^a dr^b \wedge dr^c}{|r|^3},$$

where $r = x_1 - x_2 \in \mathbb{R}^3$. This is the closed 2-form on $C_2(\mathbb{R}^3)$ representing the linking number: $\int_{S^2} G = 1$. In the Axelrod–Singer perturbative expansion of Chern–Simons theory [?Kon94], this propagator appears as the kernel of the gauge-fixed Green’s operator d^{-1} .

PROPOSITION 28.2.5 (*Residue as linking sphere integral*;). For an E_n propagator G on $\mathbb{R}^n$ and a smooth function f on a neighborhood of the diagonal, the E_n residue is:

$$\text{Res}_\Delta(G \wedge f) := \lim_{\varepsilon \rightarrow 0} \int_{|x_1 - x_2| = \varepsilon} G \cdot f(x_1, x_2) = f(x, x),$$

where the integral is over the linking sphere $S_\varepsilon^{n-1} \subset C_2(\mathbb{R}^n)$ of radius ε around the diagonal. This generalizes the residue operation $\text{Res}_{z_1=z_2}$ in the chiral ($n = 2$) case.

Proof. By the singularity condition (ii) of Definition 28.2.1, G restricts on the sphere $|r| = \varepsilon$ to the standard volume form on S^{n-1} (normalized to total volume 1) plus terms vanishing as $\varepsilon \rightarrow 0$. Hence the integral extracts the value $f(x, x)$, exactly as a contour integral residue extracts the leading Laurent coefficient. $\square$

28.3 THE E_2 BAR COMPLEX

Definition 28.3.1 (E_2 bar complex;). Let A be an E_2 -algebra (equivalently, an algebra over the little 2-disks operad). The E_2 bar complex is the chain complex

$$\overline{B}_{E_2}(A) = \bigoplus_{k \geq 1} \Omega^*(\overline{C}_k(\mathbb{R}^2)) \otimes_{\Sigma_k} (s^{-1}\tilde{A})^{\otimes k},$$

with differential

$$d_{E_2} = d_{\text{dR}} + \sum_{S \subset \{1, \dots, k\}, |S| \geq 2} \text{Res}_{\partial_S}(G_S \wedge \mu_S), \quad (28.1)$$

where:

- $G_S = \bigwedge_{i < j, i, j \in S} \alpha_{ij}$ is the product of propagators for pairs within the colliding subset S ,
- Res_{∂_S} is the linking-sphere residue along the boundary stratum ∂_S of $\overline{C}_k(\mathbb{R}^2)$ (Proposition 28.2.5),
- $\mu_S: \tilde{A}^{\otimes |S|} \rightarrow \tilde{A}$ is the E_2 -multiplication indexed by the FM operad element corresponding to the stratum ∂_S .

THEOREM 28.3.2 ($d^2 = 0$ from Totaro relations;). The differential d_{E_2} of Definition 28.3.1 satisfies $d_{E_2}^2 = 0$.

Proof. The proof follows the same structure as the chiral case (Corollary ??), with the Arnold relations replaced by Totaro relations.

We compute $d_{E_2}^2$ on a bar element $\alpha \in \Omega^*(\overline{C}_k(\mathbb{R}^2)) \otimes (s^{-1}\tilde{A})^{\otimes k}$. The square decomposes into three terms:

$$d_{E_2}^2 = \underbrace{d_{\text{dR}}^2}_{=0} + \underbrace{[d_{\text{dR}}, d_{\text{res}}]}_{(\star)} + \underbrace{d_{\text{res}}^2}_{(\star\star)},$$

where $d_{\text{res}} = \sum_S \text{Res}_{\partial_S}(G_S \wedge \mu_S)$.

For $(\star)$: the de Rham differential commutes with the residue operation because G is closed ($dG = 0$), so the cross-term $[d_{\text{dR}}, d_{\text{res}}]$ reduces to $\sum_S \text{Res}_{\partial_S}(dG_S \wedge \mu_S) = 0$.

For $(\star\star)$: the square d_{res}^2 involves iterated residues along pairs of boundary strata. For three distinct points i, j, k , the iterated residue $\text{Res}_{\partial_{\{i,j\}}} \circ \text{Res}_{\partial_{\{j,k\}}}$ plus cyclic permutations gives a sum of three terms. The Totaro relation

$$\alpha_{ij} \cdot \alpha_{jk} + \alpha_{jk} \cdot \alpha_{ki} + \alpha_{ki} \cdot \alpha_{ij} = 0 \quad \text{in } H^{2(n-1)}(C_3(\mathbb{R}^n))$$

at $n = 2$ ensures that this sum vanishes. More precisely: each term in d_{res}^2 corresponds to a codimension-2 boundary stratum of $\overline{C}_k(\mathbb{R}^2)$, and the Totaro relation is exactly the statement that the codimension-2 contributions cancel in cohomology.

For nested collisions (e.g., $\{i, j\} \subset \{i, j, k\}$), the iterated residue factors through the operadic composition $\mu_{\{i,j,k\}} = \mu_{\{i,j\}} \circ \mu_{\{j,k\}}$, and cancellation follows from the E_2 -algebra axiom (associativity up to coherent homotopy, encoded by the FM operad structure).

For the algebraic contribution: iterated residues at the same stratum S produce the square $\mu_S \circ \mu_S$, which vanishes by the A_∞ relations encoded in the E_2 structure.

The argument generalizes Idrissi's result [Idrissi22] that Poincaré duality on configuration spaces ensures $d^2 = 0$ for the propagator-based differential, specialized to $n = 2$ with explicit Totaro generators. $\square$

Remark 28.3.3 (Comparison with the chiral bar complex). The E_2 bar complex (Definition 28.3.1) and the chiral bar complex (Chapter 7) differ in propagator and dependence: the chiral complex uses the holomorphic $\eta_{ij} = d \log(z_i - z_j)$ and depends on the complex structure, while the E_2 complex uses the topological $G = (1/2\pi) d \arg(z_1 - z_2)$ and depends only on oriented topology. For a chiral algebra $\mathcal{A}$ on X there is a comparison after forgetting the $\mathcal{D}$ -module structure, restricting to the genus-0 locally constant surface shadow, and replacing the meromorphic residue by the S^1 linking integral. This comparison is an equivalence only under the corresponding local-constancy and completion hypotheses; it is not an equality of the chiral bar complex with the bare E_2 bar complex. The chiral bar complex carries strictly more information: genus- g quantum corrections $\kappa(\mathcal{A}) \cdot \lambda_g$ (Theorem ??) live in the chiral bar complex but not in the E_2 bar complex.

28.4 E_n KOSZUL DUALITY

Definition 28.4.1 (E_n bar-cobar adjunction). For each $n \geq 1$, the E_n bar functor and E_n cobar functor are defined on augmented complete filtered objects:

$$\begin{aligned} \overline{B}_{E_n} : E_n\text{-Alg}^{\text{aug,comp}} &\longrightarrow E_n\text{-CoAlg}^{\text{conil,comp}}, \\ \Omega_{E_n} : E_n\text{-CoAlg}^{\text{conil,comp}} &\longrightarrow E_n\text{-Alg}^{\text{aug,comp}}, \end{aligned}$$

where the ambient category is chain complexes with a complete augmentation-adic filtration, coalgebras are conilpotent, and morphisms are continuous. The bar construction uses the chain complex $C_*(\overline{C}_k(\mathbb{R}^n))$ with the differential of (28.1) generalized to dimension n . The cobar construction uses the completed tensor algebra and the universal twisting morphism. It is an ordinary linear dual only in finite type; otherwise every dual is the continuous dual for the chosen completion.

Convention 28.4.2 (Five objects in the E_n comparison). The notation in this section separates five objects.

$$A, \quad \overline{B}_{E_n}(A), \quad A^i, \quad A^!, \quad Z_{\text{ch}}^{\text{der}}(A).$$

Here A is the input algebra and $\overline{B}_{E_n}(A)$ is its completed conilpotent bar coalgebra. A quadratic presentation supplies the separate coalgebra $A^i = C(s^{-1}V, s^{-2}R)$ and its comparison $q_A : A^i \rightarrow \overline{B}_{E_n}(A)$; on the Koszul locus $H^\bullet(q_A)$ computes bar cohomology from the presentation. Finite-type or completed continuous duality forms the dual of the full bar, and a chosen-pair map reaches the Koszul partner $A^!$. The derived chiral center $Z_{\text{ch}}^{\text{der}}(A) = \text{RHom}_{A^c}(A, A)$ is a Hochschild cochain object. The counit $\Omega_{E_n} \overline{B}_{E_n}(A) \rightarrow A$ performs bar-cobar reconstruction. On the chiral Ran surface, Verdier duality sends the symmetric $\mathcal{D}$ -module bar coalgebra to the algebra $K_X(A)$. Factorization homology and higher Hochschild chains $\int_{\mathcal{M}} A$ are trace objects depending on a chosen manifold $\mathcal{M}$; the Hochschild cochain construction supplies the centre $Z_{\text{ch}}^{\text{der}}(A)$.

THEOREM 28.4.3 (E_n Koszul duality;). (i) (Lurie [?HA], §5.2) The functors $\overline{B}_{E_n}$ and Ω_{E_n} form an adjoint pair

$$\Omega_{E_n} \dashv \overline{B}_{E_n} : E_n\text{-CoAlg}^{\text{conil,comp}} \rightleftarrows E_n\text{-Alg}^{\text{aug,comp}}.$$

(ii) (Francis [?Francis2013], Theorem 4.20) For a complete augmented E_n -algebra A that is E_n -Koszul (the E_n bar spectral sequence is convergent and collapses on the stated Koszul locus), the counit $\Omega_{E_n}(\overline{B}_{E_n}(A)) \xrightarrow{\sim} A$ is a quasi-isomorphism.

- (iii) (Ayala–Francis [?AF15], Theorem 7.8) For a closed oriented n -manifold $\mathcal{M}$ and an augmented E_n -algebra A satisfying the Ayala–Francis dualizability and completion hypotheses, Poincaré–Koszul duality identifies factorization homology with compactly supported factorization cohomology with coefficients in the completed E_n -bar coalgebra:

$$\int_{\mathcal{M}} A \simeq \int_{\mathcal{M}}^c \overline{B}_{E_n}(A).$$

A quadratic presentation gives $q_A: A^i = C(s^{-1}V, s^{-2}R) \rightarrow \overline{B}_{E_n}(A)$. Under the Koszul comparison and finite-type or completed continuous duality, the right-hand side admits its chosen-pair algebra model; the dualizing local system of $\mathcal{M}$ carries the orientation shift.

Remark 28.4.4 (Chain-level content of this monograph). Ayala–Francis prove part (iii) at the ∞ -categorical level. Main Theorems A, B, C are the chiral chain-level refinement of the $n = 2$ oriented-surface shadow: explicit propagators, residue formulas, and spectral sequences. The genus- g quantum corrections (Theorem B) and complementarity (Theorem C) are specific to curves with complex structure, invisible to the topological E_2 theory.

COROLLARY 28.4.5 (*Topological $n = 2$ shadow of chiral bar-cobar;*). Let $\mathcal{A}$ be a chiral algebra on a complex curve X whose underlying factorization algebra is locally constant after forgetting the $\mathcal{D}$ -module and holomorphic structure, and assume the augmentation filtration is complete. The E_2 bar-cobar adjunction of Theorem 28.4.3(i) recovers the oriented-surface shadow of the genus-0 chiral bar-cobar adjunction of Theorem 14.1.103. It does not recover the full chiral adjunction: the meromorphic OPE, Ran-space $\mathcal{D}$ -module structure, and genus corrections remain additional chiral data.

Proof. On a coordinate disk,

$$d \log(z_i - z_j) = d \log |z_i - z_j| + i d \arg(z_i - z_j).$$

The radial term is invisible to the oriented topological linking class, while $(2\pi i)^{-1} d \log(z_i - z_j)$ and $(2\pi)^{-1} d \arg(z_i - z_j)$ have the same integral on the small linking circle around the diagonal. The Arnold relation is the $n = 2$ Totaro relation, so the square-zero calculation descends to the topological shadow by Theorem 28.3.2. The step uses local constancy and completion to compare bar-cobar counts. It does not identify the full $\mathcal{D}$ -module bar complex with the bare topological E_2 bar complex. $\square$

28.5 CONNECTION TO AYALA–FRANCIS

Ayala–Francis [?AF15] establish Poincaré–Koszul duality as an ∞ -categorical equivalence between factorization homology and compactly supported factorization cohomology with Koszul-dual coefficients:

THEOREM 28.5.1 (*Poincaré–Koszul duality, AF [?AF15];*). Let $\mathcal{M}$ be a closed oriented n -manifold and let A be an augmented E_n -algebra satisfying the Ayala–Francis dualizability and completion hypotheses. There is a natural equivalence

$$\int_{\mathcal{M}} A \simeq \int_{\mathcal{M}}^c \overline{B}_{E_n}(A),$$

where the right hand side denotes compactly supported factorization cohomology with coefficients in the Koszul-dual coalgebra. In a finite-presentable model this may be expressed as a mapping object out of the unit coalgebra, but no ordinary vector-space dual is implied without finite-type or continuous-dual hypotheses.

PROPOSITION 28.5.2 (*Chiral chain model over the AF $n = 2$ shadow;*). At $n = 2$, after forgetting the $\mathcal{D}$ -module structure and restricting to the locally constant genus-0 surface shadow, the chain-level bar complex $\overline{B}^{\text{ch}}(\mathcal{A})$ of Chapter 7 maps to a chain model for the E_2 bar construction of Theorem 28.5.1, in the following sense:

- (a) The FM propagator integrals $\int_{\overline{C}_k(X)} \prod_{(i,j)} \eta_{ij} \otimes \prod_v a_v$ compute the topological realization of $\int_X \mathcal{A}$ on the locally constant shadow.
- (b) The Verdier duality pairing on $\overline{C}_k(X)$ (§??) realizes the Poincaré duality of Theorem 28.5.1 after compact-support and continuous-dual hypotheses are imposed.
- (c) The spectral sequence from bar filtration to bar cohomology maps to the descent spectral sequence of factorization homology with respect to the FM cover; convergence uses the complete bounded-below bar filtration.

Proof. Part (a): by the fundamental theorem of factorization homology [?AF15], the locally constant surface shadow of $\int_X \mathcal{A}$ is computed by a Čech complex with respect to a Weiss cover by disks. The FM compactification $\overline{C}_k(X)$ provides a resolution of that diskwise calculation. Integrals against η_{ij} have the same local linking residues as the angular E_2 propagator, while the bar elements $\otimes_v a_v$ provide the coefficients. The global holomorphic dependence remains in the chiral model and is forgotten by the AF shadow.

Part (b): Verdier duality $\mathbb{D}_{\overline{C}_k(X)}$ supplies the compact-support duality pairing on the FM compactification. This is the geometric input behind the Poincaré duality in Theorem 28.5.1; it pairs factorization homology with factorization cohomology of the Koszul-dual coalgebra $\mathcal{A}^i$, not with an unqualified ordinary dual. See Theorem 8.0.35 for the precise statement at $n = 2$.

Part (c): the FM cover filtration $F_p = \bigoplus_{k \leq p} C_*(\overline{C}_k(X)) \otimes (s^{-1}\tilde{A})^{\otimes k}$ gives a spectral sequence with $E_1^{p,q} = H^q(\overline{C}_p(X)) \otimes (s^{-1}\tilde{A})^{\otimes p}$ converging under the complete bounded-below filtration hypotheses. This is the bar spectral sequence of Theorem 9.10.34, mapped to the descent spectral sequence for the factorization homology presheaf on the topological shadow. $\square$

28.6 GENERAL n AND KONTSEVICH FORMALITY

28.6.1 The E_n bar complex for arbitrary n

Definition 28.6.1 (E_n bar complex, general n). For $n \geq 1$ and an E_n -algebra $\mathcal{A}$, the E_n bar complex is:

$$\overline{B}_{E_n}(\mathcal{A}) = \bigoplus_{k \geq 1} \Omega^*(\overline{C}_k(\mathbb{R}^n)) \otimes_{\Sigma_k} (s^{-1}\tilde{A})^{\otimes k}, \quad d = d_{\text{dR}} + d_{\text{res}},$$

where $d_{\text{res}} = \sum_S \text{Res}_{\partial_S}(G_S \wedge \mu_S)$ uses the E_n propagator of Definition 28.2.1 and linking-sphere residues (Proposition 28.2.5).

THEOREM 28.6.2 ($d^2 = 0$ for the E_n bar complex;). For $n \geq 2$ and any E_n -algebra $\mathcal{A}$, the E_n bar differential satisfies $d^2 = 0$. For $n = 1$ this is the usual A_∞ bar differential and its Stasheff-associahedral square-zero identity.

Proof. For $n \geq 2$ the argument is identical to the $n = 2$ case (Theorem 28.3.2), with the Arnold/Totaro relations in $H^*(C_3(\mathbb{R}^n))$ providing the cancellation of d_{res}^2 . For general n , the Totaro relation holds in degree $2(n-1)$, and the cancellation works in any degree.

The result also follows from the general formality framework of Idrissi [?Idrissi22]: Poincaré duality on the FM compactification $\overline{C}_k(\mathbb{R}^n)$ provides an explicit quasi-isomorphism between the de Rham complex of $\overline{C}_k(\mathbb{R}^n)$ and its cohomology algebra (the Totaro algebra), and the propagator differential is compatible with this quasi-isomorphism. For $n = 1$, $C_k(\mathbb{R})$ is a disjoint union of ordered chambers and the compactified boundary strata are the Stasheff faces; the associahedral A_∞ identities give $d^2 = 0$. $\square$

28.6.2 Configuration space Betti numbers and the E_n shadow obstruction tower

The Poincaré polynomial of $C_k(\mathbb{R}^n)$ for $n \geq 2$ is

$$P(C_k(\mathbb{R}^n), t) = \prod_{j=0}^{k-1} (1 + j t^{n-1}), \quad (28.2)$$

yielding total Betti number $\sum b_i = k!$ for all $n \geq 2$. The generator degree $n - 1$ controls the bar complex grading: the E_n propagator is a closed $(n-1)$ -form, so the degree- k bar complex $\overline{B}_{E_n}(A)_k$ has summands in degrees $0, n-1, 2(n-1), \dots, (k-1)(n-1)$ weighted by the Betti numbers of (28.2).

PROPOSITION 28.6.3 (*Kappa universality across n ;*). Let $\{A_n\}_{n \in I}$ be a compatible family of augmented E_n -algebras, $I \subset \{1, 2, \dots\}$, whose binary operation is equipped with the same invariant pairing of level k under the standard identification of the binary linking class. Then the degree-2 modular characteristic is independent of n :

$$\kappa_{E_n}(A_n) = k \quad (n \in I).$$

For the standard chiral examples, this says that any topological E_n shadow built from the same leading OPE pairing has the same binary invariant: $\kappa(H_k) = k$ for Heisenberg, $\kappa(V_k(\mathfrak{g})) = \dim(\mathfrak{g})(k + h^\vee)/(2h^\vee)$ for affine Kac–Moody, and $\kappa(\text{Vir}_c) = c/2$ for Virasoro. This is a statement about the binary pairing transported to an E_n shadow, not a claim that these vertex algebras carry canonical strict E_n -algebra structures for every n .

Proof. The modular characteristic κ is determined by the degree-2 component of the bar complex. For $n \geq 2$ this component involves $C_2(\mathbb{R}^n) \simeq S^{n-1}$, whose top cohomology is one dimensional. Normalising the propagator to integrate to 1 over the linking sphere makes $\int_{S^{n-1}} G \cdot \mu_2(a, b)$ equal to the chosen invariant binary pairing. For $n = 1$ the Stasheff interval model has the same binary contraction after the usual suspension convention. Thus the dimension changes the degree of the generator, not the scalar extracted from the fixed binary pairing. $\square$

PROPOSITION 28.6.4 (*Shadow stabilization threshold;*). Let $\{A_n\}_{n \geq 2}$ be a compatible family of formal E_n -algebras with a fixed binary level pairing and complete bounded-below bar filtrations. For the degree- r shadow in that family, positive-degree configuration-space corrections vanish once $n \geq r$. Hence

$$S_r^{E_n}(A_n) = S_r^{E_\infty}(A_\infty) \quad (n \geq r)$$

inside the compatible formal family. No stabilization statement is asserted for unrelated E_n -algebras or for non-formal filtered deformations with distinct MC classes.

Proof. At degree r , the relevant positive-degree classes in $H^*(C_r(\mathbb{R}^n))$ begin in degree $n-1$. The MC equation at shadow degree r has total propagator budget $r-2$. If $n-1 > r-2$, every positive-degree topological correction lies above the budget. Formality and equality of the transported MC class then

identify the remaining tree-level term with the commutative E_∞ shadow. The compatibility hypotheses are load-bearing: if the E_n -structures have different MC classes, degree counting alone does not identify the shadows. $\square$

Remark 28.6.5 (The G/L/C/M classification under E_n). For a compatible formal E_n family with fixed binary pairing and matching MC class, the shadow depth class (G/L/C/M of Theorem ??) is unchanged by raising n in the stable degree range of Proposition 28.6.4. Operad formality alone does not identify arbitrary algebra structures. In the standard chiral landscape the labels are inherited from the chiral calculation: Heisenberg is class G ($r_{\max} = 2$), affine Kac–Moody is class L ($r_{\max} = 3$), the $\beta\gamma$ system is class C ($r_{\max} = 4$), and Virasoro is class M ($r_{\max} = \infty$).

Remark 28.6.6 (The dimensional ladder). The transition from n to $n + 1$ trades algebraic structure for topological generality:

n	Propagator	Relations	Bar complex computes
1	$\text{sgn}(t_1 - t_2)$	Stasheff polytopes	Hochschild chains on S^1 ; cochains for the center
2	angular class; holomorphic lift $d \log(z_1 - z_2)$	Arnold (OS)	E_2 shadow; chiral Koszul dual with $\mathcal{D}$ -data
3	linking 2-form	graph cohomology	Vassiliev invariants
n	$(n-1)$ -form	Totaro	E_n -factorization homology

At each level, the propagator is a closed $(n - 1)$ -form, the relations in $H^*(C_3(\mathbb{R}^n))$ ensure $d^2 = 0$, and the bar cohomology computes the Koszul dual in the appropriate operadic sense.

28.6.3 Knudsen’s higher enveloping algebras

THEOREM 28.6.7 (Higher enveloping algebras;). (Knudsen [?Knudsen18]) For a Lie algebra $\mathfrak{g}$ and $n \geq 1$, the n -th enveloping algebra $U_n(\mathfrak{g})$ is an E_n -algebra satisfying:

- (i) $U_1(\mathfrak{g}) = U(\mathfrak{g})$ is the classical universal enveloping algebra.
- (ii) (PBW) There is an equivalence of graded objects $\text{gr } U_n(\mathfrak{g}) \simeq \text{Sym}^{E_n}(\mathfrak{g}[n - 1])$, where Sym^{E_n} is the free commutative E_n -algebra.
- (iii) (Koszul duality) $\overline{B}_{E_n}(U_n(\mathfrak{g}))$ is quasi-isomorphic to $\text{CE}_*^{E_n}(\mathfrak{g})$, the E_n -Chevalley–Eilenberg complex of $\mathfrak{g}$.

This result is the higher-dimensional analogue of the PBW theorem and the classical bar-CE comparison. At $n = 2$, the E_2 enveloping algebra $U_2(\mathfrak{g})$ is the topological shadow of the chiral universal enveloping algebra $\widehat{U}(\mathfrak{g}_k) = V_k(\mathfrak{g})$ (the vacuum module). Knudsen’s Koszul duality at $n = 2$ is the topological shadow of our chiral Koszul duality.

28.6.4 Kontsevich formality and deformation quantization

THEOREM 28.6.8 (Formality of E_2 ;). (Kontsevich [?Kon03], Tamarkin [?Tamarkin00]) The E_2 operad is formal over $\mathbb{Q}$: there is a quasi-isomorphism of operads

$$C_*(E_2; \mathbb{Q}) \simeq H_*(E_2; \mathbb{Q}).$$

After choosing a formality morphism, the filtered deformation groupoid of E_2 -structures near a fixed cofibrant model is equivalent to the corresponding filtered Gerstenhaber deformation groupoid. This is

an operad-level statement. A strict algebra map on a prescribed cochain complex, or formality of that cochain complex as an algebra, requires equality of MC classes and a rectification datum.

Remark 28.6.9 (Formality and deformation quantization). Kontsevich formality [?Kon03] implies star products on arbitrary Poisson manifolds. In our framework (Chapter ??), E_2 Koszul duality exchanges the bar complex of polyvector fields with that of polydifferential operators, exchanging Poisson brackets with star products. The explicit Kontsevich star product arises from propagator integrals on $\overline{C}_k(\mathcal{H})$, a specific E_2 bar complex model with boundary conditions.

PROPOSITION 28.6.10 (E_n formality for $n \geq 2$;). (Fresse–Willwacher [?FresseWillwacher20], Idrissi [?Idrissi22]) The E_n operad is formal over $\mathbb{R}$ for all $n \geq 2$. The formality map is constructed explicitly via configuration space integrals on $\overline{C}_k(\mathbb{R}^n)$ using the propagator of Definition 28.2.1, with the Kontsevich graph expansion providing the explicit formulas. For $n = 2$ and for rational chain models the representative depends on a Drinfeld associator; changing the associator transports the algebra-level representative by the GRT_1 action. Thus formality supplies equivalences after cofibrant replacement and deformation-groupoid comparison, not canonical strict maps on original complexes.

28.7 THE KONTSEVICH GRAPH COMPLEX AND THE SHADOW OBSTRUCTION TOWER

The modular convolution algebra $\mathfrak{g}_{\mathcal{A}}^{\text{mod}}$ maps to the Kontsevich graph complex GC_2 via the formality quasi-isomorphism. The shadow invariants $S_r(\mathcal{A})$ project to specific graph cocycles, and the G/L/C/M depth classification corresponds to truncation in GC_2 .

Definition 28.7.1 (The graph complex GC_n). The Kontsevich graph complex GC_n is the cochain complex spanned by isomorphism classes of connected graphs Γ with all vertex valences ≥ 3 (no bivalent or univalent vertices), with cohomological degree

$$\deg(\Gamma) = |E(\Gamma)| - 2|V(\Gamma)|,$$

and differential given by edge contraction:

$$d(\Gamma) = \sum_{e \in E(\Gamma)} \pm \Gamma/e,$$

where Γ/e denotes contraction of the edge e (discarding terms that produce self-loops or bivalent vertices), and the sign is determined by the position of e in the ordered edge list. The loop order of Γ is the first Betti number $\ell(\Gamma) = |E(\Gamma)| - |V(\Gamma)| + 1$.

THEOREM 28.7.2 (*Wheel cocycles and grt_1* ;). (i) (Willwacher [?Willwacher15]) $H^0(\text{GC}_2) \cong \text{grt}_1$, the Grothendieck–Teichmüller Lie algebra.

(ii) The generators of grt_1 include the *wheel cocycles* σ_{2k+1} for $k \geq 1$, represented by the wheel graph W_{2k+1} with $2k+1$ spokes. The wheel W_{2k+1} has $2k+2$ vertices, $2(2k+1)$ edges, loop order $2k+1$, and degree -2 . It is a cocycle in GC_2 if and only if the number of spokes is odd (the dihedral $\mathbb{Z}/2$ -symmetry of W_n provides cancellation of the differential only for n odd).

(iii) The wheel cocycles correspond to the Deligne–Drinfeld elements, encoding odd zeta values $\zeta(3), \zeta(5), \zeta(7), \dots$ in the Lie algebra of the motivic Galois group.

PROPOSITION 28.7.3 (*Shadow obstruction tower to GC_2 bridge*;). The shadow invariants of a chiral algebra $\mathcal{A}$ project to GC_2 via the formality quasi-isomorphism: the odd-degree shadows $S_{2k+1}(\mathcal{A})$ map to the wheel cocycles $\sigma_{2k+1} \in H^*(\text{GC}_2)$, while even-degree shadows $S_{2k}(\mathcal{A})$ map to exact forms (coboundaries in GC_2). The projection respects the depth classification:

Shadow class	Nonzero wheels	Algebra
G (depth 2)	none ($S_3 = 0$)	Heisenberg, lattice
L (depth 3)	σ_3, σ_5	Affine Kac–Moody
C (depth 4)	$\sigma_3, \sigma_5, \sigma_7$	$\beta\gamma$
M (depth ∞)	all σ_{2k+1}	Virasoro, $\mathcal{W}_N$

Proof. The formality quasi-isomorphism $\Phi: \mathfrak{g}_{\mathcal{A}}^{\text{mod}} \xrightarrow{\sim} H^*(\mathfrak{g}_{\mathcal{A}}^{\text{mod}})$ sends the MC element $\Theta_{\mathcal{A}}$ to a sum of graph cocycle components. At degree r , the image $\Phi(S_r)$ lies in the weight- r part of GC_2 . For odd $r = 2k+1$, the wheel graph W_{2k+1} is a cocycle (Theorem 28.7.2(ii)), and $\Phi(S_{2k+1})$ is proportional to σ_{2k+1} by uniqueness of the cocycle in the relevant degree. For even r , the wheel W_{2k} is *not* a cocycle (it bounds), so $\Phi(S_{2k})$ is necessarily exact: it maps to a coboundary in GC_2 .

The depth truncation follows from the shadow obstruction tower termination: if $S_r(\mathcal{A}) = 0$ for all $r > r_{\max}$, then the GC_2 projection has nonzero wheel components only for σ_{2k+1} with $2k+1 \leq 2r_{\max} - 1$. $\square$

Remark 28.7.4 (Graph complex signs for multigraphs). The $d^2 = 0$ identity on the Kontsevich graph complex GC_2 requires care for multigraphs: the naive canonicalize-then-differentiate approach fails because the canonical labeling absorbs intermediate sign data. Two correct approaches: (i) label edges, compute d , then take the canonical quotient; (ii) work in the coinvariant quotient from the start with the half-edge orientation framework. The bar complex signs agree with GC_2 signs because both use $\det(E(\Gamma))$ for edge-ordering.

Definition 28.7.5 (Shadow zeta values). For a chiral algebra $\mathcal{A}$ with $\kappa(\mathcal{A}) \neq 0$, the *normalized shadow zeta values* are the dimensionless invariants

$$\zeta_r^{\text{sh}}(\mathcal{A}) := \frac{S_r(\mathcal{A})}{|\kappa(\mathcal{A})|^{r/2}}, \quad r \geq 2.$$

These are rational functions of the central charge or level parameter and are invariant under rescaling. The normalized shadow zeta values encode the profile of the shadow obstruction tower, independent of the overall scale set by κ .

28.8 THE $n = 3$ CASE: CHERN–SIMONS THEORY

The $n = 3$ case of E_n Koszul duality connects directly to perturbative Chern–Simons theory and the Kontsevich integral of Chapter I.

Conjecture 28.8.1 (E_3 bar complex and Chern–Simons;). For $\mathfrak{g}$ a finite-dimensional Lie algebra with invariant inner product, the E_3 bar complex $\overline{B}_{E_3}(U_3(\mathfrak{g}))$ computes the perturbative Chern–Simons invariants of 3-manifolds:

- (i) The propagator is the Chern–Simons propagator of Example 28.2.4: the Green’s 2-form of the gauge-fixed Laplacian on M .
- (ii) The Feynman diagrams of Axelrod–Singer are the contributions from individual boundary strata of $\overline{C}_k(M)$.
- (iii) The bar cohomology $H^*(\overline{B}_{E_3}(U_3(\mathfrak{g})))$ should recover the Kontsevich graph complex with Lie algebra coefficients.

Remark 28.8.2 (Scope). Part (ii) (Feynman diagrams = boundary strata) is established (Axelrod–Singer, Kontsevich [?Kon94], Cattaneo–Mnev [?CattaneoMnev10]). What is conjectured is the full chain-level identification (iii): showing the Axelrod–Singer compactification models the E_3 bar complex (the $n = 2$ analogue is our Prism Principle, Theorem 36.13.26). The $n = 3$ case requires modular E_3 -operads, not yet developed. (Contributing to Conjecture ??.)

28.9 THE SWISS-CHEESE CASE: HOLOMORPHIC–TOPOLOGICAL FACTORIZATION

The dimensional ladder has so far been one-dimensional: $n = 1$ (associative), $n = 2$ (chiral), $n = 3$ (Chern–Simons). But the ordered bar complex $\overline{B}^{\text{ord}}(\mathcal{A})$ of this monograph already carries a *mixed* structure that does not fit on this line. The differential $d_{\overline{B}}$ lives on $\text{FM}_k(\mathbb{C})$ (the $n = 2$ slot); the coassociative coproduct Δ lives on $C_k(\mathbb{R})$ (the $n = 1$ slot). Together, a bar element of degree k is parametrized by

$$\text{FM}_k(\mathbb{C}) \times C_k(\mathbb{R}), \quad (28.3)$$

the product of holomorphic and topological configuration spaces. This product structure is the operadic fingerprint of a *two-colored* operad: the Swiss-cheese operad $\text{SC}^{\text{ch},\text{top}}$.

Definition 28.9.1 (Holomorphic–topological Swiss-cheese operad;). Define the two-colored topological operad $\text{SC}^{\text{ch},\text{top}}$ with colors $\{\text{ch}, \text{top}\}$ (closed/holomorphic and open/topological) by:

- (i) *Closed output, closed inputs only:* $\text{SC}^{\text{ch},\text{top}}((\text{ch}, \dots, \text{ch}); \text{ch}) := \text{FM}_k(\mathbb{C})$.
- (ii) *Open output, mixed inputs:* $\text{SC}^{\text{ch},\text{top}}(\underbrace{(\text{ch}, \dots, \text{ch})}_k, \underbrace{(\text{top}, \dots, \text{top})}_m; \text{top}) := \text{FM}_k(\mathbb{C}) \times E_1(m)$.
- (iii) *No open-to-closed:* $\text{SC}^{\text{ch},\text{top}}(\dots, \text{top}, \dots; \text{ch}) = \emptyset$.

Composition is componentwise: FM insertion in $\mathbb{C}$, interval insertion in E_1 . The no-open-to-closed rule ensures that the closed color is an operadic retract: it receives no information from the open color.

Remark 28.9.2 (Generator surface of $\text{SC}^{\text{ch},\text{top}}$). The definition above gives an operation-space model, not yet a minimal generators-and-relations presentation. On compactified models the codimension-1 generator families are:

- (i) closed collision faces $\partial_S \text{FM}_k(\mathbb{C})$ with $|S| \geq 2$;
- (ii) open interval-splitting faces in a Stasheff compactification of $E_1(m)$, equivalently cuts of the ordered open inputs into consecutive blocks;
- (iii) in the mixed space $\text{FM}_k(\mathbb{C}) \times E_1(m)$, the product faces $\partial_S \text{FM}_k(\mathbb{C}) \times E_1(m)$ and $\text{FM}_k(\mathbb{C}) \times F$, with F an interval-splitting face as in (ii), supplying the bulk-to-boundary generators.

The codimension-2 relations come from pairwise intersections of these codimension-1 faces: Arnold–Orlik–Solomon in the closed factor, Stasheff associativity in the open factor, and commuting mixed squares comparing a closed collision with an open split. Later arguments use this boundary-stratum description; the full minimal presentation is not written out here.

PROPOSITION 28.9.3 ($\text{SC}^{\text{ch},\text{top}}$ *boundary-relation ledger;).* [Type signature: (Open/closed, operation spaces, level = 3, hypothesis package = compactified FM $\times$ compactified E_1)]. For the operation spaces of Definition 28.9.1, the following relations are the canonical codimension-2 relations.

- (i) In the closed colour, the boundary strata of $\text{FM}_k(\mathbb{C})$ give the Arnold–Orlik–Solomon relation

$$\omega_{ij}\omega_{jk}\omega_{ki}\omega_{ki}\omega_{ij} = 0 \quad (i, j, k \text{ distinct}). \quad (28.4)$$

- (ii) In the open colour, the codimension-2 corners of the Stasheff compactification of $E_1(m)$ give the associativity relation

$$(a_1 a_2) a_3 - a_1 (a_2 a_3) = 0 \quad (28.5)$$

on the strict associated-graded operation, with the usual A_∞ boundary signs before passing to homology.

- (iii) In the mixed operation space $\mathrm{FM}_k(\mathbb{C}) \times E_1(m)$, a closed collision face and an open interval-splitting face meet as a product corner. Hence the mixed square commutes:

$$(\partial_S^{\mathrm{cl}} \times \mathrm{id}) \circ (\mathrm{id} \times \partial_I^{\mathrm{op}}) = (\mathrm{id} \times \partial_I^{\mathrm{op}}) \circ (\partial_S^{\mathrm{cl}} \times \mathrm{id}). \quad (28.6)$$

- (iv) The no-open-to-closed rule

$$\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}(\dots, \mathrm{top}, \dots; \mathrm{ch}) = \emptyset \quad (28.7)$$

implies that the closed colour is an operadic retract: restriction to closed inputs is a morphism of operads and receives no operation with a topological input.

Thus the derived chiral centre may carry the $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ structure produced by the centre theorem, while the bar complex itself remains only the E_1 -chiral coassociative computational coalgebra of Theorem 28.9.5.

Proof. The closed-colour operation space is the Fulton–MacPherson compactification of configurations in $\mathbb{C}$. The codimension-2 boundary strata where three points collide are the standard Orlik–Solomon boundary cells, and the de Rham relation among their logarithmic generators is exactly (28.4). The open-colour operation space is the compactified ordered configuration space on an interval, whose codimension-2 faces are the two parenthesisations of three consecutive inputs; this is the Stasheff associativity relation (28.5), with higher A_∞ signs before strictification.

For mixed operations the compactified space is the product $\mathrm{FM}_k(\mathbb{C}) \times E_1(m)$. A closed collision changes only the first factor and an open split changes only the second factor, so the two face maps commute, giving (28.6). Finally Definition 28.9.1 has no operation with topological input and holomorphic output, which proves (28.7) and the retract statement. The last sentence follows from Theorem 28.9.5 and the centre theorem: $\overline{B}^{\mathrm{ord}}(\mathcal{A})$ is the ordered E_1 coalgebraic resolution, while $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A})$ is the cochain object on which the closed-colour centre action is produced. $\square$

Principle 28.9.4 (The bar complex is E_1 -chiral coassociative; $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ emerges on the derived center). The ordered bar complex $\overline{B}^{\mathrm{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}})$ is an E_1 -chiral coassociative coalgebra: a coalgebra over the Koszul dual cooperad $(\mathrm{Ass}^{\mathrm{ch}})^!$. It has a differential (from OPE collision residues) and a coassociative deconcatenation coproduct. These are the two structures of a dg coalgebra. The bar complex does *not* carry $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ structure. The product space $\mathrm{FM}_k(\mathbb{C}) \times C_k(\mathbb{R})$ is an operation-space witness for the product operad, not a chain-level Deligne–Tamarkin output. Producing an E_2 or $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ action requires passage to the derived chiral center through Theorem 28.10.7 and the chiral Deligne–Tamarkin principle (Remark 28.10.12).

The $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ structure emerges on the *derived chiral center* $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A}) = C_{\mathrm{ch}}^\bullet(\mathcal{A}, \mathcal{A})$, computed *using* the bar complex as a resolution. This derived center is the cochain-level local closed-sector slot attached to the boundary algebra $\mathcal{A}$. When an HT boundary comparison supplies an OCA quasi-isomorphism from physical local bulk observables to this cochain object, it identifies those observables of the corresponding 3d holomorphic-topological theory on $X \times \mathbb{R}$:

- It carries E_2 structure from $\mathrm{FM}_k(\mathbb{C})$ (the operadic center theorem, Theorem 28.10.7).
- With an inner conformal vector at non-critical level, this E_2 upgrades on BRST cohomology to E_3 via the topologization theorem (Theorem 28.13.4).
- Without a conformal vector, $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A})$ carries $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ structure (holomorphic E_2 coupled to topological E_1), strictly weaker than E_3 .

The passage from bar complex to derived center is where the $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ structure is *produced*: the bar complex is the E_1 -chiral computational engine; the derived center is the $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ (or E_3) output. The five theorems A–D+H extract invariants of $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A})$ by computing in $\overline{B}^{\mathrm{ord}}(\mathcal{A})$.

THEOREM 28.9.5 (*Bar complex as E_1 -chiral coassociative coalgebra;*). Let $\mathcal{A}$ be an augmented chiral algebra on a curve X . The *ordered* bar complex

$$\overline{B}^{\mathrm{ord}}(\mathcal{A}) = T^c(s^{-1}\tilde{\mathcal{A}}) = \bigoplus_{n \geq 0} (s^{-1}\tilde{\mathcal{A}})^{\otimes n},$$

equipped with its bar differential $d_{\overline{B}}$ and the *deconcatenation* coproduct Δ , is a dg coassociative coalgebra over the Koszul dual cooperad $(\mathrm{Ass}^{\mathrm{ch}})^\dagger$:

Bar structure	Operadic origin	Configuration space
Differential $d_{\overline{B}}$	chiral product (OPE residues)	$\mathrm{FM}_k(\mathbb{C})$: collision at boundary strata
Deconcatenation Δ	cofree coalgebra structure	$C_k(\mathbb{R})$: consecutive splitting
Coderivation: $d_{\overline{B}} \circ \Delta = (\Delta) \circ d_{\overline{B}}$	dg compatibility	product structure $\mathrm{FM}_k(\mathbb{C}) \times C_k(\mathbb{R})$

The bar complex is a *single-colored* E_1 -chiral coalgebra. It does not carry $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ structure (Principle 28.9.4). The $\mathrm{SC}^{\mathrm{ch},\mathrm{top}}$ structure emerges on the derived chiral center $Z_{\mathrm{ch}}^{\mathrm{der}}(\mathcal{A}) = C_{\mathrm{ch}}^\bullet(\mathcal{A}, \mathcal{A})$, computed using $\overline{B}^{\mathrm{ord}}(\mathcal{A})$ as a resolution (Theorem 28.10.7). The coproduct is the $(n+1)$ -term deconcatenation $\Delta[a_1 | \cdots | a_n] = \sum_{i=0}^n [a_1 | \cdots | a_i] \otimes [a_{i+1} | \cdots | a_n]$ on the tensor coalgebra $T^c(s^{-1}\tilde{\mathcal{A}})$, *not* the 2^n -term coshuffle that appears on the symmetric bar $\overline{B}^\Sigma(\mathcal{A}) = S^c(s^{-1}\tilde{\mathcal{A}})$ used in Theorem A. The relation between the two is that $\overline{B}^\Sigma(\mathcal{A})$ is recovered as the lossy R -twisted Σ_n -coinvariant shadow of $\overline{B}^{\mathrm{ord}}(\mathcal{A})$ (braid-twisted symmetrization, with the chiral R -matrix encoding sign and braiding). Theorem A's factorization-coalgebra structure on $\overline{B}^\Sigma$ uses the coshuffle coproduct; the E_1 -chiral coassociative coalgebra structure in this theorem lives on the ordered bar with its deconcatenation coproduct.

Proof. The deconcatenation Δ on the tensor coalgebra $T^c(s^{-1}\tilde{\mathcal{A}})$ is coassociative by construction. The ordering of tensor factors $a_1 \otimes \cdots \otimes a_n$ corresponds to the ordering of points $t_1 < \cdots < t_n$ on $\mathbb{R}$; the splitting at index i corresponds to cutting the interval at t_i . This is the E_1 coassociative coalgebra structure on the ordered bar $\overline{B}^{\mathrm{ord}}(\mathcal{A})$: the deconcatenation coproduct is determined by the interval-cutting combinatorics of $C_k(\mathbb{R})$.

The differential $d_{\overline{B}}$ extracts residues along collision divisors $D_S \subset \partial \mathrm{FM}_k(\mathbb{C})$ (Theorem 7.1.38). Working at genus 0 on the ordered bar, $d_{\overline{B}}$ is a coderivation of Δ : the co-Leibniz rule

$$\Delta \circ d_{\overline{B}} = (d_{\overline{B}} \otimes \mathrm{id} + \mathrm{id} \otimes d_{\overline{B}}) \circ \Delta$$

holds because collision residues at *adjacent* factors (a_i, a_{i+1}) in the chiral product commute with cutting at non-adjacent indices on $\mathbb{R}$, while a collision residue at the splitting index produces equal contributions

on both sides of the co-Leibniz identity. This is the content of the product structure: at genus 0 the spaces $\mathrm{FM}_k(\mathbb{C})$ and $C_k(\mathbb{R})$ contribute independently.

The no-open-to-closed constraint is automatic: the deconcatenation coproduct (open-color structure) does not appear in the differential (closed-color structure). The bar differential $d_{\overline{B}}$ is built purely from the chiral product μ and the FM boundary strata, with no reference to the tensor ordering except via the adjacency requirement of the chiral product, which is preserved by Δ .

The passage to the symmetric bar $\overline{B}^\Sigma(\mathcal{A})$ via R -twisted Σ_n -coinvariants converts the deconcatenation coproduct into the coshuffle coproduct (whose summands are indexed by (p, q) -shuffles of $\{1, \dots, n\}$, totalling 2^n rather than $n + 1$); the E_1 -chiral coassociative coalgebra structure of this theorem is a property of the ordered bar prior to that symmetrization. $\square$

Remark 28.9.6 (Physical interpretation). A three-dimensional holomorphic–topological (HT) quantum field theory on $\mathbb{C}_z \times \mathbb{R}_t$ produces local observables that factorize holomorphically in z and associatively in t . The BV quantization of such a theory produces an algebra over $W(\mathrm{SC}^{\mathrm{ch}, \mathrm{top}})$ (the Boardman–Vogt resolution), and the resulting higher operations m_k are realized by configuration-space integrals on $\mathrm{FM}_k(\mathbb{C}) \times C_k(\mathbb{R})$, the same spaces that parametrize bar elements of degree k . Volume II develops this identification in full.

Construction 28.9.7 (Promotion functor: from chiral algebra to $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ -algebra). A chiral algebra $\mathcal{A}$ is one-coloured (an algebra over the closed colour of $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$). The operadic bar relative to the full two-coloured operad requires a $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ -algebra $(\mathcal{A}_{\mathrm{cl}}, \mathcal{A}_{\mathrm{op}})$ as input (a closed-colour algebra and an open-colour algebra with mixed operations). On the commutative/local surface, the *promotion functor* $\mathcal{A} \mapsto (\mathcal{A}, \mathcal{A})$ uses self-action: a commutative algebra acts on itself as a module, supplying the open-colour and mixed data canonically. For a genuine E_1 -chiral algebra this is not canonical; one must choose the open module/action data separately. The operadic bar $B_{\mathrm{SC}}(\mathcal{A}, \mathcal{A})$ decomposes:

- Closed sector: $B_{\mathrm{Com}}(\mathcal{A}) = \mathrm{Lie}^c \circ s^{-1} \tilde{\mathcal{A}}$ (Harrison).
- Open sector: $B_{\mathrm{Ass}}(\mathcal{A}) = T^c(s^{-1} \tilde{\mathcal{A}})$ (tensor).
- Mixed sector: dimension $(k-1)! \binom{k+m}{m}$ at bi-degree (k, m) (Proposition 28.10.2).

Theorem 28.9.5 is the statement that, on a surface where the required open action has been supplied, the bar of the resulting $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ -algebra naturally carries the E_1 -chiral coassociative dg coalgebra structure.

Remark 28.9.8 (Symmetric Verdier duality and ordered opposite-duality). Theorem A and Convention 7.0.2 place the *symmetric* bar on $\mathrm{Ran}(X)$ and form the Verdier algebra

$$K_X^\Sigma(\mathcal{A}) := \mathbb{D}_{\mathrm{Ran}} \overline{B}^\Sigma(\mathcal{A}).$$

A chosen symmetric Koszul pair supplies $\nu_{\mathcal{A}}^\Sigma: K_X^\Sigma(\mathcal{A}) \rightarrow \mathcal{A}^!$; the cohomological coalgebra preceding this dualization is $\mathcal{A}^!$. The ordered bar belongs instead to the ordered configuration spaces $\mathrm{Conf}_n^<(X)$. Pushforward along the Σ_n -quotient produces $\overline{B}^\Sigma$ and passes from ordered data to coinvariants. Its native E_1 duality is *opposite-duality*: $\overline{B}^{\mathrm{ord}}(\mathcal{A}^{\mathrm{op}}) = \overline{B}^{\mathrm{ord}}(\mathcal{A})^{\mathrm{cop}}$ (the two-colour double Koszul duality theorem, Theorem 27.14.2).

Remark 28.9.9 (Curved Swiss-cheese at higher genus, and the corrected differential). At genus $g \geq 1$ the situation is more subtle than a naive “scalar curvature” picture, and the precise statement matters for the higher-genus open/closed comparison.

- (i) *The fibrewise differential is curved.* The bar differential d_{fib} obtained by extending the genus-0 collision residue along the universal curve satisfies $d_{\text{fib}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ (Theorem ??). Here ω_g is the κ -class on $\overline{\mathcal{M}}_g$, not a scalar in the ground field; the equality is a curvature identity in $H^2(\overline{\mathcal{M}}_g)$, not a centre relation in the bar coalgebra.
- (ii) d_{fib} is not a coderivation of the deconcatenation coproduct. The naive Leibniz check fails: applying $d_{\text{fib}}^2 = \kappa \cdot \omega_g$ to a splitting at an interior index produces a factor-2 discrepancy between the two sides of the co-Leibniz identity, because the curvature ω_g contracts the closed-color collision class against the same $\mathbb{R}$ -interval on both branches of the splitting. In particular, the genus-0 “scalar coderivation” picture does *not* extend unmodified to $g \geq 1$, and the product structure (28.3) requires the corrected differential below to remain a coalgebra map.
- (iii) *The corrected differential D_g is a flat coderivation.* The corrected differential of Theorem ?? adds period-integral terms built from the Fay trisecant identity: schematically $D_g = d_{\text{fib}} + \sum_{i,j} \int_{\gamma_{ij}} \Phi_{ij}$, where Φ_{ij} are Fay-form contributions on the universal curve. These extra terms exactly cancel the factor-2 discrepancy from item (ii) at every interior splitting, and the result is both *flat* ($D_g^2 = 0$ over $\overline{\mathcal{M}}_g$) and a genuine coderivation of the deconcatenation coproduct on $\overline{B}^{\text{ord},(g)}(\mathcal{A})$. The genus tower of E_1 coassociative coalgebras is therefore controlled at the chain level by D_g , not by d_{fib} , and the modular characteristic $\kappa(\mathcal{A})$ together with the $\hat{A}$ -genus generating function records the resulting $\overline{\mathcal{M}}_g$ -class (Theorem ??).

The slogan is therefore: at genus 0 the bar differential is a coderivation of Δ for free; at higher genus this *fails* for the fibrewise differential, and the “curved E_1 coalgebra” picture is rescued only by passing to the period-corrected differential D_g .

Remark 28.9.10 (Position in the dimensional ladder). The Swiss-cheese operad $\text{SC}^{\text{ch},\text{top}}$ is the $(n_{\text{hol}}, n_{\text{top}}) = (2, 1)$ entry in a two-parameter family of mixed operads. The one-parameter diagonal $n_{\text{hol}} = n, n_{\text{top}} = 0$ recovers the E_n ladder of this chapter. The off-diagonal entries mix holomorphic and topological factorization in different dimensions. The classical Swiss-cheese of Voronov [Voronov99] is the $(n, n - 1)$ case; ours is the holomorphic refinement at $(2, 1)$.

28.10 THE CHIRAL CENTER THEOREM: OPERADIC PROOF

The chiral center theorem identifies the chiral Hochschild cochain complex $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ as the *operadic center* of an open-color algebra $\mathcal{A}$ in the Swiss-cheese operad $\text{SC}^{\text{ch},\text{top}}$. The topological analogue (the classical Deligne conjecture and its higher-dimensional generalizations) identifies Hochschild cochains of an associative algebra as an E_2 -algebra via the center construction in the classical Swiss-cheese operad. The chiral version requires the operadic route, and the passage from the topological to the chiral setting creates genuine new difficulties at each step.

The proof proceeds in five steps: the abstract operadic center (Step 1), its chain-level computation (Step 2), the geometric recognition that makes the theorem inevitable (Step 3), the comparison with the brace-algebra model (Step 4), and the universal property (Step 5). Two further developments complete the picture: a scope analysis restricting the operadic center theorem to E_∞ -chiral input (Remark 28.10.8), and an investigation of essential surjectivity of the center functor (§28.10.6), which asks whether every $\text{SC}^{\text{ch},\text{top}}$ -pair lies in the essential image of the universal construction.

28.10.1 The operadic center of a two-colored algebra

Definition 28.10.1 (*Two-colored operad with vanishing constraint;*). A two-colored operad with vanishing open-to-closed operations is a symmetric colored operad $\mathcal{O}$ with color set $\{c, o\}$ (closed and open) satisfying:

- (i) $\mathcal{O}((c, \dots, c); c)$ is an operad in color c (the *closed sector* $\mathcal{O}^c$);
- (ii) $\mathcal{O}((c^k, o^m); o)$ defines a right module over $\mathcal{O}^c$ and a bimodule over the o -operad $\mathcal{O}^o := \mathcal{O}((o, \dots, o); o)$;
- (iii) $\mathcal{O}((\dots, o, \dots); c) = \emptyset$: no open-to-closed operations.

The Swiss-cheese operad $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ (Definition 28.9.1) is the primary example.

PROPOSITION 28.10.2 (*Koszul dual cooperad of $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$; three sectors;*). The Koszul dual cooperad $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}, !}$ has three sectors:

- (i) *Closed* ($c^n \rightarrow c$): $\dim = (n-1)!$ (Lie cooperad, since $\mathrm{Com}^! = \mathrm{Lie}$).
- (ii) *Open* ($o^m \rightarrow o$): $\dim = m!$ (Ass cooperad, self-Koszul-dual).
- (iii) *Mixed* ($c^k, o^m \rightarrow o, k \geq 1$): $\dim = (k-1)! \binom{k+m}{m}$. This differs from the plain tensor product $(k-1)! \cdot m!$ by the factor $\binom{k+m}{m}/m!$, encoding the (k, m) -shuffle interleaving of closed inputs among ordered open inputs.

Computational verification: `sc_koszul_dual_cooperad_engine.py` (82 tests).

Proof. The closed sector is $\mathrm{Com}^{!,c} = \mathrm{Lie}^c$ with $\dim \mathrm{Lie}(n) = (n-1)!$ (partition-lattice calculation, Theorem 3.8.1). The open sector is $\mathrm{Ass}^{!,c} = \mathrm{Ass}^c$ with $\dim = m!$ (self-duality). The mixed sector is computed by the Künneth factorization: $\mathrm{Lie}^c(k)$ contributes $(k-1)!$, and the (k, m) -shuffle count $\binom{k+m}{m}$ arises from interleaving k closed leaves among m ordered open leaves on the $\mathrm{FM}_k(\mathbb{C}) \times E_1(m)$ operation space. $\square$

COROLLARY 28.10.3 (*Convolution algebra factorization*). The $\mathrm{SC}^{\mathrm{ch}, \mathrm{top}}$ -convolution algebra of an augmented chiral algebra $\mathcal{A}$ decomposes as

$$\mathfrak{g}_{\mathcal{A}}^{\mathrm{SC}} = \mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}} \times \mathfrak{g}_{\mathcal{A}}^{\mathbb{R}},$$

where $\mathfrak{g}_{\mathcal{A}}^{\mathrm{mod}} = \mathrm{Conv}(\mathrm{Lie}^c, \mathrm{End}_{\mathcal{A}})$ controls the closed direction (shadows $\kappa, \mathfrak{C}, \mathfrak{Q}$) and $\mathfrak{g}_{\mathcal{A}}^{\mathbb{R}} = \mathrm{Conv}(\mathrm{Ass}^c, \mathrm{End}_{\mathcal{A}})$ controls the open direction (r -matrix, KZ associator, Yangian deformation). The two factors commute. The mixed sector (Proposition 28.10.2(iii)) governs their interaction: cochain-level closed-sector operators act on boundary states via iterated brace evaluation (Proposition ??).

Proof. The closed and open cooperads split as Lie^c and Ass^c by Proposition 28.10.2. Applying $\mathrm{Conv}(-, \mathrm{End}_{\mathcal{A}})$ sends this product decomposition to the displayed product of dg Lie algebras. The mixed operations are precisely the brace-action terms of Proposition ??. $\square$

Definition 28.10.4 (*Operadic center;*). Let $\mathcal{O}$ be a two-colored operad satisfying Definition 28.10.1, and let A_o be an algebra over $\mathcal{O}^o$. The *operadic center* $Z_{\mathcal{O}}(A_o)$ is the terminal object in the category of $\mathcal{O}$ -algebra pairs:

$$Z_{\mathcal{O}}(A_o) := \varprojlim_{\substack{(B, A_o) \in \\ \mathcal{O}\text{-Alg}}} B,$$

where the limit is taken over the category $\mathcal{O}\text{-Alg}_{/A_o}$ of $\mathcal{O}$ -algebra pairs (B, A_o) in which the open-color algebra is the given A_o . More explicitly, $Z_{\mathcal{O}}(A_o)$ carries the structure of a $\mathcal{O}^c$ -algebra together with a coherent family of action maps

$$\alpha_{k,m}: \mathcal{O}((c^k, o^m); o) \otimes Z_{\mathcal{O}}(A_o)^{\otimes k} \otimes A_o^{\otimes m} \longrightarrow A_o, \quad (28.8)$$

satisfying the equivariance and associativity axioms of an $\mathcal{O}$ -algebra, and is *universal* with this property: for every $\mathcal{O}^c$ -algebra B equipped with action maps (28.8) making (B, A_o) an $\mathcal{O}$ -algebra, there exists a unique $\mathcal{O}^c$ -algebra morphism $B \rightarrow Z_{\mathcal{O}}(A_o)$ through which all action maps factor.

Remark 28.10.5 (Concrete description via internal Hom). When $\mathcal{O}^o$ -algebras form a category enriched over chain complexes, the operadic center admits an explicit model. Let $\text{End}_{A_o}(m) := \text{Hom}(A_o^{\otimes m}, A_o)$ denote the endomorphism operad of A_o . The action maps (28.8) assemble into an operad morphism

$$\gamma: \mathcal{O}^c \longrightarrow \text{End}_{Z_{\mathcal{O}}(A_o)}$$

subject to the compatibility condition that for each k, m , the composite

$$\mathcal{O}((c^k, o^m); o) \otimes Z_{\mathcal{O}}(A_o)^{\otimes k} \xrightarrow{\gamma \otimes \text{id}} \text{Hom}(A_o^{\otimes m}, A_o)$$

equals the given $\mathcal{O}$ -algebra structure. This makes the center a *derived mapping object*:

$$Z_{\mathcal{O}}(A_o) \simeq \text{RHom}_{\mathcal{O}^o\text{-bimod}}(\mathcal{O}(c, -; o), \text{End}_{A_o}),$$

where $\mathcal{O}(c, -; o)$ is regarded as a $\mathcal{O}^o$ -bimodule via the mixed composition maps.

PROPOSITION 28.10.6 (*Existence of the operadic center;*). Let $\mathcal{O}$ be a two-colored operad as in Definition 28.10.1, working in chain complexes over a field of characteristic zero. For any $\mathcal{O}^o$ -algebra A_o , the operadic center $Z_{\mathcal{O}}(A_o)$ exists and is computed by the equalizer

$$Z_{\mathcal{O}}(A_o) \hookrightarrow \prod_{m \geq 0} \text{Hom}_{\Sigma_m}(\mathcal{O}((c, o^m); o), \text{Hom}(A_o^{\otimes m}, A_o)) \rightrightarrows (\cdots) \quad (28.9)$$

where the two maps enforce (a) $\mathcal{O}^c$ -algebra equivariance (the closed-sector operadic composition) and (b) $\mathcal{O}^o$ -bimodule equivariance (the open-sector composition). In the derived setting, the equalizer is replaced by a homotopy equalizer computed via a bar-type resolution.

Proof. This is a standard construction in the theory of colored operads. The product $\prod_m \text{Hom}_{\Sigma_m}(\mathcal{O}(c, o^m; o), \text{Hom}(A_o^{\otimes m}, A_o))$ assembles all possible action maps with one closed input. Equivariance with respect to $\mathcal{O}^c$ -composition (inserting further closed inputs) and $\mathcal{O}^o$ -composition (inserting open inputs into the open arguments) is imposed by the two arrows. The equalizer exists because chain complexes are complete. In the derived setting, one replaces $\mathcal{O}$ by a cofibrant resolution $\mathcal{O}_{\infty} \xrightarrow{\sim} \mathcal{O}$ and takes the homotopy equalizer in the model-categorical sense; the resulting object is well-defined up to quasi-isomorphism. $\square$

28.10.2 Chain-level realization for $\text{SC}^{\text{ch}, \text{top}}$

THEOREM 28.10.7 (*The operadic center of $\text{SC}^{\text{ch}, \text{top}}$ is the chiral Hochschild complex;*). Let $\mathcal{A}$ be a logarithmic chiral algebra (an algebra over the closed sector $(\text{SC}^{\text{ch}, \text{top}})^c = \{\text{FM}_k(\mathbb{C})\}$ of the holomorphic-topological Swiss-cheese operad, with operations extending to the log compactification of $C_k(\mathbb{C})$), and

let $A = \mathcal{A}|_{\{z_o\}}$ denote the fiber at a basepoint (an E_1 -algebra via the open sector). There is a quasi-isomorphism of E_2 -algebras

$$Z_{\text{SC}}(A) \simeq C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}),$$

where the right-hand side is the chiral Hochschild cochain complex (Definition 28.11.5), equipped with its braces and cup product.

Proof. We compute the center using Definition 28.10.4 and the operation-space description of $\text{SC}^{\text{ch}, \text{top}}$ (Definition 28.9.1).

Step 2a: Identifying the components. By Definition 28.9.1, the mixed-output spaces are $\text{SC}(\mathfrak{c}^k, \mathfrak{o}^m; \mathfrak{o}) = \text{FM}_k(\mathbb{C}) \times E_1(m)$. An element of the center at degree (k, m) is a map

$$\phi_{k,m}: \text{FM}_k(\mathbb{C}) \times E_1(m) \longrightarrow \text{Hom}(A^{\otimes m}, A)$$

equivariant for the Σ_k -action on $\text{FM}_k(\mathbb{C})$ and the Σ_m -action on $E_1(m)$. Setting $m = \mathfrak{o}$ and noting that $E_1(\mathfrak{o}) = \text{pt}$:

$$\phi_{k,\mathfrak{o}}: \text{FM}_k(\mathbb{C}) \longrightarrow A,$$

which is a k -cochain on configuration space valued in A . For general m , the $E_1(m)$ -factor provides the “ m open inputs” that the center element acts on via the E_1 -multiplication on A .

Step 2b: Center elements are chiral Hochschild cochains. We construct an explicit isomorphism between the degree- k component of $Z_{\text{SC}}(A)$ and $C_{\text{ch}}^k(\mathcal{A}, \mathcal{A})$. By Proposition 28.10.6, the center is the equalizer

$$Z_{\text{SC}}(A) \hookrightarrow \prod_{m \geq \mathfrak{o}} \text{Hom}_{\Sigma_m}(\text{SC}((\mathfrak{c}, \mathfrak{o}^m); \mathfrak{o}), \text{Hom}(A^{\otimes m}, A)) \rightrightarrows (\cdots),$$

where the two arrows impose closed-sector equivariance (composing further closed inputs) and open-sector bimodule equivariance (composing open inputs via E_1). Substituting $\text{SC}((\mathfrak{c}, \mathfrak{o}^m); \mathfrak{o}) = \text{FM}_1(\mathbb{C}) \times E_1(m) \cong \text{pt} \times E_1(m)$ at $k = 1$, the product over m assembles into $\prod_m \text{Hom}_{\Sigma_m}(E_1(m), \text{Hom}(A^{\otimes m}, A)) \cong \text{End}_A^{E_1}$, the E_1 -endomorphism operad of A .

At general degree k , the closed-sector equivariance arrow forces a center element to be a Σ_k -equivariant family over $\text{FM}_k(\mathbb{C})$ of such E_1 -endomorphisms. The open-sector bimodule arrow forces compatibility with the E_1 -algebra structure on A : inserting the identity at any open slot recovers the original element (a unitality condition), and pre-/post-composing with the E_1 multiplication on A is compatible with the interval-insertion maps $E_1(m) \times E_1(j) \rightarrow E_1(m + j - 1)$.

The degree- k center component is therefore

$$Z_{\text{SC}}(A)_k \cong [\Omega^*(\text{FM}_k(\mathbb{C}), \log D) \otimes \mathcal{A}^{\boxtimes k} \otimes \mathcal{A}_{\text{out}}]^{\Sigma_k},$$

where the Σ_k -equivariance acts simultaneously on the configuration space coordinates and on the algebra factors, the logarithmic forms $\Omega^*(\text{FM}_k(\mathbb{C}), \log D)$ arise from the chain-level model for $\text{FM}_k(\mathbb{C})$, the k copies of $\mathcal{A}$ correspond to the k closed inputs, and $\mathcal{A}_{\text{out}}$ is the output fiber at the basepoint $z_o \in X$. This is a section of $\mathcal{A}^{\boxtimes(k+1)}$ over the compactified configuration space $\overline{C}_{k+1}(X)$ of $k + 1$ points (one output and k inputs), tensored with logarithmic forms, which is the definition of $C_{\text{ch}}^k(\mathcal{A}, \mathcal{A})$ (Definition 28.11.5). The open-sector bimodule condition ensures that the evaluation at the output point z_o and the insertion of algebra elements at the input points are compatible with the chiral product, which is the Hochschild cochain compatibility condition (the cochain evaluates inputs via the chiral product and returns an output in $\mathcal{A}$).

Step 2c: Matching the differentials. The center $Z_{\text{SC}}(A)$ carries three differential contributions; we identify each with a component of the chiral Hochschild differential $d_{\text{Hoch}} = d_{\text{int}} + d_{\text{fact}} + d_{\text{config}}$ (Theorem 35.2.8).

(c.1) *Internal differential.* The $\mathcal{D}_X$ -module differential $d_{\mathcal{A}}$ of the chiral algebra acts on each fiber $\mathcal{A}(z_i)$ independently. Under the identification of Step 2b, $d_{\mathcal{A}}$ acts on the $\mathcal{A}^{\boxtimes(k+1)}$ factor, producing $d_{\text{int}}(\phi)(z_1, \dots, z_k) = \sum_{i=0}^k (-1)^{|\phi_0| + \dots + |\phi_{i-1}|} \phi_0 \otimes \dots \otimes d_{\mathcal{A}}\phi_i \otimes \dots \otimes \phi_k \otimes \omega$, which is the component d_{int} of Theorem 35.2.8.

(c.2) *Factorization differential.* The closed-sector operadic composition $\circ_i: \text{FM}_k(\mathbb{C}) \times \text{FM}_\ell(\mathbb{C}) \rightarrow \text{FM}_{k+\ell-1}(\mathbb{C})$ inserts a degree- ℓ closed element into the i -th slot of a degree- k element. At the chain level, for a center element $\phi \in Z_{\text{SC}}(A)_k$, this composition acts by restricting ϕ to the boundary stratum $\partial_{ij}\text{FM}_k(\mathbb{C})$ where $z_i \rightarrow z_j$ and extracting the residue of the chiral product μ :

$$(d_{\text{fact}}\phi)(z_1, \dots, z_{k-1}) = \sum_{1 \leq i < j \leq k} (-1)^{\epsilon(i,j)} \text{Res}_{z_i=z_j} [\phi(\dots, z_i, \dots, z_j, \dots) \cdot \mu(a_i, a_j)],$$

where $\epsilon(i, j)$ is the Koszul sign from permuting a_i past $a_{i+1}, \dots, a_{j-1}$. This is the factorization component d_{fact} from Theorem 35.2.8: the residue extraction at collision divisors $D_{ij} \subset \partial\text{FM}_k(\mathbb{C})$ using the chiral product. The signs agree because both are determined by the codimension-1 boundary orientation of $\text{FM}_k(\mathbb{C})$ and the Koszul convention for graded-symmetric tensor products.

(c.3) *Configuration-space differential.* The de Rham differential d_{dR} on $\text{FM}_k(\mathbb{C})$ acts on the logarithmic form factor ω in $\phi = a_0 \otimes \dots \otimes a_k \otimes \omega$. Under the identification of Step 2b, this is the component $d_{\text{config}} = d_{\text{dR}}$ of Theorem 35.2.8: it raises the form degree on $\overline{C}_{k+1}(X)$ by 1.

(c.4) *Verification that $d^2 = 0$ is preserved.* The identity $d_{\text{Hoch}}^2 = 0$ is proved in Theorem 35.2.8 by checking three pure squares and three anticommutators. Under the identification of Steps 2b–2c, each cancellation in the center differential maps to the corresponding cancellation in the Hochschild differential: $d_{\text{int}}^2 = 0$ from $d_{\mathcal{A}}^2 = 0$; $d_{\text{config}}^2 = 0$ from $d_{\text{dR}}^2 = 0$; $d_{\text{fact}}^2 = 0$ from the Borchers identity (iterated residues at overlapping collision divisors); $\{d_{\text{int}}, d_{\text{fact}}\} = 0$ because μ is a $\mathcal{D}_X$ -module map; $\{d_{\text{int}}, d_{\text{config}}\} = 0$ because $d_{\mathcal{A}}$ and d_{dR} act on independent tensor factors; $\{d_{\text{fact}}, d_{\text{config}}\} = 0$ by the Arnold–Orlik–Solomon relations on $\text{FM}_k(\mathbb{C})$. Hence the identification of Step 2b is an isomorphism of cochain complexes.

Step 2d: The E_2 -algebra structure. The closed sector $(\text{SC}^{\text{ch}, \text{top}})^c = \{\text{FM}_k(\mathbb{C})\}$ is a model for the E_2 operad (Proposition 28.1.6). By the universal property of the center (Definition 28.10.4), $Z_{\text{SC}}(A)$ is an algebra over $(\text{SC}^{\text{ch}, \text{top}})^c \simeq E_2$, and this E_2 -structure transfers to $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ via the isomorphism of Steps 2b–2c. We verify directly that the two generating operations match.

(d.1) *Cup product.* The E_2 multiplication is the $(2, 0)$ -degree closed-sector composition: for $f \in C_{\text{ch}}^p$ and $g \in C_{\text{ch}}^q$, the operadic composition $\circ: \text{FM}_2(\mathbb{C}) \times Z(A)^{\otimes 2} \rightarrow Z(A)$ yields a map $(f \cup g)(z_1, \dots, z_{p+q}) = \int_{\text{FM}_2(\mathbb{C})} f(z_1, \dots, z_p) \otimes g(z_{p+1}, \dots, z_{p+q})$, where the two clusters of points are separated by the $\text{FM}_2(\mathbb{C})$ operad element (one point in each cluster approaches the corresponding component of the degree-2 FM configuration). This is the cup product on chiral Hochschild cochains: the concatenation of two cochains separated by the propagator, identical in structure to the classical Gerstenhaber cup product except that the propagator is $d \log(z_1 - z_2)$ rather than the topological $d \arg(z_1 - z_2)/(2\pi)$.

(d.2) *Braces.* The brace operation $f\{g_1, \dots, g_k\}$ arises from the $(1, k)$ -degree composition: one element f in the “outer” position with k elements $g_1, \dots, g_k$ inserted into k of its slots. At the chain level, this is the composition map $\text{FM}_1(\mathbb{C}) \times \text{FM}_k(\mathbb{C}) \times Z(A) \times Z(A)^{\otimes k} \rightarrow Z(A)$, which by the FM operad composition rule corresponds to inserting the k cochains g_i at k distinct points within the

configuration underlying f . The $\mathrm{FM}_k(\mathbb{C})$ -factor labels the relative positions of these insertion points, yielding the chiral brace operations. These satisfy the pre-Lie and higher brace identities because the operadic composition maps of $\mathrm{FM}_k(\mathbb{C})$ satisfy the corresponding associativity and equivariance, which is the content of the E_2 -operad axioms for $\{\mathrm{FM}_k(\mathbb{C})\}$ (Proposition 28.1.6).

(d.3) *Compatibility.* The cup product and braces together generate the full E_2 -structure, and we have shown both are induced by the same operadic composition maps that define the center's E_2 -algebra structure. For a more systematic proof that the center of an E_1 -algebra in a two-colored $E_1 \hookrightarrow E_2$ extension is an E_2 -algebra, see Francis [?Francis2013], Theorem 5.16 (which proves the stronger result that the tangent complex of an E_n -algebra carries an E_n -algebra structure, specialized here to $n = 2$) and Lurie [?HA], §5.3.1 (which establishes the E_n -center of an E_1 -algebra as an E_{n+1} -algebra at the ∞ -categorical level, specialized to $n = 1$). $\square$

Remark 28.10.8 (Scope: E_∞ -chiral input). Theorem 28.10.7 requires the chiral algebra $\mathcal{A}$ to be E_∞ -chiral (logarithmic): the operations extend to the log compactification of $C_k(\mathbb{C})$, equivalently, the factorization $\mathcal{D}$ -module descends to the symmetric powers $X^{(n)}$ via the Σ_n -equivariance built into the $\mathrm{FM}_k(\mathbb{C})$ -action. For genuinely E_1 -chiral input (Yangians, Etingof–Kazhdan quantum vertex algebras), the factorization $\mathcal{D}$ -module does *not* descend to $X^{(n)}$, the symmetric bar $\overline{B}^\Sigma(\mathcal{A})$ does not exist, and $C_{\mathrm{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ as defined above is ill-formed. In the E_1 setting, the correct replacement is the *ordered* Hochschild complex $\mathrm{HH}_{\mathrm{ord}}^{E_1}(\mathcal{A}, \mathcal{A})$, defined via the ordered bar complex $\overline{B}^{\mathrm{ord}}(\mathcal{A})$ with deconcatenation coproduct. The output carries E_2 structure from the classical Deligne conjecture (Kontsevich–Soibelman), *not* from the chiral Deligne–Tamarkin theorem (Theorem 28.11.20). The passage from E_2 to E_3 for E_1 -chiral input requires the Drinfeld center construction (Theorem 27.30.29). See Warning 3.11.11.

Remark 28.10.9 (Chiral vs. topological: the spectral-parameter difficulty). In the topological setting ($\mathrm{SC}_{\mathrm{top}}$, Voronov [?Voronov99]), Step 2 is the content of the Deligne conjecture (Kontsevich–Soibelman [?KS00], McClure–Smith, Kaufmann): the Hochschild cochain complex $C^*(A, A)$ of an associative algebra is an E_2 -algebra. The chiral setting introduces three genuine new difficulties:

- (a) *Meromorphic vs. smooth propagator.* The topological propagator $d \arg(z_1 - z_2)/(2\pi)$ is smooth on $C_2(\mathbb{R}^2)$; the chiral propagator $d \log(z_1 - z_2)$ is meromorphic. This forces the chiral Hochschild complex to live on the *compactified* configuration space $\overline{C}_{k+2}(X) = \mathrm{FM}_{k+2}(X)$ with logarithmic forms, not on the open configuration space. The Arnold relations (three-term identity on residues) replace the smooth Stokes theorem as the mechanism for $d^2 = 0$.
- (b) *Dependence on curve geometry.* The topological center $Z_{\mathrm{SC}_{\mathrm{top}}}(A)$ depends only on the homotopy type of the associative algebra A . The chiral center $Z_{\mathrm{SC}}(A)$ depends on the underlying curve X : the configuration spaces $\mathrm{FM}_k(X)$ carry the complex structure of X , and the propagator depends on the choice of coordinate (globally: on the choice of meromorphic 1-form with prescribed singularities). This geometric dependence is invisible in genus 0 (where $X = \mathbb{C}$ and $\mathrm{FM}_k(\mathbb{C})$ is canonically defined) but essential at genus $g \geq 1$, where the center carries a flat connection over $\overline{\mathcal{M}}_g$.
- (c) *Curvature at higher genus.* The bar differential $d_{\overline{B}}$ satisfies $d_{\overline{B}}^2 = 0$ at genus 0, but $d_{\overline{B}}^2 = \kappa(\mathcal{A}) \cdot \omega_g$ at genus $g \geq 1$ (Theorem ??). This means the chiral Hochschild complex is *curved* at higher genus: the center is a curved E_2 -algebra, and the curvature κ is the modular characteristic. No such phenomenon occurs in the topological setting.

Difficulty (a) is handled by the Arnold–Orlik–Solomon formalism of Chapter 6. Difficulties (b) and (c) are addressed by the modular extension (Chapter ??). At genus 0, difficulties (b) and (c) are absent, and the chiral center theorem reduces to a holomorphic refinement of the Deligne conjecture.

28.10.3 Geometric inevitability via the recognition theorem

The geometric content of the chiral center theorem is the formal consequence of the Vol. II local-shadow recognition theorem in its product-formal ambient. The argument below separates the three slots that the word “bulk” otherwise tends to conflate: the closed colour of the Swiss-cheese operad, the cochain-level derived centre, and the physical 3d HT bulk obtained only after a separate bulk-boundary comparison.

THEOREM 28.10.10 (*Geometric inevitability of the chiral center*;). Let $\mathcal{A}$ be a chiral algebra on a curve X , and let $\mathcal{F}_{\mathcal{A}}$ denote the corresponding prefactorization algebra on $X \times \mathbb{R}$ obtained from the $\text{SC}^{\text{ch}, \text{top}}$ -algebra structure (Theorem 28.9.5). Work in the product-formal local-shadow ambient of the Vol. II recognition theorem (Theorem ??), imported as a comparison theorem. Under this theorem, which identifies $\text{SC}^{\text{ch}, \text{top}}$ -algebras with prefactorization algebras on $D \times \mathbb{R}$, the following identifications hold:

- (i) *Closed colour = holomorphic chiral sector.* The closed-colour algebra $\mathcal{O}_{\text{cl}} := \mathcal{F}_{\mathcal{A}}(\text{disks in } X)$ is the chiral algebra $\mathcal{A}$ itself. This is not yet the physical 3d HT bulk.
- (ii) *Open color = boundary observables.* The open-sector algebra $\mathcal{O}_{\text{bdy}} := \mathcal{F}_{\mathcal{A}}(\text{half-disks touching } X \times \{0\})$ is the E_1 -algebra $\mathcal{A} = \mathcal{A}|_{\{z_0\}}$, the fiber of $\mathcal{A}$ at a point, equipped with its associative multiplication.
- (iii) *Centre = cochain-level closed-sector slot.* The universal closed object acting on the boundary algebra is the chiral Hochschild cochain complex $C_{\text{ch}}^{\bullet}(\mathcal{A}, \mathcal{A})$. When an independent 3d HT bulk theory and a bulk-boundary comparison are supplied, this cochain object is compared with local bulk observables; the comparison is not part of the definition of the operadic centre.

Proof. The proof combines the E_1 -chiral coassociative coalgebra structure (Theorem 28.9.5) with the imported Vol. II recognition theorem ???. The recognition theorem is used only at this open/closed comparison surface.

Part (i): By definition of $\text{SC}^{\text{ch}, \text{top}}$, the closed-sector operations are indexed by $\text{FM}_k(\mathbb{C})$, which is the configuration space of points in the complex plane. A disk $D \subset X$ in the holomorphic closed colour supports local observables of $\mathcal{A}$ that multiply via the chiral product (OPE on colliding points in X). The recognition theorem identifies this closed-colour sector with $\mathcal{A}$.

Part (ii): Half-disks touching the boundary correspond to the open-sector operations, indexed by $E_1(m)$ (configurations of m points on the real line). The fiber $\mathcal{A} = \mathcal{A}|_{\{z_0\}}$ is a vector space equipped with an associative product from the E_1 -structure: this is the boundary vertex algebra.

Part (iii): This is the key identification. Consider a closed-colour insertion which is allowed to act on the open boundary algebra through the mixed Swiss-cheese operations. Such an insertion must satisfy two constraints simultaneously:

- (a) They act on boundary observables through an action map $\mathcal{O}_{\text{cl}} \otimes \mathcal{A}^{\otimes m} \rightarrow \mathcal{A}$, the mixed action (28.8).
- (b) They compose in the holomorphic closed colour via the chiral product on X : nesting disks in the holomorphic direction uses $\text{FM}_k(\mathbb{C})$ -composition.

Constraint (a) says that the closed-sector cochain is an element of $\text{Hom}(A^{\otimes m}, A)$ for each m , and constraint (b) says these elements are coherently related by the $\text{FM}_k(\mathbb{C})$ -composition. But this is exactly the definition of the operadic center (Definition 28.10.4).

The resulting complex $\bigoplus_k \Omega^*(\text{FM}_k(\mathbb{C})) \otimes_{\Sigma_k} \text{Hom}(A^{\otimes k}, A)$ is the chiral Hochschild cochain complex: the configuration-space forms provide the bar degree, and the Hom-space provides the coefficient. The differential is the standard chiral Hochschild differential (Theorem 35.2.8), composed of the factorization differential (from the chiral product), the de Rham differential (from the configuration space geometry), and the internal differential (from the $\mathcal{D}_X$ -module structure).

This identification is *inevitable*: once the Swiss-cheese structure is established, the only object satisfying both constraints simultaneously *is* the Hochschild cochain complex. There is no room for an alternative. $\square$

Remark 28.10.11 (The open/closed map and the center). The no-open-to-closed constraint ($\text{SC}(\dots, \text{o}, \dots; \text{c}) = \emptyset$) is crucial: it means information flows from closed to open but not back. The center reverses this flow *universally*: it is the largest closed-sector algebra that acts on the given open-sector algebra. Physically, the centre extracts from the boundary theory all the information that can be reconstructed about the 3d HT bulk (T18(iii)). This is the algebraic incarnation of the holographic principle: the chiral algebra $\mathcal{A}$ (closed sector of the 3d HT bulk) determines the boundary (E_1 -algebra A) via restriction, and the centre construction recovers from A the largest closed-sector algebra acting on it.

Remark 28.10.12 (The chiral Deligne–Tamarkin principle and the dimensional jump). Theorems 28.10.7 and 28.10.10 together constitute the *chiral Deligne–Tamarkin principle*: for every local A_∞ -chiral algebra $\mathcal{A}$, the chiral Hochschild cochain complex $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ is the universal closed-sector algebra acting on $\mathcal{A}$ through the Swiss-cheese structure. The chain of implications is:

$$\mathcal{A} \xrightarrow{\text{center}} (C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A}) \in \text{Alg}_{W(\text{SC}^{\text{ch}, \text{top}})} \xrightarrow{\text{recognition}} \text{local 3d HT theory on } D \times \mathbb{R}. \quad (28.10)$$

The left arrow is Theorem 28.10.7 (proved here). The right arrow is the recognition theorem identifying $W(\text{SC}^{\text{ch}, \text{top}})$ -algebras with holomorphic-topological prefactorization algebras on $D \times \mathbb{R}$ (Volume II, items F4–F5; not proved in this volume).

This is the mechanism by which a 2-dimensional chiral algebra on a curve X produces a 3-dimensional holomorphic-topological bulk/boundary system on $X \times \mathbb{R}$. The extra dimension is the universal normal-collar direction of a codimension-one boundary condition, forced by the center construction.

An independent physical construction corroborating this picture is given by Khan–Zeng [?KhanZeng25], who build a mixed holomorphic-topological gauge theory on $\mathbb{R} \times \mathbb{C}$ from a freely generated Poisson vertex algebra and prove that gauge invariance holds if and only if the λ -Jacobi identity is satisfied [?KhanZeng25, § 2.2]. They show [?KhanZeng25, § 4.3] that an inner Virasoro element upgrades the holomorphic-topological symmetry to fully topological symmetry. The conjectural comparison with the Khan–Zeng gauge theory realizes the right-hand arrow of (28.10): the universal algebraic thickening $(C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A}), \mathcal{A})$ is identified with the perturbative local observable algebra of their holomorphic-topological gauge theory.

28.10.4 Comparison with the brace-algebra center

The brace-algebra approach to the Hochschild complex defines the E_2 -structure on $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ directly, via brace operations $f\{g_1, \dots, g_k\}$, without passing through the operadic center. We show that the two constructions agree.

Definition 28.10.13 (*Chiral brace operations*;). For cochains $f \in C_{\text{ch}}^p(\mathcal{A}, \mathcal{A})$ and $g_1 \in C_{\text{ch}}^{q_1}, \dots, g_k \in C_{\text{ch}}^{q_k}$, the *chiral brace operation* is:

$$f\{g_1, \dots, g_k\}(z_1, \dots, z_N) := \sum_{\substack{S_1 \sqcup \dots \sqcup S_k \sqcup T \\ = \{z_1, \dots, z_N\}}} \pm \text{Res}_{\substack{w_1 \rightarrow z_{S_1} \\ \vdots \\ w_k \rightarrow z_{S_k}}} f(w_1, \dots, w_k, z_T) \prod_{j=1}^k g_j(z_{S_j}), \quad (28.11)$$

where the sum is over ordered partitions of the input set, the residue is at the collision loci $w_j \rightarrow z_{S_j}$ in $\text{FM}_k(\mathbb{C}) \subset \overline{\text{C}}_{k+N}(X)$, and the sign $\pm$ follows the Koszul convention for the desuspended tensor product.

PROPOSITION 28.10.14 (*Brace operations from the operadic center*;). The brace operations of Definition 28.10.13 are recovered from the E_2 -algebra structure on $Z_{\text{SC}}(\mathcal{A})$ by restricting the closed-sector composition to the specific boundary strata of $\text{FM}_{k+1}(\mathbb{C})$ where the first point simultaneously collides with the remaining k points. Precisely, the brace $f\{g_1, \dots, g_k\}$ is the image of $(f, g_1, \dots, g_k) \in Z_{\text{SC}}(\mathcal{A})^{\otimes(k+1)}$ under the operadic composition map

$$\text{FM}_{k+1}(\mathbb{C}) \otimes Z_{\text{SC}}(\mathcal{A})^{\otimes(k+1)} \longrightarrow Z_{\text{SC}}(\mathcal{A}),$$

restricted to the open stratum of $\text{FM}_{k+1}(\mathbb{C})$ where the first point is at the center and the remaining k are close to it.

Proof. The operadic composition in $(\text{SC}^{\text{ch}, \text{top}})^c = \{\text{FM}_k(\mathbb{C})\}$ at degree $(k+1)$ composes a $(k+1)$ -ary closed operation with individual closed operations. In configuration-space terms, this is the insertion map $\text{FM}_{k+1}(\mathbb{C}) \times \text{FM}_{q_1}(\mathbb{C}) \times \dots \times \text{FM}_{q_k}(\mathbb{C}) \rightarrow \text{FM}_N(\mathbb{C})$ that replaces each of the k satellite points by a cluster of q_j points.

At the cochain level, an element $f \in C_{\text{ch}}^p$ is represented by a form on $\text{FM}_{p+1}(\mathbb{C})$, and $g_j \in C_{\text{ch}}^{q_j}$ is a form on $\text{FM}_{q_j+1}(\mathbb{C})$. The operadic composition inserts the g_j -clusters into the f -configuration and extracts the residue along the collision loci. Unraveling the definitions, this is exactly the brace formula (28.11): the sum over partitions corresponds to the sum over ways of assigning the N input points to the k insertion sites, and the residues arise from the boundary strata of $\text{FM}_{k+1}(\mathbb{C})$ where satellite points collide with their centers. $\square$

THEOREM 28.10.15 (*Comparison theorem: operadic center = brace center*;). The following three models of the “center” are quasi-isomorphic as E_2 -algebras:

- (i) The operadic center $Z_{\text{SC}}(\mathcal{A})$ (Definition 28.10.4).
- (ii) The chiral Hochschild cochain complex $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ with braces (Definition 28.10.13).
- (iii) The derived endomorphism algebra $\text{REnd}_{\mathcal{A}^e}(\mathcal{A})$, where $\mathcal{A}^e = \mathcal{A} \otimes \mathcal{A}^{\text{op}}$ is the enveloping algebra.

Proof. (i) $\simeq$ (ii): Theorem 28.10.7 identifies $Z_{\text{SC}}(A)$ with $C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ as chain complexes. Proposition 28.10.14 shows the E_2 -structure on the center recovers the braces. Since the E_2 -structure on the Hochschild complex is *generated* by the braces and cup product (this is the content of the higher Deligne conjecture, proved in the topological setting by Kontsevich–Soibelman [KS00] and extending to the chiral setting by the same FM-operad mechanism), the two E_2 -structures agree.

(ii) $\simeq$ (iii): The chiral Hochschild cochain complex computes $\text{RHom}_{\mathcal{A}^e}(\mathcal{A}, \mathcal{A}) \simeq \text{REnd}_{\mathcal{A}^e}(\mathcal{A})$ by the bar resolution (Theorem 35.3.1). The derived Hom carries the standard E_2 -structure from the Eilenberg–Zilber operad; the bar resolution provides the comparison.

The transitivity (i) $\simeq$ (ii) $\simeq$ (iii) completes the comparison. $\square$

Remark 28.10.16 (Role of homotopy-Koszulity). The comparison in Theorem 28.10.15 uses the homotopy-Koszulity of $\text{SC}^{\text{ch}, \text{top}}$ at a single point: the bar-cobar resolution of the SC-operad must be a Quillen equivalence, so that derived mapping objects computed from the bar side agree with those computed from the operadic side. Volume II, Theorem thm:homotopy-Koszul, proves homotopy-Koszulity of $\text{SC}^{\text{ch}, \text{top}}$ via the three-input package: (1) Koszulity of the classical Swiss-cheese operad (Ginzburg–Kapranov, Voronov; [GK94, Voronov99]); (2) Kontsevich formality of $C_*(\text{FM}_\bullet(\mathbb{C}))$ as the chiral closed colour [Kon03]; (3) transfer of homotopy-Koszulity through quasi-isomorphisms of coloured dg operads [Val07]. Classical Swiss-cheese Koszulity alone is not the input used here; the chiral comparison and transfer are part of the imported package. *Without homotopy-Koszulity*, the operadic center still exists as a derived object but may not be computed by the explicit formula (28.9); the cochain-level model would need to be replaced by a homotopy-coherent (i.e., ∞ -categorical) one.

28.10.5 Universality and terminality

THEOREM 28.10.17 (Terminality of the center;). Let A be an E_1 -algebra (equivalently, an open-sector $\text{SC}^{\text{ch}, \text{top}}$ -algebra). Define the *universal SC-pair* as

$$U(A) := (Z_{\text{SC}}(A), A).$$

Then $U(A)$ is the terminal object in the category of $\text{SC}^{\text{ch}, \text{top}}$ -algebra pairs (B, A) with fixed open component A . That is, for every $\text{SC}^{\text{ch}, \text{top}}$ -algebra pair (B, A) , there exists a unique morphism of closed-sector algebras

$$\varphi: B \longrightarrow Z_{\text{SC}}(A)$$

such that the diagram of action maps

$$\begin{array}{ccc} \text{FM}_k(\mathbb{C}) \otimes B^{\otimes k} \otimes A^{\otimes m} & \xrightarrow{\alpha_{k,m}^B} & A \\ \varphi^{\otimes k} \downarrow & \nearrow \alpha_{k,m}^{\text{univ}} & \\ \text{FM}_k(\mathbb{C}) \otimes Z_{\text{SC}}(A)^{\otimes k} \otimes A^{\otimes m} & & \end{array}$$

commutes for all $k, m \geq 0$.

Proof. Existence. By the universal property of the operadic center (Definition 28.10.4), any $\text{SC}^{\text{ch}, \text{top}}$ -algebra structure on (B, A) determines, for each k and m , action maps $\alpha_{k,m}^B: \text{FM}_k(\mathbb{C}) \otimes B^{\otimes k} \otimes A^{\otimes m} \rightarrow A$. The $k=1, m=0$ component gives a map $\alpha_{1,0}^B: B \rightarrow \text{Hom}(\mathbb{C}, A) = A$, and more generally the full collection $\{\alpha_{k,m}^B\}$ is exactly the data of an element in

$$\prod_{k,m} \text{Hom}_{\Sigma_k \times \Sigma_m}(\text{FM}_k(\mathbb{C}) \times E_1(m), \text{Hom}(B^{\otimes k} \otimes A^{\otimes m}, A)).$$

Taking the “ B -linear” part (the component linear in a single copy of B , i.e., $k = 1$) gives a map $\varphi: B \rightarrow Z_{\text{SC}}(A)$ defined by

$$\varphi(b)_m := \alpha_{i,m}^B(-, b, -) \in \text{Hom}(A^{\otimes m}, A).$$

The full equivariance conditions on the $\alpha_{k,m}^B$ ensure that φ is a map of E_2 -algebras (the closed-sector algebra structure on B is intertwined with the closed-sector structure on $Z_{\text{SC}}(A)$), and the commutativity of the diagram follows from the associativity of the SC-algebra axioms.

Uniqueness. Suppose $\varphi, \varphi': B \rightarrow Z_{\text{SC}}(A)$ are two morphisms making the diagram commute. Then for each $b \in B$ and each m , the commutativity of both diagrams gives $\alpha_{i,m}^{\text{univ}}(-, \varphi(b), -) = \alpha_{i,m}^B(-, b, -) = \alpha_{i,m}^{\text{univ}}(-, \varphi'(b), -)$. Since the universal action maps $\alpha_{i,m}^{\text{univ}}$ are injective in the center argument on the derived level (the center derived-Hom model is computed by RHom , which is faithful on the derived category of bimodules), $\varphi(b) = \varphi'(b)$ for all b , hence $\varphi = \varphi'$.

Alternatively, uniqueness follows formally from the terminal property in Definition 28.10.4: the center is defined as a limit, and morphisms to/from limits are unique by the universal property of limits. $\square$

COROLLARY 28.10.18 (*The fiberwise center section;*). The assignment $A \mapsto U(A) = (Z_{\text{SC}}(A), A)$ defines a section over objects

$$U: E_1\text{-Alg} \longrightarrow \text{SC}^{\text{ch,top}}\text{-Alg}$$

of the forgetful functor $\text{forget}_o: \text{SC}^{\text{ch,top}}\text{-Alg} \rightarrow E_1\text{-Alg}$ extracting the open component. For each fixed open algebra A , $U(A)$ is terminal in the homotopy fibre $\text{forget}_o^{-1}(A)$, and the terminal morphism from a pair (B, A) is the canonical closed-sector map $B \rightarrow Z_{\text{SC}}(A)$ of Theorem 28.10.17. A global right adjoint to forget_o would require functorial transport of the closed action along arbitrary open algebra maps; that extra functoriality is not asserted here.

Proof. The object assignment is clear from the construction of the operadic center. If the open component is fixed to be A , then Theorem 28.10.17 gives, for every $\text{SC}^{\text{ch,top}}$ -pair (B, A) , a unique closed-sector morphism $B \rightarrow Z_{\text{SC}}(A)$ compatible with all mixed operations. This is precisely terminality in the fibre over A . An arbitrary map of open algebras $A \rightarrow A'$ does not, by itself, transport an action of B on A to an action on A' ; therefore the fibrewise statement is the theorem used below. $\square$

Remark 28.10.19 (*The chiral center theorem as a composite statement*). Assembling Steps 1–5, the chiral center theorem is the conjunction of four assertions:

- (1) *Existence:* The operadic center $Z_{\text{SC}}(A)$ exists for every E_1 -algebra A (Proposition 28.10.6).
- (2) *Identification:* $Z_{\text{SC}}(A) \simeq C_{\text{ch}}^\bullet(\mathcal{A}, \mathcal{A})$ as E_2 -algebras (Theorem 28.10.7).
- (3) *Geometric realization:* The center computes the cochain-level closed-sector slot acting on boundary observables; comparison with physical 3d HT bulk observables requires the separate bulk-boundary theorem (Theorem 28.10.10).
- (4) *Universality:* $(Z_{\text{SC}}(A), A)$ is terminal among SC-pairs with fixed open component (Theorem 28.10.17).

In the topological setting, these four assertions are respectively: existence of the Hochschild complex, the Deligne conjecture, the bulk-boundary correspondence in 2d TFT, and Keller’s recognition theorem. The chiral setting enriches each with holomorphic geometry (meromorphic propagators, configuration-space compactifications, curve-dependence) and with curvature (the modular characteristic κ at higher genus).

Remark 28.10.20 (Why the chiral setting is genuinely harder). The difficulties identified in Remark 28.10.9, cast at the level of the complete proof, stratify as follows:

- (a) *Steps 1–2* (algebraic/chain-level) are parallel to the topological case, with Arnold relations replacing smooth Stokes. The key input is the FM compactification of $C_k(X)$, which provides the same combinatorial structure as $\text{FM}_k(\mathbb{R}^2)$ but with holomorphic forms.
- (b) *Step 3* (geometric realization) requires the recognition theorem (F_4/F_5), which itself requires homotopy-Koszulity of $\text{SC}^{\text{ch},\text{top}}$. The proof of homotopy-Koszulity uses Kontsevich formality, which is the single deepest input. In the topological case, Koszulity of the classical Swiss-cheese operad suffices.
- (c) *Step 4* (comparison) requires that the E_2 -structure from the operadic center and the E_2 -structure from braces agree. In the topological case, this is part of the Deligne conjecture proof. In the chiral case, the comparison also requires that the configuration-space forms are compatible with the brace insertion, which is guaranteed by the Arnold relations.
- (d) *Step 5* (universality) is formal and identical in both settings.

The single genuinely new ingredient is the passage from smooth to meromorphic propagators and the resulting replacement of Stokes by Arnold. Everything else (operadic center, universality, comparison) is structural and follows the same architecture. The higher-genus curvature κ introduces a further novelty (curved E_2 -algebras) not present in any topological analogue.

28.10.6 Center-generated Swiss-cheese pairs

Corollary 28.10.18 establishes the fiberwise center section

$$U: E_1\text{-Alg} \longrightarrow \text{SC}^{\text{ch},\text{top}}\text{-Alg}, \quad A \longmapsto (Z_{\text{SC}}(A), A),$$

and terminality in each fibre of the forgetful functor extracting the open component. Terminality (Theorem 28.10.17) guarantees that every $\text{SC}^{\text{ch},\text{top}}$ -pair (B, A) admits a *unique* closed-sector morphism $\eta_B: B \rightarrow Z_{\text{SC}}(A)$ in the fibre over A . The remaining question is whether η_B is an equivalence: which SC-pairs are center-generated?

In the topological setting, the analogous question has a negative answer. Not every E_2 -algebra arises as the Hochschild cochain complex $\text{HH}^\bullet(A, A)$ of an E_1 -algebra: the Hochschild cochain complex carries additional structure (the calculus package, compatibility with the bar construction, the BV operator at the chain level) that constrains the essential image.

The chiral setting introduces three layers of obstruction.
